Mr. Patrick Wruck
Commission Secretary and Manager
Regulatory Support
British Columbia Utilities Commission
Suite 410, 900 Howe Street
Vancouver, BC V6Z 2N3

Dear Mr. Wruck:

RE: British Columbia Utilities Commission (BCUC or Commission)
British Columbia Hydro and Power Authority (BC Hydro)
Fiscal 2023 to Fiscal 2025 Revenue Requirements Application

BC Hydro writes to file the attached Fiscal 2023 to Fiscal 2025 Revenue Requirements Application (the **Application**).

BC Hydro is requesting various approvals from the BCUC which, if approved, would result in a net bill decrease of 1.4 per cent on April 1, 2022, followed by net bill increases of 2.0 per cent on April 1, 2023 and 2.7 per cent on April 1, 2024. This represents an average annual increase of 1.1 per cent.[1]

BC Hydro is providing the Application as follows:[2]

Exhibit B-2	Application (Public)
Exhibit B-2-1	Appendices A to II (Public)
Exhibit B-2-2	Chapter 6 (Confidential Version)
Exhibit B-2-3	Chapter 10, Appendices U, V and W (Confidential until further notice)
Exhibit B-2-4	Appendices I and V (Confidential Version)
Exhibit B-2-5	Appendix JJ (Confidential)

BC Hydro has previously proposed a timetable for review of the Application.[3]

1 The net bill increase for a given year is the combination of the rate increase and the change in the Deferral Account Rate Rider for that year.

2 Appendix H is marked “confidential” but is now public.

3 Refer to Exhibit B-1.

BC Hydro requests the following information to be held confidential in accordance with Part IV of the BCUC's Rules of Practice and Procedure, for the reasons explained below:

1. Certain information in Chapter 6, Appendix I, and Appendix V, which is either customer-specific and/or commercially sensitive;
2. The entirety of Chapter 10, Appendix U, Appendix V, and Appendix W, which is to be released through a public announcement in mid to late September and needs to remain confidential until that time; and
3. The entirety of Appendix JJ related to Mandatory Reliability Standards.

Chapter 6, Appendix I and Appendix V - Customer-Specific / Commercially Sensitive Information

In Chapter 6 and Appendix I, BC Hydro has redacted the name of a BC Hydro project where the project either:

- Is driven by, or specially for, a customer (disclosure of such information may prejudice a customer's commercial or competitive position); or
- Pertains to a substation acquisition (disclosure of such information may prejudice BC Hydro's position in future negotiations).

In Appendix V, the information redacted pertains to the name or identifiable information of a customer. If disclosed, the information may potentially prejudice the customer's competitive position. BC Hydro has a contractual obligation to keep the information specifically related to the customer and the customer's project confidential.

For the purpose of this proceeding and on appropriate undertakings, as contemplated by the BCUC's Rules of Practice and Procedure, BC Hydro is able to make non-customer specific project information in Chapter 6 and Appendix I available to registered interveners. BC Hydro reserves the right to object to a request for access to confidential information on a case-by-case basis.

Chapter 10, Appendix U, Appendix V, and Appendix W – Information to be Released Soon Through Public Announcement

At this time, BC Hydro is filing Chapter 10 and Appendices U, V and W confidentially with the BCUC and can make this information available to registered interveners upon request and upon signing an appropriate undertaking to keep the information confidential. This information relates to BC Hydro's Electrification Plan.

The Electrification Plan will be released through a public announcement in mid to late September. Once that public announcement has been made, BC Hydro will provide notice to the BCUC so that these materials can be posted publicly and form part of the public record. Providing this information confidentially to the BCUC and interveners in advance of the public announcement will allow all parties to review the materials and draft information requests, on the same timeline as the rest of the Application.

Appendix JJ – Confidential Mandatory Reliability Standards Information

In the Application, we have split the discussion on Mandatory Reliability Standards (**MRS**) between public content in Chapter 5 and nine pages of confidential content in Appendix JJ. Appendix JJ is confidential and made available to the BCUC only for two related reasons:

- First, information related to the protection of cyber infrastructure is highly security sensitive and could compromise the safety and reliability of the Bulk Electric System by exposing it to physical attacks by malicious actors or cyberattacks; and
- Second, the BCUC's MRS Rules of Procedure, including the Compliance Monitoring Program Rules and Penalty Guidelines, make the framework and processes for reporting, auditing and oversight of MRS compliance confidential. While certain information about an entity's violations, if confirmed, may become public after the fact, there remains a presumption of confidentiality. The presumption of confidentiality is especially important where the subject-matter relates to a cyber-security incident or may otherwise jeopardize the security of the Bulk Electric System.

For further information, please contact Joe Maloney at 604-623-4348 or by email at bchydroregulatorygroup@bchydro.com.

Yours sincerely,

Chris Sandve
Chief Regulatory Officer

IN THE MATTER OF
the *Utilities Commission Act*, RSBC 1996, Chapter 473

and

British Columbia Hydro and Power Authority (BC Hydro)
Fiscal 2023 to Fiscal 2025 Revenue Requirements Application

BEFORE:
Commissioner
Commissioner
Commissioner

on Date

ORDER

WHEREAS:

A. On August 31, 2021, the British Columbia Hydro and Power Authority (BC Hydro) filed its Fiscal 2023 to Fiscal 2025 Revenue Requirements Application (**Application**) with the British Columbia Utilities Commission (**BCUC**) pursuant to sections 58 to 61 and 90 of the *Utilities Commission Act* (**UCA**) and s. 15 of the *Administrative Tribunals Act (***ATA***)*, requesting, among other things:

(i) Interim and, after certain future determinations in other proceedings, permanent approval of an increase in rates by 0.62 per cent, effective April 1, 2022, 0.97 per cent, effective April 1, 2023 and 2.18 per cent, effective April 1, 2024;

(ii) Interim and, after certain future determinations in other proceedings, permanent approval of the fiscal 2023, fiscal 2024, and fiscal 2025 Open Access Transmission Tariff (**OATT**) rates as set out in Table 9-4 of the Application, effective April 1, 2022, April 1, 2023 and April 1, 2024, respectively; and

(iii) Set the Deferral Account Rate Rider (**DARR**) on an interim and permanent basis at (2.0) per cent, effective April 1, 2022 for fiscal 2023; and, on a permanent basis at (1.0) per cent, effective April 1, 2023 for fiscal 2024 and (0.5) per cent, effective April 1, 2024, for fiscal 2025.

B. In the Application, BC Hydro also requested that the proposed general and OATT rates remain interim following the BCUC's final decision on this Application, pending the BCUC's determinations in other proceedings regarding an expenditure schedule for demand-side management expenditures for the test period, BC Hydro's cost of capital in fiscal 2024 and fiscal 2025, and, in respect of fiscal 2025, the extent to which Site C Clean Energy Project capital and deferred costs are recoverable from ratepayers;

C. BC Hydro requests that certain information in Chapter 6, Appendix I and Appendix V and all of Appendix JJ be treated as confidential;

…/2

D. BC Hydro requests that all of Chapter 10, Appendix U, Appendix V and Appendix W be treated as confidential until that information is released through a planned public announcement, expected to occur in mid to late September 2021;

E. The BCUC has commenced review of the Application and finds that a regulatory timetable for the review is warranted.

NOW THEREFORE, pursuant to sections 58 to 61 and 90 of the UCA and s. 15 of the ATA, and for the reasons outlined in the decision issued concurrently with this order, the BCUC orders as follows:

1. A hearing is established for the review of the Application in accordance with the regulatory timetable attached as Appendix A to this order (Regulatory Timetable).

2. BC Hydro is to publish the Public Notice, attached as Appendix B to this order, by September X, 2021, in [INSERT] to provide adequate notice to those parties who may have an interest in or be affected by the Application.

3. As soon as practicable, BC Hydro is directed to publish, together with any supporting materials other than those determined to be confidential in this order, the Application, this order and the regulatory timetable by using appropriate communication methods, including BC Hydro's website and social media accounts.

4. Certain information in Chapter 6, Appendix I, Appendix V and all of Appendix JJ will be held confidential unless determined otherwise by the BCUC. All of Chapter 10, Appendix U, Appendix V and Appendix W will be held confidential until the information is released through a planned public announcement, unless determined otherwise by the BCUC. The confidential information, other than that in Appendix JJ, will be made available to registered interveners upon executing the BCUC's form of undertaking, unless determined otherwise by the BCUC.

5. In accordance with BCUC's Rules of Practice and Procedure, parties who wish to actively participate in this proceeding must submit the Request to Intervene Form, available on the BCUC's website at https://www.bcuc.com/get-involved/get-involved-proceeding.html, by the date established in the Regulatory Timetable.

DATED at the City of Vancouver, in the Province of British Columbia, this (XX) day of (Month Year).

on Date

ORDER

WHEREAS:

A. On August 31, 2021, the British Columbia Hydro and Power Authority (BC Hydro) filed its Fiscal 2023 to Fiscal 2025 Revenue Requirements Application (**Application**) with the British Columbia Utilities Commission (**BCUC**) pursuant to sections 58 to 61 and 90 of the *Utilities Commission Act* (**UCA**) and s. 15 of the *Administrative Tribunals Act (***ATA***)*, requesting, among other things:

(i) Interim and, after certain future determinations in other proceedings, permanent approval of an increase in rates by 0.62 per cent, effective April 1, 2022, 0.97 per cent, effective April 1, 2023 and 2.18 per cent, effective April 1, 2024;

(ii) Interim and, after certain future determinations in other proceedings, permanent approval of the fiscal 2023, fiscal 2024, and fiscal 2025 Open Access Transmission Tariff (**OATT**) rates as set out in Table 9-4 of the Application, effective April 1, 2022, April 1, 2023 and April 1, 2024, respectively; and

(iii) Set the Deferral Account Rate Rider (**DARR**) on an interim and permanent basis at (2.0) per cent, effective April 1, 2022 for fiscal 2023; and, on a permanent basis at (1.0) per cent, effective April 1, 2023 for fiscal 2024 and (0.5) per cent, effective April 1, 2024, for fiscal 2025.

B. In the Application, BC Hydro also requested that the proposed general and OATT rates remain interim following the BCUC's final decision on this Application, pending the BCUC's determinations in other proceedings regarding an expenditure schedule for demand-side management expenditures for the test period, BC Hydro's cost of capital in fiscal 2024 and fiscal 2025, and, in respect of fiscal 2025, the extent to which Site C Clean Energy Project capital and deferred costs are recoverable from ratepayers;

C. BC Hydro requests that certain portions of the Application be held confidential in accordance with Part IV of the BCUC's Rules of Practice and Procedure, primarily on the basis that (i) aspects relate to matters deemed

…/2

to be confidential by the BCUC's Rules of Procedure, and (ii) the remainder is security-sensitive information relating to the protection of critical infrastructure, the release of which could compromise the safety and reliability of the Bulk Electric System by exposing it to malicious attacks;

D. By Order No. G-XX-21, the BCUC established the regulatory timetable for the review of the Application; and

E. The BCUC has considered the Application, the evidence, and submissions filed in the proceeding.

NOW THEREFORE, pursuant to sections 58 to 61 and 90 of the UCA and s. 15 of the ATA, and for the reasons outlined in the decision issued concurrently with this order, the BCUC orders as follows:

1. The requested rate increase of 0.62 per cent, 0.97 per cent and 2.18 per cent as applied for in the Application is approved, effective April 1, 2022, April 1, 2023 and April 1, 2024 respectively, but rates will remain interim for the limited purpose of reflecting the BCUC's future determinations regarding:
   (i) An expenditure schedule(s) for demand-side management expenditures for the test period;
   (ii) BC Hydro's cost of capital in fiscal 2024 and fiscal 2025; and
   (iii) The extent to which Site C Clean Energy Project capital and deferred costs are recoverable from ratepayers, in so far as they affect fiscal 2025.

2. The request to set the DARR on a permanent basis at (2.0) per cent, effective April 1, 2022, for fiscal 2023; (1.0) per cent, effective April 1, 2023, for fiscal 2024; and (0.5) per cent, effective April 1, 2024, for fiscal 2025, is approved.

3. The following requests related to deferral and regulatory accounts are approved as follows:
   (i) Load Attraction Costs Regulatory Account

   The request to establish a Load Attraction Costs Regulatory Account to defer actual load attraction operating costs to this account each year beginning in fiscal 2023 and ending in fiscal 2027 is approved. The interest applied to the balance of the account is to be based on BC Hydro's current weighted average cost of debt and the forecast interest charged to the account each year is to be amortized each year. The forecast annual operating cost amount in the account will be amortized into rates starting the fiscal year following the expenditures over the benefit period of 20 years. The forecast balance at the end of a test period related to the difference between the amortization of the forecast annual load attraction operating cost amount and the calculation of the amortization based on the actual annual load attraction operating cost amounts is to be recovered over the next test period. The forecast balance at the end of a test period related to the difference between the forecast interest recovered and the actual interest charged to the account during that test period is recovered over the next test period.

   (ii) MRS Costs Regulatory Account

   The request to defer the following actual unplanned Mandatory Reliability Standards (**MRS**) costs to the MRS Costs Regulatory Account, effective in fiscal 2023 and on an ongoing basis, is approved:

   - Costs related to the implementation of new or revised Standards adopted as a result of a future Assessment Report filed with the BCUC where the BCUC's adoption of such new or revised Standards occurred too late to be reflected in the forecast for the test period; and

- Costs incurred in a test period to address possible non-compliances with MRS, if and as required, where the work related to such possible non-compliances was identified too late to be reflected in the forecast for the test period. This does not include any penalties assessed against BC Hydro.

BC Hydro will recover amounts deferred to the MRS Costs Regulatory Account in respect of completed fiscal years, including any under/over recovered balance from fiscal 2022, over the next test period, starting in fiscal 2026 and on an ongoing basis, subject to BCUC review and approval of these amounts. BC Hydro will apply interest to the balance of the account based on BC Hydro's weighted average cost of debt. BC Hydro will recover actual interest charged to the account for amounts related to any completed fiscal years over the next test period.

(a) Dismantling Cost Regulatory Account

The request to continue to defer any variances between forecast and actual dismantling costs in fiscal 2023 to fiscal 2025 to the Dismantling Cost Regulatory Account is approved. The interest applied to the balance of the account each year is to be based on BC Hydro's current weighted average cost of debt, and the forecast interest charged to the account each year is to be recovered from the account each year. The forecast account balance at the end of a test period is to be recovered over the next test period.

(b) Low Carbon Fuel Credits Account

The request to recover the balance of the Low Carbon Fuel Credits Regulatory Account through the DARR mechanism is approved.

(c) Depreciation Study Impact Regulatory Account

The request to recover the forecast March 31, 2022 balance in the Depreciation Study Impact Regulatory Account for over this test period is approved. BC Hydro will apply interest to the balance of the account each year based on BC Hydro's current weighted average cost of debt. BC Hydro will recover the forecast interest charged to the account each year beginning in fiscal 2023. BC Hydro will recover any remaining balance at the end of the Test Period, as a result of actual amounts being different than the forecast amount, over the following test period.

(d) Cost of Energy Variance Accounts

The request to recover or refund the balances in the Cost of Energy Variance Accounts through the DARR using the DARR table mechanism as described in Chapter 7, section 7.3.3.3 is approved. Specifically, starting in fiscal 2023 and on an ongoing basis, the DARR percentage effective April 1 of a given year will be set based on the percentage in the DARR table mechanism corresponding to the forecast net balance of the Cost of Energy Variance Accounts at the end of the preceding fiscal year.

(e) Site C Regulatory Account

The request to commence recover the forecast balance in the account as at December 31, 2024 on January 1, 2025 over the forecasted weighted average life of the Site C assets of 84 years is approved. The request to, on an ongoing basis beginning in fiscal 2026, amortize the forecast balance in the Site C Regulatory Account at the end of the prior test period over the remaining weighted average useful life is approved.

(f) Customer Crisis Fund Regulatory Account

The request to recover the forecast March 31, 2022 balance for COVID Relief Fund for Residential Customers in the Customer Crisis Fund Regulatory Account over this test period is approved. The interest applied to the balance of the account in each year is to be based on BC Hydro's current weighted average cost of debt. The forecast interest charged to the account attributable to the COVID Relief Fund for Residential Customers balance each year is to be recovered from the account each year beginning in fiscal 2023.

(g) Mining Customer Payment Plan Regulatory Account

The request to recover the forecast March 31, 2022 balance for COVID-19 Relief measures for commercial customers in the Mining Customer Payment Plan Regulatory Account over this test period is approved. The interest applied to the balance of the account each year is to be based on BC Hydro's current weighted average cost of debt. The forecast interest charged to the account attributable to COVID-19 Relief measures for commercial customers each year is to be recovered from the account each year beginning in fiscal 2023.

(h) Real Property Sales Regulatory Account

The request to continue to defer actual net gains realized on the sale of properties to the Real Property Sales Regulatory Account is approved. The interest applied to the balance of the account will continue to be based on BC Hydro's current weighted average cost of debt. If an amount is owing to ratepayers at the end of the test period, the balance in the account is to be refunded to ratepayers over the next test period. If an amount is recoverable from ratepayers at the end of the Test Period, the balance in the account is to be recovered from ratepayers over the next test period.

(i) Electric Vehicle Costs Regulatory Account

The request to recover the forecast March 31, 2022 balance for the Electric Vehicle Costs Regulatory Account over this test period and recover any balance remaining at the end of this test period over the next test period is approved. The interest applied to the balance of the account each year is to be based on BC Hydro's current weighted average cost of debt. The forecast interest charged to the account each year is to be recovered from the account each year beginning in fiscal 2023.

(j) DSM Regulatory Account

The request to not change the recovery of the Low Carbon Electrification Component of the DSM Regulatory Account is approved.

4. With respect to depreciation rates:

(i) The request to implement for ratemaking purposes the updated useful lives and positive salvage rates and changes in asset classes, effective fiscal 2022, as set out in Chapter 8, section 8.3, is approved.

(ii) The request to implement for ratemaking purposes the net salvage rates beginning in the next test period, using a phased-in approach, as set out in Chapter 8, section 8.4, is approved.

5. The requested OATT rates as set out in Appendix II, Table II-2 of the Application are approved, effective April 1, 2022, April 1, 2023 and April 1, 2024, respectively, but rates will remain interim for the limited purpose of reflecting the BCUC's determinations regarding the items identified in paragraph 1.

6. Within 30 days of the date of this Order, BC Hydro is to file the applicable Tariff sheets reflecting the approved general and OATT rates for fiscal 2023.

7. The request to hold certain information in Chapter 6, Appendix I and Appendix V and all of Appendix JJ confidential is granted.

8. BC Hydro is directed to comply with all other directives contained in the decision issued concurrently with this order.

DATED at the City of Vancouver, in the Province of British Columbia, this (XX) day of (Month Year).

BC Hydro Fiscal 2023 to Fiscal 2025
Revenue Requirements Application

Appendix C

Government Mandate Letter and
BC Hydro Service Plan

BRITISH
COLUMBIA

June 15, 2021

Mr. Doug Allen
Chair
BC Hydro
18th Floor, 333 Dunsmuir Street
Vancouver, BC V6B 5R3

Dear Mr. Allen:

On behalf of Premier John Horgan and the Executive Council, I would like to extend my thanks to you and your board members for the dedication, expertise and skills with which you serve the people of British Columbia.

Every public sector organization is accountable to the citizens of British Columbia. The expectations of British Columbians are identified through their elected representatives, the members of the Legislative Assembly. Your contributions advance and protect the public interest of all British Columbians and, through your work, you are supporting a society in which the people of this Province can exercise their democratic rights, trust and feel protected by their public institutions.

You are serving British Columbians at a time when people in our province face significant challenges as a result of the global COVID-19 pandemic. Recovering from the pandemic will require focused direction, strong alignment and ongoing engagement between public sector organizations and government. It will require all Crowns to adapt to changing circumstances and follow Public Health orders and guidelines as you find ways to deliver your services to citizens.

This mandate letter, which I am sending in my capacity as Minister responsible for BC Hydro on behalf of the Executive Council, communicates expectations for your organization. It sets out overarching principles relevant to the entire public sector and provides specific direction to BC Hydro about priorities and expectations for the coming fiscal year.

I expect that the following five foundational principles will inform your agency's policies and programs:

Ministry of
Energy, Mines and
Low Carbon Innovation

Office of the Minister

Mailing Address:
PO Box 9060, Stn Prov Govt
Victoria, BC V8W 9E2

Telephone: 250 953-0900

- **Putting people first:** We are committed to working with you to put people first. You and your board are uniquely positioned to advance and protect the public interest, and I expect that you will consider how your board's decisions maintain, protect and enhance the public services people rely on and make life more affordable for everyone.

- **Lasting and meaningful reconciliation:** Reconciliation is an ongoing process and a shared responsibility for us all. Government's unanimous passage of the *Declaration of the Rights of Indigenous Peoples Act* was a significant step forward in this journey – one that all Crown agencies are expected to support as we work in cooperation with Indigenous peoples to establish a clear and sustainable path to lasting reconciliation. True reconciliation will take time and ongoing commitment to work with Indigenous peoples as they move towards self-determination. Guiding these efforts, Crown agencies must also remain focused on creating opportunities that implement the Truth and Reconciliation Commission's recommendations through your mandate.

- **Equity and anti-racism:** Our Province's history, identity and strength are rooted in its diverse population. Yet racialized and marginalized people face historic and present-day barriers that limit their full participation in their communities, workplaces, government and their lives. The public sector has a moral and ethical responsibility to tackle systemic discrimination in all its forms – and every public sector organization has a role in this work. All Crowns are expected to adopt the Gender-Based Analysis Plus (GBA+) lens to ensure equity is reflected in your operations and programs. Similarly, appointments resulting in strong public sector boards that reflect the diversity of BC will help achieve effective and citizen-centred governance.

- **A better future through fighting climate change:** Announced in December 2018, the CleanBC climate action plan puts our Province on the path to a cleaner, better future by building a low-carbon economy with new clean energy jobs and opportunities, protecting our clean air, land and water and supporting communities to prepare for carbon impacts. As part of the accountability framework established in CleanBC, and consistent with the *Climate Change Accountability Act*, please ensure your organization aligns operations with targets and strategies for minimizing greenhouse gas emissions and managing climate change risk, including the CleanBC target of a 50% reduction in public sector building emissions and a 40% reduction in public sector fleet emissions by 2030. Your organization is expected to work with government to report out on these plans and activities as required by legislation.

- **A strong, sustainable economy that works for everyone:** I expect that you will identify new and flexible ways to achieve your mandate and serve the citizens of BC within the guidelines established by the Provincial Health Officer and considering best practices for conducting business during the pandemic. Collectively, our public sector will continue to support British Columbians through the pandemic and economic recovery by investing in health care, getting people back to work, helping businesses and communities, and building the clean, innovative economy of the future. As a public sector organization, I expect that you will consider how your decisions and operations reflect environmental, social and governance factors and contribute to this future.

The Crown agencies and Board Resourcing Office (CABRO), with the Ministry of Finance, will continue to support you and your board on recruitment and appointments as needed, and will be expanding professional development opportunities in 2021/22. The Governing in the Public Interest online certificate program is now available, and all board members are encouraged to complete this new offering.

As the Minister Responsible for BC Hydro, I expect that you will make substantive progress on the following priorities and incorporate them in the goals, objectives and performance measures in your 2021/22 Service Plan:

- Provide leadership in advancing CleanBC’s climate and economic development objectives, including electrification, fuel switching, and energy efficiency initiatives in the built environment, transportation, mining, oil and gas, and other sectors.

- Keep electricity affordable by ensuring that rates do not increase above inflation, on a cumulative basis, over the next decade.

- Continue delivering affordability measures that support BC’s Poverty Reduction Strategy, including demand-side management programs targeted to low-income customers, in a manner consistent with new and emerging CleanBC policies.

- Maintain or improve customer satisfaction by providing timely and responsive service.

- Safely complete the Site C project within the lowest cost and approved schedule, and implement the recommendations of the Milburn Report, reports from independent dam safety experts, other directions from the Minister responsible, and provide quarterly progress and other reporting to Treasury Board and the BC Utilities Commission.

- Continue to implement government direction resulting from the Comprehensive Review of BC Hydro. Priority initiatives for 2021/22 should include:

- Supporting the implementation of the BC Hydrogen Strategy;
- Expanding BC Hydro's network of electric vehicle DC fast-charging stations;
- Supporting clean technology innovation through Powertech;
- Increasing industrial electrification by making it easier and faster for customers to connect to the electricity grid; and
- Re-investing new low carbon fuel standard credit revenues in transportation electrification infrastructure, incentives and programs.

- Develop a short-term electrification plan that builds on the key results of the Comprehensive Review of BC Hydro and supports CleanBC.

- Working with customers, develop efficient and flexible rate proposals for BC Utilities Commission review that will incent greenhouse gas emission reductions and keep rates affordable.

- Actively market 100% clean energy through Powerex to realize new trading opportunities and income for the benefit of BC Hydro ratepayers.

- Partner with the Province and the federal government to implement the CleanBC Remote Community Energy Strategy to help remote communities, with a focus on Indigenous communities, reduce diesel use and replace it with clean energy.

- Work with the Province to secure additional federal funding and bring into service transmission projects that will reduce or avoid greenhouse gas emissions and help meet its climate goals.

Each board member is required to sign the Mandate Letter to acknowledge government's direction to your organization. The signed Mandate Letter is to be posted publicly on your organization's website in spring 2021.

I look forward to continuing to work with you and your Board colleagues to build a better BC.

Sincerely,

Bruce Ralston
Minister

Board Chair's Accountability Statement

The 2021/22 – 2023/24 BC Hydro Service Plan was prepared under the Board's direction in accordance with the *Budget Transparency and Accountability Act*. The plan is consistent with government's strategic priorities and fiscal plan. The Board is accountable for the contents of the plan, including what has been included in the plan and how it has been reported. The Board is responsible for the validity and reliability of the information included in the plan.

All significant assumptions, policy decisions, events and identified risks, as of February 28, 2021 have been considered in preparing the plan. The performance measures presented are consistent with the *Budget Transparency and Accountability Act*, BC Hydro's mandate and goals, and focus on aspects critical to the organization's performance. The targets in this plan have been determined based on an assessment of BC Hydro's operating environment, forecast conditions, risk assessment and past performance.

Doug Allen
Board Chair

Table of Contents

Strategic Direction and Alignment with Government Priorities

In 2021/22, British Columbians continue to face significant challenges as a result of the global COVID-19 pandemic. Recovering from the pandemic will require focused direction, strong alignment and ongoing engagement between public sector organizations and the Government of British Columbia. The government has identified five foundational principles that will inform each Crown agency's policies and programs and contribute to COVID recovery: putting people first, lasting and meaningful reconciliation, equity and anti-racism, a better future through fighting climate change and meeting our greenhouse gas commitments, and a strong, sustainable economy that works for everyone.

BC Hydro is one of the largest electric utilities in Canada and is publicly owned by the people of British Columbia. We generate and provide electricity to 95 percent of B.C.'s population and serve over four million people. The electricity we generate and deliver to customers throughout the province powers our economy and quality of life.

As a provincial Crown Corporation, BC Hydro reports to the Provincial Government through the Minister of Energy, Mines and Low Carbon Innovation. Government's expectations are expressed through the following legislation and policy:

- The *Hydro and Power Authority Act*
- The *Utilities Commission Act*
- The *BC Hydro Public Power Legacy and Heritage Contract Act*
- The *Clean Energy Act* (CEA)
- CleanBC

Our mission is: we are here to safely provide our customers with reliable, affordable, clean electricity. We have set out a three-year plan with strategies, performance measures and targets, aligned with the priorities in the B.C. Government's Mandate Letter to BC Hydro, to fulfill our mission on behalf of our customers and the Province.

Climate change, technological advances and evolving customer energy needs continue to transform our business. While we navigate these ongoing developments, we have the important responsibility of keeping electricity rates affordable for our customers and funding necessary investments in our system to ensure British Columbians continue to receive reliable and clean electricity.

We are implementing the outcomes from the Comprehensive Review of BC Hydro to strategically position BC Hydro for long-term success, while meeting the Province's climate goals and keeping rates affordable for British Columbians. To help advance the Province's CleanBC climate and economic development objectives, we are encouraging our customers to use our clean and reliable electricity to power their homes, vehicles and businesses in order to reduce greenhouse gas (GHG) emissions. We are also advancing affordability initiatives to help our customers save money on their electricity bills and continuing to focus on making it easier for our customers to do business with us.

To ensure sustained economic and social benefits for customers, we manage our capital portfolio with an emphasis on cost consciousness, respect for the environment and communities in which we work, and in particular, strengthening our relationships with Indigenous communities.

BC Hydro will continue making investments to expand and maintain the system to meet our customers' growing needs and expectations, while managing our costs, helping keep electricity bills affordable for our customers and improving our service.

Operating Environment

As a utility that operates in a high hazard industry, we are committed to ensuring our workforce goes home safely every day and that the public is safe around our system. We are continuously working to improve our performance by implementing integrated safety and compliance framework and programs.

The COVID-19 pandemic has presented unprecedented challenges for BC Hydro and our customers. However, it has also made our role as an essential service, providing clean, reliable and affordable electricity to our customers more important than ever. As a Crown Corporation, we will continue to support the Province and our customers to help B.C.'s economy recover from the effects of COVID-19.

BC Hydro will continue to address the considerable challenges of the Site C project to allow us to continue to provide the clean, reliable and affordable electricity that is vital to British Columbia's economic prosperity. Prior to the onset of COVID-19, BC Hydro had identified that the project was facing significant cost pressures that were being assessed, monitored and managed to the best extent possible. The COVID-19 pandemic, along with the need for foundation enhancements on the right bank to contend with unanticipated geotechnical conditions, added further significant cost and schedule pressures.

On February 26, 2021, the Province of B.C. announced an updated cost estimate for the Site C project of $16 billion. This includes a new expected in-service date of 2025, a one-year delay due to COVID-19. The Province also released the independent review of the project by Peter Milburn, with 17 recommendations aimed at improving oversight and governance. The Province and BC Hydro accepted all recommendations and will work to implement them in order to safely complete the Site C project.

BC Hydro is regulated by the British Columbia Utilities Commission (BCUC). As the independent regulator of BC Hydro, the BCUC reviews BC Hydro's costs, proposed rate increases, integrated resource planning and almost all regulatory accounts, programs and capital projects. On December 22, 2020, BC Hydro submitted the Fiscal 2022 Revenue Requirements Application to the BCUC and in 2021/22, we will prepare a comprehensive Revenue Requirements Application for Fiscal 2023 onwards. These applications reflect our efforts to continue to deliver safe and reliable power, while keeping electricity affordable for our customers.

We are developing an Integrated Resource Plan that will outline how BC Hydro is preparing for the evolving energy landscape that includes climate goals, technological advances, changing customer preferences and market conditions. The plan, which will be filed with the BCUC this year, will include electrification scenarios to show how BC Hydro will leverage our clean electricity to support the Province's CleanBC plan to transform and electrify British Columbia's economy. BC Hydro is also developing new measures to monitor our progress in supporting the plan.

The electricity we generate and deliver throughout B.C. meets a high standard of reliability, but we are always looking for ways to improve our service to our customers and help power British Columbia's strong, sustainable economy. We are continuing to build our resilience against cyber and physical attacks on our system to continue to safely provide reliable electricity to our customers.

BC Hydro is focused on delivering our renewed customer service strategy, with the goal of making it easier to do business with us and helping customers make smart energy choices through our conservation and energy management programs. Part of this focus includes working to understand the evolving needs of our customers and how they use the electricity we provide. We will also continue to advance affordability initiatives to help our customers save money on their electricity bills. To help advance the Province's CleanBC climate and economic development objectives, we are encouraging our customers to use our clean and reliable electricity to power their homes, vehicles and businesses in order to reduce GHG emissions.

We continue to make significant investments to expand the system and maintain aging infrastructure, while prudently managing all costs to help keep electricity affordable for our customers. We work across teams, suppliers and experts to ensure thoughtful assessment of how to successfully deliver these projects on time and on budget while respecting the unique community, environmental and Indigenous interests associated with each project.

Operating, maintaining and expanding BC Hydro's extensive electricity system impacts a significant number of Indigenous communities across the province. We continue to pursue meaningful, long-term relationships with Indigenous groups to better understand their interests, so they can be incorporated in our planning and business operations. With the historic passing of the *Declaration on the Rights of Indigenous Peoples Act* in November 2019, BC Hydro is working to implement the United Nations Declaration on the Rights of Indigenous Peoples, the Calls to Action of the Truth and Reconciliation Commission and the Draft Principles that Guide the Province of British Columbia's Relationship with Indigenous Peoples into our business.

With thoughtful planning and prudent decision-making, BC Hydro is well positioned to safely provide reliable, affordable, clean electricity throughout B.C., today and into the future.

Performance Planning

Goal 1: Safety Above All

Objective 1.1: Safety at BC Hydro is a core value. We are committed to ensuring our workforce goes home safely every day, and that the public is safe around our system.

Key Strategies

- Form a strong partnership with operational teams to guide and assist them in creating and sustaining a safe work place.
- Implement an integrated and sustainable safety and compliance framework with defined governance, processes, accountabilities and responsibilities to manage risk.
- Support a learning culture within BC Hydro by using incident and near miss data and investigation learnings to inform improvements in job planning, work methods, training and other elements of our safety framework.
- Continue to standardize and consolidate safety information in one location so employees can easily find and understand rules, procedures and work methods they require to complete their work.
- Continue public education efforts on hazards associated with electricity.
- Protect the public from hazards around our reservoirs and dams through adherence to the Canadian Dam Association Public Safety Around Dams guidelines.
- Develop safety analytic and reporting services that will assist the organization to turn data into actionable information that improves safety outcomes.

Performance Measure(s)[1]	2020/21 Forecast	2021/22 Target	2022/23 Target	2023/24 Target
1.a Zero Fatality & Serious Disabling Injury[2] [Loss of life or the injury has resulted in a permanent disability]	0	0	0	0
1.b Lost Time Injury Frequency [Number of employee injury incidents resulting in lost time (beyond the day of the injury) per 200,000 hours worked]	0.70	0.76	0.74	0.74
1.c Timely Completion of Corrective Actions (%)	97	97	98	98

[1] Performance Measure descriptions, rationale, data source information and benchmarking are available online at www.bchydro.com/performance
[2] Zero Fatality and Serious Disabling Injury – BC Hydro's safety performance measures do not include contractor or public safety injuries or fatalities.

Linking Performance Measure to Objective

1.a Achieving our target of Zero Fatality and Serious Disabling Injury supports our objective that everyone goes home safely, every day.

1.b Lost Time Injury Frequency (LTIF) is an indicator of the likelihood of a full-time employee sustaining a time loss injury in a normal work year and is a comparable metric to other provincial organizations and the Canadian Electricity Association. LTIF of 1 equates to a 1 per cent chance of a time loss injury for any given employee in a work year.

1.c Timely Completion of Corrective Actions supports our strategy towards becoming a learning organization by addressing systemic improvements to our business to manage risk in a timely manner.

Discussion

BC Hydro forecasts that it will achieve its LTIF 2020/21 target largely due to a continued focus on job planning and ergonomics, as most of our lost time injuries result from body mechanic injuries. The 2022/23 target has been reduced by 2.0 percent, while the 2023/24 target has been set to sustain future performance.

Our Timely Completion of Corrective Actions targets focus on meeting the due dates of these actions. Results are reported using the definition of the measure introduced in the 2018/19 – 2020/21 Service Plan: the percentage of safety corrective actions closed on or before the scheduled due date on an annual basis. The 2021/22 and 2022/23 targets sustain our current performance, which supports regulatory reporting requirements and our goal to learn from safety incident data.

Goal 2: Set the Standard for Reliable and Responsive Service

Objective 2.1: BC Hydro will reliably meet the evolving expectations of our customers by prudently planning and investing in the system, improving our service and advancing reconciliation with Indigenous Peoples.

This objective has been updated using more concise language to ensure alignment with Goal 2.

Key Strategies

- Ensure the reliability and resilience of the generation, transmission and distribution system by effectively implementing capital, maintenance and vegetation programs to manage the overall condition of the power system and ensure supply to meet customer load.
- Safeguard the system with risk-prioritized security solutions and prepare our operations with well-practiced emergency response plans to support system reliability and resilience.
- Continue to make it easier for customers to do business with us through a series of customer facing improvements such as: exploring new contact centre technologies, engaging customers in our rate design and project planning processes; exploring new rate proposals to meet our customers' needs; and incorporating the Gender Based Analysis Plus lens to broaden our understanding of how policies and practices impact our customers.
- Sustain gold-level certification under the Progressive Aboriginal Relations program by successfully preparing and presenting BC Hydro's 2021 Progressive Aboriginal Relations Certification submission and clearly demonstrating the corporation's continuous improvement in advancing practices in the areas of leadership, employment, business development and community relationships.
- Continue to advance reconciliation by incorporating the United Nations *Declaration on the Rights of Indigenous Peoples Act*, the Calls to Action of the Truth and Reconciliation Commission and the Draft Principles that Guide the Province of British Columbia's Relationship with Indigenous Peoples into our business.

Performance Measure(s)[1]	2020/21 Forecast	2021/22 Target	2022/23 Target	2023/24 Target
2.a SAIDI (System Average Interruption Duration Index)[2] [Total outage duration (in hours) of sustained interruptions experienced by an average customer in a year (excluding major events)]	3.09	3.20	3.17	3.17
2.b SAIFI (System Average Interruption Frequency Index)[2] [Total number of sustained interruptions experienced by an average customer in a year (excluding major events)]	1.41	1.40	1.38	1.38
2.c Key Generating Facility Forced Outage Factor (%)	1.25	1.80	1.80	1.80
2.d CSAT Index[3] [Customer Satisfaction Index: % of customers satisfied or very satisfied]	91	85	85	85
2.e Progressive Aboriginal Relations Certification[4]	Gold	Gold	Gold	Gold

[1] Performance Measure descriptions, rationale, data source information and benchmarking are available online at www.bchydro.com/performance
[2] Reliability targets are based on specific values, however performance within 10 per cent is considered acceptable given the reliability projection modelling uncertainty, the wide range of variations in weather patterns and the uncontrollable elements that can significantly disrupt the electrical system. BC Hydro reports reliability under normal circumstances, because major events are not predictable and largely uncontrollable. The reliability measure is therefore based on data that excludes major events. BC Hydro reviews performance during major events and takes the performance into consideration in reliability improvement initiatives.
[3] Customer Satisfaction Index (CSAT) is an index measuring customer satisfaction of BC Hydro's three main customer groups (residential, commercial and key accounts). The index is comprised of the five key drivers of satisfaction weighted equally across the three customer types.
[4] Progressive Aboriginal Relations is a certification program by the Canadian Council of Aboriginal Business. It is reviewed on a three-year cycle.

Linking Performance Measure to Objective

2.a &b Customer reliability is measured using the System Average Interruption Duration Index (SAIDI) and System Average Interruption Frequency Index (SAIFI). These, along with correlated cause analysis for customer outages, support targeted investment, planning and process improvements to meet our customers' needs for reliability.

By measuring the average number of service interruptions and number of hours of sustained interruptions experienced by the average customer in a year, we are able to track our ability to reliably meet the electricity requirements of customers.

2.c A forced outage occurs when a generating unit is unable to start generating or does not stay in service when needed. The Key Generating Facility Forced Outage Factor shows the trend of how the generation assets are performing and supports investment decisions to maintain asset reliability.

2.d The Customer Satisfaction (CSAT) Index measures customer satisfaction with BC Hydro on five key drivers: value for money; commitment to customer service; providing reliable electricity; acting in the best interest of British Columbians; and efforts to communicate to customers and communities. This measure gauges the degree to which BC Hydro is meeting customers' electricity and service needs.

2.e The Canadian Council of Aboriginal Business's Progressive Aboriginal Relations (PAR) Gold certification offers validation of BC Hydro's continuous improvement and focus on enhanced Indigenous relations. With BC Hydro's extensive footprint throughout the province, and our role as a Crown corporation, the comprehensiveness of the PAR certification acts as a measure for us to ensure our policies and practices across the company appropriately reflect Indigenous interests and our employees understand the importance of building and maintaining strong relationships with Indigenous Peoples.

Discussion

SAIDI and SAIFI targets are based on several factors including long-term historic reliability trending, current year performance, previous years' investments and future years' investment plans, while also accounting for annual variability due to weather. Consistent focus on customer reliability has continued to enable the 2021/22 targets to remain stable and to improve in 2022/23 to align with historical performance, planned investment, ongoing process improvements and expected benefits from planned increased investment in transmission and distribution vegetation programs.

There are seven Key Generating Facilities, representing those plants with installed capacity greater than 200 megawatts (MW). Together, they provide over 90 percent of the average annual electricity generated by BC Hydro's facilities. Key Generating Facility Forced Outage Factor is reported as a five-year rolling average and defined as the total forced outage time in a period relative to the total number of hours in the same period (usually one year). Annually, the Forced Outage Factor can be relatively volatile, and applying the historical five-year rolling average smooths the range to provide a more stable measure for which targets can be set. The objective is to keep the Forced Outage Factor below 1.80 percent of the total number of hours per year, which demonstrates the effectiveness of BC Hydro's maintenance and capital investment programs.

BC Hydro's CSAT 2020/21 forecast result reflects our responses to the COVID-19 pandemic, which included providing payment assistance to residential, small business and industrial customers. In 2021/2022 - 2023/2024, we will work to meet a CSAT index of 85.0 by consistently improving customer experience and meeting customers' growing expectations based on their interactions with other organizations.

The Canadian Council of Aboriginal Business' PAR is a certification program designed to help Canadian businesses benchmark, improve and signal their commitment to progressive relationships with Indigenous communities, businesses and people. It evaluates four areas of performance including: leadership actions; employment; business development; and community relations. PAR certification provides a high degree of assurance to Indigenous communities, as certification every three years is supported by an independent third-party verification and is determined by a jury comprised of Indigenous business people. BC Hydro has attained the highest, gold-level designation from the Canadian Council for Aboriginal Business since 2012. In 2021/22, BC Hydro will apply for the next certification and seek to sustain our gold level certification.

Goal 3: Help Keep Electricity Bills Affordable for our Customers

Objective 3.1: BC Hydro will help keep electricity bills affordable by managing our costs, exploring innovative solutions to support our customers and making cost-effective investments to maintain and expand our electricity system.

Key Strategies

- Working with the Province, continue delivering affordability measures, including demand-side management programs targeted to low-income households, to help our customers manage their electricity bills.
- Advance efficient and flexible rate proposals with the BCUC to help keep customers' electricity bills affordable.
- Submit Revenue Requirements Applications to the BCUC consistent with the goal of achieving rate increases that are less than the provincial rate of inflation, on a cumulative basis, for the period of Fiscal 2021 to Fiscal 2030.
- Make all reasonable efforts to keep rates affordable by implementing the outcomes of Phase 1 of the Comprehensive Review, including strategies to reduce future energy procurement costs.
- Implement recommendations of Phase 2 of the Comprehensive Review, to improve affordability of electricity, enable clean technological innovation, reduce GHG emissions through electrification, and advance reconciliation with Indigenous Peoples.
- Safely complete the Site C project within lowest practicable cost by the new expected in-service date of 2025. This includes work to:
    - Implement foundation enhancement measures to address geotechnical issues on the project's right bank.
    - Implement the recommendations of the independent consultant (Milburn) report, which include enhancing the independence, mandate and expertise of the Site C Project Assurance Board and strengthening BC Hydro's risk reporting and management.
    - Provide quarterly progress and exception reporting to Treasury Board.
- Implement our 10 Year Capital Plan so that our customers can continue to receive clean, reliable and affordable electricity.
- Continue to refine and enhance our systematic and disciplined project delivery methodology to ensure that our projects are put into service safely, on time, on budget and to a high standard of quality.
- Achieve benefits of improved procurement and supply chain management practices and tools.

Performance Measure(s)[1]	2020/21 Forecast	2021/22 Target	2022/23 Target	2023/24 Target
3.a Affordable Bills – Residential[2]	1st quartile	1st quartile	1st quartile	1st quartile
3.b Affordable Bills – Commercial[2]	1st quartile	1st quartile	1st quartile	1st quartile
3.c Affordable Bills – Industrial[3]	1st quartile	1st quartile	1st quartile	1st quartile
3.d Project Budget to Actual Cost[4]	-4.09% on $4.07 billion[5]	Within+5% to -5% of budget excluding project reserve amounts	Within+5% to -5% of budget excluding project reserve amounts	Within+5% to -5% of budget excluding project reserve amounts

[1] Performance Measure descriptions, rationale, data source information and benchmarking are available online at www.bchydro.com/performance

[2] As of 2020/21, BC Hydro calculates the Affordable Bills performance measure for residential and commercial customers as the median consumption level for residential and commercial customer classes compared to the equivalent power consumption sub-category from Hydro Quebec's annual report on North American electricity rates. The rankings of the 22 participating utilities are then allocated into quartiles. The 1st quartile ranking represents the six utilities that have the lowest monthly electricity bills on April 1 of a given year.

[3] BC Hydro measures affordability within the industrial category based on the largest consumption level from Hydro Quebec's annual report on North American electricity rates.

[4] This measure compares actual project costs at completion to the original approved expected cost budget for the project, not including project reserve amounts, for capital projects that were put into service during the five-year rolling period.

[5] This represents projects that went or are forecasted to go into service for the five-year period of 2016/17 to 2020/21.

Linking Performance Measure to Objective

3.a, b & c The Affordable Bills measures are based on BC Hydro's rankings in the residential, commercial, and transmission service rate categories in the annual Hydro Quebec report, Comparison of Electricity Prices in Major North American Cities. The report is used as a benchmark to demonstrate that our bills are affordable compared to other major North American utilities.

3.d Since 2015/16, BC Hydro has utilized the Project Budget to Actual Cost measure for the delivery of capital projects, with a target of actual project costs to be within +5 percent to -5 percent of the budget, excluding project reserves at the portfolio level. The +/- 5 percent target is the same over the plan period, as it is the objective to have the entire project portfolio in-service within this actual cost range. BC Hydro has consistently met this performance target, as we continue to prudently manage capital expenditures and keep rates affordable for our customers.

Discussion

The Affordable Bills measure was previously based on residential customers only and was calculated by averaging BC Hydro's ranking across multiple residential sub-categories, as reported in Hydro Quebec's annual report on North American electricity rates. While affordability in the residential rates category is important, we recognize that it is also important to our other customer classes and this measure has now been expanded to include commercial and industrial customers. The methodology for calculating these performance measures uses the median consumption level for the residential and commercial performance measures and the largest consumption level for the industrial performance measure. Median consumption level provides a better representation of the central tendency than average and the largest consumption level provides the best indication of BC Hydro's performance regarding rate competitiveness for large industrial customers.

The Project Budget to Actual Cost measure includes Dam Safety, Generation, Transmission Line, Substation and large Distribution projects, managed by BC Hydro Capital Infrastructure Project Delivery and Properties for the last five years. Annually, BC Hydro reports the past five years' performance at the portfolio level in delivering capital projects.

Goal 4: Help Make Renewable, Clean Power British Columbia's Leading Energy Source

Objective 4.1: BC Hydro will encourage the use of its renewable, clean power for electrification to reduce greenhouse gas emissions and will continue to invest in its energy-efficiency and conservation programs.

This objective was restated to highlight importance of electrification.

Key Strategies

- Support the implementation of the CleanBC plan to increase British Columbians' use of clean energy in transportation, buildings and industry by advancing an electrification plan and related performance measures.
- Support customers with initiatives and rate structures that help them make smart energy choices through our energy management (e.g. energy efficiency and conservation programs) and low carbon electrification initiatives.
- Provide customers with the opportunity to more easily access clean, renewable power to displace the use of higher carbon energy sources.
- As part of the CleanBC plan, partner with the Province and the federal government to help remote communities, with a focus on Indigenous communities, reduce or eliminate diesel generation and replace it with energy from cleaner sources.

Performance Measure(s)[1]	2020/21 Forecast	2021/22 Target	2022/23 Target	2023/24 Target
4.a Energy Conservation Portfolio (New incremental GWh/year)[2]	765	500	500	500
4.b Clean Energy (%)	98.0	93.0	93.0	93.0

[1] Performance Measure descriptions, rationale, data source information and benchmarking are available online at www.bchydro.com/performance
[2] BC Hydro's future Energy Conservation Portfolio targets will be informed by the next Integrated Resource Plan, filed with the BCUC.

Linking Performance Measure to Objective

4.a The Energy Conservation Portfolio performance measure reflects new incremental energy savings from programs, codes and standards and conservation rates. This measures the success of BC Hydro's planned conservation targets. Targets are rounded values and considered to be achieved if performance is within 10 percent of the stated values.

4.b The Clean Energy performance measure demonstrates BC Hydro's efforts to generate clean, sustainable, affordable electricity in order to reduce GHG emissions in the province and continue to meet the 93 percent minimum clean energy objective in the *Clean Energy Act*. The higher the percent clean energy that BC Hydro achieves, the lower the GHG emissions in the province.

Discussion

The targets for Energy Conservation Portfolio are based on BC Hydro's forecast of annual new incremental energy savings and do not reflect past performance and/or adjustments made to energy savings in prior years (e.g., persistence, evaluations, measurement and verification). In some cases, the timing of savings for anticipated codes and standards and timing of large customer projects can shift, which will cause actual incremental energy savings to vary from the targets that have been set for the period.

The Clean Energy performance measure represents the minimum threshold generation output in accordance with the B.C. Government's requirement that at least 93 percent of electricity generation in the province be from clean or renewable resources, as specified in the *Clean Energy Act.* While actual output of the non-clean resources in the system supports system reliability and can vary depending on market conditions and water inflows to our reservoirs, BC Hydro expects that the actual performance will remain close to 98 percent.

Financial Plan

Summary Financial Outlook

Consolidated Statement of Operations[1] ($ millions)	2020/21 Forecast	2021/22 Budget	2022/23 Budget	2023/24 Budget
Domestic	5,191	5,527	5,641	5,765
Trade	1,080	1,121	984	949
Total Revenues	**6,271**	**6,648**	**6,624**	**6,714**
Operating Costs				
Cost of energy	2,231	2,389	2,460	2,494
Personnel expenses, materials & external services[2]	1,236	1,317	1,332	1,364
Amortization	1,006	1,033	1,022	1,041
Grants and taxes	265	274	286	302
Finance charges	838	552	480	435
Other	198	101	120	111
Total Expenses	**5,775**	**5,667**	**5,700**	**5,747**
Net Income before movement in regulatory balances	497	981	924	967
Net movement in regulatory balances	194	(269)	(212)	(255)
Net Income	**691**	**712**	**712**	**712**
Other Selected Financial Information:				
Dividends	**-**	**-**	**-**	**-**
Net Debt[3]	**25,338**	**28,115**	**30,590**	**31,819**
Equity	**6,346**	**7,058**	**7,770**	**8,482**
Capital Expenditures	**3,573**	**4,738**	**4,413**	**3,305**

[1] Table may not add due to rounding.
[2] These amounts are net of capitalized overhead and consist of the following:

	2020/21	2021/22	2022/23	2023/24
Domestic Base Operating Costs	833	905	918	937
Other	403	412	415	427
	1,236	1,317	1,332	1,364

Other largely consists of Powerex & Powertech operating costs, IFRS-ineligible capital overhead phased into operating costs over a 10-year period ending in 2020/21, and expenses subject to regulatory deferral.
[3] Debt figures are net of sinking funds and cash and cash equivalents.

Key Forecast Assumptions, Risks and Sensitivities

Key Assumptions	2020/21 Forecast	2021/22 Budget	2022/23 Budget	2023/24 Budget
Growth and Load				
B.C. Real Gross Domestic Product Growth (%)[1]	(6.7)	3.0	3.8	2.7
Domestic Sales Load Growth (%)[2, 3]	(2.46)	3.54	1.54	2.43
Load and System Exports:				
Domestic Sales Volume (GWh)	50,655	52,448	53,258	54,552
System Exports Volume (GWh)	9,220	6,979	5,893	4,827
Line Loss and System Use (GWh)	4,947	5,376	5,417	5,509
Total Load and System Exports (GWh)	64,821	64,802	64,568	64,887
Energy Generation				
Total System Water Inflows (% of average)	110	100	100	100
Sources of Supply:				
Hydro Generation (GWh)	48,807	46,718	45,635	45,253
System Imports (GWh)	1,257	1,836	2,588	3,291
Independent Power Producers and Long-term Purchases (GWh)	14,502	15,970	16,059	16,036
Thermal Generation & Other (GWh)	255	278	287	307
Sources of Supply (GWh)	64,821	64,802	64,568	64,887
Average Mid-C Price (U.S.$/MWh)	27.87	30.83	29.78	28.67
Average Natural Gas Price at Sumas (U.S.$/MMBTU)	3.11	3.08	2.61	2.46
Financial				
Canadian Short-Term Interest Rates (%)[4]	0.24	0.24	0.30	0.60
Canadian Long-Term Interest Rates (%)[4]	1.49	1.86	2.12	2.37
Foreign Exchange Rate (U.S.$:Cdn$)[4]	0.7452	0.7630	0.7660	0.7712

[1] Economic assumption based on calendar year, 2020/21 to 2021/22 from Ministry of Finance September 2020 First Quarter Report; 2022/23 to 2023/24 from Conference Board of Canada – August 2020.
[2] Includes the impact of Demand Side Management programs.
[3] Excludes system exports.
[4] Financial assumptions from Ministry of Finance, October 2020.

Sensitivity Analysis

Factor	Change	Approximate change in 2021/22 earnings before regulatory account transfers (in $ millions)
Customer Load[1]	+/- 1%	35
Interest Rates[2]	+/- 100 basis points	30
Electricity/Gas trade margins[3]	+/- 10%	30
Hydro Generation (GWh)[4]	+/- 1%	10
Exchange rates (US/ CDN)	+/-$0.01	5

[1] Assumes a percentage change is applied equally to all customer classes. Assumes a change in customer load is offset by a corresponding change in system imports or exports.
[2] Relates to debt subject to interest rate variability.
[3] Trade revenues less trade energy costs.
[4] Assumes a change in hydro generation is offset by a corresponding change in system imports or exports.

Management's Perspective on the Financial Outlook

In December 2020, BC Hydro filed an application with the BCUC for its revenue requirements for 2021/22. BC Hydro expects a decision in spring 2021 which may change the financial projections for revenues and expenses.

The current financial projections for revenues and expenses through 2023/24 were approved by the BC Hydro Board of Directors and submitted to the Ministry of Finance in March 2021.

The COVID-19 pandemic continues to adversely impact global economic activity and has contributed to significant volatility in financial markets. The pandemic could have a sustained adverse impact on economic and market conditions and could adversely impact BC Hydro's future performance if it were to cause a prolonged decrease in customer load, volatility in electricity/gas trade margins and interest rates, difficulty accessing debt, project delays and project cost escalations.

While BC Hydro engages in emergency preparedness (including business continuity planning) to mitigate risks, the persisting uncertainty of this situation limits the ability to predict the ultimate adverse impact of COVID-19 on BC Hydro's performance, financial condition, results of operations and cash flows.

This plan contains forward looking statements, including statements regarding the business and anticipated financial performance of BC Hydro. These statements are subject to a number of risks and uncertainties such as customer load, interest rates, electricity/gas market conditions and our ability to deliver our capital projects on-time and on-budget. These and other risks and uncertainties may cause actual results to differ from those contemplated in the forward-looking statements.

Capital Expenditures by Year and Type and Function

($millions)	2020/21 Forecast	2021/22 Forecast	2022/23 Forecast	2023/24 Forecast
Capital Expenditures by Type[1]				
Sustaining	1,004	1,146	1,259	1,234
Growth	2,569	3,592	3,154	2,071
Subtotal – BC Hydro Capital Expenditures before CIA	3,573	4,738	4,413	3,305
Contributions-in-Aid (CIA)[2]	(160)	(214)	(167)	(171)
Total – BC Hydro Capital Expenditures net of CIA	3,413	4,524	4,246	3,134
Generation	351	388	427	486
Transmission and Distribution	891	995	1,091	1,153
Properties, Technology and Other	224	226	210	215
Site C Project[3]	2,107	3,129	2,685	1,451
Subtotal – BC Hydro Capital Expenditures before CIA	3,573	4,738	4,413	3,305
CIA	(160)	(214)	(167)	(171)
Total BC Hydro Capital Expenditures net of CIA	3,413	4,524	4,246	3,134

1. BC Hydro classifies capital expenditures as either sustaining capital or growth capital:
    - Sustaining capital includes expenditures to ensure the continued availability and reliability of generation, transmission and distribution facilities. It also includes expenditures to support the business, such as vehicles and information technology.
    - Growth capital includes expenditures to meet customer load growth and other business investments. Growth capital includes expenditures to expand existing generation assets as well as expand and reinforce the transmission and distribution system, and includes Site C.
2. Contributions in aid of construction are amounts paid by certain customers toward the cost of property, plant and equipment required for the extension of services to supply electricity.
3. Site C project forecast expenditures have been updated to reflect the costs estimated at $16 billion, which was announced on February 26, 2021.

Projects over $50 million

BC Hydro has the following projects, each with capital costs expected to exceed $50 million, listed according to targeted completion date. These projects have been approved by the Board of Directors.

Major Capital Projects (over $50 million)	Targeted Completion Date (Calendar Year)	Project Cost to Dec 31, 2020 ($ millions)	Estimated Cost to Complete ($ millions)	Anticipated Total Capital Cost of Project ($ millions)
Projects Recently Put Into Service				
Fort St. John and Taylor Electric Supply This project maintained adequate supply capability, reduced line losses and improved reliability to the loads in the Fort St. John and Taylor areas by re-terminating 138kV transmission lines at the new Site C switchyard, and the addition of a 75 MVA transformer and new feeder positions.	2020 In-Service	$51	$1	$52
UBC Load Increase Stage 2 Project This project was on behalf of BC Hydro's customer, the University of British Columbia, to continue to reliably meet the growing electricity needs of its Point Grey campus and the surrounding community.	2020 In-Service	$48	$7	$55

Major Capital Projects (over $50 million)	Targeted Completion Date (Calendar Year)	Project Cost to Dec 31, 2020 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Total Capital Cost of Project ($ millions)
Ongoing				
South Fraser Transmission Relocation Project* This project is intended to relocate certain sections of two 230kV transmission circuits (Circuit 2L62 and Circuit 2L58) from their present location adjacent to Highway 99 and in the George Massey tunnel to accommodate the replacement of the tunnel. These two 230kV circuits form a critical part of BC Hydro's transmission network supplying power to customers in Richmond, Delta and the Greater Vancouver area. ***Construction work on the South Fraser Transmission Relocation project is currently suspended pending the government's review of the George Massey Tunnel replacement.***	TBD	$30	$46	$76
Downtown Vancouver Electricity Supply: West End Strategic Property Purchase This project is to acquire property rights to build and connect a new underground substation that will upgrade the aging electricity system in downtown Vancouver.	2021 Targeted In-Service	$67	$14	$81

Major Capital Projects (over $50 million)	Targeted Completion Date (Calendar Year)	Project Cost to Dec 31, 2020 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Total Capital Cost of Project ($ millions)
Peace Region Electricity Supply (PRES) Project This project is needed to provide sufficient transmission system capacity to serve load growth and increase the reliability of electricity supply to existing customers in the South Peace. This project will facilitate reductions in provincial greenhouse gas emissions by enabling electrification of natural gas production, processing, and compression. **The total cost represents the gross cost of the project and has not been netted for potential Federal Government contributions.*	2021 Targeted In-Service	$193	$92	$285*
LNG Canada Load Interconnection Project This project is to facilitate the interconnection of LNG Canada's facility. A new double circuit 287kV transmission line will be constructed from Minette Substation (MIN) to LNG Canada's facility and system reinforcements at MIN will also be implemented. Under BC Hydro's standard tariffs, the customer is required to pay for a portion of this project's costs. **The total cost represents the gross cost of the project and has not been netted for a customer's contribution of $24M.*	2021 Targeted In-Service	$65	$17	$82*

Major Capital Projects (over $50 million)	**Targeted Completion Date (Calendar Year)**	**Project Cost to Dec 31, 2020 ($ millions)**	**Estimated Cost to Complete ($ millions)**	**Approved Total Capital Cost of Project ($ millions)**
Bridge River 2 Upgrade Units 7 and 8 Project This project will replace the two generators and other related equipment to restore the historical operating capacity. Units 7 and 8 were placed into service in 1960, are unreliable and in poor and unsatisfactory condition.	2021 Targeted In-Service	$50	$36	$86
Wahleach Refurbish Generator Project This project will improve the reliability of the generator at Wahleach Generating Facility, and its scope includes replacement of the stator and rotor poles, refurbishment of the remaining major components, and a combination of new, replacement, and refurbishment of the auxiliary components. The project also includes the installation of a new powerhouse crane and structural upgrades to the powerhouse building.	2022 Targeted In-Service	$24	$27	$51
Mica Replace Units 1 to 4 Generator Transformers Project This project will address the reliability and safety risks of the Unit 1-4 Generator Step-up Unit transformers at the Mica Generating Station, which are nearing end of life. There is a heightened reliability and safety risk from continuing to operate these transformers in an underground powerhouse as they age.	2022 Targeted In-Service	$41	$39	$80

Major Capital Projects (over $50 million)	Targeted Completion Date (Calendar Year)	Project Cost to Dec 31, 2020 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Total Capital Cost of Project ($ millions)
G.M. Shrum G1 to 10 Control System Upgrade This project will replace the controls equipment, provide full remote-control capability from the remote-control center, and rectify deficiencies in the current system. The condition of the legacy controls for the GMS generating units, which were originally installed in the 1960s and 1970s, is of growing concern due to increasing maintenance requirements, lack of available spare parts and decreasing reliability. The controls are well beyond their expected life, which causes operating problems and increases the risk of damage to major equipment.	2022 Targeted In-Service	$51	$24	$75
Mount Lehman Substation Upgrade Project This project will increase the firm capacity of the Mount Lehman Substation to address safety and asset health concerns at both the Clayburn and Sumas Way substations.	2023 Targeted In-Service	$20	$39	$59

Major Capital Projects (over $50 million)	Targeted Completion Date (Calendar Year)	Project Cost to Dec 31, 2020 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Total Capital Cost of Project ($ millions)
Street Light Replacement Program The program will convert approximately 95,000 BC Hydro owned and maintained High Pressure Sodium (HPS) and Mercury Vapour (MV) street lights to Light Emitting Diode (LED) street lights. This is required to meet federal polychlorinated biphenyl (PCB) environmental regulations by the end of 2025, manage increasing operations and maintenance costs, and better meet our customers' expectations. Lights have started to be converted and conversions will complete in 2023.	2023 Targeted In-Service	$4	$76	$80
5L063 Telkwa Project This project will increase the reliability and reduce the safety risks of the 500kV radial transmission line (5L063) that provides service for customers in Northwest British Columbia. A portion of the 5L063 line will be relocated away from the current area of unstable terrain.	2023 Targeted In-Service	$15	$51	$66
Mica Modernize Controls Project This project will address the reliability, maintainability, and operability of the Units 1-4 exciters, governors, unit controls and control room controls at the Mica Creek Generating Station.	2023 Targeted In-Service	$26	$30	$56

Major Capital Projects (over $50 million)	Targeted Completion Date (Calendar Year)	Project Cost to Dec 31, 2020 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Total Capital Cost of Project ($ millions)
Capilano Substation Upgrade Project This project will address the existing asset health, reliability, safety, and environmental issues associated with the Capilano Substation, and to ensure that the capacity of the substation meets the long term area needs. The project will also introduce a 25kV source to enable 25kV voltage conversion and facilitate the execution of other future substation projects in the North Shore area.	2024 Targeted In-Service	$11	$76	$87
Sperling Substation (SPG) Metalclad Switchgear Replacement Project This project will address the existing asset health, reliability and safety risks associated with the 12kV 60 series feeder section and the bulk oil breaker in the 12 kV 70/80 series feeder section, insufficient electrical clearances in the 60 series feeder section, and arc flash safety risks associated with the 12kV indoor metalclad switchgear.	2024 Targeted In-Service	$5	$49	$54

Major Capital Projects (over $50 million)	Targeted Completion Date (Calendar Year)	Project Cost to Dec 31, 2020 ($ millions)	Estimated Cost to Complete ($ millions)	Estimated Total Capital Cost of Project ($ millions)
Site C Project*** This project will construct a third dam and a hydroelectric generating station on the Peace River approximately seven kilometres southwest of Fort St. John. It will be capable of producing approximately 5,100 gigawatt-hours of electricity annually and 1,100 megawatts of capacity. Site C will provide clean, renewable and cost-effective power in B.C. for more than 100 years. **Planned in-service date for all units.* ***Site C project total anticipated cost and project cost to date include capital costs, charges subject to regulatory deferral and certain operating expenditures.* ****As announced on February 26, 2021, the cost of the Site C project is estimated at $16 billion, with a one year delay to 2025 for the project in-service date.BC Hydro continues to review the updated cost estimate, along with risks, further to recommended actions in the Milburn Report*	2025* Targeted In-Service	$6,455	$9,545	$16,000**

Information Technology (IT) Projects over $20 million

BC Hydro has the following IT project with capital costs expected to exceed $20 million. This project has been approved by the Board of Directors.

Significant IT Projects (over $20 million in total)	Targeted Completion Date (Calendar Year)	Project Cost to Dec 31, 2020 ($ millions)	Estimated Cost to Complete ($ millions)	Anticipated Total Capital Cost of Project ($ millions)
Project Recently Put Into Service				
Supply Chain Applications Project This project replaced BC Hydro's existing PassPort supply chain information technology (IT) system with an SAP-based IT system and made improvements to BC Hydro's supply chain business processes for third-party materials and service acquisitions.	2020 In-Service	$67	$2	$69

Appendix A: Additional Information

Corporate Governance

Information about Corporate Governance can be found at:

http://www.bchydro.com/about/accountability_reports/financial_reports/service_plan.html.

This includes links to information regarding, and includes all information detailed in the Best Practice Guidelines: Governance and Disclosure Guidelines for Governing Boards of British Columbia Public Sector Organizations:

- Board of Directors
- Executive Team
- Code of Conduct
- Board Governance Manual

Organizational Overview

Information about BC Hydro's organizational overview can be found at:

https://www.bchydro.com/toolbar/about.html

This includes links to information about BC Hydro's operations, governance and mandate.

Appendix B: Subsidiaries and Operating Segments

Active Subsidiaries

As wholly-owned subsidiaries, and like BC Hydro itself, Powerex Corp. and Powertech Labs Inc. follow best practices in corporate governance and subsidiary activities align with BC Hydro's mandate, strategic priorities and fiscal plan.

Powerex Corp.

Powerex Corp., an energy marketer, is a wholly-owned corporate subsidiary of BC Hydro and a key participant in wholesale energy markets across North America. Powerex's business consists of trading wholesale power and natural gas, environmental products (renewable energy credits or other similar products), carbon products (allowances and other similar products), ancillary energy services, and financial energy products.

Through its contractual agreements with BC Hydro, Powerex supports BC Hydro's system requirements by importing and exporting energy. Powerex also markets, through a contractual agreement with the Province, the Canadian Entitlement to the Downstream Power Benefits under the Columbia River Treaty.

The Chief Executive Officer (CEO) of Powerex reports directly to the Board of Directors of Powerex. The Chair of the Powerex Board ensures the Board of BC Hydro is informed of Powerex's key strategies and business activities. The Powerex CEO also informs the BC Hydro President & CEO and Executive Team of Powerex's key strategies and business activities.

Powerex operates in competitive and complex wholesale energy-markets, which can cause net income in any given year to vary significantly. Market, economic and weather conditions, reduced hydro system flexibility, unrealized mark-to-market gains or losses and the strength of the Canadian dollar can materially impact Powerex net income. The Service Plan forecast includes annual trade income from Powerex of approximately $190 million per year for 2021/22 to 2023/24, based on the average earnings over the last five fiscal years. For more information, visit powerex.com

Board of Directors:

- Ken Peterson – Chair
- Len Boggio
- Valerie Lambert
- Chris O'Riley

Powertech Labs Inc.

Powertech Labs Inc., operating in Surrey since its inception in 1979, is a wholly-owned subsidiary of BC Hydro. Powertech is internationally recognized as technical experts in a range of fields related to the electric utility and clean energy industries and offers services and solutions including performance and type testing, asset lifecycle management solutions, engineering studies, and power system modelling and analysis to energy clients, including BC Hydro, and other sectors globally. Powertech is also a technical leader in hydrogen energy, providing certification, performance, and safety testing services for hydrogen components and systems, as well as the design and construction of innovative hydrogen vehicle refueling systems.

The President and CEO of Powertech reports to Powertech's Chair of the Board. The Powertech Board is chaired by BC Hydro's President and CEO and its Directors include senior Executives of BC Hydro.

The Service Plan forecast includes annual net income from Powertech ranging from approximately $2 to $4 million per year for 2021/22 to 2023/24. For more information, visit powertechlabs.com.

Board of Directors:

- Chris O'Riley - Chair
- Melissa Holland
- Kip Morison
- David Wong

Other Subsidiaries

BC Hydro has created or retained a number of other subsidiaries for various purposes, including holding licences in other jurisdictions, to manage real estate holdings and to manage various risks.

All the staff and management needs of the active subsidiaries below are fulfilled by BC Hydro employees, who perform these duties without additional remuneration. Three of these subsidiaries are considered active:

BCHPA Captive Insurance Company Ltd.
Procures insurance products and services on behalf of BC Hydro.

Columbia Hydro Constructors Ltd.
Administers and supplies the labour force to specified projects.

Tongass Power and Light Company
Provides electrical power to Hyder, Alaska from Stewart, B.C. due to its remoteness from the Alaska electrical system.

Nominee Holding Companies and/or Inactive/Dormant Subsidiaries
BC Hydro's remaining subsidiaries either serve as nominee holding companies (indicated with an *) or are considered to be inactive/dormant. The inactive/dormant subsidiaries do not carry on active operations. As of February 28, 2021, these other subsidiaries consisted of the following:

1. British Columbia Hydro International Limited
2. British Columbia Power Exchange Corporation
3. British Columbia Power Export Corporation
4. British Columbia Transmission Corporation
5. Columbia Estate Company Limited*
6. Edmonds Centre Developments Limited*
7. Fauquier Water and Sewerage Corporation
8. Hydro Monitoring (Alberta) Inc.*
9. Victoria Gas Company Limited
10. Waneta Holdings (US) Inc.*
11. 1111472 BC Ltd.

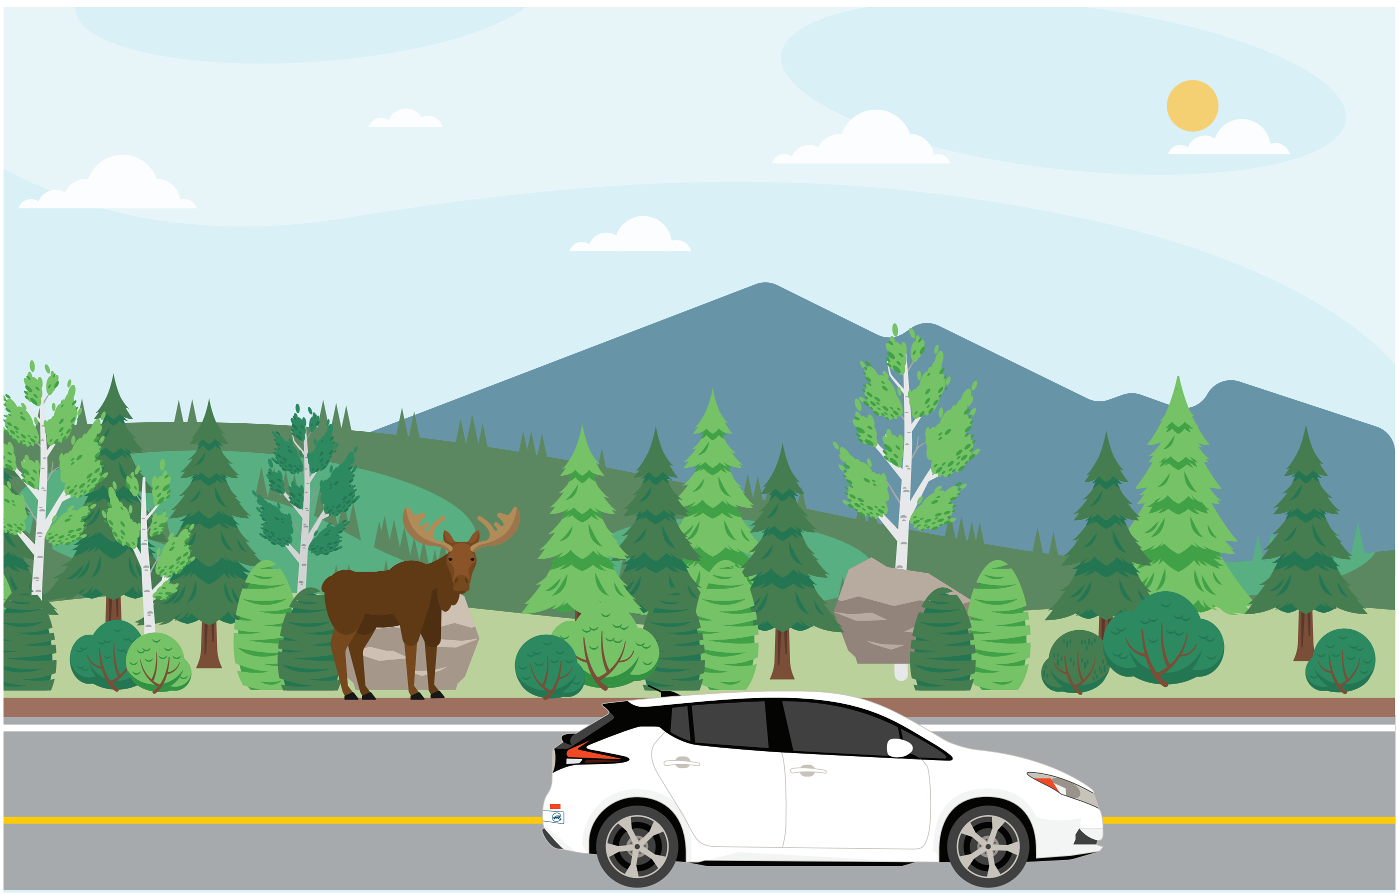
BC Hydro Fiscal 2023 to Fiscal 2025
Revenue Requirements Application

Appendix D

Five-year Strategy

Powering a cleaner more sustainable future for all British Columbians

BC Hydro's five-year strategy Fiscal years 2022 – 2026



BC Hydro Power smart

CS–16

Contents

How we operate

At its core, our job is to safely keep the lights on for the people of British Columbia.

This work is constant, complex and important to who we are as a utility.

- It's about planning and managing our reservoirs, generation and downstream discharges, while also considering factors like dam safety, flooding, and fish and fish habitat.
- It's about having the right people and processes in place to safely restore power when a storm brings widespread outages to our neighbourhoods.
- It's about making sure we keep goods and services moving through our company so that everything from pens to power poles to personal protective equipment (PPE), gets where it's needed on time.
- It's about building relationships within our communities and supporting customers who reach out about everything from programs and bill requests, to reporting outages and requesting new connections.
- It's about keeping safety at the heart of everything we do, so that every person working for BC Hydro and interacting with our system goes home safely each day.
- It's about operating our system and making the right capital investments to support our customers' needs today, tomorrow and 20 years from now.

Our core work doesn't change.

An ambitious plan for a sustainable future

This plan represents our strategy for the next five years, ending in fiscal year 2026.

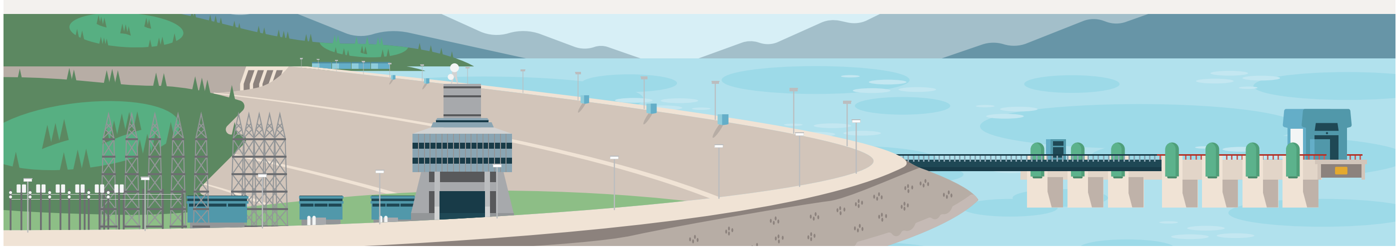
It lays out where we are choosing to invest in addition to our core work. Focusing on these areas will allow us to maximize opportunities, manage challenges, and leave BC Hydro and British Columbia more resilient and better off.

We've considered the outcomes of the government's Comprehensive Review of BC Hydro to contain rate increases, control costs and position BC Hydro for future success. We've accounted for the significant changes and shifts taking place in B.C. and continental energy sectors, in addition to evolving technologies and the changing needs of current and future BC Hydro customers.

We recognize the opportunity we have to strengthen relationships with Indigenous communities. We know our clean electricity can make significant positive impact on climate change and the environment by supporting the reduction of greenhouse gas (GHG) emissions.

This is an ambitious plan. Achieving the objectives we've laid out will require us to make trade-offs to get the most out of scarce resources. It will take targeted investment, organizational focus, and hard work.

We are up for the challenge.



Five years is just a snapshot of a much longer path forward

Doug Allen
Board Chair

Chris O'Riley
President &
Chief Executive Officer

Hi everyone,

We are fortunate to be part of BC Hydro at this juncture in its history; our industry is standing on the precipice of change and we are looking out at new opportunities and growth.

At the same time, we must balance our optimism for the future, with a critical look and appreciation for our changing landscape and the challenges before us. These times call for a clear understanding of our situation and an articulation of a viable path forward.

Our sector is experiencing transformational trends in areas like climate change, technological advances, and the evolution of customer energy use. At the same time, we are dealing with the immediate impacts and uncertainties of the COVID-19 pandemic. The intersection of these events points to the need to reflect on what has driven our success up to now, and what will drive our success moving forward.

Since its formation, BC Hydro has played a pivotal role in the growth and economic prosperity of British Columbia. Development of some of the world's most ambitious hydroelectric projects in the 1960s, 70s and 80s has endowed our province with a large-scale hydro reservoir system that provides an abundance of flexible capacity and clean electricity. Successfully completing Site C will further contribute to this legacy providing British Columbians with clean, reliable and affordable electricity for the next 100 years. While the system has evolved over the years, capacity and flexibility are, and will continue to be, a differentiating strength. Our clean energy has the potential to make a massive difference to the health of the environment, both within B.C. and beyond by displacing more carbon intensive energy sources.

"Development of some of the world's most ambitious hydroelectric projects in the 1960s, 70s and 80s has endowed our province with a large-scale hydro reservoir system that provides an abundance of flexible capacity and clean electricity."

We have a big task before us. We are embarking on the development of our next Integrated Resource Plan, we're completing work to understand and meet the evolving needs of our customers and there's an important role for us to play in supporting British Columbia's climate action and economic growth objectives. Throughout, our core work of providing our important service to our customers will remain constant. It's imperative that we have a corporate strategy in place to guide us as we invest and work toward our refreshed vision: a cleaner, more sustainable future for all British Columbians.

Ours is a long game. Five years is just a snapshot of a much longer path forward. It represents an opportunity to make incremental progress in those areas that will ensure British Columbians get the most benefit from the strengths of the system we manage.

This strategy represents the culmination of a huge amount of work done by staff, the Executive Team and members of the Board on many different streams, including the Government's Comprehensive Review, over the past several years.

We thank everyone for their passionate involvement.

Thriving in a dynamic world

Our plan takes into consideration the environment we operate in, the strengths we have as an organization and the opportunities and challenges that lie ahead.

Check out Appendix B for more details on these considerations.

Here are some of the key drivers that influenced our thinking:

- **Climate Change** is impacting how our system operates, and driving focus on clean energy
- **Technology** is changing how electricity is produced, distributed, and consumed
- **Grid modernization** is enabling efficiency and new functionality
- Increased demand for **storage and capacity resources**
- Commitment to **Indigenous reconciliation and Calls to Action of the Truth and Reconciliation Commission**
- **COVID-19** impacts
- **Customers expect more** information, input into decisions and involvement in managing energy use
- **Economic shifts** have changed who is consuming energy and how much

Site C: a multi-generational investment in affordable, reliable and renewable energy

As we launch this five-year strategic plan, the construction of Site C is at the halfway mark. The project, which will provide British Columbians with clean, reliable and affordable electricity for the next 100 years, is one of the most significant infrastructure investments undertaken in B.C. in recent history.

In October 2020, Site C reached its most important milestone to date when the Peace River was successfully diverted around the dam site. The project also completed and energized the Site C substation, and the first of two new transmission lines was placed into service. Both of these milestones were completed ahead of schedule.

The difficulties facing the project are considerable and have resulted in significant challenges for our team. The global COVID-19 pandemic, along with the need for foundation enhancements on the right bank to deal with unanticipated geotechnical conditions, have resulted in schedule delays and significant cost pressures to completing Site C.

BC Hydro will work with government to implement recommendations resulting from the recent independent review of the Site C project to enhance oversight and management of the project. BC Hydro is committed to completing Site C safely, meeting all compliance requirements, within the revised project schedule and budget.

Successfully completing Site C is key to this strategy and our vision of powering a cleaner more sustainable future for all British Columbians. Site C will provide the clean energy needed to grow our load and decarbonize the economy through electrification. Its clean capacity will support the integration of renewables now and into the future.

A look at our five-year plan

Our mission
stays constant

It's the driver of our core work

We are here to safely provide our customers with reliable, affordable, clean electricity.

Our vision
for the future is clear

It's clean power

A cleaner, more sustainable future for all British Columbians.

Our values
define our culture

They guide our approach to powering the province

We are safe.

We are here for our customers.

We act with integrity and respect.

We are one team.

We are forward thinking.

We include everyone.

To get where we want to be, we'll need to focus on what our province needs.

- Maintain affordability of electricity.
- Meet rising customer expectations.
- Reduce greenhouse gas emissions through efficient electrification.
- Advance reconciliation with Indigenous Peoples.

FOUROVERFIVE

Four goals make up our plan to move BC Hydro forward over the next five years.

- Grow our load
- Control our costs
- Strengthen our resilience and agility
- Advance reconciliation with Indigenous Peoples

A refreshed vision and values

Our vision celebrates our clean energy advantage and our environmental stewardship role in B.C. Sustainability is about making the best choices with available resources; this means leveraging our clean electricity for all British Columbians. For us, respect for our province and the integrity to act in good faith go hand-in-hand, so we've combined these values. To be successful, we need to include a diversity of perspectives and experiences in our decision making. Our new value—We include everyone—declares this expectation and our responsibility to one another.

Four goals will carry us forward

1 Grow our load

Increase load through low carbon electrification.

Develop and implement rate design strategy.

Implement Site C review recommendations and successfully complete Site C.

Strengthen our business development and sales capabilities.

Promote electric vehicle adoption.

Increase understanding of customers.

Develop Integrated Resource Plan.

Identify opportunities for Indigenous Nations.

Cost-effective efficiency programs.

Attract new industries to B.C.

Adopt 100% Clean Energy Standard.

2 Control our costs

Continue culture of cost management.

Pursue agile technology solutions.

Implement integrated work management system.

Achieve process improvements.

Achieve benefits from improved procurement and supply chain.

Build compelling Revenue Requirements Applications.

3 Strengthen our resilience and agility

Implement robust compliance program.

Complete implementation of safety management and assurance system.

Increase investment in training and development.

Increase investment in cybersecurity.

Increase investment in vegetation management and Mandatory Reliability Standards compliance.

Implement COVID-19 learnings. Improve support for front-line employees.

Strengthen our inclusivity.

4 Advance reconciliation with Indigenous Peoples

Finalize Relationship Agreements.

Develop and implement UNDRIP plan.

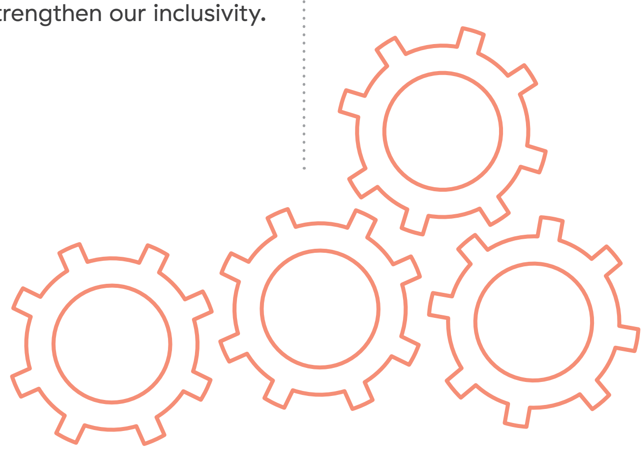
Explore new Indigenous procurement opportunities.

Increase opportunities for Indigenous employment.

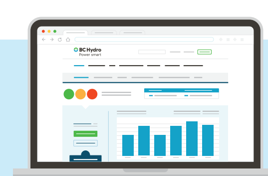
Reduce reliance on diesel generation.

Pursue ownership opportunities such as new radial transmission.

Increase engagement and participation in planning.



We'll track our progress and measure our success as we go along using clearly defined metrics (see Appendix A).



Grow our load

Why it's important

Maintaining and efficiently growing load is a critical part of how we keep our rates affordable and competitive for our customers.

Over the last number of years, we've seen load declining in some sectors due to economic factors and shifts in how we use energy.

Adding to this pressure is the unprecedented loss of load due to the COVID-19 pandemic.

Globally, we're seeing the world react to climate change and the need to urgently reduce carbon emissions. In B.C., we already know the power of clean electricity. We know that encouraging customers to switch to our clean electricity supports the reduction of greenhouse gas emissions (GHGs). The opportunity to grow load through electrification is significant—currently electricity represents only 19% of total energy consumption in B.C.

We have an opportunity to use our clean electricity to electrify the economy. The positive impact electrification can have on the environment, both within B.C., and beyond, is significant. B.C. will need more renewable energy to support growth, transition away from fossil fuels and meet our climate targets. Site C will help our province achieve these important objectives. Wherever possible, we'll extract more value out of technology and infrastructure we've already put in place to avoid the development of additional significant generation infrastructure. Growth can only be successful when we also focus on understanding and delivering on the needs of our existing customers as well as potential new customers.

The affordability equation

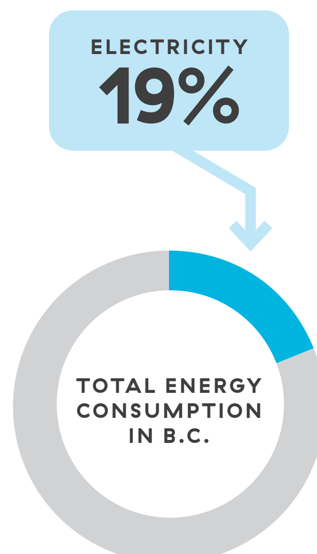
Our rates are the result of dividing the costs to run the system by the volume of electricity we sell.

As with other utilities, many of our costs are fixed, which means they stay the same whether we sell more or less electricity.

How does this relate to rates and affordability for our customers? You can think of it like a math equation or "affordability equation." Our rates are essentially the result of an equation where costs are the numerator and electricity demand is the denominator.

$$\frac{\text{COSTS}}{\text{DEMAND}} = \text{RATES}$$

When electricity demand falls, it puts upward pressure on future rates as our system costs need to be recovered through a lower volume of electricity sales. And when costs increase without load growth or productivity gain, we see a negative impact on affordability.



Grow our load

What we plan to do

- Develop an electrification plan to grow existing and secure new load, pursuing efficient electrification opportunities with industrial customers, the transportation sector, and the built environment (structures and buildings).
- Develop and implement a rate design strategy that supports the objectives of economic efficiency, affordability, decarbonization, and flexibility, and promotes growth of load.
- Implement Site C review recommendations and successfully complete Site C.
- Strengthen our business development and sales capabilities and partner with government to promote B.C.'s clean electricity advantage.
- Implement transportation electrification measures that reduce customer connection costs, encourage off-peak charging of electric vehicles, build out charging infrastructure, and support the growing clean transportation economy.
- Use data analytics and engagement to better understand what our current and future customers need from BC Hydro.
- Develop an Integrated Resource Plan (IRP) to meet future load requirements of the system, while controlling costs.
- Identify opportunities for Indigenous Nations to participate in the efficient growth of electricity load in the province.
- Maintain cost effective efficiency programs, including programs targeted to low-income ratepayers, to support customers to be efficient with their current use of electricity and leverage these programs to offer low carbon electrification programs that encourage growth of electricity.
- Attract innovative new industries to British Columbia and promote B.C.'s clean energy advantage including leveraging Powertech Lab's leadership and experience.
- Pursue a 100% clean energy standard to ensure continued market access and to increase the value of our product.

What success will look like

- We have grown our load and reduced GHGs, balanced with efficiency and conservation, and have the revenue required to make key investments while maintaining affordability.
- We have safely completed Site C, within revised schedule and budget.
- We successfully managed the generation and transmission demands of our load growth while considering cost effectiveness, including mitigating system capacity impacts through rates such as optional time of use and demand response.
- We have helped our customers leverage government programs like the CleanBC Industry Fund to support GHG reduction through electrification.
- We have found opportunities for Indigenous Nations to participate in and benefit from efficient load growth.
- We have attracted new businesses to B.C. by being cost competitive. This could include new industries such as hydrogen, bio-technology, as well as highly mobile energy intensive operations like data centres. This diversification has mitigated load lost from declining sectors.
- The public and our customers clearly understand how conservation and load growth work together.

Growth and conservation: complementary strategies

Our demand-side management programs have always been about the smart and efficient use of electricity. In addition to providing customers with bill savings and giving us more flexibility on the system, it's a more sustainable use of our clean resource.

Electrification is about the efficient use of energy overall. Helping our customers switch to clean electricity helps us reduce carbon emissions.

In this way, growth and conservation are complementary strategies. We can encourage residential customers to improve home insulation to reduce heating costs, while also encouraging them to switch from a gas to an electric vehicle.

Grow our load

Measuring our success

Performance measures supporting five-year strategy	Targets
Load growth supporting CleanBC (GWh)	4700 GWh by end of F26
New connected commercial and industrial load (MW)	750MW (5000 GWh) by end of F26
GHG emissions reduction – electrification (tonnes CO_2e/year)	2.5 million tonnes/year by end of F26
GHG emissions reduction — BC Hydro operations	45% reduction from 2007 levels by 2025
Clean electricity standard	100% clean energy by Q3 F25
Customer Interconnection studies completed on time	80% annual target
Demand-side management capacity (MW)	Target to be developed and included in 2021 Integrated Resource Plan
Customer satisfaction index	85% annual target

Our environmental advantage: clean energy

CleanBC, the provincial government's plan for creating a more sustainable future, sets big goals—and we're a big part of them.

The plan outlines how we'll reduce our greenhouse gas emissions by transforming our buildings, transportation, and how we power our economy and use cleaner energy. A key component of how we'll do that is through clean electricity.

We used to say our conservation program, Power Smart, was our largest environmental program. Today, it's our electrification program because of the reach and affect it can have on emissions. Playing a bigger role in this space, gives us the opportunity to have meaningful impact on the environment, in the economy and in broader society.

CleanBC sets the stage for a new era at BC Hydro—one where clean electricity is the preferred energy source.

CleanBC GHG reduction targets

Sectoral GHG targets for 2030 are expressed as a percentage reduction from 2007 sector emissions:

- Transportation: 27 to 32%
- Industry: 38 to 43%
- Oil and gas: 33 to 38%
- Buildings and communities: 59 to 64%

$ Control our costs

Why it's important

Managing costs is critical to providing affordable and competitive rates that our customers expect.

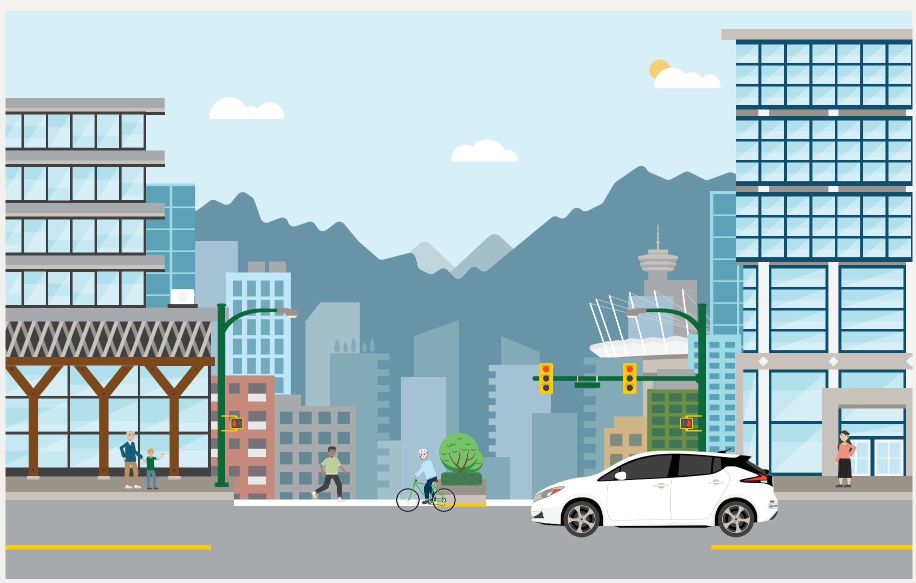
It allows us to address new demands on the business and make investments where they're needed most.

Our ability to absorb cost increases is being challenged and tested by the growing complexity of the business, particularly in areas such as critical infrastructure protection, mandatory reliability standards and cybersecurity. The pandemic has further reduced our revenues adding more pressure to our ability to manage costs.

We have an opportunity to build on the cost-control measures already taken as part of Phase One of the Comprehensive Review of BC Hydro. We'll make focused investments in systems that will increase our efficiency. We'll also identify process improvements that will allow us to meet growing expectations in a resource-constrained environment, while preserving our core mandate of affordability.

Expectations are high

What we're expected to deliver today is far more than the expectations placed on the utilities of the 1950s and 1960s. Along with the growth we've seen in society, there's also been an increase in the expectations for service, for accountability and corporate social responsibility, and for broad protection of the electrical grid. Understanding and meeting changing expectations will always be a focus and key to our success.



Control our costs

What we plan to do

- Continue to promote a culture of sustained cost management throughout the organization.
- Pursue agile technology solutions that are more modest in cost and have a smaller implementation burden than traditional enterprise solutions.
- Invest in an integrated work management system and business process that increases our efficiency and ability to deliver in a cost-constrained environment.
- Increase our capacity to meet growing expectations with existing resources through our process improvement program Work Smart.
- Achieve benefits of improved procurement and supply chain management practices and tools. This includes a focus on category strategies, contract and supplier management and supply chain related business process improvement.
- Encourage regulatory structures and requirements that permit achieving regulator's objectives at least cost to BC Hydro customers.
- Develop revenue requirements applications that build confidence and support for BC Hydro's cost management and budgeting.

What success will look like

- We have successfully managed cost pressures, matched capital investment to load, achieved efficiencies through process improvement and investment in systems, and have been able to maintain affordability for current and future customers.
- We have kept electricity rates affordable by ensuring that rates do not increase above inflation, on a cumulative basis, for the period of Fiscal 2022 to Fiscal 2030.
- We have undertaken necessary investments in management systems and processes required to minimize costs and employ BC Hydro's human and physical capital as efficiently as possible.
- We have maximized opportunities via Powertech and Powerex to maintain affordability and keep rates low.

Control our costs

Measuring our success

Performance measures supporting five-year strategy	Targets
Affordable bills	1st Quartile (residential, commercial and industrial customer classes) annual target
Project budget to actual cost: cumulative five-years	Within +/– 5% of budget excluding reserve amounts

Clean Power 2040: Our power system strategy

The Integrated Resource Plan (IRP), Clean Power 2040, is our long-term plan for cost-effective delivery of secure and reliable energy services over a 20-year horizon: it's the what, when and why of our actions to meet customers' evolving electricity needs. The outcomes of the Comprehensive Review and this strategy provide policy direction and strategic context for our next IRP.

For example: Clean Power 2040 will consider the power system impacts of increased electric vehicle use and actions to manage system capacity constraints. The insights gained may inform our approach to implementing our Electric Vehicle (EV) strategy.

Strengthen our resilience and agility

Why it's important

We need to be prepared for threats ranging from cybersecurity attacks and impacts of climate change, to natural disasters and global pandemics.

Training and development, robust compliance, financial discipline, and strong safety performance all support resilience and ensure our people, assets and facilities are safe. Considering the effects of climate change on our system allows us to plan better and increase our resilience to impacts such as extreme weather events or changes in precipitation patterns impacting our reservoirs. Maintaining the financial health of the organization increases our resilience to challenging economic conditions. It also gives us greater flexibility to take advantage of commercial opportunities.

The day-to-day work we do to deliver on our core business is getting more and more complex. The flexibility and skills employees are demonstrating during the pandemic represent the type of agility we'll need to foster moving forward to be successful in our strategy, as well as our evolving sector. We also need to focus on becoming a more inclusive workplace to give our employees the space to deliver their best work.

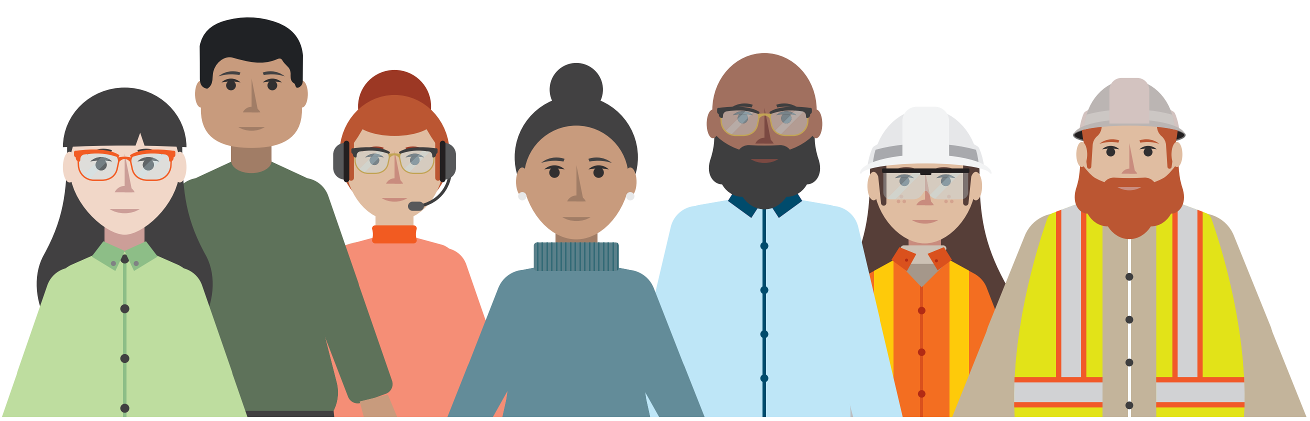
Resilience is the new reliability

resilience [ri-'zil-yən(t)s] *noun*
The capacity to recover quickly from difficulties.

Resilience sets us up to manage through challenges and prevents disruptions to the important service we provide. Being resilient enables reliability—something our customers count on—and it gives us the space to be agile, while knowing our core functions continue to operate successfully.

agility [ə-'ji-lə-tē] *noun*
The ability to think, understand and act quickly.

Agility allows us to position our company to take advantage of opportunities when they arise, and to innovate and find better ways of doing things. Agility is an organizational characteristic we must continue to strengthen.

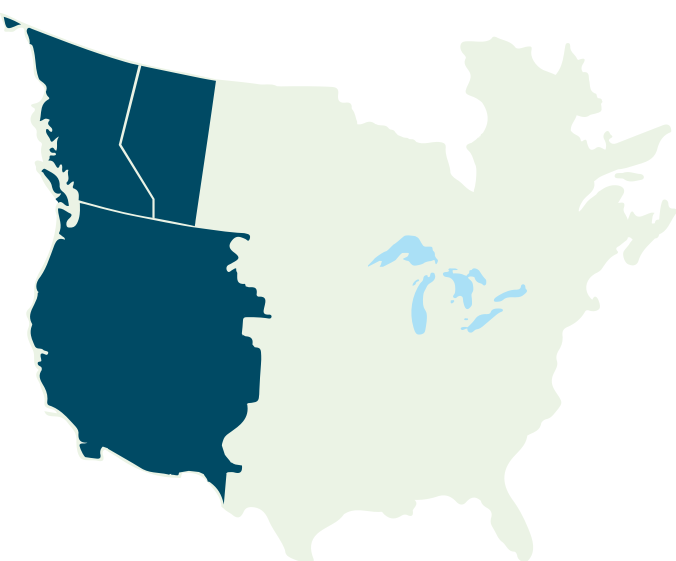


Strengthen our resilience and agility

What we plan to do

- Implement a robust compliance program.
- Complete implementation of a safety management and assurance system to improve the safety performance of our employees and contractors.
- Increase investment in training and development focused on building workforce capabilities that support resilience.
- Increase our investment to defend against cybersecurity threats.
- Increase investment in vegetation management and mandatory reliability standards compliance.
- Implement flexible work model for our office-based employees that incorporates learnings from the pandemic and supports further development of our workforce and properties strategies.
- Improve how we support our front-line employees and managers to safely deliver reliable, clean, and affordable electricity.
- Strengthen our inclusivity within the organization and in the way we engage externally.

WESTERN INTERCONNECTION



What success will look like

- We are in full compliance with all regulatory requirements, have systems to effectively implement new requirements, and are resilient to external threats and disruptions.
- We have built on our experiences during the pandemic and further institutionalized our agility and ability to adapt across a range of domains from technology to workforce.
- A strong, inclusive, highly-engaged workforce that reflects the diversity of B.C.'s workforce.
- We have no significant compliance violations or successful cyber attacks.

More than compliance: Mandatory Reliability Standards

We're part of an interconnected electrical system that covers the western third of North America. Mandatory Reliability Standards (MRS) are designed to assure the reliability and security of that connected system. They were developed following a widespread blackout that affected over 50 million people in the eastern part of North America in 2003. With utilities around the world increasingly being targeted by cyber threats, we each need to do our part to comply with these standards to prevent this from happening again.

Compliance starts with awareness of the standards and how they apply to our work areas. Our MRS Internal Compliance Program outlines how we plan to set up our processes and controls across our company, with clear protocols and ensuring everyone gets the training needed for their work area.

Strengthen our resilience and agility

Measuring our success

Performance measures supporting five-year strategy	Targets
Employee engagement index	At or above Global Utility Index
Workforce diversity	Meet or exceed the representation in the available workforce by 2026: Indigenous people: 5% Women: 30% Visible minorities: 25% People with disabilities: 10%
Inclusion and diversity leadership training	100% of people leaders trained in inclusion and diversity leadership by end of F24
Training hours – operations (incremental to safety training)	34 Training Hours average per Operations employee annually
Zero fatality & serious disabling injury	Zero
Lost time injury frequency	F22 — 0.76 F23 — 0.74, and maintain thereafter
Mandatory Reliability Standards violations	12 or fewer violations in F26

Advancing reconciliation with Indigenous Peoples

Why it's important

Advancing reconciliation is an important part of the role BC Hydro plays in the province.

Reconciliation is a process of learning from our history and coming together to find a path forward. It starts with listening and understanding.

We recognize that mutually-beneficial relationships with Indigenous Nations are critical to operating and growing our system of clean electricity. As a Crown corporation, BC Hydro has an important role to play supporting the province's commitment to reconciliation. In 2019 the provincial government passed the *Declaration on the Rights of Indigenous Peoples Act*, to adopt the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP), which the Truth and Reconciliation Commission confirms as the framework for reconciliation.

We're working with Indigenous Nations to find meaningful paths to reconciliation. Our progress to date includes entering into 13 Relationship Agreements in addition to three historic grievance settlements, as well as other opportunities related to procurement and employment. We have a strong platform to continue building from.

We recognize that many remote communities not connected to our integrated system are Indigenous Nations. Due to many of these communities being serviced by diesel generation, they often face high electricity costs and reliability issues. This represents a significant opportunity for us to help address social and environmental concerns created by lack of access to reliable, clean electricity.

Celebrating Kwantlen's culture and history: Ruskin Dam collaboration

During the redevelopment of the Ruskin Dam an important Kwantlen archeological site was uncovered. Working together, BC Hydro and Kwantlen developed a cultural centre to house the artifacts that were discovered. This experience brought us closer together and led to six panels designed by a Kwantlen artist being installed on the Ruskin Dam. These panels acknowledge the depth of Kwantlen's spiritual, cultural and physical presence in the area, and our commitment to a lasting relationship with them that is built on reconciliation.

Advancing reconciliation with Indigenous Peoples

What we plan to do

- Renew existing Relationship Agreements and finalize four more with Indigenous Nations who are most impacted by our infrastructure.
- Meet our commitments in our Relationship Agreements.
- Develop and publish an UNDRIP implementation plan to demonstrate our commitment to reconciliation and to build transparency around our company's efforts.
- Meet or exceed our Indigenous procurement commitments (in addition to Site C) by exploring opportunities in other parts of our business such as Operations or Properties.
- Continue to create programs that increase opportunities for Indigenous employment and career growth at BC Hydro, such as the Indigenous Professionals in Development (IPID) program or the Try-a-Trade program.
- Reduce reliance on diesel generation in communities that are not connected to BC Hydro's integrated system.
- Pursue Indigenous ownership opportunities such as new BC Hydro radial transmission lines and customer connections.
- Increase opportunities for Indigenous Nations to participate in BC Hydro's planning decisions at a regional level, including co-designing approaches to minimize impacts on the land base.

What success will look like

- We have worked together with Indigenous communities to understand and further reconciliation in a way that creates sustainable benefits.
- All employees understand what UNDRIP is and what it means for BC Hydro and we are actively implementing our UNDRIP action plan.
- We have co-developed unique approaches to environmental protection with Indigenous Nations, such as a new approach to cumulative effects.
- We have successfully come to understand and navigate the complexity of relationships between Indigenous governments and the provincial government and have realized efficiencies in consultation and regulatory processes.
- We have played a role to help address capacity gaps in Indigenous communities and this has greatly helped communities achieve meaningful benefits and engagement with the energy system.
- We have developed new and innovative models for Indigenous participation that are aligned to our business, such as exploring different ownership models for transmission lines or new clean energy projects in remote communities.
- We have introduced new Relationship Agreement models that reflects the principles of UNDRIP and seek to address the ongoing impacts of our facilities.

Advancing reconciliation with Indigenous Peoples

Measuring our success

Performance measures supporting five-year strategy	Targets
Indigenous procurement	$1 billion by the end of F26 (cumulative since 2015)
Non-integrated areas (NIA) diesel reduction	TBD
Indigenous employment at BC Hydro	25% increase from F21 baseline by end of F26
Indigenous awareness training at BC Hydro	80% of employees trained in INDIG-101 and/or INDIG-201 by end of F26
Progressive Aboriginal Relations Certification	Gold level

Understand your role in the plan

This plan is our roadmap for the next five years. It helps frame the work we do at BC Hydro, now and in the future. It's ambitious, and we have the right team to get the job done.

We have an important job. Whether we're working on the electrical system at the front lines, supporting customers in our Contact Centre, managing water resources from our offices and control centres or procuring the goods and services we need to keep the lights on—all our work is important, and this core work always comes first.

We know that as the volume and complexity of our work increases, it can become more difficult to get our work done. This strategy helps us be thoughtful about where we put our incremental efforts over the next five years to maintain the service our customers count on, while also pushing forward to the future.

THINK AHEAD

Think about how your work supports our goals, or what might need to change to make them happen.

Think about how you and your team will have time and energy to advance the strategies.

TALK WITH YOUR TEAM

Get involved and have a voice. Speak up if you don't know or understand something.

Discuss how you can advance the priorities without making a bunch of new initiatives.

Acknowledge the constraints on all of us and be solutions-focused.

TAKE ACTION

Build the priorities into your work plans and performance objectives.

Keep talking with your team about our progress.

Appendix A: Measuring our success

Metrics and targets are an important component of measuring our success but they're not the only thing we need to pay attention to. Not everything is easily measured or quantified. In addition to our measures and targets, we also need to be accountable for qualitative outcomes. For example, it's difficult to quantify the quality of a relationship when thinking about advancing reconciliation with Indigenous Nations, yet this is a critical component of success. Our strategy contains metrics and targets, as well as descriptions of "what success looks like"—and are both important.

Grow our load	
Performance measures supporting five-year strategy	**Targets**
Load growth supporting CleanBC (GWh) This measure tracks growth in load (GWh) related to CleanBC (fuel switching and new clean industries) and represents efforts to support CleanBC through electrification.	*4700 GWh by end of F26 (measured against F20 actual results)
New connected commercial and industrial load (MW) This measure captures load from new or expanded commercial and industrial load.	*750MW (5000 GWh) by end of F26 (measured against F20 actual results)
GHG emissions reduction – electrification (tonnes CO_2e/year) This metric tracks performance on reducing GHGs and supporting CleanBC. It uses the results from the metric "Load Growth Supporting CleanBC" to calculate an associated GHG reduction benefit.	2.5 million tonnes/year by end of F26 (measured against F20 actual results)
GHG emissions reduction — BC Hydro operations (% reduction) This metric tracks BC Hydro's progress reducing GHG emissions related to its own operations in areas such as fleet, buildings, SF_6, non-integrated areas, independent power producers (IPPs), thermal, air travel, and supply chain.	45% reduction from 2007 levels by 2025
Clean electricity standard (% clean energy) This measure represents BC Hydro's provision of a sufficient quantity of clean energy to meet BC Hydro's annual average load served by the integrated power system over a four-year period of time. **Note — final methodology and target subject to government consultation and resulting legislation and regulation.**	100% clean energy by Q3 F25 and maintained thereafter
Customer interconnection studies completed on time (%) This measure tracks BC Hydro's performance meeting the overall timeline for the completion of studies (all types) required for customers to be connected to the grid. The measure encompasses the timeliness of actions of BC Hydro, the customers and third parties to complete the studies.	80% annual target

* The Load Growth Supporting CleanBC and New Connected Commercial and Industrial Load targets are not additive and are not designed to be mutually exclusive; there will be some new projects that are captured in both of the two metrics. Accounting for overlap, the combined targets represent 6,900 GWh/year of load growth from F2021 to F2026, an increment of 2,200 GWh for F2026 over the December 2020 reference load forecast (4,700 GWh). The new commercial/industrial load target measures gross new load growth and does not account for any loss of existing load.

Appendix A: Measuring our success

Grow our load	
Performance measures supporting five-year strategy	**Targets**
Demand-side management capacity (MW) This measure reflects the annual new incremental capacity (MW) savings from the energy conservation portfolio including programs, codes and standards and conservation rates that measure BC Hydro's performance against annual energy targets.	Target to be developed and included in 2021 Integrated Resource Plan
Customer satisfaction index (%) This is an index measuring customer satisfaction of BC Hydro's three main customer groups (residential, commercial and industrial). The index is comprised of the five key drivers of satisfaction weighted equally across the three customer types.	85% annual target

Control our costs	
Performance measures supporting five-year strategy	**Targets**
Affordable bills (quartile benchmark) This metric measures BC Hydro's average bills compared to a sample of North American utilities across three different customer classes, based on survey information taken from the annual Hydro Quebec report, Comparison of Electricity Rates in Major North American Cities.	1st Quartile (residential, commercial and industrial customer classes) annual target
Project budget to actual cost: cumulative five years (% variance) This measure compares actual project costs at completion (not including Site C) to the original approved full scope implementation budgets, not including project reserve amounts, for capital projects that were put into service during the five-year rolling period.	Within +/- 5% of budget excluding reserve amounts – five-year cumulative target

Appendix A: Measuring our success

Strengthen our resiliency and agility	
Performance measures supporting five-year strategy	**Targets**
Employee engagement index (% index) This is a measure of employee engagement. It is derived from a confidential survey. Results are presented based on Percent Favourable score. External benchmarks to global utilities are also provided.	At or above Global Utility Index – reporting based on survey frequency
Workforce diversity This is a measure of the diversity of BC Hydro's workforce in the representation of women, visible minorities, Indigenous people, and people with disabilities. The targets are based on available B.C. workforce in the subset of the labour market in the occupations we hire, as derived from the current census (2016).	Meet or exceed the representation in the available workforce by 2026: Indigenous people: 5% Women: 30% Visible minorities: 25% People with disabilities: 10%
Inclusion and diversity leadership training (% complete) People leaders play an important role in creating an inclusive and harassment-free workplace. This measure assesses progress against the goal of all people leaders completing the training by F24. Leadership training modules include Bias and Diversity, Safety and Inclusion, and Supporting Mental Health.	100% of people leaders trained in inclusion and diversity leadership by end of F24 and maintained thereafter on an annual basis
Training hours – Operations (average hours per Operations employee incremental to safety training) This is a measure of annual training completed by Operations employees incremental to safety training. It represents an investment in workforce capability and resiliency.	34 training hours average per Operations employee annually
Zero fatality & serious disabling injury (number of injuries) This is a measure of an incident where there has been a loss of life or an injury has resulted in a permanent disability (for which a disability pension has been received or is expected). This measure excludes contractors or public safety incidents.	Zero
Lost time injury frequency (frequency) This is a measure that shows the number of injuries resulting in lost time per 200,000 hours worked (excluding contractors). Lost time injuries are those where the employee was absent from work beyond the day of injury. **Note: This metric may be replaced by a 'leading' safety metric in future years.**	F22 – 0.76 F23 – 0.74, and maintain thereafter
Mandatory Reliability Standards violations (number of reportable violations) Measure of BC Hydro's externally reportable MRS violations.	12 or fewer violations in F26

Appendix A: Measuring our success

Advancing reconciliation with Indigenous Peoples	
Performance measures supporting five-year strategy	**Targets**
Indigenous procurement ($) This is a measure of the total dollar value of procurement at BC Hydro with Indigenous Nations across all business groups and procurement. It represents opportunities for Indigenous Nations to share in the benefits of the work that BC Hydro does to build, operate, and maintain the system.	$1 billion by the end of F26 (cumulative since 2015)
Non-integrated areas diesel reduction (%) This measure demonstrates BC Hydro's progress on reducing reliance on diesel generation in communities that are not connected to BC Hydro's integrated system.	TBD
Indigenous employment at BC Hydro (%) This is a measure of Indigenous employment at BC Hydro. It supports efforts to increase the percentage of Indigenous employees at BC Hydro with a particular focus on growing Indigenous participation in non-trade areas. (Currently 4% of BC Hydro employees are Indigenous)	25% increase from F21 baseline by end of F26
Indigenous awareness training at BC Hydro (% complete) This measure evaluates BC Hydro's workforce awareness of Indigenous issues which supports our efforts in advancing reconciliation. The measure assesses progress against employees completing INDIG-101 and/or 201 training over a five-year time period.	80% of employees trained in INDIG-101 and/or INDIG-201 by end of F26
Progressive Aboriginal Relations certification (level – external certification) This measure demonstrates BC Hydro's commitment to progressive relationships with Indigenous communities, businesses and people. BC Hydro prepares a submission once every three years outlining its approach, programs and results, examples and testimonials, and other supporting information. This submission is reviewed and evaluated by Indigenous business leaders in Ottawa where a final determination of certification level (bronze, silver, gold) is provided by an independent jury.	Gold level

Appendix B: A detailed look at the drivers behind our strategy

Our five-year strategy is designed to respond to the context we operate in, our strengths and the opportunities and challenges that lay ahead.

Key trends impacting our sector

COVID-19 AND ECONOMIC UNCERTAINTY

COVID-19 is having a significant impact on economies around the world and British Columbia is no exception. For BC Hydro, there was an unprecedented drop of nearly 10% in provincial energy demand in the months following the onset of COVID-19—twice as much as what resulted from the 2008 recession. This drop in load was largely driven by commercial and industrial customers reducing their operations.

The economic impact and load loss resulting from COVID-19 will be a challenge for BC Hydro as costs increase, load decreases, and affordability becomes more important than ever to our customers.

The trajectory and fall-out of the COVID-19 pandemic will mean unprecedented levels of uncertainty over the next five years. It'll be critical for us to use scenarios and active risk management approaches, and we'll need to maintain flexibility, leaving room to course correct in the decisions we make. Flexibility in combination with strengthened resiliency and values-based decision making are our best lines of defence during this challenging time.

Did you know?

We experienced an unprecedented drop of nearly 10% in provincial energy demand in the months following the onset of COVID-19 – twice as much as what resulted from the 2008 recession.

CLIMATE CHANGE IS TRANSFORMING THE ENERGY LANDSCAPE

Climate change is impacting the frequency and extremes of weather, precipitation and temperature events, reservoir inflow predictability, and patterns in electricity demand and supply. This has led to an increase in infrastructure damage as a result of more extreme storms, wildfires and floods.

Utilities are at the centre of plans to increase focus on low carbon electrification to displace fossil fuels and reduce greenhouse gas emissions. We're starting on strong footing here in B.C. Our investment in hydroelectricity gives us a clean energy advantage and positions B.C. as a leader over jurisdictions that rely heavily on fossil fuel generation.

TECHNOLOGIES ARE EVOLVING, AND THE COMPETITIVE LANDSCAPE IS SHIFTING

The costs of solar and wind generation and small-scale battery storage have decreased significantly, resulting in more utilities and even customers adopting these technologies. We're also seeing customers use electricity in new ways as technologies advance and electricity becomes a more prevalent fuel option in all aspects of life, from electric vehicles to more efficient space heating and cooling.

Our competitive landscape is impacted not only by competing fuel choices such as natural gas, but also by new options for self-generation of electricity by organizations and customers. Under this model, we see the role of the traditional utility shift from providing a product (energy), to providing reliability and energy management services. Rate design and price signals become important as well. This will challenge our ability to retain existing customers, while also attracting new ones.

Appendix B:
A detailed look at the drivers behind our strategy

Did you know?

British Columbia's electricity grid is part of a much larger network that includes Alberta, plus portions of 14 western U.S. states and a small part of Mexico. Power trading with these jurisdictions supports grid reliability and affordability for our customers.

TRADITIONAL LOAD PROFILE IS CHANGING

Economic drivers in B.C. are changing, resulting in many traditional power users, such as pulp and saw mills, reducing operations or shutting down. To encourage economic growth, increase demand for electricity and drive clean innovation, we must adapt to this changing economic environment, both supporting existing customers while also attracting new ones.

CUSTOMER EXPECTATIONS ARE SHIFTING

Customers today expect more from energy providers than just reliable service. They want more information, input into decisions that affect them and more ability to manage their energy use. Traditionally conservative utilities face the challenge of meeting customer expectations for customized services set by more agile and innovative industries, such as telecommunications providers. We've made progress in enhancing the customer experience by introducing tools such as access to analytics to monitor energy use and a mobile platform for our customers to interact with us. Understanding and meeting changing customer expectations will always be a focus.

GRID MODERNIZATION IS CHANGING THE WAY WE OPERATE

Smart-grid technology provides opportunities for smart and flexible end-use devices or community-based energy resources. We've made significant investments in grid modernization to date, including the introduction of smart meters, an expansive network of automatic reclosers, and new technology in the control centres. This platform puts us in a strong position to take advantage of enhanced functionality and make incremental investments in modernizing our grid. Enhanced functionality includes demand forecasting tools, distributed energy management systems, and communication and control technologies.

ELECTRICITY TRADE IS EVOLVING

We're seeing utilities in other jurisdictions rapidly increase their use of intermittent renewables, as well as system-wide interest in clean supply. As these utilities retire thermal resources, resource adequacy becomes an increasingly important issue. We already have a strategic advantage thanks to our investment in hydroelectricity, which can help with the integration of intermittent resources. Moving forward, optimizing our system flexibility and ensuring market access will be key components of our strategy to maximize trade opportunities, particularly with jurisdictions looking for clean, reliable supply.

Appendix B:
A detailed look at the drivers behind our strategy

Did you know?

The CleanBC Plan sets a target of a 40% reduction in GHGs by 2030 (from a 2007 baseline). We anticipate that policy designed to meet the 2030, 2040 and 2050 GHG reduction targets, could create significant additional demand for our clean electricity.

Our strengths

We are starting from a strong foundation. Our organization thrives on challenges. We are highly capable, experienced, and have a broad range of resources and tools at our disposal.

OUR SUPPLY OF CLEAN ELECTRICITY

We will have a surplus of electricity expected to last until the end of the decade due to the supply of electricity from our existing assets, long-term electricity purchase agreements and the clean electricity generated by Site C when it comes online in F2025. This surplus provides an opportunity to electrify additional loads, support clean growth and reduce provincial greenhouse gas (GHG) emissions, while limiting the need to develop significant generation infrastructure.

To meet this opportunity, we're not relying solely on this expected surplus. We have proven demand-side management resources at our disposal, as well as the declining cost of renewables and batteries as additional options for procuring clean and cost-effective supply.

OUR FOCUS ON EFFICIENT ENERGY USE

We're in a position to support both efficiency and electrification with customers as complementary strategies. Demand-side management can reduce overall costs for BC Hydro, provide customers bill savings opportunities and preserve flexibility, all while supporting government programs that will reduce emissions. We're also starting to promote converting existing use of fossil fuels to efficient use of clean electricity wherever possible.

OUR STRONG FINANCIAL FOOTING

Phase One of the Comprehensive Review of BC Hydro, released in 2019, included two key outcomes to keep electricity rates affordable and set BC Hydro up for future success: enhanced regulatory oversight of BC Hydro, and a new five-year rate forecast that reflects cost and revenue strategies to keep rates affordable

We worked with the government to develop a number of strategies to keep rates affordable:

- Wrote off the $1.14 billion balance in our rate smoothing account: This reduced the amount of money we need to collect from our customers and reduced pressure on rates.
- Reduced our forecast capital program by $2.7 billion over the next 10 years: We've carefully considered system impacts in this decision, and for the most part, these reductions are due to project deferrals.
- Managed the cost of energy procurement: We have worked with the provincial government to develop a new Biomass Energy program that will address the expiry of electricity purchase agreements for biomass projects in the next few years. We will acquire less energy from biomass producers at lower prices than current contracts. The Standing Offer Program was also suspended indefinitely.

Appendix B:
A detailed look at the drivers behind our strategy

Did you know?

BC Hydro has made significant progress in improving the customer experience. We receive high customer satisfaction ratings and our rates are among the most affordable in North America.

OUR FOCUS ON OUR CUSTOMERS

We exist to serve our customers and provide them with an important service they rely on every day. With a service area covering most of the province, we must take the time to understand our diverse customer base. While we won't always be able to meet every individual need, we are always better off when we listen and are open to input. We need to maintain focus in this area.

OUR STRONG, CAPABLE AND RESILIENT WORKFORCE

We have a dedicated, engaged, and highly-skilled workforce. From the front line to the office, our employees drive our day-to-day success and our ability to manage effectively through challenging circumstances, like storms or wildfires.

We're now seeing this commitment extend to the global emergency of the COVID-19 pandemic. Our team has adopted new protocols to continue safe delivery of critical services. Many employees transitioned to working remotely in a matter of days, and the entire team maintained an impressive level of effectiveness while adapting to new working circumstances.

The day-to-day work we do to deliver on our core business is getting more and more complex. We believe the flexibility and skills employees are demonstrating during the pandemic represent the type of agility we'll need to foster moving forward to be successful in our strategy, as well as our evolving sector. We also need to focus on becoming a more inclusive workplace to give our employees the space to deliver their best work.

OUR RELATIONSHIPS

High-quality relationships based on trust enable us to successfully fulfill our mandate. We recognize that building trust requires us to be open and transparent, to listen and take input, and to build upon the efforts of those who came before us. It is essential that we maintain and strengthen the relationships we have with our employees, customers, Indigenous Peoples, the public, regulators and our shareholder.

Appendix B:
A detailed look at the drivers behind our strategy

Did you know?

We have successfully entered into 13 Relationship Agreements in addition to three historic grievance agreements with Indigenous Nations. These agreements have given us a deeper understanding of the interests of Indigenous Nations so we are able to find better alignment with our business.

OUR COMMITMENT TO ADVANCING INDIGENOUS RECONCILIATION

We acknowledge the impact the development and ongoing operations of our electricity system has on Indigenous Nations. Indigenous Nations were displaced when BC Hydro flooded land for Williston reservoir, and as our infrastructure expanded across the province, so did the impacts of that infrastructure.

BC Hydro is committed to doing better. We are guided by our Statement of Indigenous Principles and have made a commitment to incorporate the United Nations Declaration of Rights of Indigenous People (UNDRIP) and the Calls to Action of the Truth and Reconciliation Commission into its business.

We've built strong relationships with Indigenous Nations and the progress we've made in this area will serve as a platform to build on moving forward. We have shifted the company to take a relationship-based approach with Indigenous Nations, particularly those where we have a significant infrastructure presence. This has led to significant growth in Indigenous procurement (over $500M in the last several years), new employment and training programs for Indigenous Peoples and an approach to environmental protection that better represents Indigenous values. Moving forward, we must continue to explore ways to bring more transparency and participation into our planning decisions by creating deeper involvement through the Integrated Resource Plan and regional plans.

OUR STEWARDSHIP ROLE IN BRITISH COLUMBIA

As a Crown corporation, BC Hydro plays a stewardship role in British Columbia that recognizes social, environmental and community objectives. Water Use Planning is an example of our broader stewardship role. When we make decisions on how to operate our hydro system we consider not just economic and electric power needs, but also what is environmentally and socially responsible. This includes valuing biodiversity for the benefit of future generations and finding a balance between uses of water such as domestic water supply, flood management, fish and wildlife, recreation, heritage and electric power needs.

We adhere to a set of environmental principles that guide our actions and decisions. Our environmental strategy is based on four key objectives: being in environmental compliance; minimizing habitat loss and fragmentation from BC Hydro projects and operations; achieving environmental benefits that also have additional value; and, supporting climate actions and targets.

Appendix B: A detailed look at the drivers behind our strategy

Did you know?

A 100% clean standard would see B.C. commit to meeting 100% of its electricity loads with clean electricity, something western U.S. states have committed to. By building on our hydroelectric base, it's possible B.C. could achieve this standard much sooner than other jurisdictions, making our province a regional leader.

OUR MARKET ACCESS AND ELECTRICITY TRADING CAPABILITIES THROUGH POWEREX

Powerex, a wholly-owned subsidiary of BC Hydro, is a leading marketer of wholesale electricity. Powerex's power marketing and trade activities help optimize BC Hydro's electricity system resources, improve the security and reliability of electricity supply for the province, and provide significant economic benefits to the people of British Columbia.

The flexibility of BC Hydro's predominantly hydroelectric generating system enables Powerex to purchase electricity from the market when prices are lower, and sell electricity to the market when prices are higher. This flexibility also enables Powerex to take advantage of differences in demand between the winter-peaking north and summer-peaking southern U.S., and between peak and off-peak periods.

Looking ahead, we need to ensure our continued participation in energy markets. Pursuing a 100% clean energy standard is one way B.C. can ensure continued market access and increase the value of our product.

OUR LEADERSHIP IN INNOVATION AND CLEAN TECHNOLOGY THROUGH POWERTECH LABS

Powertech Labs, a wholly-owned subsidiary of BC Hydro, is one of the largest and most diverse testing and research labs in North America. Powertech can leverage its team of scientists, technicians, professional engineers, researchers, and specialists to stimulate economic growth here in B.C. One way they can do this is by supporting the province's Hydrogen Strategy and increase its focus on the development of hydrogen technology and production for transportation, industry and low carbon fuel production.

Appendix B:
A detailed look at the drivers behind our strategy

The opportunities and challenges that lay ahead

We know we will face both opportunities and challenges as we implement our strategy. The following highlights what we consider to be some of these.

ACHIEVING ADEQUATE LOAD GROWTH TO UTILIZE EXISTING AND PLANNED RESOURCE CAPACITY

Growing load through efficient electricity use is fundamental to this strategy. It is the primary path that allows us to maintain affordability while managing cost pressures and making critical investments. While we cannot control external factors such as economic uncertainty, we can foster a growth mentality and ensure the tools we have at our disposal, such as rate design, and capital investment, fully support our load growth objective.

UNDERSTANDING THE DIVERSE POPULATION WE SERVE

To best serve the diverse population we interact with (employees, customers, stakeholders, Indigenous Nations, and others), we're applying Gender-Based Analysis Plus (GBA+) in our decision making to help us better understand the different impacts programs and services have on different segments of B.C.'s population. This tool will help ensure programs and services are working for all British Columbians and ensure the voices of a shifting demographic are heard and considered in decision making.

BUILDING RELATIONSHIPS THAT ADVANCE INDIGENOUS RECONCILIATION

BC Hydro plays an important role in progressing reconciliation with Indigenous Peoples in B.C. This is a time where we must continue to listen to and learn from Indigenous Peoples as we continue building this path towards reconciliation. We have been investing in building stronger relationships with Indigenous communities and we believe only by working together will we be able to achieve mutual success.

COMPLETING SITE C

Site C has been and will continue to be a challenging project. COVID-19 resulted in significant impacts to the Site C project due to the activities that were scaled back at the dam site at the onset of the pandemic. Pandemic aside, we were already managing significant financial pressures on the project, including a geological risk on the right bank. The Site C review provided 17 recommendations aimed at improving oversight and governance to ensure the project is completed safely and results in clean, reliable and affordable power for decades to come. We need to fulfill these recommendations and work together with our contractors to complete the project in the most efficient and safe way possible.

Did you know?

Gender-Based Analysis Plus (GBA+) is an analytical tool used to assess how diverse groups of people may experience policies, programs and initiatives. It examines a range of identity factors (e.g. Indigeneity, age, gender, education, language, race, ability, economic situation, etc.)

Appendix B: A detailed look at the drivers behind our strategy

Did you know?

The consequences of not meeting our compliance requirements are high.

1. It opens us up to increased risk, impacting the safety, security and reliability of our grid.
2. It hurts our reputation as a responsible utility capable of minimizing risk to the bulk electric system, and it means we lose the confidence of our regulators and utility partners.
3. It can result in hefty fines that take dollars away from programs we want and need to invest in, hurting our customers' best interests.

INCREASING EXPECTATIONS AND COMPLIANCE REQUIREMENTS

Expectations and compliance requirements are increasing in volume and complexity. Our ability to absorb cost increases is being challenged and tested by the increasing complexity of the business, particularly in areas such as critical infrastructure protection, Mandatory Reliability Standards and cybersecurity. We're also seeing an increase in service and societal expectations, along with diverse regulatory requirements from bodies such as the BC Utilities Commission and the Canada Energy Regulator. To accommodate these demands we need to find efficiencies in other areas of our business and find better approaches for rolling out new requirements.

MAINTAINING AFFORDABILITY FOR CUSTOMERS

Factors impacting affordability for customers extend beyond the cost of electricity. Our customers are facing rising costs in a range of areas and some also face other financial hardships which impact affordability. As a Crown corporation, and extension of the government, this increases pressure on us to ensure we not only provide affordable electricity, but also recognize and address the hardships some of our customers may be facing.

MAINTAINING OUR LARGE SYSTEM AND AGING INFRASTRUCTURE

One of our strengths is our flexible provincewide system of generation, transmission, and distribution infrastructure. At the same time, we remain aware that as the average age of our assets continues to grow, maintenance costs increase. These costs put pressure on our objective of maintaining affordability.

ADAPTING TO THE IMPACTS OF CLIMATE CHANGE

Climate change impacts our system and operations in many ways. From increased risk of wildfires to changes in water flows. These impacts require us to look at increasing the resilience of our infrastructure, adapting how we plan and operate the system, and being prepared to respond to severe weather events.

MANAGING ORGANIZATIONAL CAPACITY

Delivering on our mission of safely providing our customers with reliable, affordable, clean electricity is getting more challenging. The environmental factors and challenges outlined in this plan put additional pressure on our resource-constrained company. We need to get incrementally more efficient at how we do our work to better utilize our resources. This plan is intended to ensure we are targeted in where we put incremental effort.

BC Hydro's Electric Load Forecast Report Fiscal 2021 to Fiscal 2041

Load Forecasting
Energy Planning & Analytics

December 2020

BC Hydro
Power smart

Executive Summary

This report provides a forecast of electricity sales to our customers and total gross system electricity requirements from fiscal 2021 to fiscal 2041. BC Hydro's load forecasts are used in a variety of business applications. In particular the December 2020 Load Forecast is being used in the Fiscal 2023 to Fiscal 2025 Revenue Requirements Application and the 2021 Integrated Resource Plan (IRP). This report is supplemental to the information provided in those documents. Its purpose is to provide further information on the methodology and drivers underlying the forecast results.

After introducing key concepts, we describe the methodology and results of the major sector forecasts that make up the December 2020 Load Forecast, namely; Residential, Commercial, Light Industrial, and Large Industrial. These sector forecasts are followed by details on the anticipated demand from emerging demand from electric vehicles. We present the high and low forecast uncertainty bands then we discuss our peak demand forecast and Non-Integrated Area forecast.

Where possible, the report identifies Low Carbon Electrification (LCE) or fuel switching components within the load forecast which capture specific policies and measures contained in the CleanBC Plan, such as the Zero Emission Vehicles (ZEV) Act. This report also includes the results of an accelerated electrification scenario, which estimates the total demand from electrification if provincial GHG reduction targets are achieved. This work was developed by Navius Research for consideration in the IRP and the report is included as an appendix to this document.

The summary table on the following page contains the results of the December 2020 Load Forecast on a billed sales basis from fiscal 2021 to fiscal 2041. In addition to developing this reference sales forecast, we also develop a high and a low band around the reference forecast. The bands represent a range in future demands for electricity and demonstrate some of the range of uncertainty. The uncertainty bands for the December 2020 Load Forecast were generally developed by considering discrete low and high scenarios for all major sectors.

COVID-19 Pandemic

The Load Forecasting department began work on the December 2020 Load Forecast in mid-April 2020 which was still early in our understanding of how the COVID-19 pandemic would impact customer demand. The approach taken was to build on the COVID-19 scenarios that were developed in March and April 2020 and to incorporate updated information and assumptions, such as updated actual sales data and a new economic outlook from the Conference Board of Canada. Due to timing issues associated with developing up-to-date assessments of the COVID-19 pandemic's economic impacts, the Conference Board of Canada developed an economic forecast for only the Metro Vancouver area, which we extrapolated for use in our regional models.

While the December 2020 Load Forecast incorporates the estimated impacts of COVID-19 on electricity demand, considerable uncertainty remains. Determining the full impact of the pandemic to the economy (and by extension, BC Hydro's load) over the next few years will continue to be a challenge. In general, the December 2020 reference load forecast assumes the economy will return to pre-pandemic growth trends beginning in fiscal 2021, although recovery pathways will differ across various sectors. This is often described as a "K-shape" recovery. The reference load forecast also incorporates structural changes in the economy over the long term, which relate to people continuing to work or study from home. The December 2020 high forecast generally assumes COVID-19 results in no adverse impacts over the forecast period, while the low forecast assumes more adverse COVID-19 impacts relative to the reference case.

Energy Demand

The energy demand forecast captures the total consumption of energy (or sales) in a given year. In summary, our total firm sales forecast is expected to grow by an average of 1.1 per cent per year over the next twenty years, after adjusting for rate impacts and

Demand-Side Management Savings (DSM)[1]. Most of this growth is due to increased demand in oil and gas and Liquified Natural Gas (LNG) in the Large Industrial Sector and demand from light duty Electric Vehicles which is included in our Residential and Commercial Load Forecasts. Forecast values are provided in Table 1.

Peak Demand

The peak demand forecast estimates the highest consumption of electricity in a one-hour period over the course of a year. The peak forecast closely follows the growth pattern of the energy forecast., with the following exceptions:

a) Distribution peak (which is comprised of residential, commercial, and light industrial sectors) has a higher contribution to the time of the system peak than transmission peak (large industrial sector). This results in the distribution peak representing a larger share of the total peak forecast in comparison to the energy forecast.

b) The Electric Vehicle forecasts have a proportionally higher impact on peak demand than energy due to charging profile assumptions.

Table 2 shows the twenty-year forecast for the major components of the peak forecast.

[1] The DSM plan used in the December 2020 Load Forecast was approved in the Fiscal 2022 to Fiscal 2024 Annual Business Plan. It does not include any potential recommended actions from the 2021 Integrated Resource Plan.

Table 1 – December 2020 Energy Load Forecast after Adjustments for Rate Impacts and Demand-Side Management

	Major Customer Sectors					Other Loads			Total Domestic Sales		
Fiscal Year	Residential	Commercial	Light Industrial	Light Industrial & Commercial	Large Industrial	Irrigation & Street Lights	Inter Utility Sales to City of New Westminster & FortisBC Electric	Total Firm Export Sales to Seattle City Light & Hyder Alaska	Total Domestic Sales - Reference	Low Domestic Sales	High Domestic Sales

Table 1 Notes

1. All forecast values include all adjustments for LCE/fuel switching, rate impacts, Demand-Side Management savings, and voltage-ampere reactive and voltage optimization (VVO) savings.
2. Light Industrial/Commercial is the sum of the loads in the light industrial sector and commercial sectors.
3. Total Domestic Sales is the sum of the loads from the Main Customer Sectors and Other Loads. BC Hydro own use is not included.

Table of Contents

1.0 Introduction

BC Hydro is the third largest utility in Canada and serves 95 per cent of British Columbia's population. BC Hydro's total energy requirements, including losses and sales to other utilities and non-integrated areas (NIAs), were 57,003 GWh in fiscal 2020. Excluding the NIAs, the total integrated system energy requirements were 56,663 GWh.

Load forecasting is central to BC Hydro's long-term planning, medium-term investments, and short-term operational & forecasting activities. BC Hydro's Electric Load Forecast is used to provide decision-making information for electricity rates, as well as where, when, and how much electricity we expect to need from the BC Hydro system. About two thirds of the forecast is based on Statistically Adjusted End Use (SAE) econometric (regression) models that use historical billed sales data combined with economic forecasts and inputs from internal, government and third-party sources. The other one third of the forecast is derived from individual forecasts of our large industrial customers.

BC Hydro's load forecasting activities include the preparation of a number of time and location specific forecasts before and after certain adjustments in order to provide information for decision makers.

In developing the reference load forecast, BC Hydro evaluates the impact of public policy commitments such as the CleanBC plan based on the legislation, regulations and funding in place to achieve the policy's stated objectives. The December 2020 reference load forecast incorporates legislative and policy measures related to CleanBC that were already in place or were close to being enacted, giving them a higher degree of certainty. For example:

- Light duty electric vehicle (EV) load - The CleanBC Plan made a firm commitment to a Zero Electric Vehicle (ZEV) mandate that was enacted in legislation on May 20, 2019. Accordingly, the EV forecast is included in the Load Forecast.
- BC Government-Funded Fuel Switching – The impact of the fuel switching component of the government-funded CleanBC Better Buildings/Homes program, which BC Hydro is administering on behalf of the Government of B.C, is captured in the Load Forecast.
- BC Hydro Low Carbon Electrification (LCE) – BC Hydro's Low Carbon Electrification (LCE) projects/programs, described in Appendix N of the Fiscal 2022 Revenue Requirements Application, support CleanBC strategies.
- Large Industrial Electrification. The CleanBC Plan includes providing clean electricity supply to natural gas production in the Peace region and increasing access to clean electricity for large operations with new transmission lines and interconnectivity to existing lines. Accordingly, forecast load growth from specific projects in the oil and gas (including LNG) sub-sector is included in the Load Forecast and in our estimate of electrification-related loads.

Where possible, specific load forecast components that are also captured in the Clean BC plan, such as the examples listed above, will be identified and quantified in this document. However, its important to note the December 2020 Load Forecast is a comprehensive load forecast encompassing updates to many inputs and model calibration periods. Accordingly, for many of the load forecast components it is not practical to precisely isolate specific quantitative impacts of the CleanBC policy measures from other changes between load forecast vintages.

BC Hydro has been supporting electrification and greenhouse gas emission reductions for a number of years. In August 2020 BC Hydro initiated work to develop an Electrification Plan designed to consolidate the actions already underway as well as new actions to increase low carbon electrification, attract additional load, and connect customers more efficiently. Electrification from fuel switching helps to achieve provincial greenhouse gas targets, while new customer load not tied to fuel switching aids provincial economic growth, and both help to keep rates affordable while BC Hydro is in an energy surplus situation.

The December 2020 Load Forecast was finalized prior to the Electrification Plan. Because the Electrification Plan consolidates actions already underway, some plan components such as the CleanBC-driven measures described above are reflected in the December 2020

Load Forecast. Additional components and revised estimates for the existing components will be incorporated into future load forecasts.

The assumptions used in the December 2020 Load Forecast are reasonable for use in the Revenue Requirements Application, given the duration of the test period. For long-term planning purposes, the December 2020 Load Forecast is supplemented with additional scenario that inform contingency plans preparing BC Hydro to meet the demand anticipated from British Columbia achieving its legislated climate change greenhouse gas reduction targets on schedule. More information on this scenario is outlined in this report and a detailed summary is provided as Appendix F to this report.

BC Hydro develops an electricity sales forecast for each of its main customer sectors including residential, commercial, light industrial, and large industrial. We also develop a forecast of electricity sales to other utilities and firm exports supplied by BC Hydro. The methodology used for each sector, as well those for other utilities and firm exports, are the focus of this report.

In addition to the reference forecast, we develop high and low uncertainty bands which represent ranges around the reference forecast. These high and low uncertainty bands are produced because there is uncertainty in the input variables that predict future loads and in the predictive capabilities of the forecasting models themselves. The December 2020 Load Forecast also includes an accelerated electrification scenario which was developed for consideration in the 2021 Integrated Resource Plan. To complete this work, BC Hydro retained Navius Research to estimate the electricity demand impact using models and an analytical approach similar to that used by the BC Government's Climate Action Secretariat in developing the CleanBC Plan. The accelerated electrification scenario presents the estimated impact on load growth if provincial GHG reduction targets are consistently met over the milestone years of 2025, 2030 and 2040. The scenario estimates the demand over and above BC Hydro's December 2020 reference load forecast, and the analysis reflects the incremental need for electricity that could be expected relative to that load forecast.

The next section provides an overview of the components and steps involved in developing our total integrated gross system requirements forecast.

Finally, detailed information is available in the appendices to this report. The appendices include:

- comparison of the December 2020 Load Forecast to March 2020 Load Forecast and COVID-19 Scenarios,
- a description of the SAE models and equations,
- a description of the temperature normalization process,
- peak demand forecast methodology,
- the Conference Board of Canada's "B.C. Economic Outlook 2020" used in preparation of this load forecast,
- the Navius electrification report, and
- summary tables containing the December 2020 Load Forecast,

2.0 Load Forecast Components

The load forecast is comprised of many components which come together in various ways to compile forecasts used for different purposes. This section describes the different components and combinations.

2.1 BUILD UP OF TOTAL INTEGRATED GROSS SYSTEM REQUIREMENTS

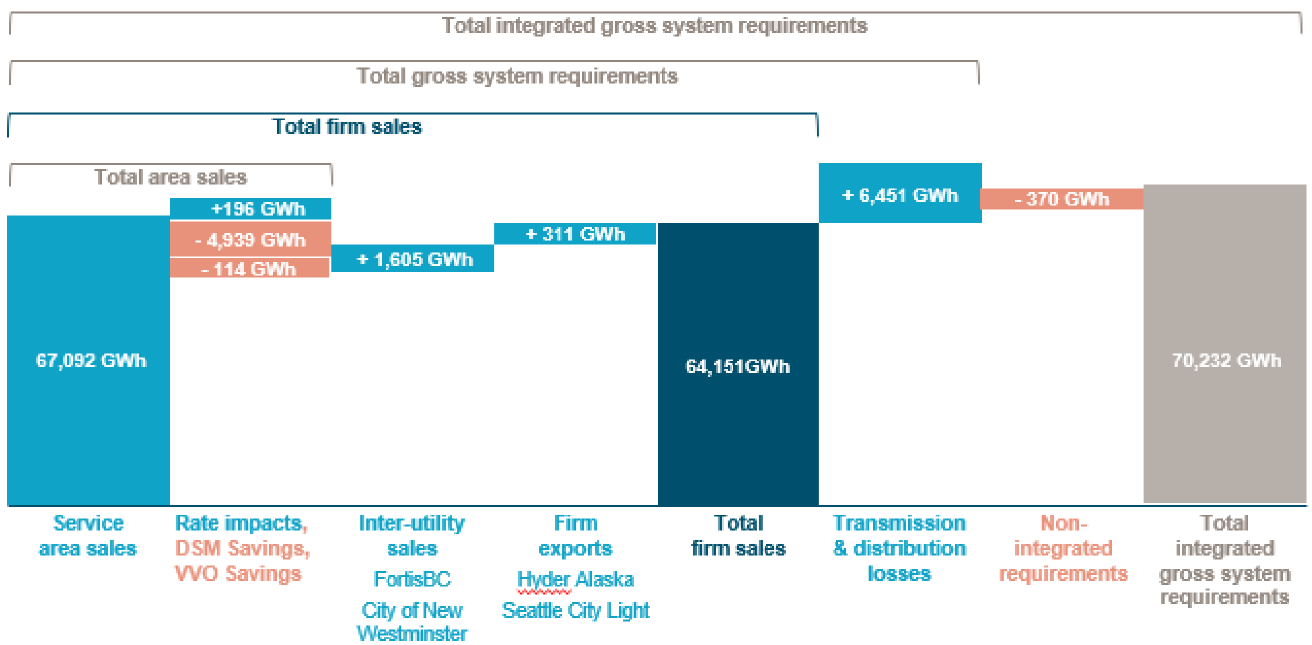
The highest level of our forecast is called total integrated gross system requirements. It is used to optimize operations of our system in the short-term and to plan our system over the long-term. For short-term analysis, the forecast is used by BC Hydro's Generation System Operations business unit in monthly energy studies.

The forecast of BC Hydro's total gross system requirements is built up from a series of components and steps, including:

- A forecast of electricity sales to all customers in our service area (service area sales). This includes a forecast for our main customer sectors (i.e., residential, commercial, light industrial and large industrial) and other loads including street lighting customers, irrigation customers, and electricity used by BC Hydro assets, such as distribution substations. We refer to this BC Hydro asset-related consumption as BC Hydro own use,
- A forecast of electricity sales to other utilities supplied by BC Hydro under contracts and tariffs. Service area sales plus sales to other utilities results in total firm sales, and
- A forecast of system distribution and transmission losses (i.e., total losses). Total firm sales and total losses results in total gross system requirements.

Figure 2.1 illustrates the build-up of our forecast of total gross system requirements and integrated total gross system requirements based on one of the three forecast types, namely: after considering rate impacts and savings associated with our Demand-Side Management (DSM) plan and voltage-ampere reactive and voltage optimization (VVO) savings.

Figure 2-1 Build-up of Total Integrated Gross System Requirements Forecast after Rate Impacts, DSM and VVO Savings for Fiscal 2041



The loads used to develop each of the major components of total integrated gross system requirements are summarized in the following sections.

2.1.1 Service Area Sales

The service area sales forecast includes the forecast for our main customer sectors (i.e., residential, commercial, light industrial, large industrial, etc.). Developing these forecasts is a detailed process which involves a number of different forecasting models.

Table 2.1 below shows that service area sales are the sum of our individual model projections plus load additions.

Table 2-1 – Summary of Model Projections and Load Additions Which Make Up Service Area Sales

Service Area Sales =	Model Projections	+ Load Additions			
Major Sector	**Model Description**	**Electric Vehicles**	**Codes & Standards Overlap**	**Low Carbon Electrification / Fuel Switching**	**Estimated DSM Persistence Drop Off**
tResidential	Accounts forecast x use per account forecast (from 4 SAE models)	85% of light duty EV forecast	**Yes**	**Yes**	N/A
Commercial	Sales forecast (from 8 SAE models)	15% of light duty EV forecast	**Yes**	**Yes**	N/A
Light Industrial	Sub-sector models and individual customer forecasts, plus construction loads	N/A	N/A	**Yes**	N/A
Large Industrial	Sub-sector forecasts by customer	N/A	N/A	**Yes**	**Yes**
Other Elements	Individual trend analysis models for Irrigation, Street Lighting, an BC Hydro own use	N/A	N/A	No	N/A

A description of each of these components is provided below.

2.1.1.1 Model Projections are Used for Each Major Customer Sector

Model projections are forecasts for our main customer sectors: residential, commercial, light industrial, and large industrial. These are laid out in the following sections of this document:

- Section 3 outlines our projections of electricity sales to the residential sector,
- Section 4 outlines our projections of electricity sales to the commercial sector,
- Section 5 outlines our projections of electricity sales to the light industrial sector, and
- Section 6 outlines our projection of electricity sales to the large industrial sector.

2.1.1.2 Load Additions are Added to Major Customer Sectors

In addition to our model projections, unique customer segments and technologies or adjustments are also included in our customer sector forecasts. A description of each load addition follows.

2.1.1.2.1 Electric Vehicles

A forecast of light duty electric vehicle load is included in our residential and commercial sector forecasts. A description of forecast methodology and results are outlined in Section 7. We are developing and implementing a new Electric Vehicle model, which expands the forecasting capability to also include medium and heavy duty vehicles. Results will be incorporated into future load forecasts when the model is available and testing of the model is complete.

Load from the light duy EV model is allocated to the residential and commercial sectors at 85 per centand 15 per cent is added to the respectively.

2.1.1.2.2 Codes and Standards Overlap

Codes and standards are minimum end-use efficiency requirements that come into effect in a jurisdiction, and that are enabled by legislation or by regulation of manufacturers. U.S. based codes and standards are reflected in the average stock efficiency forecast of residential and commercial end uses of electricity. The average stock efficiency forecasts are produced by the U.S. Energy Information Administration (EIA). The EIA efficiency forecast is one of the main inputs of the residential and commercial SAE models and the forecasts from these models are the starting point for the load forecasts for these sectors.

BC Hydro's DSM plan also includes savings that can be achieved through government policy instruments such as codes and standards that influence the use of energy and target similar end uses as those represented in the EIA efficiency forecast data. As such, there is a potential for overlap in efficiency requirements for end uses of electricity that are enabled from codes and standards as modelled by EIA assumptions and our DSM plan.

The EIA assumes that no new legislation or regulations fostering efficiency improvements beyond those currently embodied in l aw or government programs will take place over the forecast horizon. These efficiency level assumptions are documented by the EIA in the annual energy outlook. BC Hydro has reviewed the EIA's documentation on minimum efficiency standards on end use of electricity and technologies and compared those to the efficiency standards of end use electricity and technologies contained in our DSM plan. Using this information, BC Hydro was able to determine where there were overlaps in codes and standards on various residential and commercial end uses of electricity and technologies.

Some examples of overlap in codes and standards for the residential sector are lighting, dishwashers, stand-by power, TVs, freezers, refrigerators and clothes washers. For the commercial sector some examples include lighting, large clothes washers, walk in coolers, large refrigerators, air conditioning, packaged terminal air conditioning, and dry transformers.

After the areas where overlap are determined, an adjustment is made to account for the overlap in codes and standards. The adjustment is applied to the SAE models' projections to mitigate potential double counting by using an estimate of the overlap between EIA assumptions reflected in our models and codes and standards that result in electricity savings which are contained in our DSM plan.

Load adjustments for overlap in codes and standards, including lighting, have been in place since our 2010 Load Forecast. In 2019, Navigant Inc. completed an independent review of the overlap in codes and standards in the EIA projections with those within BC Hydro's DSM plan. The review determined that there were some end use technologies that appeared in both the SAE model (i.e., EIA based end use efficiencies) and the DSM plan. Accordingly, the December 2020 Load Forecast has been adjusted to improve alignment with this review.

For the non-lighting code items that were considered to be an overlap, BC Hydro applied 50 per cent of the forecast of DSM savings of these various codes and standards which overlapped with the EIA. The 50 per cent assumption is a high-level estimate because there are a number of uncertainties, we were not able to address as part of our evaluation. These uncertainties include the following:

- There are differences in timing between our service area relative to the geographic areas incorporated in the EIA model (Pacific region) on when the various code and standards come into place,
- There are differences in end uses and technology modelled in the DSM plan and those modelled in the EIA. For example, in the area of refrigeration, not all of the same types of refrigerators are modelled from the same starting point on efficiency and types of various refrigerators. There may also be differences in compliance rates between our service area relative to what is assumed in the EIA model,
- The EIA model only includes the impacts of past U.S, legislation and regulations and does not include future codes and standards. Our DSM plan includes savings from future regulations that are planned and announced , and
- Using the savings from the DSM plan as the basis to determine the impact of the overlap of codes and standards on our load forecast is at best a proxy estimate.

For lighting codes and standards, where there is also overlap for various lighting technologies (i.e., different types of a light bulbs), we have left the base year (i.e. 2020) efficiency level of indoor and outdoor lighting as provided by the EIA unchanged over the forecast period. This method for lighting was chosen to provide consistency with previous forecasts that had already identified an overlap with lighting codes and standards.

We continue to assess the extent of the overlap over the various diverse set of electrical appliances and uses of electricity as part of our continuous improvement efforts. Further work in this area may lead to revised overlap projections.

2.1.1.2.3 Low Carbon Electrification (LCE) / Fuel Switching

Low Carbon Electrification (LCE) refers to actions that encourage the use of electricity for the purposes of reducing greenhouse gas emissions. Similarly, fuel switching refers to the customer choosing electricity over a feasible fossil fuel alternative. In our load forecasting process we add estimated loads related to LCE and fuel switching to capture the following:

1) BC Hydro's Low Carbon Electrification (LCE) projects and programs; and
2) The impact of the fuel switching component of the government funded CleanBC Better Buildings/Homes program, which BC Hydro is administering on behalf of the Government of B.C.

Throughout this document the load additions related to the above load additions are referred to as LCE/fuel switching.

It should be noted that some fuel switching loads are also imbedded in the forecast for certain large industrial customers who have undertaken projects to use electricity in lieu of fossil fuel alternatives. These are captured in the large industrial forecast and not included in this load addition. Further details are provided in sections 6 and 8.2.6 of this report.

2.1.1.2.4 Estimated DSM Persistence Drop Off

In developing the large industrial load forecast, we have included the estimated DSM persistence drop off in each of the large industrial sub-sectors based on analysis by our Conservation and Energy Management group. We now assume that once an efficiency project has been implemented, the customer will continue to replace like for like equipment at the end of its lifecycle.

2.1.2 Adjustments for Rate Impacts, DSM Savings, and VVO Savings

Service area loads are adjusted to account for rate impacts, Demand-Side Management savings, and VVO energy savings.

2.1.2.1.1 Rate Impacts

Load reductions that result from rate impacts are calculated separately for each of our main sectors. Rate impacts are based on:

- an electricity price elasticity of -0.1 applied to the major sectors including residential, light industrial, commercial, and customers that make up the large industrial sector, and

- a projection of bill impacts informed by the forecast underlying the Fiscal 2022 Revenue Requirements Application which covers fiscal 2021 to fiscal 2026, with bill impacts beyond fiscal 2026 equal to an assumed annual inflation rate of two per cent.

2.1.2.1.2 Demand-Side Management (DSM) Savings

The incremental savings from our DSM plan are computed separately for each customer sector and at the BC Hydro service area level. The forecast of DSM savings reflected in our December 2020 Load Forecast is based on a DSM plan which included updated information to reflect COVID-19 impacts. DSM savings from fiscal 2021 to fiscal 2041 are based on incremental activities to the fiscal 2020 base year, which was the last year of actual sales. The DSM plan used in the December 2020 Load Forecast was approved in the Fiscal 2022 to Fiscal 2024 Annual Business Plan. It does not include any potential recommended actions from th e 2021 Integrated Resource Plan.

BC Hydro's DSM plan is comprised of initiatives that have the objective of reducing customers' energy consumption and by doing so, reducing their electricity bills. The main components of BC Hydro's DSM plan are:

- Programs: Programs are available to all customer sectors and deliver a mix of information, access to technology and services, technical assessment and support, and financial assistance to all customer classes to address barriers to cost effective Demand-Side Management. Programs are designed to capture additional Demand-Side Management potential that remains beyond that obtained from codes and standards and rate structures.
- Codes and Standards: Codes and standards refer to a range of government policy instruments that influence the use of energy, including product/equipment regulations, building codes and tax measures. BC Hydro supports the development of these codes and standards and works with communities on municipal zoning/building permitting processes, as well as enhanced approaches for Indigenous and remote communities.
- Rates: Rate structures are changes to the design of electricity rates to provide more economically efficient price signals to customers which encourage conservation. BC Hydro currently has conservation rate structures in place for residential and large industrial (transmission voltage) customers.
- Supporting Initiatives: Supporting initiatives include public engagement and awareness activities and general management and infrastructure.

2.1.2.1.3 VVO Savings

VVO savings refer to volt-ampere reactive and voltage optimization (VVO) energy savings at our distribution substations.

VVO is a strategic initiative focused on realizing financial value to BC Hydro and its distribution customers.

VVO is an industry-recognized practice of optimizing the distribution-supply voltage for distribution customers to realize a reduction in energy consumption (i.e., energy savings). In other words, VVO is a way of reducing energy consumption, and its focus is not to reduce line losses. By reducing energy consumption for distribution customers, BC Hydro can reduce the amount of energy it needs to supply (i.e., produce or purchase), resulting in financial benefits for BC Hydro, lower energy rates and energy bills for its customers. From the customer's perspective, the customer realizes a financial benefit because they receive lower rates, consume less energy, and therefore, have lower energy bills.

The principle underlying the VVO application is that when VVO is enabled at a substation, distribution supply voltage is optimized (i.e., reduced) to the lower-end of the acceptable operating voltage range for the voltage critical distribution customers - as voltage is reduced, distribution-voltage customers could draw less power and consume less energy than they would otherwise do so if VVO was not enabled.

The projected VVO energy savings are estimated and incorporated into the energy load forecast. The forecast of VVO savings is developed for our distribution system and is also incremental to the fiscal 2020 base year. VVO savings are applied to residential, light industrial and commercial sectors on load share basis

2.1.2.2 Other Elements of Service Area Sales

Forecasts for other small loads such as irrigation customers, street light customers, and BC Hydro's own use are developed separately, and these forecasts are included as part of our total area sales. With the exception of BC Hydro own use, all of these loads are developed with trend analysis. The forecast of BC Hydro own use is developed with trend analysis for the base load and supplemented with additional construction load for the Site C Project. The construction loads are based on estimates provided to BC Hydro from the various contractors involved in the construction of the Site C Project. The details of the trend analysis and forecast results for these other loads are not covered in this report.

2.1.2.3 Inter-Utility Sales and Firm Exports

The next component represented in Figure 2-1 includes sales to the City of New Westminster and FortisBC Electric. Sales to these two utilities make up total inter-utility sales. Sales to Seattle City Light and Hyder, Alaska make up total firm exports. Rate impacts using the same price elasticity and bill impact projections as described above are applied to loads from the City of New Westminster and Hyder, Alaska. Sales to Seattle City Light are determined by a treaty and as such rate impacts are not applied. For sales to FortisBC Electric, rate impacts are built into a methodology that determines the electricity sales. That methodology and the forecasted inter-utilities sales and firm exports are detailed in Section 8. The combined forecast of inter-utilities sales, firm exports, and total area sales is the forecast of total firm sales.

2.1.2.4 Transmission and Distribution Losses

When electricity is moved from one location to another, losses occur. To account for this, transmission and distribution losses are estimated by applying loss factors to the individual loads that make up total firm sales. The estimated losses are added to the total firm sales to calculate total gross system requirements, as shown in Figure 2-1.

2.1.2.5 Non-Integrated Area Requirements

The Non-Integrated Areas (NIA) consist of a number of small communities located in parts of B.C. not connected to BC Hydro's integrated transmission grid. Further details on these areas is provided in Section 11.

2.1.2.6 Total Integrated Gross System Requirements

Finally, total integrated gross system requirements are calculated by reducing total gross system requirements by the sales and losses from loads in our Non-Integrated Areas.

2.2 TYPES OF FORECASTS

Different types of forecasts are produced to serve different needs within BC Hydro and to meet requirements set out by the BC Utilities Commission (BCUC).

2.2.1 BCUC Required Forecasts

Following the BCUC Resource Planning Guidelines, BC Hydro develops three types of forecasts:

- before considering rate impacts, Demand-Side Management and VVO savings,
- after considering rate impacts, but before Demand-Side Management and VVO savings, and
- after considering rate impacts, Demand-Side Management and VVO savings.

These forecast types allow us to identify the specific effects associated with future electricity price (rate) changes and Demand-Side Management savings. Each type is calculated for each of the forecast components outlined previously in Section 2.1.

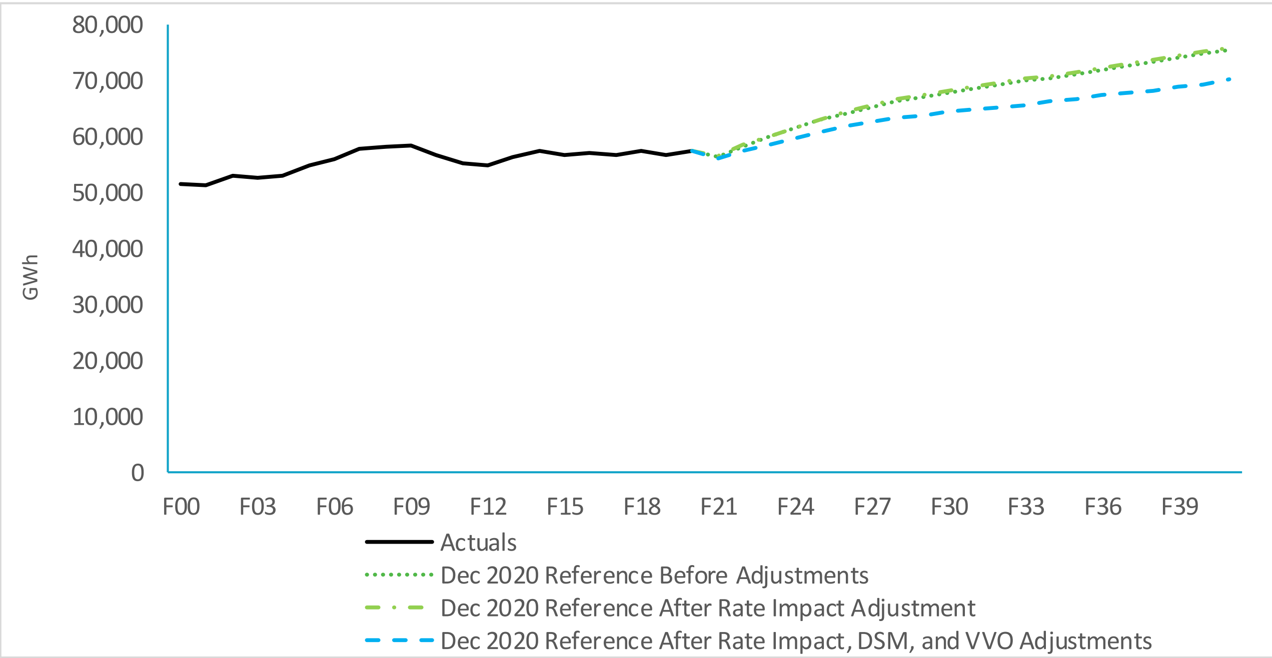
For example, we have three forecasts of total firm sales:

- the reference forecast of total firm sales before rate impacts includes all model projections for main sectors, load additions, forecasts for irrigation customers, streetlights customers, BC Hydro own use, and sales to inter-utilities and firm exports,
- the reference forecast of total firm sales after rate impacts includes the estimated effects of rate impacts, and
- the reference forecast of total firm sales after Demand-Side Management and VVO savings is the same as total firm sales after rate impacts but also includes load reductions for Demand-Side Management and VVO.

This convention for naming the three types of forecasts is used through the rest of the document.

Figure 2-2 below is provided to illustrate these three types of forecasts.

Figure 2-2 – December 2020 Reference Load Forecast Total Integrated Gross System Requirements Before and After Adjustments



As shown in Figure 2-2 the rates adjustment has a minor effect on the overall forecast while the DSM impact is more significant and serves to reduce load by an increasing amount over time.

When each of the other forecast components is calculated in the same three ways, they can be combined to make up three types of total gross system requirement and integrated gross system requirements, and the results for these forecasts are summarized in tables contained in Appendix G of this report.

2.2.2 Billed and Accrued Sales Forecasts

Our forecasts are based on relationships between load drivers and billed sales. As such, the forecast of future customer loads is in the form of billed sales projections. In our revenue requirements applications, accrued sales projections are derived from the billed sales forecasts. In general terms, billed sales represent what was billed to our customers in a month or over a fiscal year in line with our billing cycle, which may span several months. Accrued sales represent the electricity consumed during a calendar month, which involves accruals of an estimate of the unbilled sales in that month, in accordance with accounting standards.

2.2.3 Forecasts to Characterize Uncertainties

To quantify the various uncertainties in the factors that increase or decrease load, BC Hydro develops a high and a low uncertainty band around our reference forecast. The details of our uncertainty band process are contained in Section 8 of this report.

3.0 Residential Forecast

3.1 RESIDENTIAL SECTOR DESCRIPTION

At the end of fiscal 2020, there were almost 1.9 million residential accounts served by BC Hydro and electricity sales were 18,349 GWh. This represents about 35 per cent of BC Hydro's total firm sales on a billed basis. Residential customers use electricity for a variety of what we call "end-uses." These include space heating, cooling, lighting, water heating, cooking, refrigeration, and other plug-in loads which include computer equipment and home entertainment systems. Since space heating and cooling loads are dependent on the outside temperature, residential sales can be affected by temperature. As such, our forecasting process, like most utilities, develops a residential sales forecast based on a historical rolling average of temperatures over the past 10 years, or also referred to as a "temperature normalized basis." More information on temperature normalization is available in Appendix C of this report.

BC Hydro has four main service regions. In fiscal 2020 electricity use across these regions as a percentage of total residential sales was:

- Lower Mainland 54 per cent,
- Vancouver Island 25 per cent,
- South Interior 13 per cent, and
- North Region[2] eight per cent.

Historical trends in our residential sector include:

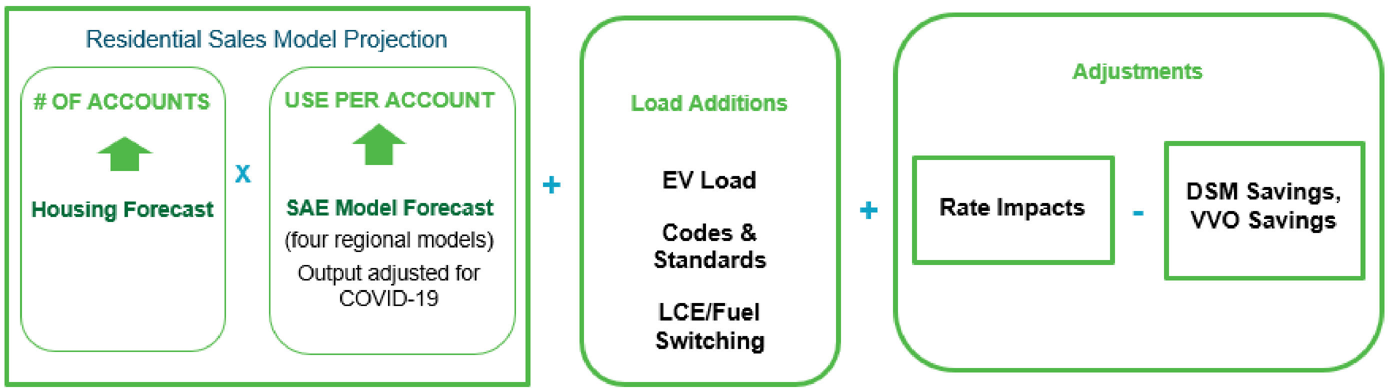
- strong historical growth in accounts which have increased an average of approximately 27,000 accounts per year over the past five years ending fiscal 2020,
- a movement to denser multiple housing units, and
- a decline in the average use per account.

3.2 RESIDENTIAL FORECAST METHODOLOGY

Figure 3-1 below shows our residential forecasting process and the build-up of the Residential Reference Load Forecast.

[2] The North Region includes customers connected to our integrated grid and those in our non-integrated areas. More information on the Non-Integrated Areas forecast is provided in Section 3.2.

Figure 3-1 Residential Reference Load Forecast Build-up



The equation used to develop the residential sales model projection, represented in the left side of Figure 3-1, is:

Equation 3-1

$$\begin{aligned}&\mathit{Residential\ Sales\ Regional\ Model\ Projection}\\&= \mathit{Number\ of\ Residential\ Accounts} \times \mathit{Average\ Use\ Per\ Account}\end{aligned}$$

This equation is used to develop model projections of sales for each of our four service regions. The sum of the four regional model projections makes up the total residential sales model projection.

The number of residential accounts comes from our residential accounts forecast, which is based housing projections that come from the Conference Board of Canada's economic forecast.

Average use per account, comes from our four regional SAE models. The SAE models' inputs include monthly billed sales data on the average use per account and other load drivers that are specific to the residential sector. The SAE models for the December 2020 forecast are calibrated using the past 10 years of historical drivers, ending in fiscal 2020. To fully utilize our available data, the SAE models included historical sales up to July 2020. For the December 2020 Load Forecast, the SAE model average use per account was adjusted to account for impacts of COVID-19, as described in section 3.2.2.3 below.

The residential sales model projection is then adjusted for load additions and adjustments for rate impacts, DSM savings, and VVO savings, as described in Section 2.1.2, to calculate the residential load forecast.

3.2.1 Residential Accounts Forecast Methodology

BC Hydro's residential accounts forecast is derived from projections of net housing stock growth provided by the Conference Board of Canada (CBoC). Typically, the CBoC provides a housing stock projection for 15 sub-areas within BC for two basic housing types: (1) single family dwellings and (2) multiple housing types (row, apartments, and mobiles). BC Hydro then applies a ratio to the housing stock projections, which reflects the relationship between housing stock to residential accounts and adds the adjusted projection to the existing number of accounts[3]. The 15 sub-area residential accounts forecasts are then aggregated to the four major service regions.

The equation used to develop the residential accounts forecast is as follows:

[8] The term "ratio" mentioned above is a historical average ratio of account growth to growth in net housing stock for two housing types housing for each of the 15 sub-regions. In December 2020 we used the same average ratio of 0.9 used in the October 2018 residential accounts forecast.

$$Number\ of\ accounts\ =\ previous\ year\ forecast\ of\ accounts\ +\ ratio\ \times\ net\ housing\ stock\ projection$$

Due to timing issues associated with developing up-to-date assessments of the COVID-19 pandemic's economic impacts, the CBoC was only able to provide BC Hydro with an economic forecast for the Metro Vancouver area, rather than at the BC Hydro 15 sub-area level. Normally, the CBoC calibrates its BC Hydro 15 sub-regional economic forecast model to its provincial model. When the CBoC released its provincial economic forecast in April 2020, it determined that the economic impact and recovery assumptions with in that forecast were too optimistic (i.e., faster economic recovery) relative to the what was actually occurring and expected to continue to occur within BC. The CBoC similarly concluded that a subsequent economic forecast using its BC Hydro model, informed by its April 2020 provincial forecast, would also be too optimistic. The CBoC also determined it was not able to update its provincial model in time to meet BC Hydro's December 2020 Load Forecast development schedule. To meet BC Hydro's load forecast schedule, the CBoC determined it could use its Metro Vancouver area economic model to provide a limited suite of the economic drivers used in BC Hydro's load forecast models. This economic forecast is contained in the CBoC's "B.C. Economic Outlook 2020" report (CBoC 2020 Report)

Using the more current Metro Vancouver area economic forecast, BC Hydro developed various methods for extrapolating the forecast results to each of BC Hydro's four service regions. The necessary trade-off in favour of using more current economic impact analysis over geographic specificity introduces additional uncertainty to the BC Hydro load forecast. However, this uncertainty is mitigated by the fact that the Metro Vancouver area represents the largest portion of BC Hydro's overall load and there is a considerable geographic overlap between the Metro Vancouver area and the Lower Mainland service region. The extrapolation method used to develop the residential accounts forecast is described below. Similar extrapolation methods were also applied to other economic drivers and customer sectors. Those methods are described further in this document, where applicable.

Since our accounts forecast requires a regional housing stock forecast as an input, we used the following methodology to develop a regional housing stock forecast using the information we had available:

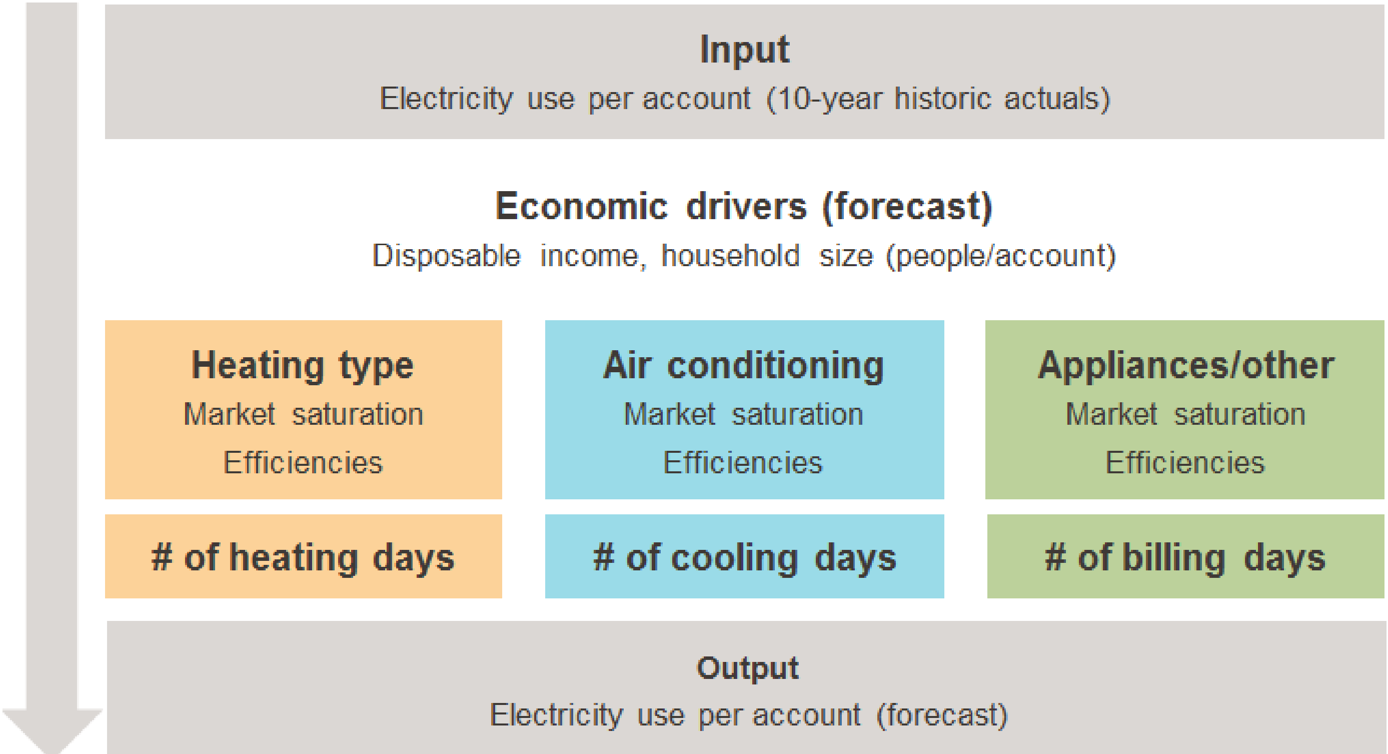
1. The historical housing stock came from CBoC's 2019 Report.
2. The Lower Mainland housing stock forecast was developed by applying the Metro Vancouver annual housing stock annual growth rate from the CBoC's 2020 Report to the last year of history (i.e., fiscal 2019).
3. An adjustment factor was calculated by comparing the newly developed Lower Mainland housing stock forecast to the July 2019 Lower Mainland housing stock forecast.
4. The adjustment factor was applied to the remaining three regional housing stock forecasts (i.e., Vancouver Island, South Interior, North Region) from the CBoC's 2019 Report.

3.2.2 Residential Average Use Per Account Methodology

BC Hydro uses an industry standard SAE model to estimate the average residential use per account for each of our four main service regions. The SAE approach is used by approximately 60 different utilities and organizations throughout North America. This method has been reviewed in several previous regulatory applications including the Fiscal 2021 – Fiscal 2021 Revenue Requirements Application.

Figure 3-2 below is a graphical representation of the SAE model inputs and outputs.

Figure 3-2 Residential SAE Model Inputs and Outputs



Our residential SAE models are an end-use regression model which establishes a historical relationship between the average use per account and the historical values for the following variables:

- economic variables including real personal disposable income and household size represented by people per account,
- non-economic variables including the average efficiency of residential end use of electricity, appliance shares (i.e., percentages of customers that have a specific residential electrical appliance), and
- temperature variables represented by heating and cooling degree days.

The forecasts for these variables and the estimated coefficients of our four regional residential SAE regression models determine the model projections of the average use per account over the forecast period for each region.

The SAE model approach has the following main characteristics:

- A regression element that develops a historical relationship between heating, cooling, and other major end uses of electricity and the average use per account developed from billing data on residential electricity sales and accounts.
- An end-use efficiency element which reflects: (i) future average efficiency projections of residential end uses of electricity for the Pacific region, as developed in 2020 from the U.S. EIA; and (ii) regional BC Hydro data on appliance shares for various end-uses of electricity such as lighting and refrigeration. Regional data on saturation rates come from our historical residential customer end use survey (REUS) while forecasts come from the EIA.
- A temperature element which is measured in heating and cooling degree days. The model is estimated with actual heating and cooling degree days and the forecast is based on a normal temperature which is defined as a ten-year rolling average of monthly heating and cooling degree days that are region specific. Using a ten-year rolling average will better reflect current trends relative to longer term averaging periods.

- An economic element that reflects future projections of economic variables such as real disposable income and household size represented by people per account. The model also contains elasticities which are estimates of the percentage increase in use per account for a one percentage increase in economic variables. The economic forecasts and elasticities are region specific for each model. As described above the CBoC could only develop economic projections for the Metro Vancouver area. BC Hydro's method for extrapolation to develop real disposable income and household size to each of our four service regions is described below. As a result, BC Hydro used the available data from the CBoC and derived its own economic forecasts using the methodology described below.

As described in section 3.2.1., the Metro Vancouver economic forecast is provided in the CBoC's "B.C. Economic Outlook 2020"(CBoC 2020 Report) was developed only for the Metro Vancouver area. BC Hydro used the 2020 forecast and the CBoC's prior July 2019 regional economic forecasts to develop its four regional disposable income and population forecasts. The methodology used is as follows.

3.2.2.1 Regional Population Forecast

The following method for developing updated population forecasts for each BC Hydro's four service regions from CBoC's Metro Vancouver area forecast is similar to that used to develop the regional residential accounts forecasts described in section 3.2.1.

1. Use the historical regional population from CBoC 2019 Report.
2. Develop the Lower Mainland population forecast by applying the Metro Vancouver annual population growth rate forecast from the CBoC 2020 Report to the last year of history (i.e., fiscal 2019).
3. Calculate an adjustment factor by comparing the newly developed Lower Mainland population forecast to the July 2019 population forecast.
4. Apply the adjustment factor to the remaining three regional population forecasts from the CBoC 2019 Report.

In the residential SAE models, the population and accounts forecasts are used to calculate the people per account for the forecast period.

3.2.2.2 Regional Disposable Income Forecast

While the CBoC 2020 Report includes the most relevant economic drivers used to develop our load forecast (i.e., housing stock, population, GDP, and employment), it does not include a regional disposable income forecast. Disposable income is not a significant driver in the residential SAE models (i.e., its elasticity coefficient is low). Nevertheless, for model input completeness, we developed a method to estimate disposable income by performing a regression analyses between disposable income and GDP, population and employment, respectively, to determine which of those other economic drivers was the most statistically significant predictor of disposable income.

Based on our analysis, we found total GDP to be the best predictor.

To develop regional GDP forecasts from the CBoC's Metro Vancouver GDP forecast, we applied the same extrapolation process used to develop regional housing stock and population forecasts. We then used a linear regression shown below to determine the required statistical parameters for developing a regional disposable income from GDP.

$$Regional\ Disposable\ Income = m \times Regional\ Total\ GDP + b$$

Where m is the slope and b is the y-intercept.

BC Hydro used the available 18 years of regional history of total GDP and disposable income from the CBoC 2019 Report and used the above equation to determine its coefficients (i.e., slope and y-intercept).

We then used those statistical coefficients as well as the regional total GDP forecast to develop a regional disposable income forecast.

3.2.2.3 COVID-19 Adjustments to Residential Use per Account Forecast

The December 2020 Load Forecast incorporates the COVID-19 pandemic's estimated impacts on residential use per account that would not otherwise be captured in our SAE models, recognizing there is uncertainty in quantifying those impacts. Two main factors we considered include:

1. People working from home due to public health measures, and
2. Changes in daily usage patterns as more people are working from home and spending more time at home.

To capture the impact of COVID-19 on the residential use per account, BC Hydro compared five months of actual residential consumption data in fiscal 2021 (April 2021 to August 2021) on an electric heating and non-electric heating basis to the previous year to observe the pattern changes associated with COVID-19. The following methodology was used to adjust the regional residential SAE use per account forecasts:

- For non-electrically heated homes, we assumed the observed five-month average increase in use per account would continue for the rest of fiscal 2021.
- For electrically heated homes, we assumed the observed five-month average increase in use per account would continue until November 2020 and will increase to an assumed 10 per cent for the remainder of the fiscal year. This assumption was based on our professional judgement.
- We calculated weights for each of the two heating types based on their associated share of accounts and a total adjustment factor was calculated.
- We used this adjustment factor to adjust the regional SAE model projections for fiscal 2021.
- For fiscal 2023 (and beyond), we assumed 10 per cent of people will continue to work from home even as the provincial economy returns to normal following the lifting of COVID-19 public health measure. For comparison, 50 per cent of people were estimated to be working from home as of August 2020. Our assumption that 10 per cent more people will continue to work from home as the post-COVID normal is based on professional judgment in consultation with the CBoC. This assumption was carried forward throughout the forecast period as we assumed there will be a permanent structural change due to COVID-19.
- For fiscal 2022, we took the monthly average of use per account between fiscal 2021 and fiscal 2023.

3.3 RESIDENTIAL FORECAST RESULTS

3.3.1 Residential Accounts Forecast

Table 3-1 outlines the December 2020 Load Forecast's expectations for residential customer accounts out to fiscal 2041.

Table 3-1 Residential Accounts History and Reference Forecast

Fiscal Year	Residential Accounts Forecast (Number of Accounts)
Actual	
F2015	1,727,945
F2016	1,751,296
F2017	1,776,503
F2018	1,803,752
F2019	1,833,106
F2020	1,863,569
Forecast	
F2021	1,882,761
F2022	1,917,132
F2023	1,945,968
F2024	1,972,370
F2025	1,999,173
F2026	2,021,681
F2027	2,044,245
F2028	2,066,835
F2029	2,089,396
F2030	2,111,897
F2031	2,132,766
F2032	2,153,073
F2033	2,172,860
F2034	2,192,177
F2035	2,211,047
F2036	2,229,491
F2037	2,247,543
F2038	2,265,216
F2039	2,282,491
F2040	2,299,356
F2041	2,315,842
Compound Annual Growth Rates	
5-year History CAGR (F15 - F20)	1.5%
5-year CAGR (F20 - F25)	1.4%
10-year CAGR (F20 - F30)	1.3%
20-year CAGR (F20 - F40)	1.1%

The account forecast shows an average annual growth of about 27,121 (1.4%) accounts over each of the next five years ending fiscal 2025. This is slightly lower than the historical five-year average growth rate which was about 27,125 (1.5%) accounts per year.

3.3.2 Residential Forecast Build-up

Table 3-2 below shows the details of the residential forecast build up for select years as examples to show how the Residential Reference Load Forecast is derived. This forecast is an aggregation of model projections including the COVID-19 adjustments described in section 3.2.3, load additions for codes and standards overlap, EVs, LCE/fuel switching and adjustments for rate impacts, DSM savings, and VVO savings.

Table 3-2 – Residential Reference Load Forecast Build-up

Fiscal Year	Accounts (# Accounts)	COVID-19 Adjusted SAE Use per Account (kWh/ Account)	Model Projection[1] (GWh)	Codes Overlap Adjustments (GWh)	EV Load Additions (GWh)	LCE/Fuel Switching Additions (GWh)	Rate Impacts[2] (GWh)	DSM (GWh)	VVO (GWh)	Residential Load Forecast (GWh)
F2021	1,882,761	10,477	19,723	37	135	17	48	(152)	(10)	19,799
F2022	1,917,132	10,304	19,753	77	229	36	61	(355)	(12)	19,789
F2023	1,945,968	10,132	19,714	108	309	36	37	(511)	(14)	19,678
F2024	1,972,370	10,112	19,943	136	400	36	52	(659)	(16)	19,892
F2025	1,999,173	10,065	20,119	164	504	36	28	(800)	(18)	20,033
F2026	2,021,681	10,037	20,289	189	624	36	62	(930)	(19)	20,250
F2031	2,132,766	10,016	21,360	288	1,534	36	68	(1,441)	(33)	21,812
F2036	2,229,491	10,108	22,534	368	2,841	19	75	(1,845)	(44)	23,948
F2041	2,315,842	10,263	23,765	448	4,270	0	83	(2,150)	(57)	26,360

Table notes:

1. A model projection is average use per account times the number of residential accounts which equals model sales. The model projection above is the sum model projections from all four regions, including the adjustments made for COVID-19.
2. Rate Impacts is an estimation of load reduction based on formula that include our forecast of real electricity rate increases, a price elasticity assumption of -0.1 and the residential model projections, load adjustments, and load additions.

3.3.3 Residential Reference Load Forecast

Table 3-3 provides the Residential sector sales history and Reference Load Forecast after adjustments.

Table 3-3 – Residential Sales History and Reference Load Forecast After Adjustments

Fiscal Year	Residential Reference Forecast (GWh)
Actual (Temperature Normalized)	
F2015	17,973
F2016	18,019
F2017	17,952

F2033	10,398
F2034	10,500
F2035	10,610
F2036	10,742
F2037	10,847
F2038	10,971
F2039	11,097
F2040	11,235
F2041	11,382
Compound Annual Growth Rates	
5-year History CAGR (F15 - F20)	(1.6%)
5-year CAGR (F20 - F25)	0.6%
10-year CAGR (F20 - F30)	0.4%
20-year CAGR (F20 - F40)	0.7%

The results indicate that average residential use per account is expected to increase relative to historic trends primarily due the change in consumption patterns due to COVID-19, which more than offsets a declining use per account trend primarily driven by increased end-use efficiency improvements. Over the forecast period, residential use per account is also expected to increase relative to historical trends due to the following factors:

- The assumption that COVID-19 will have a permanent structural change on the commercial sector causing more people (i.e., 10 per cent) to continue to work from home;
- The expected growth in light duty electric vehicles; and
- Other factors such as fuel switching and economic drivers (i.e., disposable income and people-per-account) will have tend to increase use per account although these are currently not as significant as COVID-19 structural change assumptions associated with COVID-19 and EVs.

3.5 RESIDENTIAL FORECAST UNCERTAINTIES

The Residential Reference Load Forecast reflects the combination of several forecasts such as account growth, use per account projections, adjustments for code and standards, load additions, and load reductions. There are uncertainties associated with the key economic variables (i.e., housing stock, population) and non-economic variables (temperature, end-use efficiency, COVID-19, EVs, LCE/fuel switching). Each of these uncertainties create both upside and downside risks for the residential load forecast. Certainly, COVID-19 has introduced a substantive additional layer of uncertainty to the load forecast.

As such there is uncertainty in all of these components that make up the residential forecast. While some of these uncertainties may offset each other, there could be conditions that could lead to a variance in the forecast where the actuals are higher or lower than forecast.

There are also uncertainties associated with the modelling itself, such as the accuracy of using statistically determined relationships between drivers and load to forecast loads at a point in time where the nature of those relationships may be changing. Our unadjusted residential use per account forecasts come from our SAE models, which reduces the risk that our residential forecasting models are not capturing a proper relationship between residential electricity consumption and economic drivers. However, as discussed in earlier sections, the need to modify our method to develop economic drivers for BC Hydro's four service regions based on the CBoC's Metro Vancouver economic forecast adds additional modelling uncertainty. However, we believe this uncertainty is small relative to other uncertainties given the overall robustness of our residential SAE models and that a large portion of BC Hydro's residential load is in the Metro Vancouver area.

While some uncertainties may offset each other, there could be conditions that could lead to a variance in the forecast where the actuals are higher or lower than forecast. Some of the major uncertainties that result in upside and downside risks are list below.

3.5.1 Number of Accounts

Housing trends may differ from the CBoC forecast. Factors that could impact housing trends in B.C. over the next several years include:

- provincial housing policy on affordable supply via targeted smaller unit construction,
- federal commitments to affordable housing, and
- government policy aimed at reducing demand and rising house prices through taxes and tightening of mortgage rules.

There is uncertainty as to how consumers will react to all of these measures which are occurring simultaneously.

3.5.2 Use Per Account

The unadjusted use per account forecast is based on our SAE model projections which reflect economic factors (real disposable income, household size) and changes in average efficiency and market penetration (i.e., saturation) of residential appliances. All of these factors have the potential to contribute to uncertainty in our load projections. In addition, government policies that increase or lower incentives for load adjustments, such as EVs and fuel switching under CleanBC's Better Buildings/Home program contribute to use per account variances.

Examples of other factors that influence use per account in an upward direction include:

- increases in home sizes (e.g., larger single-family dwellings),
- increases in air conditioning and other cooling devices, and
- increases in electronic devices.

Examples of other factors that decrease use per account are:

- increases in smaller home sizes (i.e., faster movement towards denser multiple housing units),

- increased use of programmable devices (e.g., thermostats), and
- customers becoming more conscious of electricity use.

3.5.3 Temperature

In the short term, temperature can be highly variable relative to our assumptions of a rolling 10-year average trend. Therefore, in any one year, there is a risk that temperature and associated weather may have an impact on residential sales. For example, after the El Nino event of fiscal 2015, sales to the residential sector declined by close to five per cent between fiscal 2014 and fiscal 2015 mainly due to warmer temperatures. Like most utilities, we develop a forecast based on historical temperature average or on a temperature normalized basis. This is standard practice across most utilities rather than developing an electricity sales forecast based on a prediction of future temperatures and weather conditions.

3.5.4 COVID-19

The COVID-19 pandemic adds uncertainty to the residential load forecast. The upside and downside risks relative to the reference forecast include the following:

- Timing of when public health measures are lifted is sooner/later than forecast.
- Pace and magnitude of the post-COVID economic recovery affecting residential load drivers (housing stock, population, disposable income) is better/worse than forecast
- People working from home due to public health policies and as permanent structural changes are higher/lower than assume, and
- Change in daily usage (use per account) patterns associated with more people are working from home and spending more time at home results in higher/lower electricity consumption than assumed .

The high and low forecasts are developed to capture some of this uncertainty. Further information on the residential high and low forecasts is provided in section 8.4.1.

4.0 Commercial Forecast

4.1 COMMERCIAL SECTOR DESCRIPTION

At the end of fiscal 2020, there were 185,488 commercial accounts and commercial billed sales totalled 14,338 GWh. The commercial sector as of fiscal 2020 was about 28 per cent of BC Hydro's total firm sales.

Within the commercial sector we group customers based on the type of service they receive:

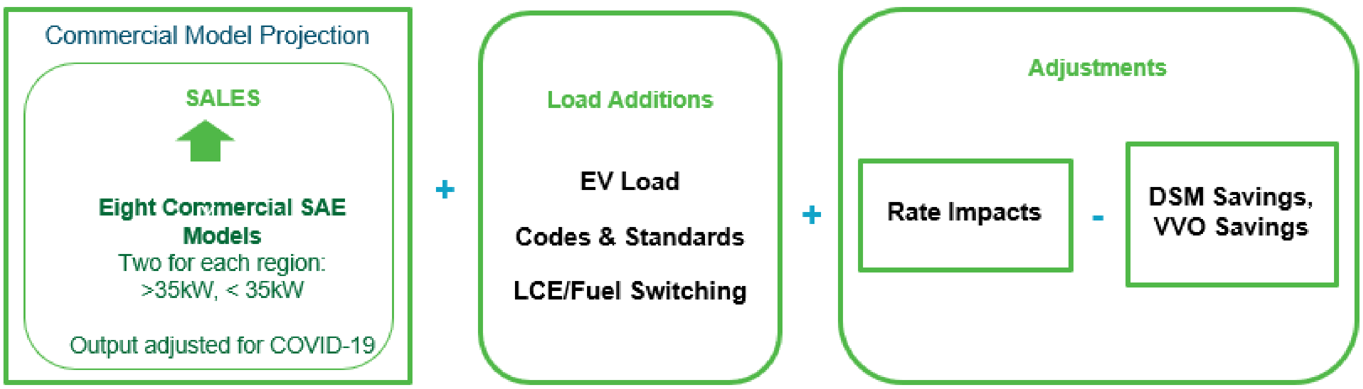
- customers with a demand under 35 kW peak demand within a month , which includes operations such as small offices, small retail stores, restaurants, and motels, and
- customers with a demand greater than 35 kW peak demand within a month which includes buildings such as large offices, larger retail stores, hospitals and hotels.

Given the diversity of businesses and type of operations within the commercial sector, commercial electricity sales are not as sensitive to temperature as the residential sector. However, some commercial customers such as schools, restaurants, and smaller health care facilities are more sensitive to temperature Therefore we still factor historical average temperature variables (i.e., heating and cooling degree days) into our commercial forecasting models. As such, the commercial forecasts are prepared on a temperature normalized basis and the actual commercial sales are temperature normalized. For details on the temperature normalization process see Appendix C of this report.

4.2 COMMERCIAL FORECAST METHODOLOGY

Similar to the residential sector, the commercial sector load forecast development begins with model projections. Our commercial model projections come from eight SAE models. These eight models correspond to our four major service regions (Lower Mainland, Vancouver Island, South Interior, and North Region) each then divided into the two levels of electrical service mentioned earlier (< 35 kW or > 35 kW). Most commercial sales are in the Lower Mainland over 35 kW customer group and Vancouver Island over 35 kW customer group. Combined, these two customer groups make up over half of the total commercial sales. Figure 4-1 shows the commercial forecasting process and build-up.

Figure 4-1 Commercial Reference Load Forecast Build-up



Looking to the left-hand portion of Figure 4-1, the starting point in the commercial forecasting process is the commercial SAE model projections.

The general structure of our commercial SAE models is the same as the SAE model diagram shown in the Residential Section (Figure 3-1 of section 3.2) with two exceptions: the inputs are different, and model projections for the commercial sector are different, as they are on a billed sales basis versus an average use per account basis.

Each of our eight commercial SAE models is an end use regression model which determines a relationship between historical commercial billed sales and historical values of these two types of variables:

- **economic variables** including employment, retail sales and commercial GDP; and
- **non-economic variables** including the average efficiency of commercial end uses of electricity and shares of commercial end uses (i.e., the percentages of commercial customers which have a specific commercial end use). The history and forecast of bo th these variables come from the 2020 dataset developed by the U.S. EIA for the Pacific region. Other non-economic variables include temperature variables represented by heating and cooling degree days.

The forecasts for these variables and the estimated regression coefficients of the eight commercial SAE regression models determine the commercial model projections of electricity sales over the forecast period. Similar to the residential SAE model, our commercial SAE models are calibrated to the past 10 years of history, ending in fiscal 2020.

Within our SAE commercial models, one factor determining the projected growth in electricity sales is the anticipated level of future economic activity and its impact. The relationship between the commercial sales and these economic variables are represented as economic elasticities (distinct from price elasticities) in the SAE model.

For December 2020 the SAE model sales forecast was adjusted for impacts of COVID-19 as described in section 4.2.2 below.

Once the billed sales forecast is complete, the same adjustments are made to the commercial forecast as the residential forecast. These adjustments are described in section 4.2.2 below.

4.2.1 Conference Board of Canada – Economic Drivers

As described in section 3.2.1, the CBoC's 2020 economic forecast was developed only for the Metro Vancouver area. BC Hydro used this forecast and CBoC's prior July 2019 regional economic forecasts to develop its four regional commercial GDP and retail sales forecasts. We used the same methodology outlined in section 3.2.2.1 (population) to derive the regional employment forecasts. Since the CBoC was not able to provide a commercial GDP forecast for Metro Vancouver, and we used a similar linear regression methodology to that methodology outlined in section 3.2.2.2 (disposable income) to derive the regional commercial GDP forecasts from the CBoC's GDP forecasts.

4.2.2 COVID-19 Adjustments to Commercial SAE Model Projections

Similar to the residential sector, the commercial sector forecast incorporates the COVID-19 pandemic's estimated impacts that would not otherwise be picked up in our commercial SAE models. Estimating the pandemic's impacts on commercial sector sales entails a greater degree of uncertainty relative to estimating its impact on residential use per account. This increased uncertainty arises because the pandemic's impact was not uniformly distributed among all commercial classes. For example, accommodation and food service (restaurants) business have been more impacted relative to food retail (i.e., grocery stores) businesses.

To capture the short term and long-term impacts of COVID-19 on such a diverse sector, we used analyzed actual consumption patterns for 15 specific business classes (NAICs codes).[4]

To capture the impact of COVID-19 on the commercial sector, we compared the available five months of actuals in fiscal 2021 (April 2021 to August 2021) to the previous year to observe the patterns associated with COVID-19. The following methodology was used to adjust the regional commercial SAE sales forecasts:

- For fiscal 2021, we used the same 15 business classes (by NAICs code) identified by the CBoC to perform the comparison between the first five months of actuals in fiscal 2021 and the previous year.
    - For each business class we used our professional judgement and the observed consumption trends up to August 2020 to assume a per cent decline at the end of F2021 (i.e., March 2021).
    - We then linearly interpolated from July 2020 (actual) to March 2021 (assumed) to come up with a trend.
- For fiscal 2022, BC Hydro took the monthly average between fiscal 2021 and fiscal 2023.
- For fiscal 2023 (and beyond), we used our historical data to calculate the proportion of office buildings load making up the total commercial sector load of office load. We then assumed 10 per cent of that office load to reflect a permanent structural change due to the pandemic. This assumed is based on professional judgment in consultation with the CBoC.

4.3 COMMERCIAL FORECAST RESULTS

4.3.1 Commercial Forecast Build-up

Table 4-1 below shows the details of the commercial forecast build-up for select years as examples to show how the Commercial Reference Load Forecast is derived. This forecast is an aggregation of model projections including the COVID-19 adjustments described in section 4.2.2, load additions for codes and standards overlap, EVs, LCE/fuel switching and adjustments for rate impacts, DSM savings, and VVO savings.

[4] NAICS - North American Industry Classification System

Table 4-1 – Commercial Reference Load Forecast Build-up

Fiscal Year	COVID-19 Adjusted SAE Model Projection[1] (GWh)	Codes Overlap Adjustment (GWh)	EV Load Addition (GWh)	LCE/Fuel Switching Load Addition (GWh)	Rate Impact[2] (GWh)	DSM (GWh)	VVO (GWh)	Commercial Load Forecast (GWh)
F2021	12,863	31	24	19	31	(97)	(8)	12,864
F2022	13,715	70	40	48	42	(252)	(10)	13,654
F2023	14,131	105	54	48	26	(386)	(11)	13,968
F2024	14,152	139	71	48	36	(513)	(13)	13,921
F2025	14,140	171	89	48	20	(633)	(14)	13,820
F2026	14,132	202	110	48	42	(744)	(15)	13,774
F2031	14,088	322	271	46	43	(1,145)	(26)	13,598
F2036	14,038	400	501	46	44	(1,451)	(35)	13,543
F2041	14,011	480	754	12	45	(1,650)	(46)	13,605

Table Notes

1. The model projection is the sum total of all commercial SAE model projections, including the adjustments made for COVID-19.
2. Rate Impacts is an estimation of load reduction based on formula that include our forecast of real electricity rate increases, a price elasticity assumption of -0.1 and the residential model projections, load adjustments, and load additions.

4.3.2 Commercial Reference Load Forecast

Table 4-2 provides the Commercial sector sales history and Reference Load Forecast, after adjustments.

Table 4-2 – Commercial Sales History and Reference Load Forecast After Adjustments

Fiscal Year	Commercial Reference Forecast (GWh)
Actual (Temperature Normalized)	
F2015	14,539
F2016	14,345
F2017	14,576
F2018	14,494

5-year CAGR (F20 - F25)	(0.7%)
10-year CAGR (F20 - F30)	(0.5%)
20-year CAGR (F20 - F40)	(0.3%)

4.4 COMMERCIAL FORECAST UNCERTAINTIES

Similar to the residential sector, COVID-19 has increased the complexity in developing a long-term commercial load forecast. For the commercial sector, this uncertainty is even greater due to the sector's broad diversity.

The commercial load forecast reflects the combination of several forecasts such as model projections, adjustments for codes and standards, load additions, and load reductions. There are uncertainties associated with the key economic variables (i.e., commercial GDP, employment, retail sales) and non-economic variables (temperature, end-use efficiency, COVID-19, EVs, LCE/fuel switching). Each of these uncertainties creates both upside and downside risks for the commercial load forecast. Even more than the residential sector, COVID-19 has introduced a substantive additional layer of uncertainty to the commercial sector forecast.

There are also uncertainties associated with the modelling itself, such as the accuracy of using statistically determined relationship between drivers and load to forecast loads at a point in time where the nature of those relationships may be changing. Our unadjusted commercial sales forecasts come from our SAE models which reduces the risk that our commercial forecasting models are not capturing a proper relationship between historical sales and drivers of commercial loads. In addition, our commercial forecasting models have multiple drivers of load as opposed to a single load driver. This reduces forecast risk in that our model projections are from multiple external forecasts rather than one external forecast of one economic variable. However, as discussed earlier sections, the need to modify our method to develop economic drivers for BC Hydro's four service regions based on the CBoC's Metro Vancouver economic forecast adds additional modelling uncertainty. However, we believe this uncertainty is small relative to other uncertainties given the overall robustness of our commercial SAE models and that a large portion of BC Hydro's commercial load is in the Metro Vancouver area.

While some uncertainties may offset each other, there could be conditions that could lead to a variance in the forecast where the actuals are higher or lower than forecast.

Examples of other factors that could result in lower than forecast commercial sales include:

- a high Canadian dollar lowers tourism and retail sales, and
- growth in online shopping and internet business that could result in less activity and future expansion in commercial stores and therefore reduce demand for electricity sales to the commercial retail sector.

Examples of other factors that could lead to higher than forecast commercial sales include:

- a lower Canadian dollar which encourages tourism and retail sales, and
- expansion of the technology sector in B.C.

The COVID-19 pandemic adds additional uncertainty to the commercial load forecast. The upside and downside risks relative to the reference forecast include the following:

- Timing of when public health measures are lifted relative to what is forecast.
- Pace and magnitude of the post-COVID economic recovery affecting commercial load drivers (commercial GDP, employment, retail sales) that may be better/worse than forecast

5.0 Light Industrial Forecast

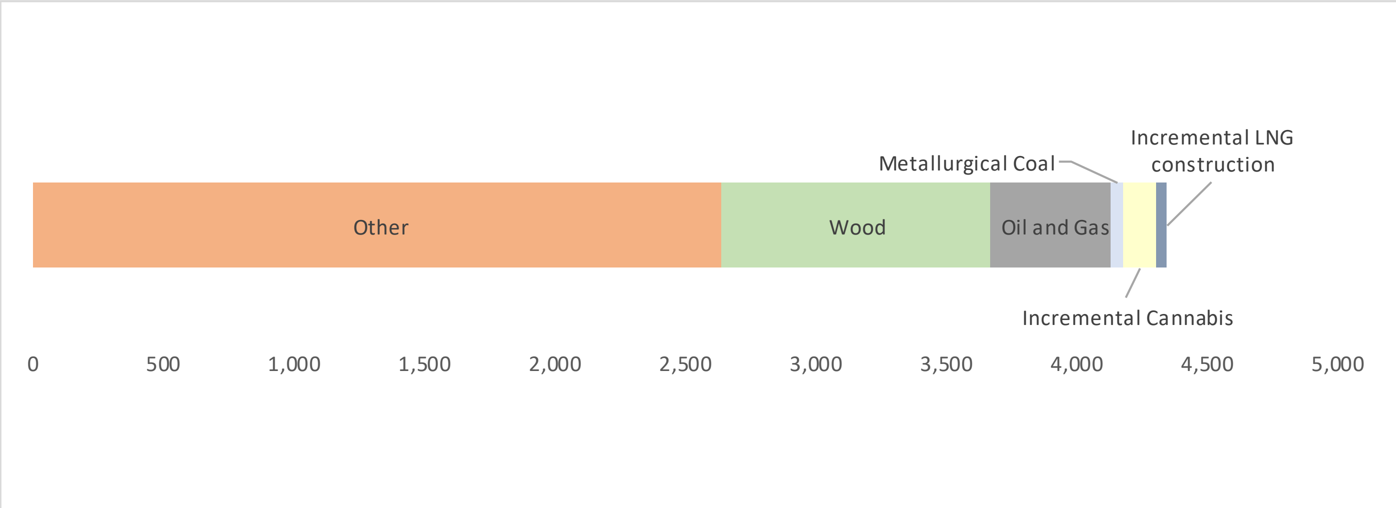
5.1 LIGHT INDUSTRIAL SECTOR DESCRIPTION

The light industrial sector consists of approximately 30,000 customers connected at the distribution level. At the end of fiscal 2020, sales to the light industrial sector were 4,311 GWh or nine per cent of our total firm sales. The light industrial sector is subdivided into the following sub-sectors:

- other industrial loads which include various activities such as agriculture, construction, and manufacturing (other),
- forestry
- oil and gas,
- metallurgical coal mining,
- incremental cannabis, and
- incremental LNG construction loads.

Figure 5-1 below shows the relative contribution of each of the above sub-sectors, based on the fiscal 2021 forecast.

Figure 5-1 – Light Industrial Sub-Sectors Fiscal 2021 (GWh)



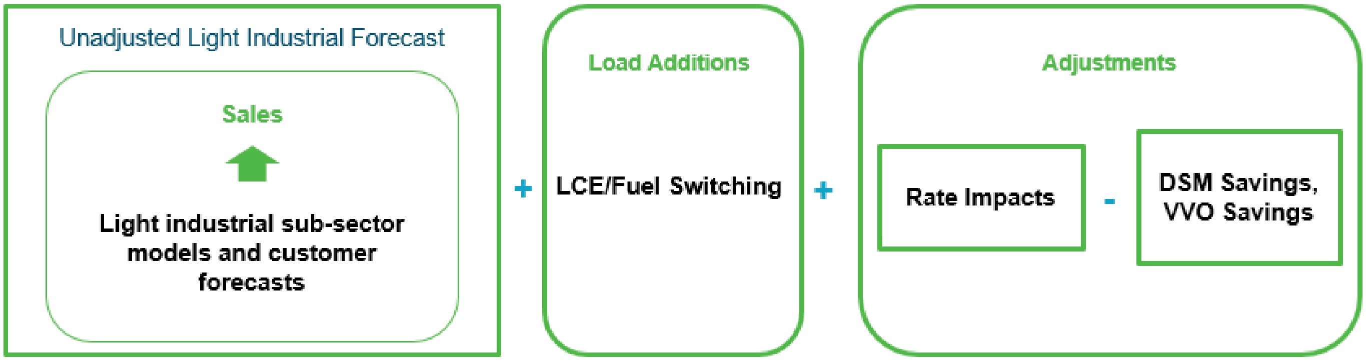
The light industrial sector is not sensitive to temperature variation and is therefore not prepared on a temperature normalized basis.

5.2 LIGHT INDUSTRIAL FORECAST METHODOLOGY

The Light Industrial Reference Load Forecast is an aggregation of model projections and customer forecasts from the sub-sectors listed above. As described in Section 2.1.2, adjustments to these base model projections are made to build up the complete light industrial load forecast.

Figure 5-2 shows the light industrial forecasting process and build-up.

Figure 5-2 Light Industrial Reference Load Forecast Build-up



Each of the sub-sectors uses a different forecast methodology. These methodologies are described below. Since the light industrial sector is not developed on an end-use basis there is no need for adjustments due to overlaps in codes and standards. In addition, there is no allocation of EV load to this sector.

5.2.1 Other Light Industrial Loads

Other light industrial load projections are based on a regression model of sales to real provincial GDP.

Equation 5-1 is the model used to develop the projections for the other light industrial loads. The parameters of this model are informed by coefficients from a regression model of the log of sales per unit of provincial GDP and a time trend.

The model used to project the other light industrial loads is the following expression:

Equation 5-1

$$INDD = \left(e^{\propto + \beta T}\right) \times GDP$$

Where:

INDD is other light industrial billed sales (excluding sales for the forestry, oil and gas, coal sub-sectors, cannabis, and LNG construction),

α and β are the regression coefficients from a log regression model of the log of sales per unit of provincial GDP, and a time trend,

e is exponential base,

T is a time trend variable, and

GDP represents the provincial real GDP forecast.

The statistical characteristic and results of the regression mode are provided in Table 5-1. These results provide the coefficients for our forecasting model. The regression model is a good fit to the historical data, and therefore viewed as a sound model to develop the forecast.

Table 5-1 – Regression Results

Variable and Statistics	Result
Constant	2.387 (p-value of 0.0%)
Independent Trend Variable	-0.004 (p-value of 0.0%)
Adjusted R-Square	0.3
Auto-correlation Range (AR)	1-1.34
Durbin-Watson Statistic	1.1
Auto-correlation test result	Indeterminate

The GDP forecast used for the December 2020 light industrial regression for the other sub-sector is shown in Table 5-2 below.

Table 5-2 - GDP forecast Used for Light Industrial Other Sub-sector

Fiscal Year	GDP Growth
F2021	(6.7%)
F2022	3.0%
F2023	3.8%
F2024	2.7%
F2025	1.8%
F2026	2.2%
F2027	2.2%
F2028	2.3%
F2029	1.9%
F2030	1.5%
F2031	1.9%
F2032	1.9%
F2033	1.9%
F2034	1.8%
F2035	1.7%
F2036	1.8%
F2037	1.7%
F2038	1.7%
F2039	1.8%
F2040	1.8%
F2041	1.9%

Table notes:

1. The source for F2021 and F2022 is the Ministry of Finance First Quarterly report released September 2020.
2. The source for F2023-F2041 is BC Hydro's provincial forecast based on the CBoC's Metro Vancouver forecast.

5.2.2 Forestry

Customers within the forestry sub-sector encompass sawmills, panel mills and pellet plants. Mill by mill production projections are developed for this sub-sector by the same experts who develop production forecasts for the large industrial wood products segment. The individual mill production forecasts are aggregated together on a regional basis and then multiplied by intensity factors (i.e. kWh/unit of production) to develop regional model projections. These projections are then aggregated to make up the total forestry sub-sector forecast.

5.2.3 Oil and Gas

Oil and gas customers are involved in production and processing, transportation (pipelines, pump stations, truck terminals) and support services for the oil and gas industry. This sub-sector's forecast is determined on an account by account basis. Account projections are developed with information from BC Hydro Distribution area planners and Load Interconnections personnel. Probability assessments are carried out on customer requests from natural gas processing plants and natural gas pipeline customers that make up most of the growth in the current forecast.

5.2.4 Metallurgical Coal Mining

There are three metallurgical coal mining customers. This forecast is developed on an account by account basis using a probability weighted approach.

5.2.5 Incremental Cannabis

The incremental forecast is developed on and account by account basis, with consideration of customer requested loads that are deemed highly probable based on their advanced stage of progress in BC Hydro's interconnection process.

5.2.6 Incremental LNG Construction Loads

The additional required load expected to power the construction of LNG plants and other facilities is considered. These construction loads are considered separately from plant operational requirements and are removed from the forecast once construction is complete.

5.3 LIGHT INDUSTRIAL FORECAST RESULTS

5.3.1 Unadjusted Light Industrial Forecast

Over the past five years, electricity sales across all light industrial customers have grown by 0.4 per cent on average (i.e., five-year average compound annual growth rate). This growth has been led by increases in sales in the other light industrial sub-sector.

Table 5-3 shows the forecast for the light industrial sector before LCE/fuel switching additions and adjustments for rate impacts, DSM and VVO savings. The load additions and adjustments are applied to the consolidated light industrial forecast, which is provided in Table 5-5.

Table 5-3 – Light Industrial Sales History and Reference Load Forecast Before Adjustments

Fiscal Year	Other (GWh)	Wood (GWh)	Oil and Gas (GWh)	Metallurgical Coal (GWh)	Incremental Cannabis (GWh)	Incremental LNG construction (GWh)	Total (GWh)
Actual							
F2015	2,486	1,211	479	51			4,227
F2016	2,471	1,199	455	22			4,148

F2024	2,848	1,155	615	43	213	12	4,886
F2025	2,887	1,155	634	43	213	7	4,938
F2026	2,936	1,155	616	43	217	7	4,974
F2027	2,985	1,155	616	43	217	7	5,024
F2028	3,040	1,155	616	43	218	7	5,079
F2029	3,084	1,155	616	43	218	7	5,123
F2030	3,115	1,155	616	43	218	7	5,154
F2031	3,158	1,155	616	43	218	7	5,197

Fiscal Year	Other (GWh)	Wood (GWh)	Oil and Gas (GWh)	Metallurgical Coal (GWh)	Incremental Cannabis (GWh)	Incremental LNG construction (GWh)	Total (GWh)
F2032	3,203	1,155	616	43	218	-	5,235
F2033	3,247	1,155	616	43	218	-	5,280
F2034	3,290	1,155	616	43	218	-	5,322
F2035	3,330	1,155	616	43	218	-	5,362
F2036	3,373	1,155	616	43	218	-	5,406
F2037	3,416	1,155	611	43	218	-	5,443
F2038	3,460	1,155	606	43	218	-	5,482
F2039	3,506	1,155	601	43	218	-	5,523
F2040	3,553	1,155	601	43	218	-	5,571
F2041	3,604	1,155	601	43	218	-	5,621
Compound Annual Growth Rates							
5-year History CAGR (F15 - F20)	2.2%	(3.5%)	(2.7%)	(0.4%)			0.4%
5-year CAGR (F20 - F25)	0.9%	2.6%	8.7%	(2.8%)	27.1%		2.8%
10-year CAGR (F20 - F30)	1.2%	1.3%	4.0%	(1.4%)	13.0%		1.8%
20-year CAGR (F20 - F40)	1.3%	0.7%	1.8%	(0.7%)	6.3%		1.3%

Table notes:

1. The actuals for cannabis are estimates based on the spot (incremental) loads for customers included in the October 2018 Load Forecast. Forecast.
2. The actuals for LNG construction are captured under the actuals for other subsector. As such, historical and forecast compound growth rates are not shown.
3. Forecast values do not indluce LCE/Fuel switching adjustments.

The light industrial subsector is expected to experience modest growth in fiscal 2021, as the drop in the other subsector due to COVID-19 pandemic impacts on provincial GDP is offset by incremental additions to cannabis and LNG construction loads, as well as a small increase in the oil and gas subsector.

The other subsector is forecast to recover in fiscal 2022 and returns to pre-pandemic load levels by the end of fiscal 2023. The light industrial sector is forecast to grow approximately 1,300 GWh by fiscal 2041, with growth led by the other subsector (~800 GWh), as well as oil and gas (~200 GWh), incremental cannabis (~200 GWh) and forestry (~100 GWh).

5.3.2 Light Industrial Forecast Build-up

Table 5-4 below shows the details of the light industrial forecast build up for select years as examples, to show the progression from the unadjusted forecast projections above to the Light Industrial Reference Load Forecast. This forecast includes the unadjusted aggregation of the various segments making up the light industrial sector, load additions for LCE/fuel switching additions and adjustments for rate impacts, DSM and VVO savings.

Table 5-4 – Light Industrial Reference Load Forecast Build-up

Fiscal Year	Light Industrial Model Projections / Customer Forecast [1] (GWh)	LCE/Fuel Switching Load Additions (GWh)	Rate Impact[2] (GWh)	DSM (GWh)	VVO Savings (GWh)	Light Industrial Load Forecast[3] (GWh)
F2021	4,341	0	11	(24)	(2)	4,326
F2022	4,675	0	14	(59)	(2)	4,628
F2023	4,878	28	9	(87)	(3)	4,825

20-year CAGR (F20 - F40)	1.0%

5.4 LIGHT INDUSTRIAL UNCERTAINTIES

The Lignt Industrial Reference Load Forecast represents an aggregation of model projections, sub-sector specific customer loads, incremental new loads, and other adjustments.

For the other sub-sector portion of the large industrial forecast there are uncertainties associated with GDP as the key economic growth driver. For this sub-sector, the regression model we have used to develop the sales projection is statistically robust (no autocorrelation) and has a good fit to the historical data (high R-square value). However, since the forecast largely relies upon the GDP forecast, there is a risk that actual GDP growth may vary from forecast. The COVID-19 pandemic's impact on provincial GDP adds further uncertainty. In addition, the other light industrial sub-sector is largely composed of manufacturing loads. These loads may respond differently to other factors such as tariffs, exchange rates, technology changes and commodity prices which could impact sales. This also ho lds true for the forestry, mining and oil and gas light industrial sub-sectors.

For discrete new loads there are uncertainties not only with respect to the likelihood those loads will materialize, but also their timing. Key examples include:

- Uncertain growth potential for the cannabis industry.
- Uncertain timing of loads associated with major projects under construction. We anticipate that these loads will materialize but they could vary over the short term based on construction schedules and when construction will begin to ramp up.

For the light industrial loads related to the other sub-sector, the forecast largely relies upon the GDP forecast, there is a risk that actual GDP growth may vary from forecast.

The high and low forecasts are developed to capture some of this uncertainty. Further information on the light industrial high and low forecasts is provided in section 8.3.3

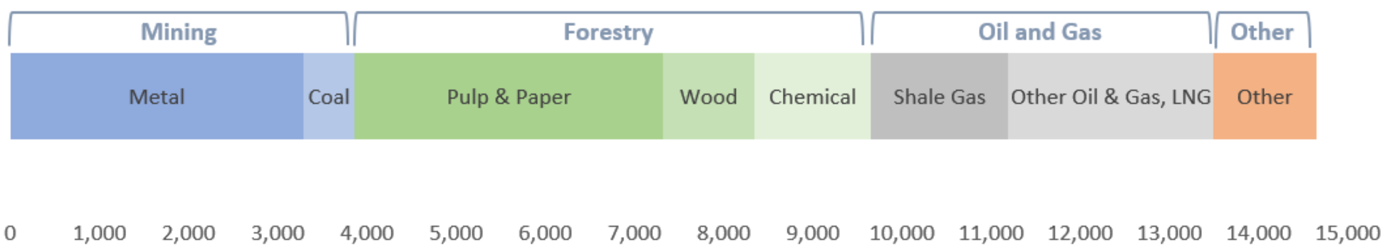
6.0 Large Industrial Forecast

6.1 LARGE INDUSTRIAL SECTOR DESCRIPTION

The large industrial sector is comprised of about 190 customers that account for about 26 per cent of BC Hydro's total firm sales. The individual customers are organized into four main sub-sectors: mining, forestry, oil and gas (including LNG), and other large industrial customers. While light industrial customers are connected at distribution voltages, large industrial customers are connected at transmission voltages. Most of our large industrial customers are involved in extracting, processing and manufacturing resource-based commodities, which are largely exported outside B.C. Export volumes can vary from year to year in response to market forces and consequently, electricity sales to this sector can also vary.

Figure 6-1 below shows the segmentation of the large industrial sector and relative size of load based on fiscal 2020 actuals.

Figure 6-1 - Large Industrial Sub-Sectors and Segments – Fiscal 2020 Actuals (GWh)

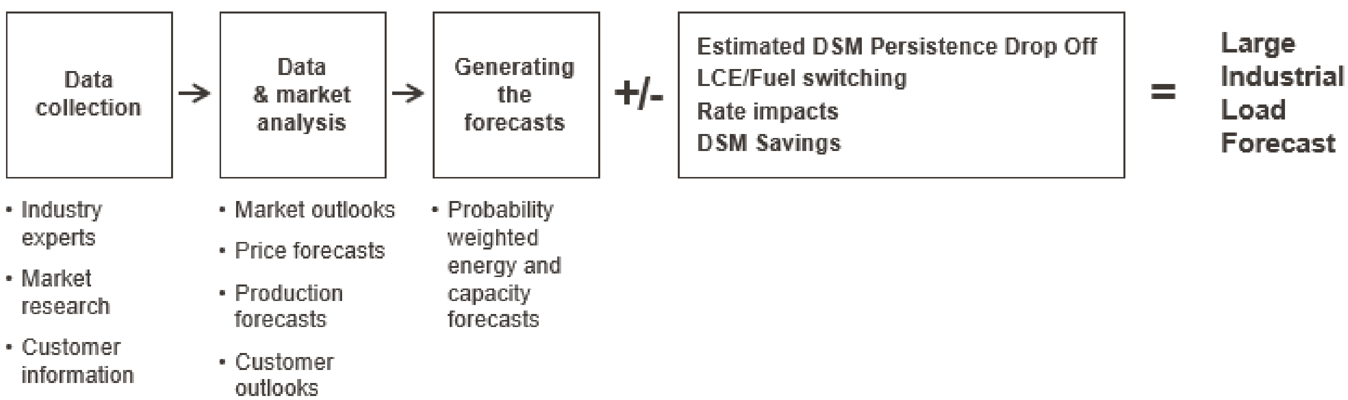


6.2 LARGE INDUSTRIAL FORECAST METHODOLOGY

6.2.1 General Process and Build-Up

Sales to the large industrial sector are forecast on an individual customer basis then aggregated into sub-sector forecasts as shown in Figure 6-1 above. The general account-by-account process that we use to produce the large industrial load forecasts is shown in Figure 6-2.

Figure 6-2 - Large Industrial Load Forecast Process (by sub-sector)



Each of the sub-sector forecasts is primarily developed from multiple quantitative and qualitative analyses provided by both internal and external experts in addition to information provided by our customers. The forecasts are developed in a collaborative process thereby allowing for alternative perspectives to be shared. The extent to which expert inputs are applied varies across each of the major sub-sectors and is a function of market complexity and uncertainty, number of customers and magnitude of the load. The main sources of information used to develop each sub-sector forecast include the following:

- industry experts: We retain external consultants who develop production and commodity price forecasts and provide facility and sector-specific market assessments,
- market research: We subscribe to a number of services from companies that provide market research and industry analyses. We also rely on various publicly available reports from government agencies, such as the BC Oil and Gas Commission, and

- information from our customers: We use customer-specific information gathered by our Key Account Management and Load Interconnections groups, who are in contact with our customers.

Using these sources of information, we develop a probability weighting for expected sales to our current customer. This probability weighting represents a risk assessment of the likelihood of future sales increasing, decreasing or remaining steady. For each potential new customer, these same sources of information are used to develop similar probability weightings to forecast if and when new demand will materialize.

Each of these probability weightings represents our professional judgement based on the synthesis of information from our sources as well as factors that are considered when assigning probability weightings. Examples of factors considered include:

- how far a customer has passed through our interconnection processes,
- the status of the customer's regulatory/approval permits and project financing,
- BC Hydro's ability to meet the customer's requested in-service date,
- consultant mill, facility and market assessments, where applicable,
- the market outlook for the customer's products,
- the credit and financial viability of the customer,
- the impact of electricity costs on the customer,[5] and
- the likelihood that the customer will take electricity supply from BC Hydro instead of self-supplying their power needs.

Due to commercial sensitivities, individual account assessments are kept confidential. To maintain this confidentiality the large industrial forecast is aggregated by sub-sector.

In developing the large industrial load forecast, we have included the estimated DSM persistence drop off in each of the large industrial sub-sectors based on analysis by our Conservation and Energy Management group. We now assume that once an efficiency project has been implemented, the customer will continue to replace like for like equipment at the end of its lifecycle.

As with the residential and commercial sectors, the large industrial sector build-up includes adjustment for LCE/fuel switching, rate impacts and DSM. LCE/fuel switching is a relatively small portion of the overall forecast large industrial LCE loads and the majority of the large industrial LCE loads are attributed to two specific customer projects. For confidentiality reasons these project loads are embedded within the oil and gas sub-sector forecast.

6.2.2 Integrating Top-Down and Bottom-Up Information

For some large industrial segments, probability weightings are developed by assessing customer operations (i.e., bottom-up) in the context of the customer's broader market conditions (i.e., top-down). This process entails the following:

Bottom-Up: In order to determine how much energy each customer needs, we typically perform a bottom-up analysis for their various operations. This analysis assesses the historical (or requested) energy usage and compares it to the volume of product a customer produces to determine load or intensity factors. We obtain this information from internal BC Hydro sources, our customers, external consultants or industry reports.

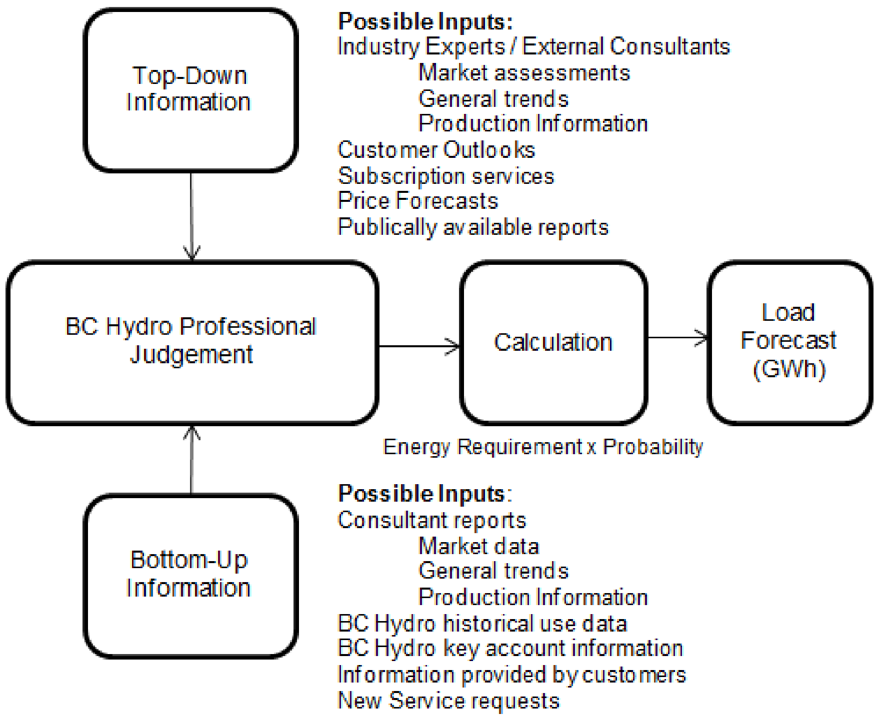
Top-Down. Industrial customers are subject to changing market conditions and it is important to understand how macro-economic influences will impact their business and ultimately their energy needs. The top-down analysis performed is the application of a supply, demand and price analysis of the markets where our industrial customers are expected to sell their products and the consideration of

[5] This factor incorporates the impacts of future electricity costs on electricity demand relative to how much their electricity costs are to overall cost of production on a sub-sector wide basis. This is separate from, but needs to be considered along with, price elasticity when assessing the overall impacts of future electricity prices.

how these market influences will impact their operations. Information from a variety of external sources is considered to shape the high-level assessment of the market.

Figure 6-3 below shows how the top-down, bottom-up analysis is conducted.

Figure 6-3 General Overview of Top-Down, Bottom-Up Forecasting Methodology



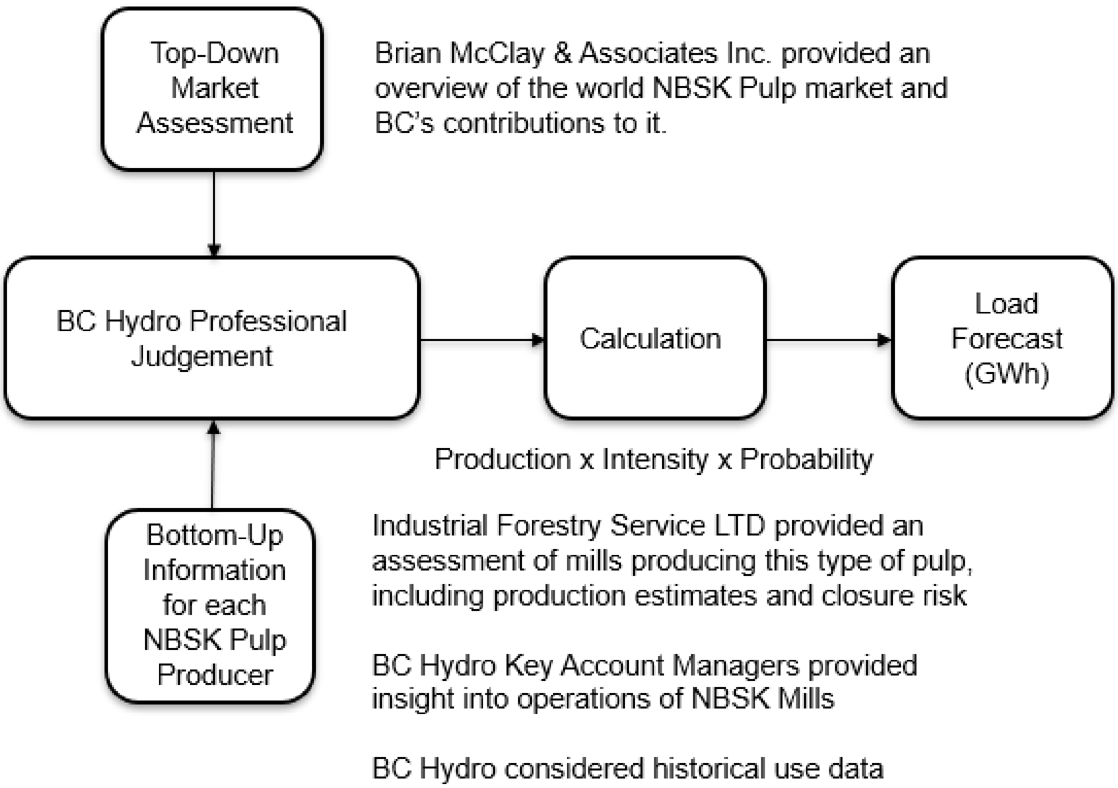
The application of this general methodology varies by subsector and segment. Figure 6-4 below shows a breakdown of the large industrial sector. The bottom-up analysis is done at the lowest level shown for each product/service line or sub-segment. The top-down analysis is performed for operations marked “Yes” under the column entitled, “T-D Done?”

Figure 6-4 BC Hydro Large Industrial Forecast Breakdown

Sector	Sub-sector	Segment	Sub-segment	Product/Service Line	T-D Done?
Large Industrial	Forestry	Pulp & Paper	Kraft	NBSK Pulp	Yes
				Self Generation	n/a
				Packaging	n/a
				Cellulose Fillament	Yes
				Biofuel	Yes
			Publication Papers	Thermal Mechanical P	Yes
				Kraft	Yes
				Newsprint	Yes
				Super Calendar	Yes
				Towelling	Yes
				Uncoated Groundwood	Yes
				Lightweight Coated	Yes
				Self Generation	n/a
			BCTMP	BCTMP	Yes
				Self Generation	n/a
			Other	Tissue & Other	Yes
		Wood Products	Sawmill	Sawmill	Yes
				Self Generation	n/a
				Chip	No
			Panel		Yes
			Pellet		Yes
		Chemical	Sodium Chlorate		No
			Caustic Soda		No
			Hydrogen Peroxide		No
			Chlorine		No
			Hydrochloric Acid		No
			Hydrogen		No
	Oil & Gas	Shale Gas	Shale Gas and Liquids		Yes
		Other Large Oil & Gas Operations	Propane Terminals		Yes
			Gas Pipelines/Compressor Stations		Yes
			Gas Processors		No
			Convential Gas		No
			Oil Pipelines		Yes
			Oil Refineries/Tank Farms		No
			Oil		Yes
			LNG Terminals		Yes
	Mining	Metal	Copper		Yes
			Gold		Yes
			Molybdenum		Yes
		Coal	Metallurgical		Yes
	Other		Universities		No
			Cement		No
			Manufacturing		No
			Ports & Terminals		No
			Airport		No
			Cryptocurrency/Data Centers		No

To illustrate how the top-down and bottom-up methodologies are applied, Figure 6-5 below shows an example of how Figure 6.3 is applied to a specific product line: Northern Bleached Softwood Kraft (NBSK) Pulp. Figure 6-4 shows this as a product line in the forestry sub-sector, pulp and paper segment, Kraft sub-segment.

Figure 6-5 Example of Application of Top-Down, Bottom-Up Forecast Methodology to NBSK Pulp



Similar approaches are applied to varying degrees for the sub-segments and product/service lines outlined in Figure 6-4 to build out the Large Industrial Reference Load Forecast.

6.2.3 Addressing Potential for Bias in the Large Industrial Forecast

BC Hydro acknowledges that there is a potential for bias in developing the large industrial forecast, such as information reported by customers. Measures are taken to reduce or eliminate this type of bias in the forecast.[6]

In general, the methodologies used to develop the light and large industrial load forecasts fo r our major sub sectors (i.e., forestry, oil and gas, mining) are not susceptible to the weakness of an "informed opinion" from an "expert" or from the customer. This is because those forecasts are primarily developed from multiple quantitative and qualitative analyses provided by both internal and external experts in addition to information provided by our customers. In other words, our major subsector forecasts are developed from multiple qualified expert inputs, including from outside parties. The forecasts are developed in a collaborative process thereby allowing for alternative perspectives to be shared.

[6] Further information can be found in BC Hydro's response to BCUC IR 1.9.1.1 to the Fiscal 2020 – Fiscal 2021 Revenue Requirements Application.

The extent to which expert inputs are applied varies across each of the major subsectors and is a function of market complexity and uncertainty, number of customers and magnitude of the load.

BC Hydro detects and addresses potential bias in large industrial customer forecasts through the means described in the sections below.

6.2.3.1 Forecast Methodology

As described in sections 6.2.1 and 6.2.2, the largest and most complex large industrial sub-sectors are primarily developed from multiple quantitative and qualitative analyses provided by both internal and external experts in addition to information provided by our customers.

There are customer segments, including those within the Other Large Industrial sub-sector, in which the load forecasts primarily rely on historical sales data, information provided by our customers regarding their long-term plans and electricity needs, and key account management's professional judgment. BC Hydro believes the approach for these customer segments are appropriate for the following reasons:

- The subsector is a small component of BC Hydro's overall load (approximately 1,200 GWh per year);
- The subsector is primarily made up of long-standing customers with relatively stable historical sales; and
- The financial costs needed to develop external assessments for each of the diverse segments making up the subsector are not justified given the first two bullets above.

6.2.3.2 Customer Application Process

For customer requests, customers refine their load requirements throughout the load interconnection process with BC Hydro's assistance. The process begins with the customer completing a Transmission Voltage Customer Interconnection Data Form. This form requires applicants to itemize plant equipment with horsepower – information that can be used to reconfirm load requirements. Next, BC Hydro works collaboratively with the customer to complete a series of interconnection studies that helps them refine their load requirements.

The interconnection process has a built-in incentive for the customer to avoid overstating their load requirements. This is because the customer will likely trigger major system upgrades if they request a greater load than what they truly need, and for which they will be financially responsible.

For example, once BC Hydro provides information on potential system upgrades in the early stages of interconnection process, the customers often review their load requirements and come back with more accurate numbers.

Comparison Against External Sources

When information is available, a project level review of the data and market analysis can be undertaken to allow for an assessment of specific customer load requests and associated timing. This is undertaken internally or via third party market research organizations. Examples of the types of information reviewed can include environmental or other permit applications and publicly disclosed capital expenditure plans.

6.2.3.3 Variance Analysis

Each month BC Hydro conducts a forecast review process where each large industrial customer's forecast is compared against the actual load. This review is a cross departmental process involving the Customer Service, Finance and Load Forecast departments. Material biases resulting in over-stated loads would result in obvious large variances that would be identified and addressed in subsequent forecasts.

6.2.3.4 Internal Reviews

Draft versions of the load forecast undergo multiple levels of internal inter-departmental reviews starting at lower levels of departments and progressively elevating to senior management. These reviews, among other things, seek to address potential bias in customer self-reporting.

6.2.3.5 External Reviews

External reviews occur by way of processes such as the August 2017 Load Forecasting Audit. These processes support external review of the underlying assumptions of the load forecast and its key drivers and identify and resolve bias from customer self-reporting.

6.2.3.6 Continuous Improvement Approach

The BC Hydro Load Forecast department is periodically audited, and it undertakes a continuous process improvement approach. This approach helps to address potential bias in customer self-reporting and allows BC Hydro to consider opportunities to improve forecast accuracy.

6.2.4 Binary Approach for First Three Years of the Forecast

Consistent with our more recent load forecasts, we apply a binary approach for the first three years of the forecast (F21-23). The binary method results in a discrete projection (i.e., in or out) of load and revenues. This approach is applied as follows:

- We continue to undertake probability assessments on an individual customer account basis.
- Where the dominant risk factor amongst all others is closure risk, customer loads included in the forecast are reflected at either their full expected load (weighted at 100 per cent probability) or zero load (weighted at 0 per cent) for the period fiscal 2019 to fiscal 2021, depending on whether the closure risk is assessed as being low or high.
- Where the main risk factor is start up likelihood, only high likelihood projects are included at their full expected load in the period fiscal 2021 to fiscal 2023. For these highly likely projects we also consider project schedule risk as part of the binary assessment. For example, there may be uncertainty on when a project actually comes into service relative to the customer requested in service date. In these situations, we will exercise our professional judgement in deciding whether to reflect the full expected load at a later date than that requested by the customer. If we determine that there is a reasonable likelihood the actual in service date will occur beyond the customer requested in service date, the full expected load (i.e., weighted at 100 per cent) will be reflected at that later date in the forecast and at zero load (i.e., weighted at 0 per cent) prior to that date.

We also made assumptions about the extent to which commodity prices will continue to be depressed as a result of the COVID-19 pandemic impacts on the global economy and then, working with BC Hydro's Key Account Management department, undertaking a customer-by-customer assessment.

As part of this assessment we communicated directly with some of our large industrial customers to assess ongoing impacts of COVID-19 pandemic on individual accounts. That allowed for an assessment of a range of possible outcomes, including:

- A temporary reduction in consumption in major industries such as forestry;
- Permanent closures of industrial facilities; and
- Potential delays in the construction of major infrastructure projects.

For the forestry and oil and gas subsectors, we also considered the exacerbating effects of other market pressures (i.e., fibre supply shortages on forestry; global oil price war on oil and gas).

BC Hydro relied on professional judgment and experience of the Load Forecast and Key Account Management departments.

6.3 LARGE INDUSTRIAL FORECASTS RESULTS

6.3.1 Large Industrial Unadjusted Forecast

The Large Industrial Reference Load forecast is an aggregation of all sub-sector and segment forecasts. Table 6-1 below provides the sector's sale history and Reference Load Forecast before adjustments for rates and DSM.

Table 6-1 Large Industrial Reference Load Forecast Before Adjustments

Fiscal Year	Mining		Forestry			Oil and Gas		Other	Total
	Metal Mines (GWh)	Metallurgical Coal Mines (GWh)	Pulp and Paper (GWh)	Wood Products (GWh)	Chemical (GWh)	Shale Gas (GWh)	Other Oil and Gas (GWh)	Large Industrial (GWh)[1]	Large Industrial (GWh)
Forecast									
F2021	3,347	608	2,686	1,039	1,249	1,448	790	1,076	12,243

F2040	3,891	853	2,453	1,088	1,368	3,158	3,607	1,242	17,660
F2041	3,891	853	2,453	1,088	1,368	3,158	3,607	1,254	17,672

Table notes:

1. Values are based on customer forecasts and do not include any load additions or adjustments.
2. Historical values are not provided in this table because they do not provide a relevant comparison to the unadjusted forecast.

6.3.2 Large Industrial Forecast Build-Up

As with the other sectors, adjustments are made to derive the final large industrial forecast. Table 6-2 below shows the details of the large industrial load forecast build up for select years as examples to show how the Large Industrial Reference Load Forecast is derived.

Table 6-2 Large Industrial Reference Load Forecast Build-up

Fiscal Year	Large Industrial Customer Forecast Before Adjustments (GWh)	Estimated DSM Persistence Drop Off (GWh)	Fuel Switching Load Additions (GWh)	Rate Impacts (GWh)	DSM (GWh)	Large Industrial Load Forecast After Adjustments (GWh)
F2021	12,243	0	3	30	(111)	12,165
F2022	12,625	0	20	39	(246)	12,437
F2023	13,445	0	36	24	(322)	13,183
F2024	14,363	0	36	36	(393)	14,042
F2025	15,394	(18)	36	21	(451)	14,982
F2026	16,342	(21)	36	48	(509)	15,896
F2031	17,466	(46)	35	51	(753)	16,754
F2036	17,622	(183)	24	51	(824)	16,690
F2041	17,672	(394)	11	51	(764)	16,575

6.3.3 Large Industrial Reference Forecast

Table 6-3 below provides the Large Industrial Oil and Gas (including LNG) sector sales history and Reference Load Forecast load after LCE/fuel switching load additions and adjustments for rate impacts and DSM. The DSM plan provides estimates of savings at a sub-sector level so the allocation of DSM to the segments shown below is an approximation.

Table 6-3 Large Industrial Sales History and Reference Load Forecast After Adjustments

Fiscal Year	Mining		Forestry			Oil and Gas		Other Large Industrial (GWh)	Total Large Industrial (GWh)
	Metal Mines (GWh)	Metallurgical Coal Mines (GWh)	Pulp and Paper (GWh)	Wood Products (GWh)	Chemical (GWh)	Shale Gas (GWh)	Other Oil and Gas (GWh)

Table notes:

1. Values include all load addtions and adjustments.

6.4 MINING

As a result of our market outlook and internal information related to service requests from potential new customers, the reference case projects modest growth in the mining sub-sector load over the next twenty years. The growth comes from increased production, equipment upgrades and new mines entering the forecast, but it’s partially offset by some of the existing mines reaching end of life. The total reference case load in the mining sub-sector in fiscal 2041 is projected to be 4,322 GWh, up 729 GWh from 3,863 GWh recorded in fiscal 2020. A number of uncertainties exist, which are reflected in the high and low forecasts.

6.4.1 Mining Sub-sector Description

The mining sub-sector accounts for about 31 per cent of sales to the large industrial sector. It is categorized into two segments: metal and metallurgical coal mines. Demand from metal mining makes up 85 per cent of the total sales in the mining sector. Since metal mining represents the vast majority of the mining load for BC Hydro, the drivers of metal mining have the most influence on the total mining load.

Metal mines typically consume more electricity than metallurgical coal mines, due to the energy required in the comminution process (crushing and grinding ore to extract the target minerals). Electricity used in metal mining operations typically represents about 10 to 15 per cent of total production costs. The metal mines in B.C. produce predominantly copper with gold, molybdenum, and silver as common secondary products. Two operating mines - Brucejack and New Afton - list gold, as the main product.

Metallurgical coal is an export commodity which is sold worldwide to integrated steel mills for steel-making purposes. Metallurgical coal mines consume less electricity than metal mines, due to the softer sedimentary nature of these deposits. Only crushing is required to break up the rock and energy intensive milling is not required. Electricity used in metallurgical coal operations typically represents about 5 per cent of production costs.

Growth in B.C.’s mining industry is linked to commodity prices, which can be volatile and cyclical. In general, demand is driven by economic growth within parts of Asia and the relative global supply/demand balance for copper, metallurgical coal, gold and to a lesser extent molybdenum. China is currently responsible for about 50 per cent of global copper demand. Other factors that impact mining sales and the development of new mines include the availability of financing, regulatory and environmental approvals, and First Nations considerations.

The mining sector is also characterized by the long timeline required to bring a project from exploration stage into production.

The metals commodity boom between 2009 and 2011 triggered an increase in mine development activity in British Columbia. This was followed by an economic downturn in 2013-2016, as growth in China slowed down. Copper prices stabilized somewhat during 2017-2019, but the beginning of the COVID-19 pandemic brought a sharp but short-lived decline in commodity prices. As China emerged relatively quickly from the lockdown and demand for copper and other commodities strengthened over the summer of 2020, copper prices recovered and exceeded pre-pandemic levels.

Due to long construction periods and additional time to ramp up or ramp down production, electricity sales in the mining sector typically lag commodity prices. Restarts and upgrades at existing operations are generally the fastest response to positive price signals, followed by greenfield additions. Prolonged low-price environments may lead to shutdowns, but most closures have also a built-in lag effect as metal miners continue to run the electric intensive mills to process stockpiles months after the shutdown of pit operations.

The recent history of mining load in B.C. is a good example of the lag effect. The commodity price boom in 2009-2011 prompted upgrades at existing operations (e.g., Gibraltar, Endako, Highland Valley) accompanied by brownfield restarts (Copper Mountain, New Afton) and greenfield additions (Mt Milligan, Red Chris Brucejack). This resulted in the metal mining load increasing by approximately 40 per cent between fiscal 2011 and fiscal 2015, despite the commodity market being in a pronounced downturn. The ramp up in mining load after fiscal 2016 was offset by shutdowns at Endako, Huckleberry and Mount Polley mines due to low commodity prices. This resulted in a flat profile for mining load between fiscal 2016 and fiscal 2020.

Mining exploration activity in the province increased in 2020 following years of reduced activity. Exploration expenditures across the province increased by 28 per cent year-over-year to $422 million close to the highs experienced in 2011 and 2013.

6.4.2 Mining Forecast Methodology

The mining sector's sales are forecast on an individual customer account basis, in line with the large industrial sector methodology. There are two independent methods of deriving the forecast of electricity sales for mining customers.

The primary forecast method is the product of expected peak demand, load factor, and probability. The load factor is a measure of the utilization rate, or efficiency of electrical energy usage. In the case of existing customers, historical consumption information is used as the starting point and is updated with new information (such as equipment upgrades). The probability weighting, which is informed by the criteria outlined in section 6.2 include factors such as the project's economics, availability of financing, regulatory progress and BC Hydro interconnection status. A mine's economics is analyzed in the context of the global market. The mining forecast includes closure risk for existing customers.

The secondary forecast method uses production, electricity intensity and probability. The production data is informed by the third-party subscription service and the electricity intensity is derived from our internal sources.

For the current metal mining load forecast, we rely on the Wood Mackenzie copper mining subscription and Consensus Economics price forecast to support the development of the metal mining forecast. We also use public reports from the Ministry of Energy, Mines and Low Carbon Innovation (Ministry), Thompson Reuters, PricewaterhouseCoopers, Deloitte, company public reports and information gathered by our Key Account Management and Load Interconnections business units.

For the metallurgical coal mining forecast we rely on Consensus Economics, the Ministry, company public reports and internal information.

6.4.3 Metal Mining Segment

6.4.3.1 Metal Mining Segment Description

In the long term, electricity sales to metal mines are tied to price expectations for copper and gold and to a lesser extent, molybdenum and silver. The prices of these commodities are influenced by global demand and supply and the state of the global economies. In the short term, month-to-month electricity sales to metal mines are relatively independent of commodity price fluctuations because these mines are fixed-cost operations, running on a continuous basis. Since the most of B.C. metal mining production is exported, mining sales are not overly dependent on domestic economic activity, but rather correlated to the global economy. The top destinations for B.C. mining exports include Japan, the United States, China and South Korea.

6.4.3.2 Metal Mining Forecast Results

Over the five years ending fiscal 2020, sales to the metal mining segment remained relatively flat. The increase from projects ramping up production such as Brucejack or Red Chris was offset by the loss of several metal mining customers (Huckleberry, Endako, Mount Polley) due to lower commodity prices. Table 6-4 shows the history and forecast of metal mining sales after fuel switching load additions and adjustments for rate impacts and DSM.

Table 6-4 Metal Mining Segment Sales History and Reference Load Forecast After Adjustments

Fiscal Year	Metal Mining Reference Forecast (GWh)

While the COVID-19 pandemic reduced copper prices in fiscal 2021, it was relatively short-lived. As a result, B.C. copper mines were able to maintain their normal production levels with only minor disruptions.

Table 6-5 Copper Reference Price Forecast

Fiscal Year	Copper Price Forecast ($/tonne)	Copper Price Forecast ($/lb)
Actual		
F2015	6,857	3.1
F2016	5,502	2.5
F2017	4,863	2.2
F2018	6,164	2.8
F2019	6,526	3
F2020	6,009	2.7
Forecast		
F2021	5,685	2.6
F2022	6,123	2.8
F2023	6,329	2.9
F2024	6,494	2.9
F2025	6,724	3
F2026-F2041	6,605	3

The copper mining reference forecast is based on a favourable short- and long-term outlook for both copper and gold (commonly found BC copper ore bodies) and internal information related to service requests from potential new customers. We are expecting approximately 250 GWh growth in the metal mining load between fiscal 2020 and fiscal 2041. Some equipment upgrades to existing operations are expected to occur between fiscal 2021 and 2025. However, any potential (probability weighted) new mining loads after fiscal 2026 are offset by expected end of life shutdowns to several existing customers. The metal mining load in fiscal 2041 increases to approximately 3,550 GWh from the current level of 3,300 GWh in fiscal 2020.

The copper market outlook[7] underpinning the reference forecast is summarized as follows:

- although high volatility is inherent with metal prices, the long-term average annual copper price is expected to continue around $3/lb as global demand grows at a moderate pace driven by construction activity in China and global electrification of various sectors (transportation, manufacturing). Reference metallurgical coal prices are provided in Table 7.2.
- short and long term COVID-19 pandemic impacts on the metal mining sector are assumed to be negligible.

At these price levels, BC Hydro expects existing customers to operate normally and there is low incentive to bring new projects into production.

[7] Copper market outlook is informed by analyst judgment, Wood Mackenzie subscription and other sources described in the methodology section.

6.4.3.3 Metal Mining Uncertainties

The major risks and uncertainties around the metal mine segment over the forecast period include:

- price volatility, boom and bust cycles,
- COVID-19 pandemic impact on world economies, particularly China,
- additional mining sector electrification associated with meeting provincial greenhouse gas (GHG) emission reduction targets,
- closures due to accidents,
- rising trend in trade protectionism which impacts global economic growth,
- demand erosion due to substitution effects from other sources (aluminium, steel, composite materials) and rise in scrap recovery,
- higher/lower than anticipated global economic growth mirrored in increased/decreased demand for metals,
- higher/lower than anticipated electrification of transportation and manufacturing resulting in increased metal demand,
- outcome of future environmental assessment applications from a number of proposed mines, and
- skilled labour shortages for mining companies due to aging workforce and competition with other sectors.

The high and low forecasts are developed to capture some of this uncertainty. Further information on the metal mining high and low forecasts is provided in section 8.2.4.

6.4.4 Metallurgical Coal Segment

6.4.4.1 Metallurgical Coal Segment Description

Metallurgical coal mines account for about 15 per cent of BC Hydro's total mining sector sales. Teck's Elk Valley Coal Partnership in southeast B.C. supplies about one sixth of the world's seaborne metallurgical coal market. Metallurgical coal is also produced in northeastern B.C.

In the long term, sales are tied to price expectations for metallurgical coal. Export markets for B.C. metallurgical coal include China, Japan, South Korea, and to a lesser extent India, Europe, South America and the United States. As a result, the state of B.C.'s economy has little effect on metallurgical coal sales; however, provincial regulatory and policy actions can have an impact.

6.4.4.2 Metallurgical Coal Forecast Results

Over the past five years ending fiscal 2020, sales to the metallurgical coal segment increased by 18 GWh or 0.6 per cent. This increase was caused by equipment upgrades at existing customer sites and increased production which offset the closure of one of the existing Teck coal mining operations, Coal Mountain. Table 6-6 shows the history and forecast of metallurgical coal sales after fuel switching load additions and adjustments for rate impacts and DSM.

Table 6-6 Metallurgical Coal Mining Segment Sales History and Reference Load Forecast After Adjustments

10-year CAGR (F20 - F30)	2.0%
20-year CAGR (F20 - F40)	1.5%

While the COVID-19 pandemic reduced metallurgical coal prices in fiscal 2021, it was relatively short-lived. B.C. metallurgical coal mines were able to maintain their normal production levels, as mines were able to continue their activity with only minor disruptions.

The metallurgical coal mining reference forecast is based on a favourable short- and long-term market outlook and internal information related to service requests from potential new customers, we are expecting approximately 200 GWh growth between fiscal 2020 and fiscal 2041. The increase is driven by equipment upgrades and increased production at existing operations.

The metallurgical coal market outlook underpinning our reference forecast is summarized as follows:

- metallurgical coal prices have gradually decreased from 2019 levels and long-term price is assumed to settle at approximately $USD140-145/tonne within the next few years, and

- short and long term COVID-19 impacts are assumed to be negligible.

At this price level, we expect existing metallurgical coal operations to maintain or increase production levels and complete equipment upgrades. No new mines are assumed to occur over the forecast period.

Figure 6-7 below illustrates the metallurgical coal price assumptions used for the December 2020 reference forecast:

Table 6-7 Metallurgical Coal Reference Price Forecast

6.4.4.3 Metallurgical Coal Uncertainties

The major risks and uncertainties around the metallurgical coal segment over the forecast period include:

- global economic outlook: higher/lower than anticipated demand for steel in Asia,
- impacts of COVID-19 on world economies and demand for metallurgical coal,
- restrictions imposed by China to trade partners, such as the recent unofficial ban of Australian coals imports to China,
- supply disruptions (or expansions) in Australia. Australia accounts for roughly two-thirds of the global metallurgical coal production; Floods during the rainy season in Australia caused major supply disruptions in recent years,
- meeting environmental compliance requirements at existing operations, particularly with regards to selenium pollution,
- rail and terminal capacity constraints in B.C.,
- future regulations and policies that could impact future coal exploration or development, and
- skilled labour shortages for mining companies due to aging workforce and competition with other sectors.

The high and low forecasts are developed to capture some of this uncertainty. Further information on the mining high and low forecasts is provided in section 8.2.4.

6.5 FORESTRY

6.5.1 Forestry Sub-sector Description

The forestry sub-sector's once dominant share of the large industrial sector has steadily declined over time. While still significant, the sub-sector now only accounts for about 50 per cent of sales to the large industrial sector. Forestry is categorized into the following three segments:

- pulp and paper,
- wood products, and
- chemical.

Proportionally, the pulp and paper segment comprises 61 per cent of forestry sales, chemical sales comprise 21 per cent and wood products comprise 18 per cent. Pulp production consists primarily of northern bleached softwood kraft. Paper production consists primarily of newsprint and newspaper inserts. Our chemical customers produce bleaching agents to whiten the products produced by the pulp and paper industry. They also produce cleaning and water purification agents for oil and gas producers and municipalities. In addition, our wood products customers produce lumber, panel sheets (like plywood and oriented strand board) and pellets for fuel. Products produced by the forestry sub-sector are primarily destined for the U.S., Chinese and B.C. economies. Detailed descriptions are provided within each forestry segment's description.

The methodologies used by each of the segments within this sub-sector are consistent with the methodology used for the large industrial sector. The forecasts are developed on an account by account basis.

6.5.2 Pulp and Paper

6.5.2.1 Pulp and Paper Segment Description

Sales to the pulp and paper segment represent 61 per cent of all forestry sales and 31 per cent of the total Large Industrial sector sales.

Pulp and paper consists of 19 mills located primarily in the south-western and north-eastern parts of B.C. These mills produce and export a wide variety of products including newsprint, coated and uncoated ground wood paper, bleached and unbleached Kraft, dissolving pulp, thermo-mechanical pulp (TMP), and bleached chemical-thermo-mechanical pulp (BCTMP). Historically, sales to this segment have been declining and we expect this to continue. This decline is primarily attributed to reduced demand for publication paper (newsprint and graphic paper), which is partially offset by increased demand for tissue/hygienic products and packaging grade. The COVID-19 pandemic appears to have accelerated both trends over the short term and adds another uncertainty dimension to electricity demand additional.

6.5.2.2 Pulp and Paper Methodology

While consistent with the large industrial sector forecast methodology, the pulp and paper segment forecast incorporates additional market evaluations and mill assessments. These are developed by third party industry experts. They forecast commodity supply, demand and prices in the markets where B.C.'s pulp, paper and wood products are sold. They also project B.C. regional market conditions for fibre supply (sawmill residuals, whole log chipping, etc.) and fibre demand (for bioenergy, pulp and paper and wood product mills). They consolidate these to produce mill line production forecasts and operational probability assessments to reflect a mill line's closure and start-up risk.

The production forecast and probability assessments are internally reviewed with input from a number of BC Hydro departments, including Key Account Management. Mill line load forecasts are developed by multiplying production forecasts, probability assessments, and mill line electricity intensities. Mill line forecasts are then aggregated to the plant level, which forms the customer load forecast. Customer account forecasts are then aggregated to form the pulp and paper forecast.

A number of pulp and paper mills also sell power to us under Electricity Purchase Agreements (EPAs). For those mills, the conditions of these agreements are considered for developing the customer's forecast.

The main drivers for this segment include:

- pulp and paper prices,
- economic growth and associate pulp and paper demand internationally,
- U.S. import duties on B.C. publication paper,
- regulations in China banning paper recycling which lift kraft and BCTMP prices and incent B.C. publication paper producers to convert paper lines to recycling,
- consumer preference for various pulp and paper products,
- B.C. fibre availability,
- global preferences for substitutes over B.C.'s pulp and paper products - particularly new eucalyptus pulp supply from the southern hemisphere,
- packaging e.g., folding box demand in China (a major driver for TMP), and
- new market development in China, India and emerging markets for publication papers.

6.5.2.3 Pulp and Paper Forecast Results

B.C.'s pulp and paper mills can be further categorized into the customer products they primarily produce:

- TMP and BCTMP,
- Kraft pulp,
- publication paper, and
- tissue and hygiene products.

From 2015 to 2020 sales declined by 1,701 GWh or 32 per cent. Reduced sales occurred across all four product types (arising from mill and mill line closures across the province). The decline in sales within each product type can be seen in Table 6-9 shows the history and forecast pulp and paper sales before adjusting for rate impacts and DSM savings for each product category. Rate impacts and DSM savings are applied to the consolidated pulp and paper segment forecast, so the table below shows the sub-segments before adjustments and the pulp and paper segment total before and after adjustments.

Table 6-9 Pulp and Paper Segment Reference Load Forecast Before and After Adjustments

Table notes:

1. Before adjustments numbers do not include fuel switching or estimated DSM persistence drop off adjustments.
2. After adjustments numbers include all adjustments for LCE/fuel switching, estimated DSM persistence drop off, rate impacts, and DSM savings.

Factors contributing to mill closures in recent years were poor market conditions, aging equipment, declining fibre availability (due to pine beetle infestation), strong competition from Kraft mills in South America, displacement of newspaper by digital media, adoption of power saving projects, and increased use of electronic media by advertisers.

Previous commodity price forecasts accurately projected a pulp price downturn. but the extent of the global market's current pulp oversupply and the depth of the downwards pricing correction was underestimated. These persistent low prices combined with ongoing fibre supply challenges resulted in production curtailments at several mills during fiscal 2020.

For future sales, the reference case assumes the COVID-19 pandemic continues to disrupt all pulp and paper markets through fiscal 2021. The reference case anticipates global GDP to return to pre-pandemic growth trends by late fiscal 2021. Over the longer term the pandemic is anticipated to accelerate existing market trends such as the decline in the use of graphic papers and the increased use of tissue/hygienic products and packaging grades. This is likely to persist over the long term given that:

- The replacement of single-use plastic products and rapidly growing e-commerce activity will drive demand higher for a widening range of F-weight packaging paperboard and Molded Fiber Products (MFP).
- Declining recovered paper (RCP) supply is creating an expanding pulp fiber gap that the virgin fibre pulp made in B.C. can help fill. As world graphic paper use drops as much as 8% year over year over the next decade, the potential supply of recovered graphic paper should shrink about 1.5 million tonnes per year. Moreover, future recovered paper supply should also be limited by accelerating e-commerce (80% of which is paper) since recycling is much less efficient from individual households than from 'bricks and mortar' stores.
- Accelerating growth in the use of household and commercial paper towels: as consumers become more hygiene conscious in the COVID-19 era, as people spend more time at home and as more electric hand dryers in public restrooms will be replaced with single-use paper towels for hygienic reasons.

For the period fiscal 2021 to fiscal 2041, reference case sales are forecast to decline by 233 GWh or nine per cent. Most of this decline occurs in fiscal 2021 due to advancing the expected closure of one major pulp mill and a permanent line closure in another mill. Over the longer-term sales are assumed to remain relatively stable as global markets return to pre-pandemic growth trends and pulp and paper prices increase in response to increasing demand of tissue, hygiene and packaging products.

The commodity price assumptions used to complete the top-down verification in the pulp and paper sector are provided in Table 6-10 below.

Table 6-10 Pulp and Paper Segment Commodity Price Forecasts

Fiscal year	Fiscal year	Kraft (US$/ADMT)	BCTMP (US$/ADMT)	Newsprint (US$/ADMT)
Actual				
F2015	$ 712	$ 530	$ 583	$ 349

6.5.2.4 Pulp and Paper Uncertainties

The major risks and uncertainties for pulp and paper over the forecast period include:

Upside risks:

- market opportunities for publication paper mills (e.g., converting newsprint lines to wastepaper recycling, tissue/hygiene product or packaging lines),
- BCTMP mill restart due to continued high growth trend in the packaging products market in China,
- biofuel production at B.C. Kraft mills due to growing demand for renewable fuels, and
- Kraft mill sustainability due to higher than expected fibre supply in B.C.

Downside risks:

- publication paper mill closures (from publication paper demand shrinkage in the North American market as the public continues to switch from print to electronic media),
- BCTMP mill failure to restart (caused by reduced Chinese market demand for B.C. BCTMP imports and increased reliance on lower cost, lower quality domestic producers),
- Kraft mill closures due to pulp fibre supply shortages caused by wildfires, beetle infestation and sawmill closures,
- foreign market import duties imposed by the US and/or Chinese governments on B.C. pulp and paper.

The high and low forecasts are developed to capture some of this uncertainty. Further information on the pulp and paper high and low forecasts is provided in section 8.4.4.3.

6.5.3 Wood Products

6.5.3.1 Wood Products Segment Description

Wood products sales make up 18 per cent of all the forestry sub-sector sales and 9 per cent of Large Industrial sector sales. Wood products consists of large industrial customers who use electricity to produce dimensional and structural lumber, oriented strand board, medium density fiberboard, plywood, fuel pellets, and other specialty wood products. There are 35 such mills, which are primarily located in the North and South Interior regions. B.C. mills are among the lowest cost lumber producers in the world [8].

Electricity sales to the wood products segment depends on regional B.C. lumber supply, global demand for wood products and the viability of some pulp and paper mills. Recent growth in lumber demand was driven by the growth in U.S. housing starts. However, B.C. lumber supply will be constrained by saw-log scarcity due to the mountain pipe beetle devastation and recent record wildfires in the province. Although the Ministry of Forests, Lands, Natural Resource Operations and Rural Development is undertaking measures to address these, we anticipate reductions in annual allowable cuts will be imposed such that sales to this sector will start declining around fiscal 2023.

6.5.3.2 Wood Products Methodology

Similar to the pulp and paper segment, the process for developing the wood products load forecast is based on mill line production forecasts that are determined from macro and regional market assessments developed by a number of third-party industry experts retained by BC Hydro.

[8] There are hundreds of other smaller wood products mills served on distribution service which are included in the forestry sub-sector in the light industrial sector.

Like the pulp and paper forecast, the wood products forecast is produced as a product of mill line production forecast, electricity intensity and probability for each customer operation. The loads for individual mill lines are aggregated to the entire load for the customer and all the customers forecasts are aggregated together to develop the forecast for the wood product segment.

The primary market drivers for wood products are:

- the U.S. market (for housing starts and repair and remodeling),
- the Chinese market (lumber and logs), and
- Japan (hemlock and SPF lumber).

6.5.3.3 Wood Products Forecast Results

Table 6-11 shows the history and forecast sales of the wood products segment after fuel switching load additions and adjustments for rate impacts and DSM. For the most part, sales to this segment were flat over the historical period up to fiscal 2020. However, similar to the pulp and paper segments, electricity sales declined between fiscal 2019 and fiscal 2020 as low commodity prices and fibre supply shortages resulted in both temporary and indefinite production curtailments. These year to year changes reflect the wood segments inherent volatility.

Table 6-11 Wood Products Segment Sales History and Reference Load Forecast After Adjustments

F2038	1,012
F2039	1,008
F2040	1,005
F2041	1,007
Compound Annual Growth Rates	

Fiscal Year	Wood Products Reference Forecast (GWh)
5-year History CAGR (F15 - F20)	(2.5%)
5-year CAGR (F20 - F25)	0.8%
10-year CAGR (F20 - F30)	0.2%
20-year CAGR (F20 - F40)	(0.1%)

For future electricity sales, the reference case assumes the COVID-19 pandemic reduces global softwood lumber demand in fiscal 2021 by 5 percent relative to fiscal 2020 levels. However, BC's wood sector is assumed to be somewhat less impacted by the pandemic's effects notwithstanding its adverse impacts on the U.S. economy, which is the largest market for BC lumber. U.S. residential construction is assumed to outperform the overall economy as home improvements are one of the few places people can spend time and money while facing public health measures and new home viewings and sales have remained robust. Nevertheless, growth is assumed to be slower relative to pre-pandemic levels as households will be cautious with big uncertainties while there is so much uncertainty. Therefore, the reference case assumes end-use and lumber markets will continue to grow, but at a still slow pace. Lumber prices are assumed to be higher than pre-pandemic levels as North American production curtailments due to COVID-19 have impacted overall supply.

Over the long term, the reference case assumes a return to normal market conditions by fiscal 2022 and steady growth in the U.S. housing market through fiscal 2041.

Notwithstanding robust demand growth, the BC wood products segment is expected to remain constrained by fibre supply shortages over both the near and long term. Consequently, reference case electricity sales are assumed to flat for the fiscal 2021 to fiscal 2041 are expected to remain flat.

Electricity sales are projected to slightly increase in the short run with a decline thereafter. U.S. housing starts are expected to continue to rise through the forecast period but the U.S.-Canada softwood lumber dispute and B.C. fibre shortage (from mountain pine beetle and recent record wildfires) will raise mill production costs and put downward pressure on sales to various mills and the sector.

6.5.3.4 Wood Products Uncertainties

There are many wildcards in the wood products segment, such as fibre supply issues, ownership, capital expenditures, exchange rate, import duties, supply chain constraints, forest disease and fires, as well as U.S. demand and export markets in China (including the ongoing U.S. – China tariff war), Japan and other markets all create many possible scenarios. Some of the major risks and uncertainties for wood products over the forecast period include:

Upside risks:

- removal of softwood lumber tariffs. The U.S. government has imposed an average 20 per cent tariff on B.C. lumber imports. Removal of the tariff would raise revenues to B.C. producers and stimulate sawmill production,
- higher than expected in U.S. housing start levels, and
- a stronger U.S. dollar.

Downside risks:

- useable timber reductions in B.C. Large wildfires and/or accelerated beetle kill deterioration of affected timber, will reduce harvestable areas, increase harvesting costs and contribute to wood product mill closures,

- lower than expected U.S. housing start levels. The U.S. is B.C.'s largest export market; depressed levels of U.S. housing starts that cause lumber prices to decline and increase wood product mill closure risk,
- U.S. recession. A prolonged economic downturn would cause housing starts to decline and remain at low levels. This would cause lumber and panel prices to decline and increase wood product mill closure risk, and
- reduced demand from China. This could arise from a prolonged economic slowdown in China and/or the Chinese government imposing import duties on Canadian lumber.

The key reference commodity price forecasts are provided in Table 6-12 below. Shortly after receiving the lumber price forecast from our consultants, lumber prices experienced volatile and significant price increases. These price increases were unanticipated consequences related to the COVID-19 pandemic, which were occurring in the U.S. economy. These consequences resulted in increased lumber demand, decreased lumber supply, lower mortgage rates and increased availability of construction labour. Since BC's wood production is largely limited by fibre supply, the substantive price increases are not expected to have a significant upward impact on electricity demand.

Table 6-12 Wood Commodity (Lumber) Reference Price Forecast

Fiscal year	Lumber (US$/MBFM)

The high and low forecasts are developed to capture some of this uncertainty. Further information on the wood high and low forecasts is provided in section 8.3.4.6.

6.5.4 Chemical

6.5.4.1 Chemical Segment Description

The chemical segment represents 21 per cent of Forestry sub-sector sales and 11 per cent of the large industrial sector. Chemical plants produce bleaching agents for the pulp and paper industry, cleaning agents or the oil and gas industry, and water purification products for municipalities. Since chemical companies use electrolysis to produce their products, electricity represents a substantial component of their operating costs.

6.5.4.2 Chemical Methodology

Consistent with the large industrial sector methodology, the chemical segment is forecast on an individual account basis. For this segment, the forecast relies on customer information provided by our Key Account Management group. The chemical forecast methodology is mainly informed via discussions with customers. Key drivers for the chemicals segment are electricity prices, demand for bleaching agents from the pulp and paper industry, and cleaning agents from the oil and gas industry. The industry also h as the ability to export its products should B.C.-based demand decline.

6.5.4.3 Chemical Forecast Results

Electricity sales in the chemical segment mirror those in the pulp and paper segment. From fiscal 2015 to fiscal 2020, chemical sales declined by about 228 GWh or 15 per cent. This decline was primarily due to savings achieved through our DSM programs as well as a plant closure in fiscal 2018.

The reference case assumes a decline in fiscal 2021 sales due to reduced demand in the pulp and paper segment as described in section (reference pulp and paper section). Beyond fiscal 2021, the reference case assumes a return to pre-pandemic sales volumes and flat growth over the long term. Table 6-13 shows the history and forecast sales to the segment after fuel switching load additions and adjustments for rate impacts and DSM.

20-year CAGR (F20 - F40)	0.2%

6.5.4.4 Chemical Uncertainties

The major risks and uncertainties for the chemical segment include the following:

Upside risks:

- higher than expected bleaching agent demand from global pulp and paper producers experiencing a sustained increase in pulp and paper prices, and
- higher than expected cleaning agent demand from oil and gas producers.

Downside risks:

- global slowdown in demand from global pulp and paper producers,
- domestic pulp and paper closures, and
- Chemical companies operating in B.C. to close and be supplied from a plant outside of BC Hydro's service area.

The high and low forecasts are developed to capture some of this uncertainty. Further information on the wood high and low forecasts is provided in section 8.3.4.4.

6.5.5 Forestry Reference Load Forecast

Table 6-14 provides the Large Industrial Forestry sub-sector sales history and Reference Load Forecast after fuel switching load additions and adjustments for rate impacts and DSM. .

20-year CAGR (F20 - F40)	(1.4%)

Sales to all forestry sub-sector customers have declined by 2,066 GWh or26 per cent from fiscal 2015 to fiscal 2020. This decrease occurred most in pulp and paper segment where a number of mill line closures occurred during this period. For the period fiscal 2021 to fiscal 2041, the reference forecast shows a decline of 522 GWh or 10 per cent. All segments contribute to this decline. This decline is primarily due to reduced sales to the pulp and paper segment, which is driven by continued softening in demand for publication papers.

6.6 OIL AND GAS

6.6.1 Oil and Gas Sub-sector Description

Sales to the large industrial oil and gas sub-sector account for 11 per cent of the total large industrial sales. Electricity is used by oil and gas customers connected to the transmission system for various operations including refining and shipping petroleum, processing, natural gas production and liquid rich natural gas processing into various liquids. Most of the electricity is used to drive compressors for production and pipeline transportation.

The oil and gas sub-sector is categorized into two segments:

- shale gas (i.e. production/processing plants), and
- other large oil and gas operations.

The other large oil and gas operations consist of:

- natural gas straddle plants
- conventional gas processing plants,

- oil (and condensate) pipelines,
- oil refineries and oil producers,
- natural gas pipelines,
- propane terminals, and
- LNG terminals.

The above segmentation delineates aspects of natural gas processing related to the removal of various liquid-state compounds (liquids), such as propane, ethane and butane that can exist at varying levels in the raw natural gas. These processing facilities employ more energy intensive compression and refrigeration to extract the liquids; the amount of work energy being a function of the amount and type of the liquids content. Three types of processing facilities are generally defined as follows:

> Shallow-cut facilities: A gas plant next to, or within, gas field plants or gas pipelines that can extract pro pane or heavier natural gas liquids (butanes and condensate) using refrigeration technologies.
>
> Deep-cut facilities: A gas plant upstream of major gas-pipeline systems that extracts ethane and other natural gas liquids using turbo-expander or absorption technologies. It can extract more ethane than a shallow-cut gas plant, but less ethane than a straddle plant.
>
> Straddle plant: A reprocessing plant located on a gas pipeline. It extracts remaining natural gas liquids from previously processed gas.

Processing plants can fit anywhere along a spectrum of the three facility types and consequently not all of BC Hydro's customer facilities self-identify as one type or another. All of BC Hydro's existing and potential new processing customers appear to fit the shallow gas plant type and are solely dedicated to shale gas production and processing. Consequently, they are included in the shale gas segment forecast. Straddle plant plants can also have deep cut processing components and are typically located where they can process both shale gas and conventional natural gas plants. Straddle and deep cut processing plants are included in the other large oil and gas operations segment forecast.

Sales to LNG terminals are included in the other large oil and gas operations segment to maintain confidentiality on the specific nature of individual LNG projects included in the load forecast. This is consistent with our practice of not publishing customer specific history and forecasts. The remainder of this section provides a summary of the forecast results for the entire sub-sector followed by a detailed discussion of the two major segments.

The methodology in the oil and gas sub-sector is consistent with the large industrial forecast process articulated in section 6.2. However, the depth of analysis carried out for each of the segments within the oil and gas sub-sector varies depending on segment size and complexity. For example, we apply a more robust and detailed analytical approach for the large and growing shale gas segment; conversely, we adopt a less rigorous approach for the oil refineries and oil producer sub-segments, which are relatively small and static. Overall, each segment forecast is developed on an individual customer account basis, with probabilities app lied, to develop a reference load forecast.

6.6.2 Shale Gas

6.6.2.1 Shale Gas Segment Description

In fiscal 2020 electricity sales to the shale gas segment represented 65 per cent of the total oil and gas sub-sector sales and 5 per cent of large industrial sales. Electricity is mainly used to drive plant compression and processing requirements.

The shale gas segment includes the production of raw natural gas from shale or tight sedimentary formations located in the B. C. Montney shale basin. The process starts with drilling wells into the formations using hydraulic fracturing techniques to access the gas. Since this technique differs from the older conventional process, gas produced in this manner is also called unconventional g as. Gas from these wells is under high pressure and is connected to gathering pipes which bring the gas to gas plants. These plants (increasingly being served by BC Hydro) perform light processing of the gas including refrigeration if needed to recover gas liquids (propane, butane and condensates). While the work energy components supplied by electricity vary from customer to customer, they generally encompass the following field compression and processing activities:

- booster stations,
- water recycling operations,
- gas processing plant (ranging from the low electrical intensity dry gas plants, to higher intensity shallow cut gas plants),
- additional compression requirements as pipeline pressure increases over time,
- higher refrigeration requirements needed for plants processing higher gas liquids ratios (i.e., shallow cut processing), and
- additional compression requirements as wells age over time.

In general, work energy intensity within the shale gas segment has been increasing as new projects focus on more liquids-rich areas and the associated shallow cut gas processing plants require relatively higher compression work energy. While BC Hydro reflects this increasing work energy trend as part the forecast methodology described in section 6.5.2.2, the primary basis for developing new customer forecasts is project-specific load information directly provided by the proponents.

Other work energy associated with activities such hydraulic fracturing can also be electrically supplied by BC Hydro, while there may be future electrification potential associated with these activities as part of future climate actions, they are not included in this load forecast. This assumption is based on the fact that BC Hydro has not received material service requests to supply fracking load. In any event, fracking load makes up a small portion of the overall work energy requirements.

6.6.2.2 Shale Gas Methodology

Consistent with the large industrial sector methodology, the shale gas segment is forecast on an individual customer account basis. However, the shale gas segment is the fastest growing within our large industrial sector and given the complex nature of the industry requires more detailed analysis relative to other industrial sectors. A comprehensive analytical framework is used to directl y link BC Hydro's internal assessment of customer accounts and new service requests (i.e., bottom up assessment) with supply and demand outlooks for natural gas, natural gas liquids and oil natural gas production forecasts developed by a third party expert assessment as well as from market intelligence information provided by various subscription services and publicly available sources. The longer-term outlook also relied on the third-party expert assessment that was developed for BC Hydro's (i.e., top down assessment).

In developing this forecast, the bottom-up assessment is a list of probability weighted customer load requests. These requests are categorized into the six sub-regional load forecasts in the Montney gas basin. The top-down assessment is a Montney gas production forecast that is converted into an electrical load forecast (organized into the same six sub-regions).

The bottom-up and top-down forecasts are iterated until they converge by adjusting the following parameters:

Bottom-up Forecast

The bottom-up forecast is based on customer specific information and analysis and is the basis for the shale gas segment forecast. The bottom-up forecast is developed by compiling the current and expected customer load requests to arrive at load forecasts for each of the six sub regions. During this process each customer request is evaluated, shaped and discounted based on information from various internal and external sources as described above. The outcome is a weighted probability assessment of energy requirements and the dates when that energy is forecasted to be supplied by BC Hydro for new start-ups or electrification of existing plants. Most of the work energy used to supply natural gas production and processing can be supplied electrically or self-supplied using diesel or extracted hydrocarbons including natural gas. Customers are also able to self-supply their electricity requirements or be electrically supplied by BC Hydro. Consequently, customer requests include two discrete probability assessments: (1) the likelihood the project will be developed, and (2) the likelihood the project will be electrically supplied by BC Hydro.

Top-Down Forecast

The top-down forecast is a macro forecast that is primarily used as a guide to check and confirm the reasonableness of the bottom up forecast. The top down forecast is derived by creating and the multiplying three data sets, as follows:

Top down forecast (MW) = gas production (MMcf/day) x energy intensity (MW/MMcf) x electricity service per cent (%)

Energy intensity and electricity service per cent are direct inputs into the top down forecast, whereas gas production is derived by varying well profile inputs and drilling activity inputs, gas demand parameters (e.g., LNG export, export to North America and gas liquids demand for oil sands production), gas supply parameters (e.g., well production characteristics and drilling activity), and finally electrification parameters (e.g., regional service electrification characteristics and electrical load electricity intensities).

The major parameters listed above are those that can be adjusted during the iterative process as necessary. In addition, there are a number of other components of the top down model that serve to inform the test for defensibility and evaluate adjustment reasonability. These include:

- A component that ensures that forecast gas production in each of the six sub regions does not exceed gas in place estimates;
- Pipeline related analysis for BC gas exports to North American markets;
- Well production costs within the BC Montney compared with the rest of North America;
- BC Montney gas liquids production forecasts;
- Natural gas and gas liquids price forecasts; and
- Oil sands development and condensate demand analysis.

Professional judgment is used to determine if any adjustments are required to the bottom up and/or top down forecasts of the six sub regions, so that the forecasts converge, while ensuring that each forecast is supported by detailed customer requested information and independent macroeconomic analysis.

For instance, if the bottom-up forecast for one of the six sub-regions is much higher than what is in the top-down forecast, we would check the bottom-up assumptions for defensibility. If it is felt that the probability weightings in the bottom-up were too high, then the iteration would be to lower them until the bottom-up and top-down forecasts align.

6.6.2.3 Shale Gas Forecast Results

From fiscal 2015 to fiscal 2020 sales to the shale gas segment increased by 1,398 GWh, a tenfold increase, due to the exponential growth of shale gas extraction in the BC Montney region and the close proximity of these wells to BC Hydro transmission assets, making it economic to electrify a portion of the shale gas growth. Table 6-15 shows the history and forecast sales after fuel switching load additions and adjustments for rate impacts and DSM. The allocation of DSM between segments is an approximation based on the total DSM for the oil and gas and LNG sub-sectors.

Table 6-15 Shale Gas Segment Sales History and Reference Load Forecast After Adjustments

F2041	3,130
Compound Annual Growth Rates	
5-year History CAGR (F15 - F20)	61.1%
5-year CAGR (F20 - F25)	10.5%
10-year CAGR (F20 - F30)	7.2%
20-year CAGR (F20 - F40)	3.6%

For future electricity sales, the reference case assumes the COVID-19 pandemic has only a relatively modest impact on B.C. shale gas production through fiscal 2021 with the electricity sales forecast to decline by approximately 100 GWh or six per cent relative to fiscal 2020 actual sales. This modest impact is based on the assessment that natural gas and natural gas liquids prices are assumed to remain at sufficient levels to support BC production. Similarly, Alberta oil sands production (a major natural gas and natural gas liquids consumer), is assumed to be largely unaffected by lower oil prices caused by reduced demand caused by the COVID-pandemic and short-lived price war between Russia and Saudi Arabia.

For the fiscal 2021 to fiscal 2041 period the reference forecast assumes sales increase by 1,686 GWh or 17 per cent. This increase is primarily driven from projects that recently started commercial operations or are currently under construction and are expected to come into service by fiscal 2021.

The shale gas reference forecast includes load associated with LCE Customer Project 1 and LCE Customer Project 2, which are mentioned in Appendix N to BC Hydro's Fiscal 2022 Revenue Requirements Application.

Broadly speaking, our analysis leads us to believe that much of the increase in global natural gas supply will occur in North America. In this context, B.C.'s Montney shale basin is considered to be a competitive low-cost gas supplier as the basin's size, productivity and mix of liquids enables it to compete with other sources of gas supply. The consultant reported that the basin's competitiveness is not considered to be dependent on access to LNG markets and forecasts continued natural gas production growth in B.C. with an increasing share of the Western Canadian gas supply market.

6.6.2.4 Shale Gas Uncertainties

While additional load growth potential is relatively low in the short term, there is considerable, albeit uncertain long-term potential. The potential downside is considered low for both the near and long term. Upside and downside risks include the following:

Upside risks include:

- future North American LNG development (B.C., U.S. west coast and U.S. gulf coast) increasing demand for B.C. natural gas,
- continued expansion of Alberta's oil sands and associated demand for gas liquids,
- continued displacement of net U.S. gas liquids imports to Alberta with B.C. gas liquids,
- higher than expected natural gas, liquids, and oil prices, and
- higher than expected electrification percentages of new facilities.

Downside risks include:

- condensate production in Alberta (large basin in Western central Alberta has a logistical advantage to oil sands producers than B.C. producers),
- Alberta importation of U.S. condensate for heavy oil production (threatens B.C. producer growth),
- increased gas liquids production in Alberta (closer to petrochemical plants in Alberta),
- lower than expected natural gas prices caused by increased natural gas production in other North American production regions,
- delay of LNG terminal operational dates, and
- lower the expected electrification percentages of new facilities

The high and low forecasts are developed to capture some of this uncertainty. Further information on the oil and gas high and low forecasts is provided in section 8.3.4.8.

6.6.3 Other Large Oil and Gas Operations

6.6.3.1 Other Large Oil and Gas Operations Segment Description

Based on fiscal 2020 actuals, sales to the other large oil and gas operations segment represents 35 per cent of all the sales to the oil and gas sub-sector. This segment consists of the following facility types:

- Natural gas straddle plants
- Conventional gas processing plants,
- Oil (and condensate) pipelines,
- Oil refineries and oil producers,

- Natural gas pipelines,
- Propane terminals, and
- LNG terminals.

In fiscal 2020 natural gas straddle plants comprised 10 per cent of BC Hydro's sales to the oil and gas sub-sector. These customers extract remaining natural gas liquids from previously processed gas. Conventional gas processing plants comprise one per cent of BC Hydro's sales to the oil and gas sub-sector. These customers use conventional means to recover gas, perform gas liquids extraction (ethane, propane, butane and pentane) and extract acid gases. Historically, the processors have served conventional gas producers. However, conventional gas production in B.C. has been declining over the past 10 years and as conventionally gas production declines, processing plants are increasingly being supplied by shale gas producers.

Oil pipelines constitute 9 per cent of BC Hydro's sales to the oil and gas sub-sector. These customers operate pipelines which serve to transport crude oil and petroleum products. Electricity is primarily used in pumping stations with power sales being correlated to the volume of liquids shipped. Future growth opportunities for this industry are due to B.C.'s proximity to Asian oil markets where oil demand is increasing and U.S. west coast oil refineries.

Oil refineries and oil producers currently make up 10 per cent of BC Hydro's sales to the oil and gas sub-sector. These customers include tank farms, oil refineries (which also produce gasoline and jet fuel) and oil producers. Electricity sales are related to B.C.'s oil pipeline shipments and to a lesser degree oil prices.

Natural gas pipelines comprise less than one per cent of BC Hydro's sales in the oil and gas sub-sector. These customers ship natural gas via pipeline. Natural gas pipelines use gas compressors instead of electrically driven compressor to power booster stations.

Propane terminals are an emerging B.C. industry with two new terminals currently under construction. When construction is complete, these customers will receive the propane by rail, store it in tanks and then pump the propane from the terminals onto ships for export. Our industry consultant produced a B.C. propane terminal supply analysis, which was used to inform the propane terminal forecast. Electricity will be used for pumps and compressors with future sales related to world propane prices, Asian demand and B.C. terminal propane. Propane supply is expected to be sourced from the B.C. Montney and the Alberta Duverney shale gas basins.

LNG is natural gas that has been cooled to a liquid state, at about negative160 degrees Celsius, for shipping and storage. The volume of natural gas in its liquid state is hundreds of times smaller than its volume in its gaseous state. This process allows the transportation of natural gas to places pipelines do not reach. LNG is shipped in special tankers between export terminals, where natural gas is liquefied, and import terminals, where LNG is returned to its gaseous state (degasified).

British Columbia has the advantage of shorter shipping distances to Asia relative to other LNG suppliers and substantial natural gas reserves including the Montney, Horn River and Liard formations. After an initial boom in global LNG project development, global LNG investment decreased following a drop in LNG prices in 2014. Investment appetite was further diminished by fears of an extended supply surplus. British Columbia's LNG sector followed similar a pattern with the more than 20 LNG project proposals, followed by a number of project cancellations. China and India led the recovery in demand for LNG following the outbreak of the pandemic with both countries increasing their LNG imports by over 10 per cent during 2020. LNG markets are still oversupplied in the short-run, but a balanced position is expected by mid-2020s driven by a combination of demand growth and a fall off in new supply coming on-stream. China's announcement of a target to become carbon neutral by 2060 is expected to support long term growth in LNG demand.

Over the past few years, BC Hydro and the provincial government have been working closely with LNG proponents on options for meeting energy needs of LNG plants with power from the BC Hydro system. LNG-related electricity demand falls into two general categories: compression and non-compression. The compression energy is about 85 per cent of the total plant's energy needs. The remaining (non-compression) energy requirement is from plant pumps, motors, other equipment, heating and lighting. Compression energy is typically supplied with direct-drive natural gas turbines, although this can also be accomplished with electric drives.

In October 2018, LNG Canada announced a positive final investment decision to proceed with its project located in Kitimat, B.C. LNG Canada is the single largest private sector investment project in Canadian history. The first phase of the p roject includes a $6.2-billion natural gas pipeline through northern British Columbia and an $18-billion liquefaction facility in Kitimat, B.C.

In addition to LNG Canada, FortisBC's Tilbury LNG plant is operating and taking electricity service from BC Hydro and a number of other B.C. based LNG projects are continuing to advance.

6.6.3.2 Other Large Oil and Gas Operations Methodology

Consistent with the large industrial sector methodology, the other large oil and gas sector is forecast on an individual customer account basis. Within this customer-based forecasting process, various calculation techniques are used to arrive at the customer's energy and peak forecasts.

The primary method is the product of expected peak demand, load factor and probability. The load factor is a measure of the utilization rate, or efficiency of electrical energy usage. Generally, the underlying drivers of the forecast are the customer's requested load, estimated operational hours, historical load patterns and operational probabilities. In case of existing customers, historical consumption information is used as starting reference point updated with newest information (such as facility expansion or contraction plans). The probability weightings are informed by considerations such as the project's economics, availability of financing, regulatory progress and BC Hydro interconnection status. A facility's economics is analyzed in the context of the market outlooks informed by external an d internal information. For the current forecast, BC Hydro relies on the following subscription services:

- New Energy Finance,
- Wood Mackenzie North America Gas Service,
- IHS Connect, and
- RBN Energy's paid for information services on North American: oil, natural gas liquids, natural gas and the Permian basin.

Additional information was obtained through an oil and gas consultant. This information included:

- B.C. conventional gas basin forecasts,
- oil price forecasts and Alberta oil supply forecasts,
- reporting on natural gas pipeline development, and
- analysis on B.C. propane terminal propane supply.

LNG customers are included in the large oil and gas segment to protect the confidentiality of our assessment of LNG projects. In developing the LNG forecasts, we continue to include in the forecast only those LNG projects that are already operational or have requested service. Probably assessments of individual LNG projects were developed based on:

- input from Key Account Management and Load Interconnections business units, and
- third party expert assessments of the global LNG market, relative competitiveness of B.C. LNG, and specific B.C. projects.

To do this we rely on the Wood Mackenzie LNG, as well as information from publicly available sources such as McKinsey's Energy Insight, National Energy Board, International Energy Agency, Canadian Energy Research Institute and Bloomberg.

6.6.3.3 Other Large Oil and Gas Operations Forecast Results

Table 6-16 below shows the history and forecast sales after fuel switching load additions and adjustments for rate impacts and DSM. From fiscal 2015 to fiscal 2020 sales in the other large oil and gas operations segment have decreased by 210 GWh or 20 per cent. The decline is primarily due to lower sales to conventional gas producers and processors. These customers have been impacted by the downward trend in natural gas prices that have occurred during this period.

Table 6-16 Other Large Oil and Gas Operations Segment Sales History and Reference Load Forecast After Adjustments

Fiscal Year	Other Large Oil and Gas Reference Forecast (GWh)
Actual	
F2015	973
F2016	836
F2017	818
F2018	797
F2019	831
F2020	763
Forecast	
F2021	788

F2041	3,532
Compound Annual Growth Rates	
5-year History CAGR (F15 - F20)	(4.7%)
5-year CAGR (F20 - F25)	26.8%
10-year CAGR (F20 - F30)	16.7%
20-year CAGR (F20 - F40)	8.0%

Sales are expected to remain fairly flat until fiscal 2022. From fiscal 2022 to fiscal 2026, sales increase by 2,388 GWh or 280 per cent. This growth is attributed to sales to LNG terminals, pipelines, and straddle plants.

While assumptions for specific LNG projects are confidential, the load forecast reflects the following publicly available information:

- FortisBC Tilbury is in operation and we included forecast sales to this LNG facility;
- LNG Canada phase 1 is currently under construction;
- Woodfibre LNG's decision to proceed with the project has not been yet announced. The forecast reflected a probability-weighted assessment;

- Kitimat LNG load reflected a probability-weighted assessment;
- Other activities contributing to oil and gas sub-sector load growth include new pipelines and propane terminals; and
- Other LNG projects are considered within the load forecast uncertainty bands. .

The commodity price assumptions used to complete the top-down assessment for the oil and gas sub-sector are provided in Table 6-17 below.

Table 6-17 – Oil and Gas Commodity Reference Price Forecasts

Fiscal year	Henry Hub (US$/MMBtu)	AECO CA$/MMbtu	WTI Cushing Oklahoma $US/Bbl
Actual			
F2015	$ 4.92	$ 102	$ 112

6.6.3.4 Other Large Oil and Gas Operations Uncertainties

The various industries making up this segment face somewhat different risks and uncertainties. This is because the products and markets within the sub-segments are different. The description for the major risks is provided below. LNG-related risks are described separately.

The risks associated with the large oil and gas operations, excluding LNG terminals, collectively tend to weigh more on the downsi de than the high side in terms of potential impacts to BC Hydro sales.

The upside risks include:

- Higher than expected Asian demand for propane would incent propane terminal expansions in B.C.,
- Higher than expected oil sands transport venues and expanded fossil fuel processing capacity in Alberta would stimulate the conventional gas processing plants to recover more natural gas liquids,
- Higher than expected oil prices would increase B.C. oil refinery oil production and oil pipeline activity, and
- Minimal fossil fuel related construction delays would lower perceived risk and incent further development.

The downside risks include:

- Oversupply of fossil fuels in global, Alberta and U.S. markets and lower than expected prices to B.C. producers. This will cause B.C. oil refineries, oil producers and conventional gas processing plants to reduce production, defer new projects, and shut plants,
- New gas liquids pipeline from the U.S. into Alberta. This will reduce profit margins for B.C. producers and reduce convention al gas processing plants activity, and

- Longer than expected infrastructure construction delays, including due to the COVID-19 pandemic or project cancellations.
- Increased climate action policies that decrease global and domestic demand for fossil fuels

For LNG terminals, the major risks are identified below. Notwithstanding LNG Canada's positive investment decision, LNG development in B.C. remains an emerging industry with uncertain growth potential. The risk profile for this industry is asymmetrical in that the potential for higher load growth relative to what is reflected in the load forecast is greater than the potential for lower load. Various risks that have can have either positive or negative impacts on B.C. LNG development include:

- Federal/provincial policies that support or restrict domestic LNG development,
- Large upturns/downturns in the energy markets leading to unexpected supply surpluses or deficits,
- Legislation that supports or restricts nuclear power in Japan and coal generation in China,
- Climate action policies that increase or decrease global demand for natural gas,
- Competition with U.S. based LNG and other major LNG export countries, and
- Indigenous community support for or against LNG and related pipeline and natural gas development.

6.6.4 Oil and Gas (Including LNG) Reference Load Forecast

Table 6-18 shows the Large Industrial Oil and Gas (including LNG) sub-sector sales history and Reference Load Forecast after adjustments for rate impacts and DSM. From fiscal 2015 to fiscal 2020, sales to the large industrial oil and gas sub-sector have increased by 1,187 GWh or 106 per cent. This is based on the combined total of sales to shale and other large oil and gas operations customers. This increase is primarily due to growth in the shale gas segment.

Table 6-18 - Oil and Gas and LNG Reference Load Forecast After Adjustments

Fiscal Year	Reference Forecast (GWh)
Actual	
F2015	1,116
F2016	1,276
F2017	1,373
F2018	1,507
F2019	2,247
F2020	2,303
Forecast	
F2021	2,232
F2022	2,395
F2023	2,958
F2024	3,964
F2025	5,042
F2026	5,966
F2027	6,263
F2028	6,546
F2029	6,602
F2030	6,664
F2031	6,696
F2032	6,694
F2033	6,692
F2034	6,688
F2035	6,683
F2036	6,678
F2037	6,674

Fiscal Year	Reference Forecast (GWh)
F2038	6,669
F2039	6,664
F2040	6,660
F2041	6,662
Compound Annual Growth Rates	
5-year History CAGR (F15 - F20)	15.6%
5-year CAGR (F20 - F25)	17.0%
10-year CAGR (F20 - F30)	11.2%
20-year CAGR (F20 - F40)	5.5%

From fiscal 2020 to fiscal 2025, the expected (reference) sales are forecast to grow by 2,739 GWh or 119 per cent. This growth is driven by new shale gas production plants that: have switched to BC Hydro service, have started operations and are ramping up production or are under construction. The reference forecast also assumes increased sales to the other large oil and gas operations segment, primarily driven by LNG terminals.

Although the oil and gas sub-sector is comprised of customers all related to the fossil fuel industry, the major risks and uncertainties for each are generally different. This is because the products and markets within the segments and sub-segments are different. Nevertheless, the risk profile for this segment is asymmetrical in that the potential for higher load growth relative to what is reflected in the load forecast is greater than the potential for lower load. This asymmetry is due to LNG terminals and pipelines, as well as potential for increased electrification in natural gas production and processing associated with the CleanBC Plan.

The high and low forecasts are developed to capture some of this uncertainty. Further information on the oil and gas high and low forecasts is provided in section 8.2.4.

6.7 OTHER LARGE INDUSTRIAL

6.7.1 Other Large Industrial Sub-sector Description

The other large industrial sub-sector is comprised of a range of customers from universities, ports, terminals and wire manufacturers to cement companies and water pumping stations. The other large industrial sub-sector also includes cryptocurrency and data centres loads that we expect to be connected at transmission voltages.

6.7.2 Other Large Industrial Methodology

Customers in the other category are forecast on an individual customer account basis consistent with the large industrial sector methodology. However, this sub-sector forecast is not directly informed by specific commodity price or market outlooks due to the sub-sector's diversity. The forecast is primarily based on customer information provided via our Key Accounts Management and Load Interconnection business units.

6.7.3 Other Large Industrial Reference Load Forecast

Table 6-19 provides the Other Large Industrial sub-sector sales history and Reference Load Forecast, after adjustments.. Over the six years ending fiscal 2020, sales to the Other Large Industrial sub-sector decreased slightly by 37 GWh. A small increase from several customers expanding activities has been more than offset by closures such as the Lafarge cement plant in Kamloops and Esco foundry in Port Coquitlam due to market conditions.

Table 6-19 – Other Large Industrial Sales History and Reference Load Forecast After Adjustments

Fiscal Year	Other Large Industrial Reference Forecast (GWh)
Actual	
F2015	1,173
F2016	1,149

F2039	1,157
F2040	1,163
F2041	1,175
Compound Annual Growth Rates	
5-year History CAGR (F15 - F20)	(0.5%)
5-year CAGR (F20 - F25)	0.2%
10-year CAGR (F20 - F30)	(0.4%)
20-year CAGR (F20 - F40)	0.1%

The COVID-19 pandemic is anticipated to have a negative effect on the other sub-sector reference forecast in fiscal 2021 with a reduction in load from large customers such as Vancouver International Airport or UBC. Load additions for cryptocurrency and data centres in the next two years coupled with the slow return to normal activities for most customers will result in the load returning to pre-pandemic level by fiscal 2022. The reference forecast grows approximately 100 GWh over the entire period primarily due to upgrades and expansions from existing customers.

6.7.4 Other Large Industrial Uncertainties

The major uncertainties around the other large industrial loads include:

- the effect of COVID-19 on large customers such as universities, airports and shipping terminals,
- uncertainty regarding cryptocurrency operations and data centres,
- economic growth and construction activity, which in turn affects the demand for cement and other industrial products,
- sectorial shifts in the B.C. economy (e.g., shift from manufacturing to services, emerging sectors such as data centres or cryptocurrency),
- slowdown or increase in shipping,
- Expansions to large customers such as Vancouver International Airport or UBC, and
- Electrification of shipping/transportation industry.

The high and low forecasts are developed to capture some of this uncertainty. Further information on the other sub-sector high and low forecasts is provided in section 8.4.4.9.

7.0 Electric Vehicle Forecast

7.1 ELECTRIC VEHICLE FORECAST DESCRIPTION

BC Hydro develops an EV load forecast to estimate electricity sales across our system due to growth in the total number of light duty electric vehicles in B.C. The EV forecast is split amongst the residential sector and commercial sectors based on Insurance Corporation of British Columbia (ICBC) data on the number of light duty electric vehicles that are for personal and business use. As a result, 85 per cent of the total EV load forecast is allotted to the residential sector and 15 per cent is allotted to the commercial sector.

We are developing and implementing a new Electric Vehicle model, which expands the forecasting capability to also include medium and heavy duty vehicles. Results will be incorporated into future load forecasts when the model is available and testing of the model is complete.

7.2 ELECTRIC VEHICLE METHODOLOGY

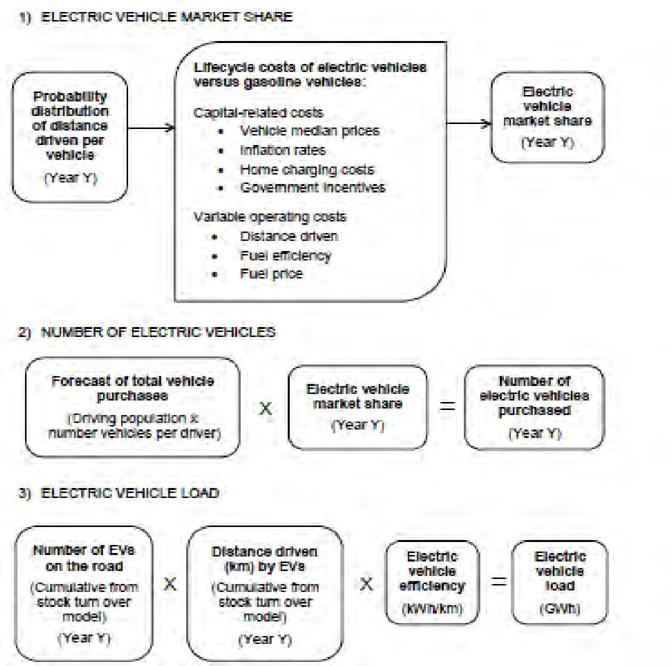
BC Hydro's EV load forecast is based on our in-house EV stock turn over model (EV model). The EV model combines both types of EVs (battery plug-in vehicles and plug-in hybrid vehicles).

7.2.1 Non-Luxury EV Forecast Model

The EV model develops a forecast of the total stock of EVs. Our EV model distinguishes between luxury EVs[9] and non-luxury EVs. A trend analysis is used to develop a forecast for the number of luxury EVs. The load forecast for luxury EVs is added to the load forecast for the non-luxury EVs which is developed by the EV model discussed below. Figure 7-1 below illustrates the key inputs and calculations of our non-luxury EV model.

[9] Luxury EVs are not eligible for government incentives as such these are modelled and forecasted separately.

Figure 7-1 Electric vehicle model



7.2.1.1 Computation of annual EV market share

The EV model starts with a forecast of the annual EV market share (ratio of the annual number of EVs to the annual number of vehicles). The key drivers for determining the market share include: (i) a distribution of the driving distance for all types of vehicles, and (ii) the costs of EVs relative to gasoline vehicles which are broken down to fixed and variable costs. The fixed cost reflects the capital related costs of vehicles, which include median sales prices (for both EVs and gasoline vehicles), announced government incentives, and home charging costs for EVs. Variable costs reflect operating costs which are determined by the annual distance driven, fuel efficiencies, and electricity rates versus gasoline prices.

The EV model randomly selects an annual distance driven from an overall probability distribution of annual distance driven per vehicle (fitted to historical data). Next, the model computes the total cost as per the randomly selected annual distance driven and compares it to a break even cost as well the range constraint, which is the maximum annual distance driven or maximum range (in kilometres) for EVs. The break-even cost is the cost at which the model estimates an indifference to gasoline vehicles and EVs. The comparison analysis results in the initial annual EV market share.

The initial market share is adjusted over the near term of the forecast period to reflect an assumed gradual development of adoption of EVs. We assume EV adoption will grow gradually because of a number of factors such as gradual increases in consumer preference, vehicle range, infrastructure improvements, and EV model availability.

7.2.1.2 Computation of the Total Number of Electric Vehicles

The forecast of the annual total number of EVs is determined by the product of the EV market share and the total vehicle purchase forecast. The total vehicle purchase forecast is determined by the product of the driving population forecast and an estimate of the number of vehicles per driver. The stock turn over portion of the EV model keeps track of the vehicle life expectancy and the annual distance driven of EVs. As such, the year over year change in the total number of EVs as shown in Table 9-1 below does not equal to the annual number of vehicles purchased.

7.2.1.3 Computation of Electric Vehicle Load

Part three of Figure 9-1 illustrates the annual EV load in GWh resulting from a product of three variables which include the total number of EVs, the annual distance driven per EV, and the average efficiency of EVs.

7.2.2 December 2020 EV Forecast Model Assumptions

The December 2020 EV energy Load Forecast reflects the CleanBC Plan's approach to light-duty EVs; specifically, to incorporate the Zero-Emission Vehicles Act (ZEV Act), which was enacted on May 30, 2019. The ZEV Act stipulates percentage targets for new light-duty vehicle sales in B.C. that must have zero emissions, as follows: 10 per cent of sales by 2025, 30 per cent of sales by 2030, and 100 per cent of sales by 2040.

Accordingly, the low-EV forecast in the December 2020 Load Forecast uses these requirements as a floor for EV adoption. In contrast, the high-EV forecast assumes the natural uptake of EVs will be higher than the minimum requirements set out in the ZEV Act, as the purchase costs decline, and consumers' preferences change over time. BC Hydro developed its reference EV forecast by taking the average of the high and low EV forecasts.

7.3 EV FORECAST RESULTS

Table 7-1 below shows the EV stock for the low, reference and high scenarios. The EV stock share is a ratio of the total number of EVs to all vehicles.

Table 7-1 – EV Stock Forecast

Fiscal year	Low Forecast (number of vehicles)	Reference Forecast (number of vehicles)	High Forecast (number of vehicles)

7.4 EV FORECAST UNCERTAINTIES

EV Load Forecast uncertainties relate to EV model inputs, such as fuel prices and capital cost, as well as uncertainties associated with the model itself. There are also a number of difficult to quantify uncertainty factors, which create risks the EV load will be higher or lower than forecast. Examples include:

- Vehicle ownership rates regardless of the drivetrain (e.g. vehicle ownership as a percentage of the total population may be higher/lower relative to historical trends),
- Impact of autonomous vehicles and car sharing on the overall vehicle sales,
- Impact of better public transportation,
- Automakers' long-term plan for introducing new EV models to convert their vehicle lineup to EVs, and
- Long-term impact of the COVID-19 pandemic if business allow employees to continue to work from home.

8.0 High and Low Uncertainty Bands

8.1 UNCERTAINTY BAND INTRODUCTION

BC Hydro's load forecasting methodology continues to incorporate high and low uncertainty bands to account for source of forecasting uncertainty. They for part of the broader suite of forecasts that encompass the December 2020 Load Forecast.

Load forecasts are sensitive to many input variables that drive the forecasts, which have varying degrees of uncertainty associated with them. These uncertainties influence the risk that future loads will be lower or higher than forecast. They can exist at a customer specific level, sector wide level or economy wide level.

There are also uncertainties associated with the various models used to develop load forecasts, such as the accuracy of using statistically determined relationships between drivers and load to forecast loads at a point in time where the nature of those relationships may be changing.

Finally, uncertainties exist when there is limited history from which to develop future projections. These uncertainties exist where there are new or emerging sectors, such as EVs, LNG, cannabis and cryptocurrency/data centres. This type of uncertainty also occurs where new public policies such as those related to climate change mitigation actions (climate action) that drive market transformation towards increased electricity use.

The December 2020 Load Forecast includes low and high uncertainty bands as well as an accelerated electrification scenario that are intended to capture the following risks and uncertainties:

- Economic risk, particularly as it relates to how global, national and provincial economies are impacted by, and recover from, the COVID-19 pandemic, and potential long-term structural changes that might result;
- The future of emerging sectors of cryptocurrency/data centres and cannabis within British Columbia;
- Customer and project specific uncertainties in each of the large industrial sub-sectors, and;
- The possibility of a large and rapid increase in low carbon electrification through climate action policies. This could impact the oil and gas and mining sub-sectors, light duty EV sales and the entire transportation sector and the built environment..

While many uncertainties and risks are accounted for in the high and low bands and Accelerated Electrification Scenario, it is normal that they will not capture every possible outcome. Some uncertainties and risks remain unaccounted for. Examples include:

- Colder or warmer than anticipated temperatures which could lead to higher or lower sales;

- Specific customer start-ups or closures not captured in the industrial low and high forecasts; and
- Housing stock growth that maybe higher or lower than Conference Board forecasts as a result of various factors impacting the housing market such as taxes, interest rates and affordable housing policies.

Additional detail on the methodology and results is described in the following sections.

8.2 UNCERTAINTY BAND METHODOLOGY AND RESULTS

BC Hydro regularly reviews and improves upon its load forecast methodology and adapts its forecast approach, where warranted, to meet changing needs. The load forecast uncertainty band methodology has been evolving in recent years towards increased used of more discrete low and high forecast assumptions rather than reliance on a Monte Carlo simulation model approach. The COVID-19 pandemic poses potential downside risk to the forecast while electrification poses potential upside. In order to capture the wide range of possibilities posed by these unprecedented phenomenons, discrete scenarios were developed to inform the high and low load forecasts for the December 2020 Load Forecast.

For the December 2020 Load Forecast, the high uncertainty band is the sum of the following discrete scenarios:

- High EV forecast;
- High large industrial forecast developed on an account-by-account basis; and
- High distribution customer load (i.e., residential, commercial, light industrial) derived using the high to reference bandwidth from the March 2020 Load Forecast Monte Carlo modelling.

Due to the COVID-19 pandemic, it was important to capture the potential for adverse impacts impacts and a scenario with little or no growth. The December 2020 low uncertainty band is the sum of the following discrete scenarios:

- Low EV forecast;
- Low large industrial forecast developed on an account-by-account basis;
- Low distribution customer load (i.e., residential, commercial, other sub-sector of light industrial) was assumed to remain at fiscal 2021 forecasted level; and
- Low light industrial forecast for wood, oil and gas, and mettalurgical coal sub-sectors using market assumptions aligned with low large industrial forecast.

As part of its continuing improvement activities, BC Hydro will be engaging a third-party consultant to review our overall methodology for developing load forecast uncertainty bands, including the use of Monte Carlo simulation modellin g. Results of the investigation will be considered in future load forecasts.

The sections below elaborate on the methodology and provide the results of the uncertainty analysis.

8.2.1 Residential

The high and low residential load forecasts were developed based on the following assumptions:

- the high residential load forecast was derived by applying the high to reference bandwidth from the March 2020 Load Forecast Monte Carlo analysis of the distribution load to the December 2020 Reference Load forecast. For example, in a given year if the March 2020 high case was x% higher than the March 2020 reference case, we increased the December 2020 reference case in that year by x% to determine the high case.
- the low residential load forecast is assumed to remain the same as the fiscal 2021 reference forecast model projections.

Table 8-1 below shows the high, reference, and low residential load forecasts. These forecasts are after adjustments fo rate impacts and, DSM , and as described in section 7.1, they include 85 percent of our low, reference, and high EV load forecasts.

Table 8-1 – Residential High, Reference, and Low Load Forecasts After Adjustments

Fiscal year	High Forecast (GWh)	Reference Forecast (GWh)	Low Forecast (GWh)
Actual			
F2015	17,973	17,973	17,973

F2037	26,835	24,379	20,038
F2038	27,467	24,852	20,144
F2039	28,083	25,328	20,267
F2040	28,716	25,833	20,409
F2041	29,346	26,360	20,620
Compound Annual Growth Rates			
5-year History CAGR (F15 to F20)	0.4%	0.4%	0.4%
5-year CAGR (F20 to F25)	2.5%	1.8%	1.3%
10-year CAGR (F20 to F30)	2.2%	1.6%	0.7%
20-year CAGR (F20 to 40)	2.3%	1.7%	0.5%

8.2.2 Commercial

Similar to the residential sector, the high and low commercial load forecasts were developed based on the following assumptions:

- the high commercial load forecast was derived by applying the high to reference bandwidth from the March 2020 Load Forecast Monte Carlo analysis of the distribution load to the December 2020 Reference Load forecast. For example, in a given year if the March 2020 high case was x% higher than the March 2020 reference case, we increased the December 2020 reference case in that year by x% to determine the high case.

- the low commercial load forecast is assumed to remain the same as the fiscal 2021 reference forecast model projections.

Table 8-2 below shows the high, reference, and low commercial load forecasts. These forecasts are after adjustments for rate impacts and DSM , and as described in section 7.1, they include 15 percent of our low, reference and high EV load forecasts.

Table 8-2 –Commercial High, Reference, and Low Load Forecast After Adjustments

20-year CAGR (F20 to 40)	0.1%	(0.3%)	(0.8%)

8.2.3 Light Industrial

The high and low light industrial forecasts were developed based on the following assumptions:

- the other sub-sector high load forecast is derived by applying the March 2020 high to reference Monte Carlo bandwidth in the same manner as the residential and commercial forecasts.
- the other sub-sector low load forecast is assumed to remain the same as the fiscal 2021 reference forecast model projections.

- discrete high and low forecasts were produced for wood, oil and gas, and metallurgical coal using market assumptions aligned with the corresponding large industrial segments described in section 8.2.4.

Table 8-3 below shows the low, reference, and high light industrial load forecasts.

Table 8-3 Light Industrial High, Reference, and Low Forecasts After Adjustments

8.2.4 Large Industrial

The high and low load forecasts for the large industrial sector are developed at a customer level, using the same methodology as the reference forecast, with different market assumptions. This section provides the major assumptions and results for all sub-sector and segment forecasts.

8.2.4.1 Metal Mining

The high forecast was developed base on the following market assumptions:

- higher than anticipated global economic growth and associated increased demand for copper,
- no lasting impact of the COVID-19 pandemic.
- reduced trade tensions,
- increased electrification rates in the transportation and manufacturing sectors,
- increased demand for electronics and electrical products,
- increased industrial development, which increases demand for machinery and equipment. The expansion of the power sector in China and India increases demand for wires and cables,
- as demand continues to grow at higher than expected rate, higher cost copper supply is brought into production, increasing th e long-term marginal cost to approximately $US4/lb, and
- life expansion and equipment upgrades for certain projects beyond expected assumptions.

The low forecast was developed based on the following market assumptions:

- aggressive mine supply growth with projects in South America, Central Africa and other parts of the world over the next few years,
- long-lasting impacts of COVID-19 in major economies that decrease copper demand,
- no mine disruptions weighing on supply,
- demand erosion due to substitution effects from other sources (aluminium, steel, composite materials) and rise in scrap metal recovery, and
- prices drop to $US2/lb in the next couple of years. As mines don't recoup total costs (including cost for sustaining production), many B.C. metal mines shut down production. The mines are not replaced by future additions due to the low-price environment and reduced B.C. competitiveness relative to other jurisdictions (domestic and foreign).

The high, reference and low metal mining forecasts are shown in Table 8-4.

Table 8-4 Metal Mining High, Reference, and Low Forecasts After Adjustments

5-year CAGR (F20 to F25)	5.0%	0.9%	(11.5%)
10-year CAGR (F20 to F31)	5.8%	1.2%	(19.1%)
20-year CAGR (F20 to F41)	3.3%	0.4%	(11.6%)

8.2.4.1.1 Metallurgical Coal

The high forecast was developed based on the following market assumptions:

- higher than expected demand for steel in Asia,
- no lingering effects of COVID-19 pandemic on Chinese and US economies,
- potential disruptions to Australian coal supply, and
- prices increase to a long-term level $US175/tonne, which is sufficient to incent new supply additions.

The low forecast was developed based on the following market assumptions:

- lower than expected demand for steel in Asia,
- prolonged and long lasting COVID-19 effects reduce the demand for metallurgical coal worldwide,
- expansion of Australian coal supply, and
- prices drop to $US100/tonne below the estimated long-term operating cost of 75 per cent of the world's seaborne metallurgical coal production.

The high, reference, and low metallurgical coal forecasts are shown in Table 8-5.

20-year CAGR (F20 to F40)	0.3%	(2.6%)	(6.7%)

The high and low forecasts are not symmetric around the reference forecast. Table 7-7 shows the high forecast is proportionally higher relative to the reference forecast than is the low forecast. The high forecast assumes market conditions evolve such that publication paper customers profitably retool and expand production. For instance, our pulp and paper market consultant has identified new growing markets like wastepaper recycling, tissue and paper packaging to displace plastic. These new market opportunities represent potential mill line conversion opportunities for B.C. publication paper mills. Moreover, with wastepaper recycling, the Chinese government has banned wastepaper imports into the country to reduce water pollution. Consequently, Chinese paper recyclers are no longer able to buy wastepaper from North America. As a result, North American paper mills are being converted into wastepaper recyclers to meet growing paper demand in China with abundant supplies of low-cost wastepaper, including in B.C.

8.2.4.4 Wood Products

High and low forecasts for the wood products segment were developed and rolled up into the high and low bands for the forestry sub-sectors.

Table 8-8 shows the historical and high, reference, and low forecasts for wood products segment. The high and low forecasts are symmetrical projections around the reference forecast.

Compound Annual Growth Rates			
5-year History CAGR (F15 to F20)	(2.5%)	(2.5%)	(2.5%)
5-year CAGR (F20 to F25)	3.8%	0.8%	(4.5%)
10-year CAGR (F20 to F30)	1.7%	0.2%	(2.6%)
20-year CAGR (F20 to F40)	0.7%	(0.1%)	(1.5%)

The high forecast assumes higher than expected demand from U.S. housing starts and lumber exports to China. While this forecast assumes high lumber prices, increased production is assumed to be constrained by increased logging and stumpage costs resulti ng from declining fibre supply.

The low forecast assumes some mills operate at reduced capacity or are closed. This is assumed to occur as a result of weaker demand from the U.S. and Chinese markets and deteriorating fibre supply. For the U.S. market, housing starts are assumed to only moderately rise and the softwood lumber dispute to remains unresolved.

The low forecast also assumes slower economic growth in China with increased market competition for B.C. wood products from o ther jurisdictions (Russia, New Zealand, and Europe). Both U.S. and Chinese market assumptions result in lower lumber prices for B.C. producers. In addition, wood harvesting costs are assumed to increase as a result wildfire and mountain pine beetle effects o n fibre supply. The net effect of the market and fibre supply conditions is assumed to trigger mill closures or mills to operate at lower production levels.

8.2.4.5 Chemical

High and low forecasts for the chemical segment were developed and included in the forestry sub-sector's high and low bands. Table 8-9 shows the high, reference, and low forecasts.

Table 8-9 Chemical Segment High, Reference, and Low Forecasts After Adjustments

Fiscal year	High Forecast (GWh)	Reference Forecast (GWh)	Low Forecast (GWh)

Compound Annual Growth Rates			
5-year History CAGR (F15 to F20)	(3.2%)	(3.2%)	(3.2%)
5-year CAGR (F20 to F25)	3.1%	0.9%	(1.0%)
10-year CAGR (F20 to F30)	1.6%	0.4%	(0.5%)
20-year CAGR (F20 to F40)	0.8%	0.2%	(0.3%)

There is relatively low uncertainty in the loads that make up the chemical segment. This is demonstrated in the historical sales between fiscal 2013 and fiscal 2020. Besides the aforementioned plant closure, there is little historical load variation. Going forward, we do not expect any material operational changes by customers within the chemical segment. We assume chemical plants have the ability to sustain operations by exporting product in the event there are pulp and paper mill curtailments in B.C. The high forecast is higher in magnitude relative to the reference forecast than is the low forecast. This is based on the assumption that prices and market conditions in the pulp and paper and oil and gas segments will be remain favourable.

8.2.4.6 Forestry Summary

Table 8-10 shows the forestry high, reference, and low forecast after adjusting for rate impacts and DSM.

5-year CAGR (F20 to F25)	17.5%	10.5%	6.0%
10-year CAGR (F20 to F30)	13.7%	7.2%	4.0%
20-year CAGR (F20 to F40)	6.8%	3.6%	1.9%

The high shale gas forecast assumes higher natural gas production growth to serve higher LNG terminal requirements, higher downstream gas and liquids exports to stronger North American markets and higher electrification percentages for new production facilities. The low shale gas forecast assumes slower production growth trending rise in natural gas production to supply lower LNG terminal requirements, weaker North American natural gas demand, and lower electrification percentage for new production facilities.

8.2.4.8 Other Oil and Gas (including LNG) Summary

Table 8-12 shows the oil and gas (including LNG) sub-sector. This includes high and low forecasts for the other large oil and gas operations segment were developed and aggregated within the overall sub-sector. The high and low forecasts for this segment are primarily driven by LNG terminal assumptions.

Table 8-12 Other Oil and Gas (including LNG) Sub-sector High, Reference, and Low Forecasts After Adjustments

Fiscal year	High Forecast (GWh)	Reference Forecast (GWh)	Low Forecast (GWh)
Actual			
F2015	973	973	973
F2016	836	836	836

F2030	8,501	3,574	2,135
F2031	8,498	3,570	2,131
F2032	8,494	3,567	2,128
F2033	8,491	3,563	2,125
F2034	8,488	3,560	2,122
F2035	8,484	3,556	2,118
F2036	8,479	3,551	2,113
F2037	8,475	3,547	2,109
F2038	8,470	3,543	2,105
F2039	8,466	3,538	2,100
F2040	8,462	3,534	2,096
F2041	8,460	3,532	2,093
Compound Annual Growth Rates			
5-year History CAGR (F15 to F20)	(4.0%)	(4.0%)	(4.0%)
5-year CAGR (F20 to F25)	31.2%	25.8%	19.3%
10-year CAGR (F20 to F30)	26.8%	16.2%	10.4%
20-year CAGR (F20 to F40)	12.6%	7.8%	5.0%

The risk profile for this segment is asymmetrical in that the potential for higher load growth relative to what is reflected in the load forecast is greater than the potential for lower load. This asymmetry is primarily due to LNG terminals.

8.2.4.9 Other Large Industrial

Table 8-13 shows the high, reference, and low forecasts for the other large industrial customers, after adjustments.

The high forecast was developed based on the following assumptions:

- no adverse effects from COVID-19 pandemic beyond fiscal 2021,
- higher global economic growth results in higher demand for industrial products and shipping affecting cement plant production, ports, terminals and manufacturing,
- higher life expectancy and load from cryptocurrency and data centres, and
- higher than anticipated growth for universities and new customers.

The low forecast was developed based on the following assumptions:

- COVID-19 pandemic has a long-lasting effect on customers such as universities or airports which are deferring expansions,
- lower global economic growth results in lower demand for products and shipping affecting cement plant production, ports, terminals and manufacturing, and
- no incremental growth from cryptocurrency and data centres.

20-year CAGR (F20 to F40)	2.7%	0.1%	(1.4%)

8.2.5 Electrification

One major source of uncertainty in this forecast is the level of electrification that will be achieved. Electrification is a term used to refer to switching from the use of fossil fuels to the use of electricity from clean energy sources, resulting in reduced greenhouse gas (GHG) emissions. BC Hydro has been supporting electrification and greenhouse gas emission reductions for a number of years. In August 2020 BC Hydro initiated work to develop an Electrification Plan designed to consolidate the actions already underway as well as new actions to increase low carbon electrification, attract additional load, and connect customers more efficiently. The December 2020 Load Forecast was finalized prior to the Electrification Plan. Because the Electrification Plan consolidates actions already underway, some plan components such as the CleanBC-driven measures described below are reflected in the December 2020 Load Forecast. Additional components and revised estimates for the existing components will be incorporated into future load forecasts as they become approved and more certain.

This section provides our estimate of loads related to the CleanBC plan which are included in the December 2020 Load Forecast and introduces an accelerated electrification scenario, which is provided as Appendix F to this report.

8.2.5.1 Estimated Loads Related to the CleanBC Plan

As with previous load forecasts, the December 2020 Load Forecast includes electrification loads that result from activities which reduce or avoid GHG emissions. The estimated electrification loads presented in this section encompass a specific set of intiatives and customer-specific assumptions, which are directly related to action and strategies outlined in the CleanBC Plan.

The December 2020 Load Forecast captures the following:

- EV load - The CleanBC Plan made a firm commitment to a Zero Electric Vehicle (ZEV) mandate that was enacted in legislation on May 20, 2019. Accordingly, the EV forecast is included in our electrification estimate.
- BC Government-Funded Fuel Switching – The estimated impact of the fuel switching component of the government-funded CleanBC Better Buildings/Homes program, which BC Hydro is administering on behalf of the Government of B.C.
- BC Hydro Low Carbon Electrification (LCE) – BC Hydro’s Low Carbon Electrification (LCE) projects/programs, described in Appendix N of BC Hydro’s Fiscal 2022 Revenue Requirements Application.
- Large Industrial Electrificaton. The CleanBC Plan includes providing clean electricity supply to natural gas production in the Peace region and increasing access to clean electricity for large operations with new transmission lines and interconnectivity to existing lines. Accordingly, forecast load growth from specific projects in the oil and gas (including LNG) sub-sector is included in the electrification estimate.

There are likely to be other electrification actions which have been or will be undertaken by some of our customers that also support provincial GHG emission reduction targets, but are not included in our estimate.

The estimated electrification load in the Load Forecast from the areas listed above, allocated by major customer sector, is provided in Table 8-14. By fiscal 2025, we estimate the December 2020 Load Forecast includes approximately 3,300 GWh of electrification load related to the CleanBC Plan. This will increase over the forecast period.

Table 8-14 - Electrification Load Included in the Load Forecast

Electrification Loads (GWh)	Fiscal Year	Total	Load Forecast Sector Allocation			
			Residential	Commercial	Light Industrial	Large Industrial
Light Duty EV Forecast	F2025	**593**	504	89	0	0
	F2030	**1,559**	1,325	234	0	0
	F2035	**2,992**	2,543	449	0	0
	F2040	**4,698**	3,993	705	0	0
Low Carbon Electrification (LCE) Program Loads	F2025	**148**	36	48	28	36
	F2030	**147**	36	48	28	35
	F2035	**127**	29	46	28	24
	F2040	**51**	0	12	28	11
Large Industrial Low Carbon Electrification (LCE) Project Loads	F2025	**2,573**	0	0	0	2,573
	F2030	**4,147**	0	0	0	4,147
	F2035	**4,096**	0	0	0	4,096
	F2040	**4,052**	0	0	0	4,052
Total CleanBC Related Load in Load Forecast	F2025	**3,313**	**539**	**137**	**28**	**2,609**
	F2030	**5,853**	**1,361**	**282**	**28**	**4,182**
	F2035	**7,215**	**2,572**	**495**	**28**	**4,120**
	F2040	**8,801**	**3,993**	**717**	**28**	**4,063**

Our estimated electrification load reflected in the Load Forecast is provided again in Table 3.x, allocated by the following CleanBC Plan categories: Transportation, Built Environment and Industry.

Table 8-15 - Estimated Electrification Load in Load Forecast by Category

Fiscal Year	Transportation (GWh)	Built Environment (GWh)	Industry (GWh)	Total (GWh)
F2025	596	80	2,637	**3,313**
F2030	1,563	80	4,210	**5,853**
F2035	2,992	75	4,148	**7,215**
F2040	4,698	12	4,091	**8,801**

8.2.5.2 Accelerated Electrification Scenario

In addition to the low and high uncertainty bands, BC Hydro worked with a consultant to develop an Accelerated Electrification Scenario for use in the 2021 IRP.

The Government of B.C. has legislated targets for reducing greenhouse gas emissions 40 per cent below 2007 levels by 2030, 60 per cent by 2040, and 80 per cent by 2050. The Government of B.C. has also introduced an interim GHG reductio n target of 16 per cent by

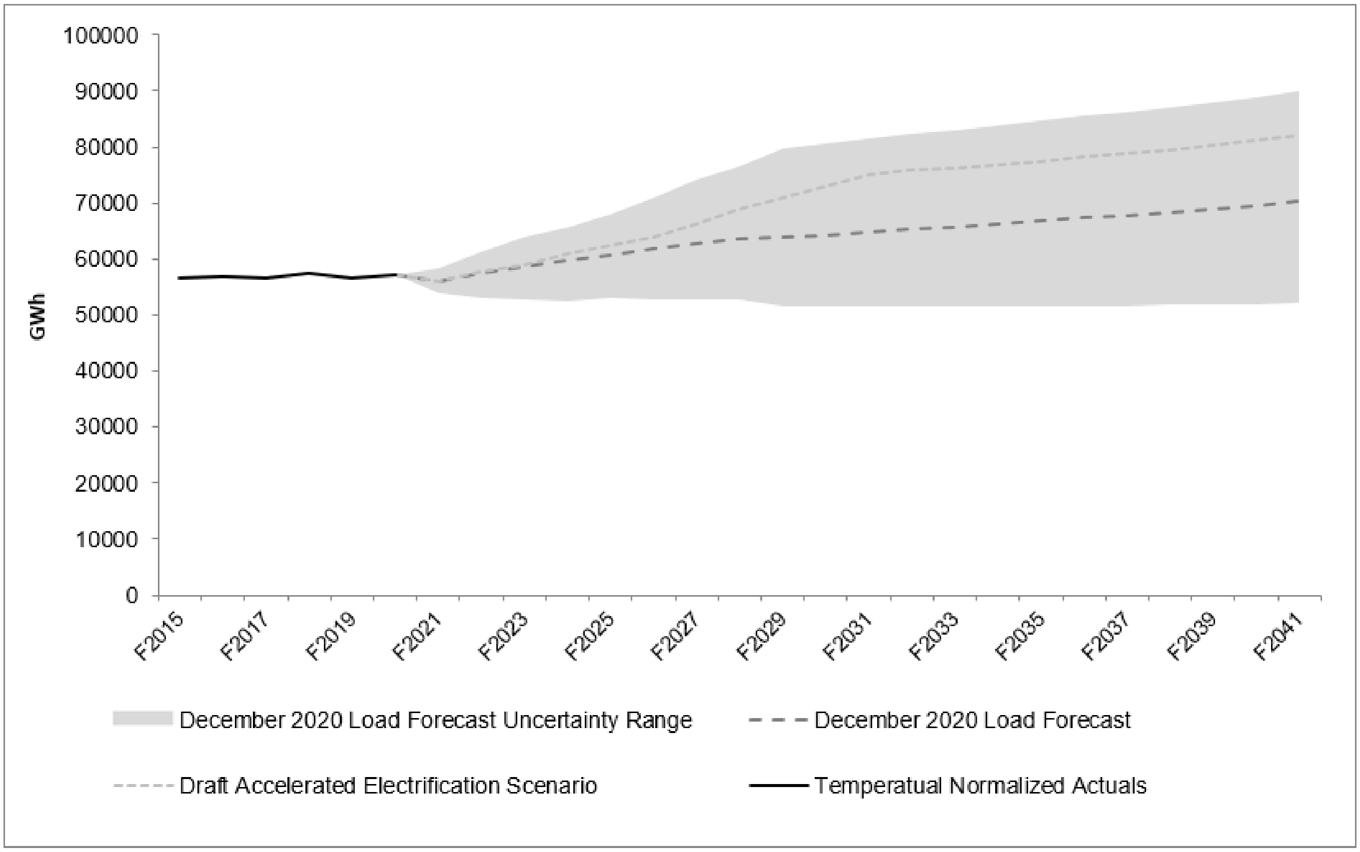
2025. The CleanBC Plan sets out a path towards the 2030 target, which includes electrification of a variety of energy end-uses supplied by fossil fuels.

BC Hydro engaged Navius Research to develop an electrification scenario that estimates the impact on load growth if all of the provincial GHG reduction targets are met over the milestone years of 2025, 2030 and 2040. The estimated loads in this scenario are incremental to the December 2020 Load Forecast. The details of the study are presented in Appendix F of this report and illustrate that by fiscal 2025, electricity consumption could be around 1,000 GWh higher than the December 2020 Load Forecast. By fiscal 2030 electricity demand could be around 8,000 GWh higher, with most of the incremental growth in electricity demand coming from the natural gas sector and electrification of residential and commercial sector buildings and transportation.

8.2.6 Total System Uncertainty

The December 2020 Load Forecast uncertainty bands and Accelerated Electrification Scenario are shown in Figure 8.1

Figure 8.1 – December 2020 Load Forecast, Total Integrated System Uncertainty Bands and Accelerated Electrification Scenario

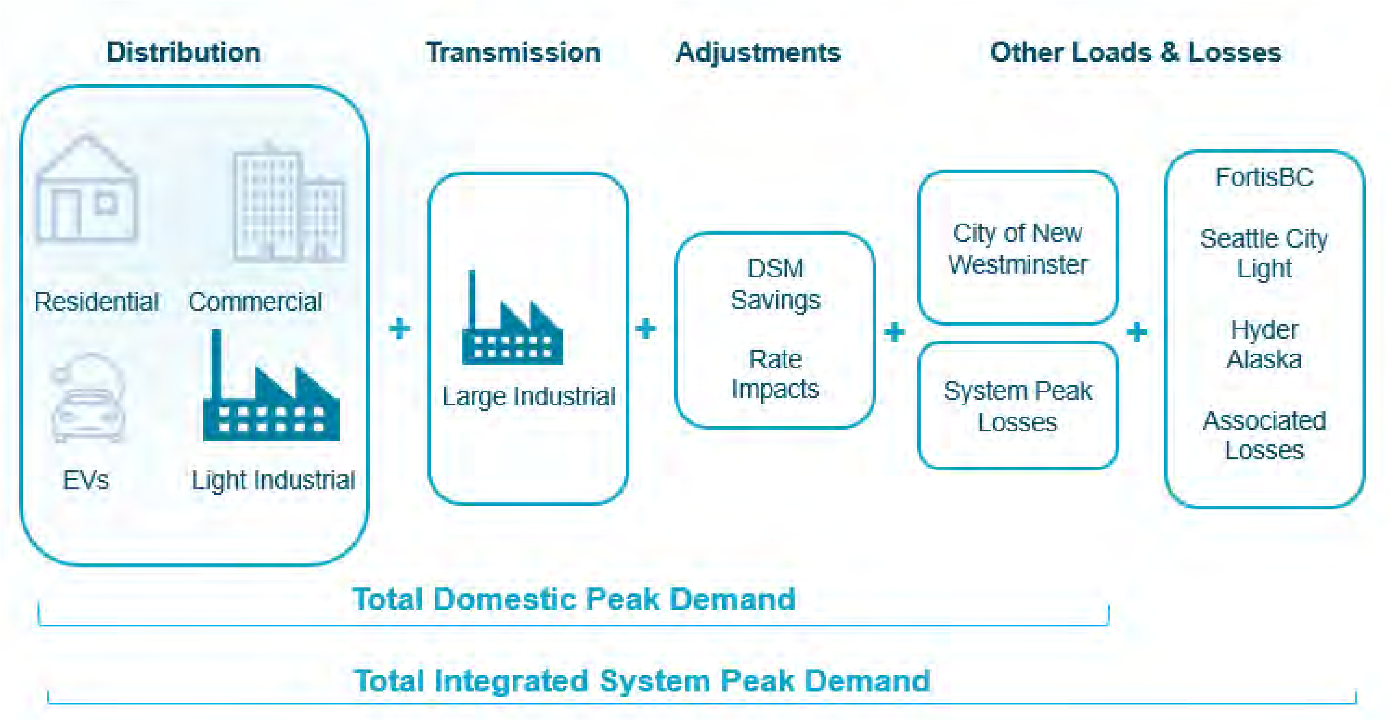


9.0 Peak Demand Forecast

9.1 PEAK DESCRIPTION

BC Hydro's peak demand is defined as the maximum expected amount of electricity consumed in a single hour under an average cold temperature assumption referred to as the design temperature. BC Hydro is a winter peaking utility, as its demand is more sensitive to colder temperatures than warmer temperatures. The total BC Hydro system typically reaches its annual peak on a cold winter day between 5:00 pm and 6:00 pm. Vancouver Island has a morning and an evening peak as residential space heating is a larger component of the Vancouver Island load. Figure 9.1 below shows the build-up of the Total Domestic Peak Demand forecast and the Total Integrated System Peak forecast.

Figure 9-1 – Total Domestic and Total Integrated System Peak Forecast Build Up



The domestic peak includes distribution substation peaks, transmission customer peaks and the peak demand of the City of New Westminster and system transmission losses. The Integrated system peak demand is the Domestic peak demand plus the peak demands from the other served utilities including FortisBC, Seattle City Light, Hyder Alaska and the system transmission losses associated with their demand.

The largest component of the domestic peak demand is the distribution peak which is estimated to be 10,253 MW in fiscal 2041. The distribution peak is the total peak demand for all distribution substations (including distribution losses) coincident (or at the time) when our system is reaching is highest point. The city of New Westminster is also part of the total domestic system as BC Hydro provides energy and capacity on a bulk system to the two substations that serve the City of New Westminster. The second largest component of the domestic peak is the coincident transmission peak demand which is forecast to be 1,984 MW fiscal 2041. The transmission peak demand is the total coincident peak demand of all large industrial customers connected at system at transmission voltage. The transmission peak forecast is developed for each of large industrial customer using the drivers and inputs that are used to develop the energy sales forecast described in section 6. Distribution peak demand is the most sensitive to ambient temperature. The future demand is driven by various factors including residential accounts and growth in distribution energy sales, which in turn is driven by economic forecasts. In addition, larger discrete loads such as shopping malls, waste treatment facilities and other infrastructure projects contribute to the peak at specific distribution substations are also considered.

Transmission peak demand is responsive to external market conditions and changes in demands for BC's key industrial commodities such as wood, oil and gas, pulp and paper, metallurgical coal, and metals.

9.2 PEAK DEMAND FORECAST METHODOLOGY

This section provides a high-level overview of how the distribution, electric vehicles, transmission and total system peak demand forecast is developed.

9.2.1 Distribution Peak Methodology

At the distribution level, electricity demand is closely linked to the historical trends in distribution substation load growth, peak intensity coefficients and the energy forecast for residential, commercial and light industrial sectors.

The distribution peak forecast is developed using a regression model referred to as the distribution peak guideline forecast and prepared for 15 different planning areas. The forecast provides forecast for growth for all of the substations serving distribution customers in that area and it is used internally for development of substation forecasts. The main drivers used in the model are the forecasts of distribution energy and the number of residential customer accounts, which is driven by housing starts.

The equation for the distribution peak guideline can be summarized as:

$$Area\ Peak\ Demand = \overbrace{kVA/Account * Accounts}^{(Residential\ Peak)} + \overbrace{kVA/kWh * Energy\ (kWh)}^{(Light\ industrial\ and\ Commercial\ Peak)}$$

The Area Peak Demand (i.e., base peak load) is adjusted with following peak demand forecasts to determine the Total Area Peak (reference) Guideline Forecast:

- The demand forecast of EVs,
- Overlap in codes and standards,
- Fuel Switching peak demand, and
- Additional spot loads.

Residential peak intensity is the average peak kW per residential account. Residential peak intensities are estimates for each of the 15 areas for two housing types (single family and multiple housing) and two heating types (electric and non-electric). The estimation involves a two-step process, in the first step, the raw intensity is estimated using historical load shapes. This results in the average kW/account for various heating types and housing types. In the second step, the intensities are calibrated and scaled such that peak guideline model's predicted historical peak demand (i.e., back-cast) matches the historical temperature normalized area peak over the past 10 years. This second step transforms the average kW per account into average kVA per account.

Light industrial and commercial peak intensity is the average peak per unity of energy (i.e. kW/kWh) and it is estimated using historical load shapes developed from historical data. The peak intensities are estimated for each of the 15 areas for customers greater than 35 kW and under 35 kW. The intensities are also estimated with a two-step process.

The residential accounts forecast, and light industrial and commercial energy forecast are prepared for each of the 15-distribution planning areas. The residential account forecast is prepared for two housing types (single family and multiple housing) and two heating types (electric and non-electric). The light industrial and commercial energy forecast is prepared for four regions and allocated to the 15 planning areas.

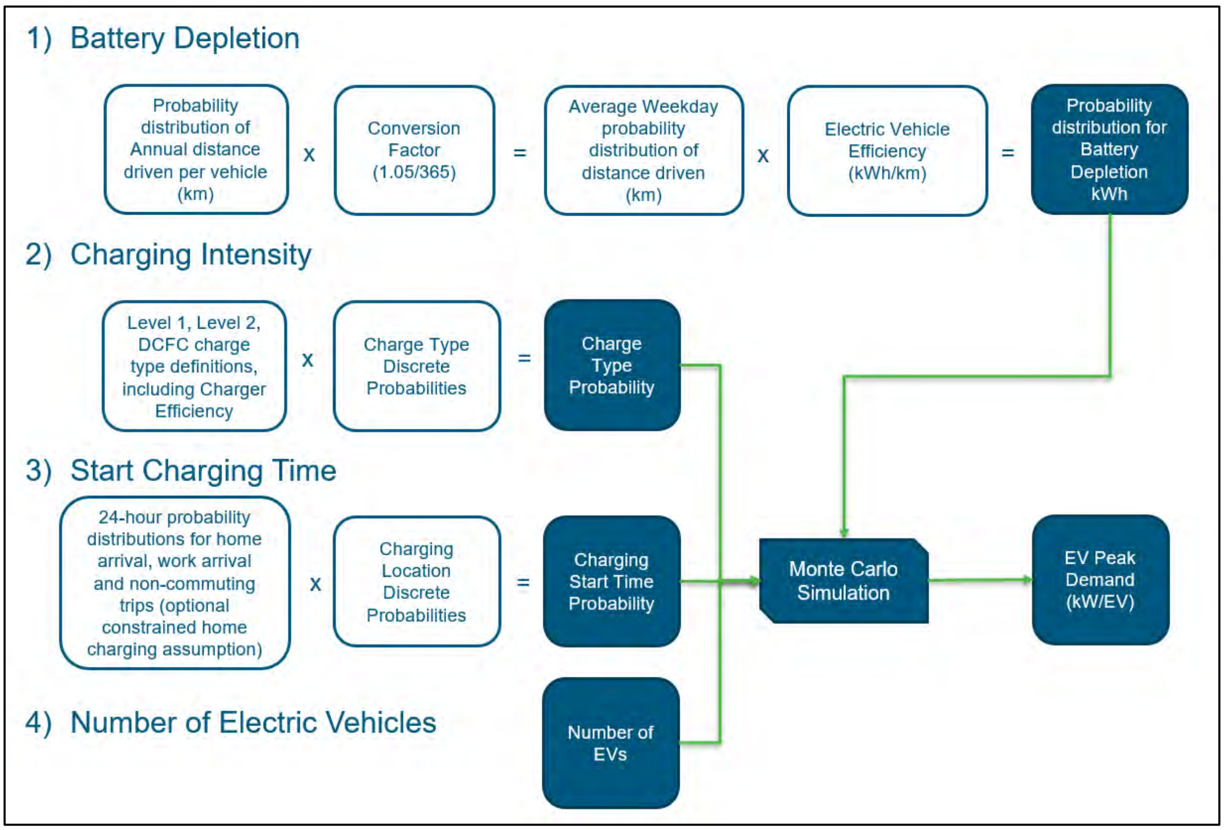
Regional power factors and coincidence factors are applied to aggregated forecasts to produce four regional coincident distribution peak forecasts. The power factors and coincident factors are based on historical averages.

A total BC Hydro distribution peak forecast is prepared as a coincident sum of the four regional distribution peak forecasts.

9.2.2 Electric Vehicle Peak Methodology

Similar to the EV model, BC Hydro's electric vehicle peak forecast is based on our in-house Electric Vehicle peak model (EV peak model). Figure 9-2 below illustrates the key inputs and calculations of our EV peak model.

Figure 9-2 Electric Vehicle Peak Model



The EV peak model has four main components:

1. Probability distribution for battery depletion in kWh. The key inputs being annual distance driven, which is converted to daily distance driven, and the average EV efficiency.
2. Charging Intensity
   a. Looking at different charging types: level 1, level 2 and DC fast charging each of which has a discrete probability,
   b. The model also accounts for charging efficiencies.
3. Charging start time probability:

a. Survey data are used to create a 24-hour probability distribution for home arrival, work arrival times plus non-commuting charging times, which includes any non-work and home related charging such as charging at the supermarket or any public charging stations.

4. Number of EVs which comes from the EV model.

All these components then feed into a Monte Carlo simulation that creates our EV peak forecast.

BC Hydro uses an additional home charging profile to reflect potential programs and incentives to shift charging behaviour to the off-peak period. The probability of charging under this profile is adjusted as follows to develop the low, reference and high EV peak forecasts.

- The high peak forecast is unconstrained, which means EV owners will charge their vehicle upon home arrival;
- The reference peak forecast is 25 per cent constrained. In this forecast, 25 per cent of EV owners will start charging their vehicle during off-peak hours; and
- The low peak forecast is 25 per cent to 75 per cent constrained, which is similar to the reference forecast with the exception that up to 75 per cent of EV owners will start charging their vehicles during off-peak hours.

9.2.3 Transmission Peak Methodology

The transmission peak demand forecast is prepared on a customer-by-customer account basis for the entire forecast period. Individual transmission customer forecasts are developed using market intelligence from BC Hydro's key account managers, historical peak demand trends, reports on industry outlooks, plus production and intensity estimates. These forecasts are aggregated into regional peak forecasts (i.e., a total transmission peak demand forecast) for each of the four main service regions. Regional coincidence factors and power factors are applied to each of these total regional peak forecasts to establish regional coincident transmission peak forecasts.

A total BC Hydro transmission peak demand forecast is prepared as a coincident sum of the four regional transmission peak forecasts.

9.2.4 Integrated System Peak Forecast Methodology

A total system peak demand forecast is prepared as the sum of the total coincident distribution peak, total coincident transmission peak, peak demands for other utilities and total system transmission losses.

The system transmission losses are assumed as 7.0 percent of the total system peak demand forecast.
The system peak demand forecast is prepared for the BC Hydro's domestic system and the total integrated system. The domestic peak demand is the sum of the total domestic distribution and transmission peaks, the peak demand of the City of New Westminster and system transmission losses. The integrated system peak demand is the domestic peak demand plus the peak demands from th e other utilities (i.e., Seattle City Light and FortisBC) and system transmission losses.

9.3 PEAK DEMAND FORECAST

BC Hydro's all-time total domestic system peak was 10,577 MW which occurred on January 14, 2020. The daily average temperature for that day recorded at the Vancouver International Airport (YVR) was -7.1 ºC colder than the design temperature of -4.7 ºC. The design temperature is the rolling average of the coldest daily average temperature over the most recent 30 years. The temperature-adjusted domestic peak for the winter of fiscal 2020 was estimated at 10,162 MW.

For the winter of fiscal 2020, the total integrated system peak forecast, including peak requirements from the other utilities served by BC Hydro, was 10,844 MW before temperature adjustments and 10,471 M, after temperature adjustments.

The integrated system peak forecast, with DSM and with rate impacts is expected to be 11,173 MW in fiscal 2025, 11,881 MW in F2031, and 13,346 MW in fiscal 2041. These increases represent growth rates of 1.3 per cent over the next five years (F2020 to

F2025), 1.2 per cent over the next 11 years (F2020 to F2031), and 1.2 per cent over the next 21 years of the forecast (fiscal 2020 to fiscal 2041).

9.3.1 Distribution Peak

The coincident distribution peak decreases more than 200 MW in fisal 2021 as a result of the drop-in commercial activity due to COVID-19 impacts, as described in section 4.3.

The compounded growth in the coincident distribution peak forecast is around 0.6 percent in the first five years (fiscal 2020 to fiscal 2025), but then slightly accelerates to 0.8 percent by fiscal 2031 and 1.2 per cent by fiscal 2041. The increase is caused by the larger impact of EVs in the latter part of the forecast, as adoption rates and total stock of EVs increase in the last ten years of the forecast horizon. Further information is provided in section 7.2.3.

Table 9-1 below shows the coincident distribution peak demand forecast after including the EV forecast and adjusting for rate impacts and DSM.

Table 9-1 Distribution Peak Demand Forecast After Adjusments

Fiscal year	December 2020 Coincident Distribution Forecast (MW)
Actual	
F2020	8,005
Forecast	
F2021	7,793
F2022	8,047

20-year CAGR (F20 to F40)	4.6%

9.3.2 EV Peak Forecast Results

Table 9-2 below shows the EV peak for the high, reference and low forecasts.

Table 9-2 – EV High, Reference, and Low Peak Forecasts

Fiscal Year	High EV Peak Forecast - Unconstrained (MW)	Reference EV Peak Forecast - 25% TOU (MW)	Low EV Peak Forecast - 25% to 75% (MW)
F2021	21	15	10
F2022	63	38	20
F2023	120	69	30
F2024	193	106	39
F2025	279	149	46
F2026	378	198	53
F2027	504	259	59
F2028	643	324	72
F2029	796	396	84
F2030	964	475	98
F2031	1,147	562	114
F2032	1,342	658	133
F2033	1,550	762	155
F2034	1,769	873	180
F2035	2,003	993	208
F2036	2,254	1,122	239
F2037	2,496	1,251	272
F2038	2,727	1,378	307
F2039	2,946	1,503	345
F2040	3,152	1,625	384
F2041	3,346	1,743	424

BC Hydro is constantly monitoring the growth of EVs and looking into different ways to mitigate the peak associated with EVs.

9.3.3 Transmission Peak

The annual compounded growth in the coincident large industrial (transmission) peak forecast is around 3.9 per cent in the first five years (fiscal 2020 to fiscal 2025) but decreases to 2.4 percent by fiscal 2031 and 1.2 per cent by fiscal 2041. The increase up to fiscal 2026 is caused mainly by additions in the oil and gas (including LNG) sub-sector, as the transmission sector growth remains relatively flat after fiscal 2026.

For more details regarding the transmission subsectors (mining, oil and gas, forestry or others), refer to the section 6 - Large Industrial Forecast. The transmission peak mirrors the growth of the transmission energy forecast.

Table 9-3 below shows the coincident transmission peak forecast after adjusting for rate impacts and DSM..

Table 9-3 - Transmission Peak Demand Forecast After Adjustments

Fiscal Year	Coincident Transmission Peak Forecast (MW)
Actual	
F2020	1,440
Forecast	
F2021	1,468
F2022	1,474
F2023	1,543
F2024	1,644
F2025	1,746
F2026	1,797

5-year CAGR (F20 - F25)	1.3%
10-year CAGR (F20 - F30)	2.4%
20-year CAGR (F20 - F40)	4.7%

9.4 PEAK DEMAND FORCAST UNCERTAINTY BAND

The peak demand forecast reflects the combination of a number of customer sector forecasts and their associated input and modelling uncertainties. In particular, large industrial sector uncertainties related to potential facility closure, facility expansions or new facility developments are included. For the residential and commercial sectors load impacted by temperature, short-term temperature can be highly variable relative to our assumptions of a rolling 30-year average trend of coldest daily average temperature. Over the longer term, projected climate changes related to warmer winters and extreme weather may impact peak demand. Finally, the economic disruptions caused by the COVID-19 pandemic likely impact short-term peak demand patterns and structural changes may impact peak demand patterns over the long term. These uncertainties create risks that peak demand is higher or lower than expected.

There are additional peak modelling uncertainties related to energy-to-peak data relationships.

The peak uncertainty bands for the December 2020 peak forecast were constructed as follows:

- For the transmission loads (i.e., large industrial sector and other transmission voltage customers) and EVs, discrete high and low peak demand forecasts were developed in concert with the discrete high and low energy forecasts. These are described in the section 6 Large Industrial and section 8 Electric Vehicles.
- For the distribution loads (residential, commercial, light industrial), before EV impacts, the high and low peak demand forecasts were developed by using the same high and low uncertainty bands (as a percentage difference relative to the reference forecast)

for the distribution energy forecast before EV impacts. The bands were calculated for each of BC Hydro's four service regions:: Lower Mainland, Vancouver Island, South Interior and North Region.

Forecast assumptions are the same for the other utilities (Fortis BC, New Westminster, Seattle City Lights, Hyder Alaska), The results of the high, reference and low total integrated peak forecasts after rate impacts and DSM are shown in Table 9-5.

Table 9-5 Total Integrated High, Reference, and Low Peak Demand Forecasts After Adjustments

Fiscal Year	High Forecast (GWh)	Reference Forecast (GWh)	Low Forecast (GWh)

F2040	16,853	13,204	9,680
F2041	17,127	13,376	9,704
Compound Annual Growth Rates			
5-year CAGR (F20 - F25)	3.2%	1.3%	(0.9%)
10-year CAGR (F20 - F30)	6.2%	2.4%	(1.4%)
20-year CAGR (F20 - F40)	10.0%	4.7%	(1.6%)

10.0 Non-Integrated Areas and Other Utilities Forecasts

This section is divided into two main parts: (i) Non–Integrated Areas and (ii) sales from BC Hydro to other utilities. We begin with describing the Non-Integrated Area sales followed by sales to other utilities. In both sections we describe the methodology and then the forecasts results.

10.1 NON-INTEGRATED AREAS

10.1.1 NIA Description

The non-integrated areas (NIA) consist of several small communities located in parts of B.C. not connected to BC Hydro's integrated transmission grid. The communities of our NIA include:

- Customers in the Purchase Areas in the South Interior. The Purchase Areas consists of the following six locations: Lardeau, Shutty Bench, Crowsnest, Newgate, Kingsgate-Yahk, and Kelly Lake. To serve customers in the Purchase Areas, BC Hydro purchases electricity from several neighbouring electric utilities,
- Customers in Zone II communities in the North Region and Vancouver Island. Zone II NIA customers include 15 communities from the following locations:[10] Masset, Sandspit, Atlin, Dease Lake, Telegraph Creek, Anahim Lake, Bella Coola, Hartley Bay, Good Hope Lake, Toad River, Jade City, Fort Ware, Kwdacha, and Tsay Keh Dene,
- Customers in Zone 1B community of Bella Bella in the North Region, and
- Customers in the Northern Rockies Regional Municipality (Fort Nelson area) in the North Region.

As of fiscal 2020, total gross requirements for the entire NIA were 303 GWh, where more than half of this amount is in the Fort Nelson area.

10.1.2 NIA Forecast Methodology

Various methodologies are used to develop the forecast for communities that make up the NIA areas. The methodologies range from trend analysis, developing specific customer load forecasts, and regression models. All of the forecasts developed from these methods are supplemented with information from local community members about future loads. BC Hydro's Distribution Area planners, which look after planning distribution station assets within the NIA, gather information from local connection offices and communities about load increase or decrease for the NIA.

For the Purchase Areas, the forecast is developed by a trend analysis of the historical total gross requirements of the communities that makes up the Purchase Areas.

For Zone II and Zone 1B communities, the forecasts are developed using a trend analysis of the historical loads that make up major sectors in these areas. A trend analysis is carried out for the residential sector, commercial and light industrial sector and other loads such as street light customers, irrigation customers and BC Hydro own use. The trend analysis establishes a base load forecast which is supplemented by other forecast information on individual projects or customers loads. This additional load information is obtained from customer service requests via local BC Hydro personal or identified by our Distribution Area planners. These load additions tend to be the main drivers of load growth within all of these communities.

For Fort Nelson area sales, the forecast is developed as the sum of the forecast for each of the major customer sectors including residential, commercial and light industrial and a large industrial sector, which consists of two major loads which are deriv ed as follows:

- The forecast for the residential sector is the product of the accounts and the average use per account. The account projection and the average use per account projection are based on a trend analysis of historical billing data. A trend analysis is used bec ause there is not enough resolution (i.e. detail in our residential end use survey) to develop a statistically sound SAE model for the residential and commercial load in communities that make up the NIA areas.
- The forecast for the commercial and light industrial sector is developed with a regress ion model involving historical sales and employment where the history and forecast of employment comes from CBoC Economic Forecast. The forecast for the wood product segment which consists of two mills, currently shutdown, is developed on an account by acc ount basis.
- The forecast for the two large industrial customers in the Fort Nelson area are also developed on an account by account basis using the same methodology that applies to other oil and gas loads connected to the integrated grid.
- The forecasts for street lighting customers, irrigation customers and BC Hydro own use within the Fort Nelson area is developed based on a trend analysis.

The NIA Load Forecast is the result of an aggregation of our load forecasting analysis (i.e., trends, customer proje ctions, and regression models, and load additions as requests for service) for all parts of the NIA listed above, less load reductions fo r rate impacts and load reductions for savings from our DSM plan.

Rate impacts are developed in the same manner as they are developed for the main customer sectors described in this document. Savings from our DSM t plan identified for the NIA area are allocated to each of the four main parts that make up the NIA on an historical sales percentage basis. An allocation of th e DSM savings is used because it is not exactly known which individual part of the NIA will engage in DSM activities.

10.1.3 NIA Forecast Results

The Non-Integrated Area Load Forecast results are shown in Table 10-1.

For the most part, the loads that make up the NIA are stable, and the forecasts indicate a slow increase much like the historical trend. The largest growth is anticipated to occur in the Fort Nelson area over the period of fiscal 2021 to fiscal 2022. During this period, it is expected that there will be an increase in the demand for electricity by the wood product segment.

Table 10-1 – NIA Total Gross Requirements Sales History and Forecast After Adjustments

Fiscal year	Purchase Area Load Forecast (GWh)	Zone II and Zone 1B Load Forecast (GWh)	Fort Nelson Load Forecast (GWh)	Total NIA Load Forecast (GWh)
Actual				
F2015	12	112	204	329
F2016	11	112	205	328
F2017	13	116	198	328
F2018	14	115	185	315
F2019	13	113	184	311
F2020	13	115	176	303
Forecast				
F2021	13	116	150	279
F2022	13	118	162	293
F2023	13	119	180	312
F2024	14	120	208	342
F2025	14	120	210	343
F2026	14	120	213	347
F2027	14	120	215	350
F2028	14	120	215	349
F2029	15	120	215	350
F2030	15	120	215	350
F2031	15	121	215	351
F2032	15	121	215	351
F2033	15	122	215	352
F2034	16	122	215	352
F2035	16	123	215	353
F2036	16	123	215	354
F2037	16	124	215	355
F2038	17	125	215	356
F2039	17	125	215	357
F2040	17	126	215	358
F2041	17	127	215	359
Compound Annual Growth Rates				
5-year History CAGR (F15 - F20)	0.5%	0.5%	(3.0%)	(1.6%)
5-year CAGR (F20 - F25)	1.7%	0.8%	3.6%	2.5%
10-year CAGR (F20 - F30)	1.6%	0.4%	2.0%	1.4%
20-year CAGR (F20 - F40)	1.5%	0.5%	1.0%	0.8%

For the most part, the loads that make up the NIA are stable and the forecasts indicate a slow increase much like the histori cal trend. Similar to the other sectors, we anticipated a decrease in energy demand for fiscal 2021 due to the pandemic. However, the largest growth is anticipated to occur in the Fort Nelson area over the period of fiscal 2023 to fiscal 2024. During this period it is expected that there will be an increase in the demand for electricity from the wood product and oil and gas sectors.

10.1.4 NIA Forecast Uncertainties

There are two main uncertainties to the NIA forecast. First is the impact of COVID-19 and second are the discrete events such as the opening or closing of operations. In some instances, the exact timing of when these p rojects are expected to transpire are difficult to predict as major developments, such as large residential or commercial projects, with in the smaller communities often require external funding. Our BC Hydro planners, NIA station managers and other personal with BC Hydro keep in contact with various communities to gather information on the types of future loads and when future loads are expected come online.

Some of the loads in the Fort Nelson area are dependent upon the future development of the resource sector. These loads can vary from the forecast due to changes in external market conditions such as fluctuations in natural gas prices and wood segment prices.

10.2 OTHER UTILITIES

The other utilities served by BC Hydro are listed below:

- City of New Westminster, located within BC Hydro's Lower Mainland Region,
- FortisBC Electric, located in southeastern B.C.,
- Seattle City Light, located in the state of Washington, USA, and
- Hyder, Alaska, located in Alaska, USA.

Hyder is served at distribution voltage while the other three utilities are served at transmission voltage.

All of these utilities have formal arrangements with BC Hydro for electrical service. In fiscal 2020, annual energy sales to City of New Westminster, FortisBC Electric, Seattle City Light, and Hyder were 464 GWh, 585 GWh, 312 GWh, and 1 GWh, respectively. Firm exports include Seattle City Light and Hyder, while sales to inter-utilities include City of New Westminster and FortisBC Electric.

10.2.1 Other Utilities Forecast Methodology

The forecast methodology varies by utility, as follows:

The forecast for the City of New Westminster is based on trend analysis and information from BC Hydro's distribution planners on new larger projects that have requested electricity service.

The forecast of sales to FortisBC Electric is based on a modelled comparison of the relative cost of purchasing electricity from BC Hydro (including future rate increases) applied to Rate Schedule 3808 versus the cost of market purchases. The model also considers information provided by FortisBC Electric on its expected purchase of electricity from BC Hydro. Since the forecasting model determines the forecast of sales to FortisBC Electric by the relative costs of purchases (i.e., market vs BC Hydro rates) it already accounts for the impact future changes in our electricity rates. As such, there is no need to apply a further rate impact to the results of the model.

The forecast for Seattle City Light is prescribed within a treaty between British Columbia and Seattle dated March 30, 1984 and which expires on January 1, 2066.

The sales forecast for Hyder, Alaska is based on a trend analysis.

10.2.2 Other Utilities Forecast Results

Table 10-2 shows the other utilities forecast with rate impacts.

Table 10-2 – December 2020 Other Utilities Sales History and Forecast After Rate Impacts

Fiscal Year	City of New Westminster (GWh)	FortisBC Electric (GWh)	Seattle City Light (GWh)	Hyder, Alaska (GWh)	Total Other Utilities (GWh)
Actual					
F2015	444	522	305	0.9	1,272
F2016	455	516	308	0.9	1,280
F2017	463	589	325	0.9	1,378
F2018	465	551	318	0.8	1,336
F2019	462	435	315	0.7	1,212
F2020	464	585	312	0.7	1,362
Forecast					
F2021	506	718	310	0.9	1,534
F2022	507	622	312	1.0	1,442
F2023	505	618	310	1.0	1,435
F2024	511	615	310	1.0	1,438
F2025	515	637	310	1.0	1,464
F2026	521	627	312	1.0	1,460
F2027	526	709	310	1.0	1,546
F2028	532	720	310	1.0	1,563
F2029	537	750	310	1.0	1,598
F2030	542	771	312	1.0	1,627
F2031	548	815	310	1.0	1,675
F2032	554	844	310	1.0	1,709
F2033	559	872	310	1.0	1,743
F2034	565	903	312	1.0	1,781
F2035	571	940	310	1.0	1,823
F2036	578	965	310	1.0	1,854
F2037	584	969	310	1.0	1,864
F2038	590	974	312	1.0	1,877
F2039	596	970	310	1.0	1,878
F2040	604	970	310	1.0	1,885
F2041	610	995	310	1.0	1,916
Compound Annual Growth Rates					
5-year History CAGR (F15 - F20)	0.9%	2.3%	0.4%	(4.3%)	1.4%
5-year CAGR (F20 - F25)	2.1%	1.7%	(0.1%)	6.7%	1.5%
10-year CAGR (F20 - F30)	1.6%	2.8%	0.0%	3.3%	1.8%
20-year CAGR (F20 - F40)	1.3%	2.6%	(0.0%)	1.6%	1.6%

Electricity sales to the City of New Westminster are forecast to grow about 2.1 per cent over the next five years. Sales to FortisBC Electric are forecast at an annual compound growth rate of 1.7 per cent over the next five years. Both Seattle City Light and Hyder Alaska are forecast to have little growth in load supplied by BC Hydro.

10.2.3 Other Utility Forecast Risks and Uncertainties

The main risk to the forecast of electricity sales to the City of New Westminster is a discrete event such as a further large new load addition. The risks to the forecast of sales to FortisBC Electric would be unforeseen changes in the market conditions which may impact how that utility plans to meet its supply arrangements.

Given that the forecast for Seattle City Light is based on a signed treaty, there is minimal sales risk over the entire forecast period. The sales risk for Hyder is also minimal given that its load is so small.

11.0 Glossary

Accrued Sales are an estimate of electricity delivered within a specific month. Most customer meters are not read at every month-end, so the amount of electricity delivered in a month is not known precisely. In accordance with GAAP, monthly accrued sales are used for monthly financial reporting.

Back-casting Estimating econometric or other models over a historical time period and comparing the predictions of the models to actual results over the same time period.

Billed Sales The amount of electricity billed. Because bills are produced after the electricity has been delivered, monthly billed sales lag monthly delivery of electricity.

Binary Variable is a variable whose value is either zero or one. Binary variables are often used as independent variables in regression models in order to account for events that either occur or do not occur. In this latter context, binary variables are often referred to as "dummy variables" in regression.

Calibration Estimating econometric or other models over a historical time period.

Coincidence Factor A ratio reflecting the relative magnitude of a region's (or customer's or group of customers') demand at the time of the system's maximum peak demand to the region's (or customer's or group of customers') maximum peak demand.

Commercial Output Commercial output focuses on the provisions of services in the economy and so includes such things as public administration, insurance agents, bankers, wholesale and retail trade, food services, accommodation provisions etc.

Consumer Price Index (CPI) An inflation index calculated by comparing the price of a typical bundle of goods in the year in question to the price of the same goods in a set reference year.

Cooling Degree Day (CDD) is a measure of warmness, defined by the number of degrees above a certain daily average temperature measured in Degrees Celsius CDDs are drivers of utility air-conditioning electricity loads.

Demand-Side Management (DSM) Activities that occur on the demand side of the revenue meter and are influenced by the utility. Demand-Side Management activities result in a change in electricity sales. Past Demand-Side Management savings include incremental load displacement and energy efficiency savings. Note that BC Hydro's historical sales include the impact of Demand-Side Management savings realized up to that year.

Design Temperature Rolling average of the coldest daily average temperature over the most recent 30 years

Distribution Voltage Customer A BC Hydro customer who receives electricity via distribution lines that operates at lower voltages (60 kV and less).

Domestic System Peak includes the peak requirements for BC Hydro's distribution and transmission customers in its service territory; sales to the City of New Westminster and system transmission and distribution losses.

Econometric Modelling The use of statistical techniques, typically regression analysis of time-series and/or cross-sectional data, to detect statistically verifiable relationships, coherent with economic theory, between an explained variable (e.g. electricity consumption) and explanatory variables (e.g. industry output, prices of alternative energy inputs and GDP).

Elasticity The proportionate change in a dependent variable (e.g. electricity consumption) divided by the proportionate change in a specified independent variable (e.g. electricity price). A dependent variable is highly elastic with respect to a given independent variable if the calculated elasticity is much greater than one. The dependent variable is inelastic if the elasticity is less than one.

End-use Model A model used to analyze and forecast energy demand, which focuses on the end uses or services provided by energy. Typical end uses are lighting, process heat and motor drive. For a given industry, the model estimates the influence of prices and technological change on the evolution of the secondary energy inputs required to satisfy the industry's end uses over time.

Energy The amount of electricity delivered or consumed over a certain time period, measured in multiples of watt-hours. A 100-watt bulb consumes 200 watt-hours in two hours.

Energy Efficiency Is the ratio of the energy service delivered from a process or piece of equipment to the energy input. Energy efficiency is a dimensionless number, with a value between 0 and 1 or, when multiplied by 100, is given as a percentage.

EV Electric Vehicle

Fuel Switching is specific to the December 2020 forecast as presented in this report. Fuel switching means switching from one kind of energy source or use to another that decreases GHG emissions in B.C., and the estimated fuel switching load included in the March 2020 forecast is based on specific government or BC Hydro programs that incent customers to switch from fossil fuel-based energy to clean electricity.

GAAP Generally Accepted Accounting Principles

Gigawatt-hour (GWh) A measure of electrical energy, equivalent to one million kilowatt-hours. (See Units of Measure)

Gross Domestic Product (GDP) A measure of the total flow of goods and services produced by the economy over a specified time period, normally a year or quarter. It is obtained by valuing outputs of goods and services at market prices (alternatively at factor cost), and then aggregating the total of all goods and services.

Heating Degree Day (HDD) Is a measure of coldness, defined by the number of degrees below a certain daily average temperature measured in Degrees Celsius. HDDs are drivers of utility space heating electricity loads.

Integrated System That portion of the BC Hydro's electricity system which is connected as one whole by a high voltage transmission grid.

Integrated System Peak includes the peak requirements for BC Hydro's distribution and transmission customers in its service territory; sales to Other Utilities, which includes Seattle City Light, New Westminster, FortisBC and Hyder Alaska (Tongass Power and Light Co. Inc.); and system transmission and distribution losses.

Intensity A unitized measure of energy consumption, typically in kilowatt-hours per unit of stock. For example, intensity is kWh per account in the residential sector or kWh per unit of production in the industrial sector.

Kilowatt (kW) A kW is 1000 watts and a watt is measure of power that can be transferred instantaneously

Kilowatt-hour (kWh) A measure of electrical energy over a period of time, equivalent to the energy consumed by a 100-watt bulb in 10 hours. (See Units of Measure)

Liquefied Natural Gas (LNG) is natural gas that has been converted temporarily to liquid form for ease of storage or transport. This process involves refrigeration, and requires no chemical transformations.

Load The total amount of electrical power demanded by the utility's customers at any given time, typically measured in megawatts.

Load Displacement Projects that involve the installation of self-generation facilities at customer sites, with the electricity generated being used on-site by the customer, with a resultant decrease in the purchase of electricity from BC Hydro.

Megawatt (MW) A unit used to measure the capacity or potential to generate or consume electricity. One MW equals one million watts. (See Units of Measure)

Megawatt-hour (MWh) A measure of electrical energy, equivalent to 1,000 kWh. (See Units of Measure)

Monte Carlo Method A technique for estimating probabilities involving the construction of a model and the simulation of the outcome of an activity a large number of times. Random sampling techniques are used to generate a range of outcomes. Probabilities are estimated from an analysis of this range of outcomes.

Megavolt-Amps (MVA) – a unit of apparent power, which is real power in MW, divided by power factor.

Natural conservation The increase in energy efficiency that would occur in the absence of any utility-induced Demand-Side Management program, all other things being equal.

Non-coincident In general is the magnitude of a region’s (or customer’s or group of customers’) demand at the time of its peak.

Non-Integrated Areas (NIA) Non-integrated facilities refer to generating facilities that are not connected to the system, located in remote areas of the province

Normalization The correction of actual customer sales and peak demand for factors such as unusually warm or cold weather.

Ordinary Least Squares (OLS) is a method of estimating parameters to minimize the sum of squares errors in a regression model.

Price Elasticity of Demand The percentage change in quantity demanded, divided by the percentage change in price that caused the change in quantity demanded.

Real Price Increases that have been adjusted for changes in prices of all goods. The nominal price of an item may rise by 10 per cent over a year, but inflation (and assumed wages) may have risen by 7% over the same time period. Therefore the effective price increase faced by the consumer is close to 3 per cent. It is necessary to deflate current prices by an appropriate inflation index (the CPI in Canada) to convert money values to constant prices or real terms.

Region A geographical sub-division of the BC Hydro service area used for Load Forecast purposes. Four regions exist: Lower Mainland, Vancouver Island, South Interior and the Northern Region.

Stock A quantity representing a number of energy consuming units. For example, in the residential sector, stock is the number of accounts or housing units; in the commercial sector, stock is represented by the floor area of commercial building space.

System Coincident Peak Demand The greatest combined demand of all BC Hydro customers faced by the generation system during a given fiscal year.

Transmission Voltage Customer A BC Hydro customer that is supplied its electricity via high-voltage transmission lines (60 kV or above).

Trinary variable is another type of binary variable that accounts for instances where sales or use per account in one moth is observed to be shifted from one month to the other.

Units of Measure The large amounts of electricity generated and consumed on a system-wide basis are discussed in multiples of the basic units of watt and watt-hours. Kilowatts and megawatts are used to measure power, and kilowatt-hours, megawatt-hours, and gigawatt-hours are used to measure energy. The equivalence is:

1 kilowatt (kW)	= 1,000 watts
1 megawatt (MW)	= 1,000 kilowatts or 1 million watts
1 kilowatt-hour (kWh)	= 1,000 watt-hours
1 megawatt-hour (MWh)	= 1,000 kilowatt-hours or 1 million watt-hours

1 gigawatt-hour (GWh)	= 1,000 megawatt-hours or 1 billion watt-hours

12.0 Overview of Appendices

The appendices cover additional elements of the December 2020 Load Forecast.

A. DECEMBER 2020 VS. MARCH 2020 LOAD FORECAST AND COVID-19 SCENARIOS

Provides a comparison of December 2020 Load Forecast to the previous forecast/scenarios.

B. SAE EQUATIONS AND FORECASTING MODELS

Provides an explanation of the general framework and equations of the SAE model.

C. TEMPERATURE NORMALIZATION PROCESS

Includes a description of our temperature normalization process for the residential and commercial sectors.

D. PEAK DEMAND FORECAST METHODOLOGY

Provides additional information on the peak forecast methodology.

E. CONFERENCE BOARD OF CANADA 2020 ECONOMIC OUTLOOK

A copy of the Conference Board of Canada's 2020 Economic Outlook report.

F. NAVIUS REPORT

A copy of the Navius report on the accelerated electrification scenario.

G. DECEMBER 2020 LOAD FORECAST TABLES

Tables showing the December 2020 reference load forecast before and after adjustments.

Appendix A: December 2020 vs. March 2020 Load Forecast and COVID-19 Scenarios

BC Hydro prepared a comprehensive 20 year load forecast (the March 2020 Load Forecast) over the winter of 2019 and spring of 2020. The March 2020 Load Forecast was completed prior to the onset of impacts associated with the COVID 19 pandemic. To address those potential impacts, BC Hydro developed two scenarios in April 2020 that were used to inform decisions based on two potential outcomes. The sales projection for fiscal 2022 from one of those scenarios (referred to as “Scenario A”) was used in the calculation of the revenue requirements in the Fiscal 2022 Revenue Requirements Application.

Table A-1 below compares the December 2020 Reference Load Forecast with the March 2020 (pre-COVID) Reference Load Forecast and the two COVID-19 scenarios.

Table A-1 – Total Firm Sales Forecast After Adjustments for Rate Impacts, DSM, and VVO

	December 2020 Reference	March 2020 Reference	COVID-19 Scenario A	COVID-19 Scenario B	December 2020 - March 2020	December 2020 - COVID-19 Scenario A	December 2020 - COVID-19 Scenario B	December 2020 vs March 2020	December 2020 vs COVIDvs19 Scenario A	December 2020 vs COVIDvs19 Scenario B

F2040	63,450	65,374	64,585	64,585	(1,925)	790	0	(2.9%)	(1.8%)	(1.8%)
F2041	64,151									
20-yr Compound Annual Growth Rate F20-F40	1.0%	1.2%	1.1%	1.1%						

The 20-year compound annual growth rate from Fiscal 2020 to Fiscal 2040 for the December Load Forecast is 1.1%, which is slightly lower than the previous forecasts, primarily due to revised outlooks for the commercial and large industrial sectors, which include updated information on expected impacts of and recovery from the COVID-19 pandemic.

Appendix B: SAE Equations and Forecasting Models

12.1 INTRODUCTION

Our unadjusted sales forecasts[11] for residential and commercial sectors are based on:

- the estimated coefficients of the SAE, and
- the forecasts of economic data, temperature data, average efficiency data and saturation data. All of these are included in the SAE models.

Section A1.2 below covers the general framework of the SAE model, the development of its main variables (i.e., Heating, Cooling and Other) and the equations for these variables.

12.2 STATISTICALLY ADJUSTED END USE FRAMEWORK

The description of the SAE framework described below for the residential sector generally applies to the commercial sector. The main difference between the residential and commercial framework is that the dependent variable in the residential framework is th e average use per account and the dependent variable in commercial framework is commercial sales.

The statistically adjusted end-use modeling framework begins by defining the dependent variable: the average electricity use per account (Use_m) in a month (m) as the sum of the average electricity use by per account from heating equipment ($Heat_m$), cooling equipment ($Cool_m$), and other equipment ($Other_m$). Formally, this is written as:

Equation B.1

$$USE_m = Heat_m + Cool_m + Other_m$$

Equation B.1 can be written in the format of a linear regression model as:

Equation B.2

$$USE_m = a + b_1 \times XHeat_m + b_2 \times XCool_m + b_3 \times XOther_m + \varepsilon_m$$

Where: USE_m is the dependent variable of the above regression model or average use per account (monthly). The independent variables in the regression model are $XHeat_m$, $XCool_m$, and $XOther_m$. These are the main explanatory variables, which are constructed monthly (m) from end-use information, economic drivers, and temperature data. The parameter ε_m represents the random error term in the above regression model. The parameters b_1, b_2, and b_3 are the coefficients of the regression model which represent the relative contribution of the main explanatory variables (i.e., major end uses) to the average residential use per account.

The equations below show the construction of the main independent variables. For each variable there is data in the historical period (i.e., estimation period) and data in the forecast period. The estimated coefficients of the model and the forecast data fo r each main variable determine the results (i.e., forecast of average use per account) that come from the SAE model.

[11] In this Appendix as well all the other sections and appendices contained in this report, the term “unadjusted forecast” and the “term model projections” are used interchangeably.

XHeat represents average heating use per account. The amount of electricity used per account for heating depends on the following types of variables:

- heating degree days (temperature),
- heating equipment saturation levels (percentage of accounts that have a certain type of heating equipment),
- average efficiency of heating equipment,
- average number of days in the billing cycle for each month, and
- economic variables. For the residential sector this includes people per account and real personal disposable income. For the commercial sector this includes employment, real retail sales, and real commercial GDP.

The heating variable $XHeat_m$ is a product of a monthly equipment index and a monthly usage multiplier. In equation form this is expressed as:

Equation B.3

$$XHeat_m = HeatIndex_m \times HeatUse_m$$

Where: $\mathrm{XHeat_m}$ is the average heating use per account in a month (m). This variable is a product of two monthly index variables: (i) $\mathrm{HeatIndex_m}$ is the aggregate amount of heating use per account in a month for the various types of heating equipment; and (ii) $\mathrm{HeatUse_m}$ is monthly index of heating usage.

The sub-equation for $HeatIndex_m$ in equation B.3 is:

Equation B.3.1

$$HeatIndex_m = \sum_{SpaceHeating} EndUseEnergy_{e,BaseYear} \times \frac{\left(Share_m / Eff_m\right)}{\left(Share_{BaseYear} / Eff_{BaseYear}\right)}$$

Where: End Use Energy is the average use per account for each type of heating equipment, e refers to the different categories of space heating, BaseYear represents the base year for the SAE model, Share mean saturation levels [12] of the different types of heating equipment which comes from our Residential End Use Survey data (REUS), Eff is the average effi ciency of the different types of space heating equipment.

The heating equipment index (i.e., HeatIndex) depends on heating equipment saturation levels normalized (i.e., divided) by average efficiency level. As a result, the heating index will increase over time if there are changes in heating equipment saturation levels, and will decrease over time if there are improvements in the average equipment efficiencies or the thermal efficiency of residences.

Space heating usage level (i.e., $\mathrm{XHeatUse_m}$) is a function of temperature (Heating Degree Days) and economic factors. The sub-equation for $\mathrm{XHeatUse_m}$ in equation B.3 is:

Equation B.3.2

$$HeatUse_m = \left[\frac{BDays_m}{30.5}\right] \times \left[\frac{WgtHDD_m}{HDD_{BaseYear}}\right] \times \left[\frac{PeoplePerAccount_m}{PeoplePerAccount_{BaseYear}}\right]^{EI1} \times \left[\frac{Income_m}{Income_{BaseYear}}\right]^{EI2}$$

Where: m refers to monthly values, Base Year is the base year of the SAE model, BDays refers to billing days and *EI1 and EI2* are the economic elasticities of average use per account for people per account and real disposable income respectively. Each annual economic variable is converted into a monthly indices which is developed as a 12 month rolling average of the annual economic variable weighted (i.e., divided) by its average monthly value in the base year of the model. The variable $WgtHDD_m$ is the actual

[12] Saturation levels are defined as the percentage of accounts that have a certain type of electrical equipment or appliance.

weighted heating degree days in a month divided by the average monthly heating degree days in the base year of the model. The weights applied to the monthly heating degree days are used to align the actual monthly heating degree days to the billing cycle data on the residential sales over the year. For the forecast period, the variable $WgtHDD_m$ is the 10 year rolling average (i.e., temperature normalized) of heating degree days in each month.

XCool represents the average cooling use per account. This variable is constructed in a similar manner to heating. The amount of electricity use per account for cooling depends on the following types of variables:

- cooling degree days (temperature variable),
- cooling equipment saturation levels (percentages of residential accounts that have a cooling appliance),
- average efficiency of cooling equipment,
- average number of days in the billing cycle for each month, and
- economic variables including people per account and disposable income.

The cooling variable, $XCool_m$, is represented as the product of an equipment-based index and monthly usage multiplier. In equation form this represented as:

Equation B.4

$$XCool_m = CoolIndex_m \times CoolUse_m$$

Where: $XCool_m$ is the average electricity use per account for cooling in a month (m), $CoolIndex_m$ is an index of average cooling equipment use per account in a month (m); and $CoolUse_m$ is the monthly usage multiplier for cooling.

The sub-equations for $CoolIndex_m$ and $CoolUse_m$ are the same equations as those above for heating (i.e., equations B.3.1 and B.3.2) with the exception the last equation B.3.2 includes cooling degree days instead of heating degree days.

As with space heating, the cooling equipment index ($CoolIndex_m$) depends on the cooling equipment saturation levels normalized (i.e., divided) by average efficiency levels. As a result, the cooling index will increase over time if there are changes in cooling equipment saturation levels, and will decrease over time if there are improvements in equipment efficiencies or the thermal efficiency of buildings. Space cooling system usage levels ($CoolUse_m$) are driven on a monthly basis by several factors, including temperature (Cooling Degree Days) and similar economic factors used to develop heating usage.

XOther: represents the average use per account for residential end-uses of electricity that are not temperature sensitive. Some examples of non-temperature sensitive end-uses are lighting, refrigeration, cooking, clothes washing and drying, entertainment equipment (TVs) and other plug in equipment. The average use per account of electricity for other equipment is driven by:

- appliance and equipment saturation levels,
- appliance efficiency levels,
- average number of days in the billing cycle for each month, and
- economic variables.

The explanatory variable $XOther_m$ is defined as:

Equation B.5

$$XOther_m = OtherEqpIndex_m \times OtherUse_m$$

The first term on the right hand side (i.e., $OtherEqpIndex_m$) of the above equation embodies information about the average usage per month of various non-temperature dependent appliances as well as their saturation levels and their average efficiency ratings. The second term ($OtherUse_m$) captures the impact of economic variables of the overall average use of electricity through the use of other non-temperature dependent equipment. These economic variables are the same ones used for explaining heating and cooling use.

The first term has the following sub-equation:

Equation B.5.1

$$Other\ Eqp\ Index_m = Weight^{Type} \times \frac{Sat_m^{Type} / Eff_m}{Sat_m^{Type} / Eff_m} \times MoMult_m^{Type}$$

The weight term is the non-temperature dependent average use per account for specific residential end uses of electricity such as lighting, dishwasher, refrigerators etc. Sat_m^{Type} is the saturation level (i.e., percentage of accounts having at least one of these types of end uses). *Eff* is the average stock efficiency from the EIA of the various non–heating and non-cooling end uses. *MoMult* is a monthly multiplier that shapes the index to our billing data on the average use per account.

The equation for second term on the right hand side of equation B.5 above can be expressed as:

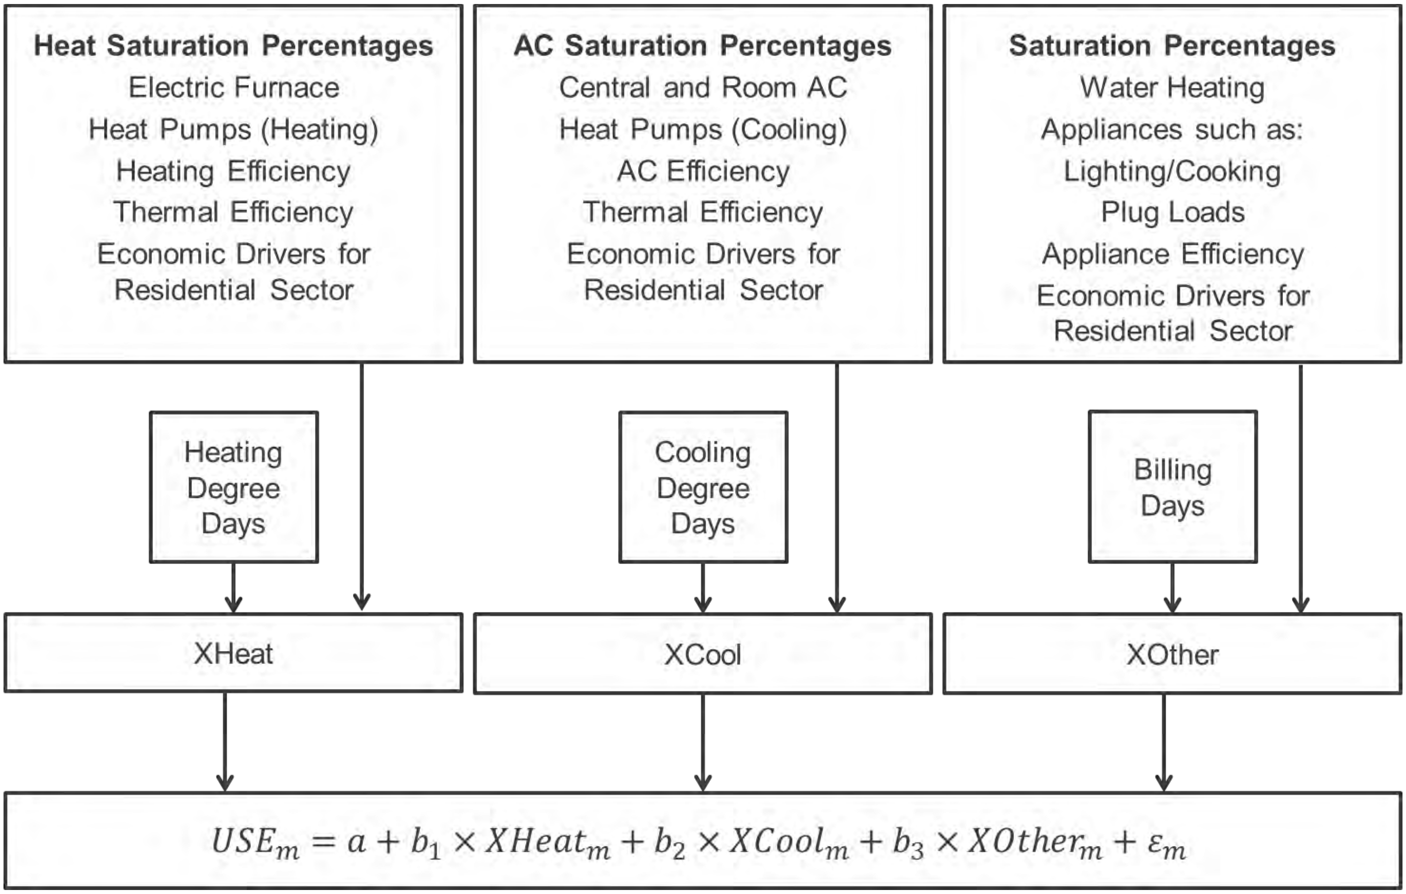
Equation B.5.2

$$Other\ Use_m = \left[\frac{BDays_m}{30.5}\right] \times \left[\frac{PeoplePerAccount}{PeoplePerAccount}\right]^{EI1} \times \left[\frac{Income_m}{Income}\right]^{EI2}$$

Where: $BDays_m$is billing days and *EI1* and EI2 are the economic elasticities of average use per account for people per account and real disposable income respectively.

In summary, Figure 16-1 below shows the inputs used in the construction of the regression variables (i.e. the independent variables) for the residential SAE models. As mentioned above the residential SAE model dependent variable is the average use per account and the commercial SAE model dependent variable is commercial electricity sales. The residential and commercial SAE models also differ in inputs in terms of economic variables, elasticities, and the regional temperatures that determine heating and cooling degree days. The latter of these two variables are discussed in Appendix C below.

Figure 0-1 Statistically Adjusted End Use (SAE) Model



Appendix C: Temperature Normalization Process

12.3 INTRODUCTION - TEMPERATURE NORMALIZATION

As mentioned in Section 5.1 of this report we develop a forecast of the average use per account and residential sales on a temperature normalized basis. We also develop a forecast of commercial sales on a temperature normalized basis. The forecasts for both of these sector forecasts are derived from our SAE models that include various drivers such as our heating and cooling degree day vari ables.

Since the forecasts are developed on a temperature normalized basis, we need to take the actual sales and temperature normalize them (i.e., adjust the historical sales for instances where actual temperature were different than assumed normal) to report variances and determine the accuracy of our forecasts. Temperature normalization is an estimation process because it involves using models and a series of steps to determine what the actual sales would have been if the actual temperatures variables (i.e., heati ng and cooling degree days) were at their normalized values (i.e., which is defined as the 10 year rolling average).

Each month, we temperature normalize the residential use per account and subsequently normalize the sales by multiplying the temperature normalized use per account by the accounts. We also temperature normalize the commercial sales. We currently temperature normalize the commercial sales at the end of the fiscal year using our SAE models. As part of the audit recommendations[13] we are working towards developing models and a process to temperature normalize commercial sales much like the way we normalize the actuals from residential sector, which is described below.

The following sections explain the temperature normalization process for the resi dential and commercial sectors.

12.4 TEMPERATURE NORMALIZATION PROCESSES STANDING APPROACH

Our current temperature normalization process for the residential and commercial sectors is described below. However, we are continuing to review the applicability of the residential approach described below to the commercial sector.

The central equation in determining a temperature normalized actual is:

Equation E.1

$$Temperature\ Normalized\ Actual = Actual + Model\ Projections\ Under\ Normal\ Temperatures - Model\ Projections\ Under\ Actual\ Temperatures$$

Where: Actual is the actual data from our billing system, Model Projections under Normal Temperature is an estimate[14] using our normal assumptions for heating and cooling degree days, and Model Projections under Actual Temperature is an under actual temperatures (i.e., actual heating and cooling degree days). The model projections are developed with an estimation period that does not include any of the forecast years. For example, our normalized residential and commercial results were done with data ending fiscal 2018.

[13] One of the Load Forecast Audit findings was to update our monthly variance report by includi ng temperature normalized commercial monthly sales and comparing those estimates to the forecast on a monthly basis.

[14] Estimate in the context of temperature normalization means predication of average use per account for the residential sector and prediction of sales for the commercial sector.

12.5 RESIDENTIAL TEMPERATURE NORMALIZATION

To temperature normalize the use per account we use equation E.1 above use the in conjunction with model projections from the following regression model (equation E.2) below:

Equation E.2

$$USE_m = \alpha + \beta_1 \times WgtHCDD_m + \beta_2 \times WgtHCDD_m^2 + \beta_3 \times WgtHCDD_m^3 + \varepsilon_m$$

Where: USE_m is monthly average use per account per account for eight segments of residential load we normalize[15], β_1 to β_3 are the coefficients of the above cubic regression model, $WgtHCDD_m$ is a combination of weighted cooling and heating degree days in a month, $WgtHCDD_m^2$ and $WgtHCDD_m^3$ are squared and cubic weighted heating/cooling degree days[16]; and ε_m is the error term. The weights are used to align the combo of heating and cooling degree days to the monthly billing data.

The most recent 36 months of data is used to estimate the regression model as described in the equation E.2 above for each of the eight residential load segments that get normalized. Every month we determine the temperature normalized average use per account and the residential billed sales using the following steps:

1. we estimate the coefficients of the regression model using data from the past 36 months,
2. from estimated coefficients in equation E.2 we determine the model's prediction of the average use per account under actual temperatures for the past 36 months, including the prediction for the last month,
3. from the estimated coefficients in equation E.2 we determine the model's prediction under normal temperature by replacing the actual combined weighted heating and cooling degree days variables with these variables on a normalized basis; and
4. finally, we determine the temperature normalized average use per account for the month we are normalizing using equation E.1 above.

Normalized residential sales are then calculated for each load segment as the normalized average use per account multiplied by the average number of accounts for the segment. The total BC Hydro service area normalized residential sales in any month is equal to the sum of normalized sales for each segment; and the total normalized sales for a year would be sum over the past 12 months.

12.6 COMMERCIAL TEMPERATURE NORMALIZATION

The process for commercial normalization is similar to the four step process outlined above for the residential sector. The main differences to the residential process are: (i) the eight commercial SAE models and the last 10 years of monthly commercial s ales data are used in the normalization process rather than monthly regression models using the past 36 months; (ii) the commercial sales are normalized at the end of year fiscal year using the commercial SAE model; and (iii) the heating and cooling degree variables in the commercial SAE models and the weights of these variables are different compared to the weights in the above residential models because the billing cycle is different for the commercial segments of load compared to the residential sector.

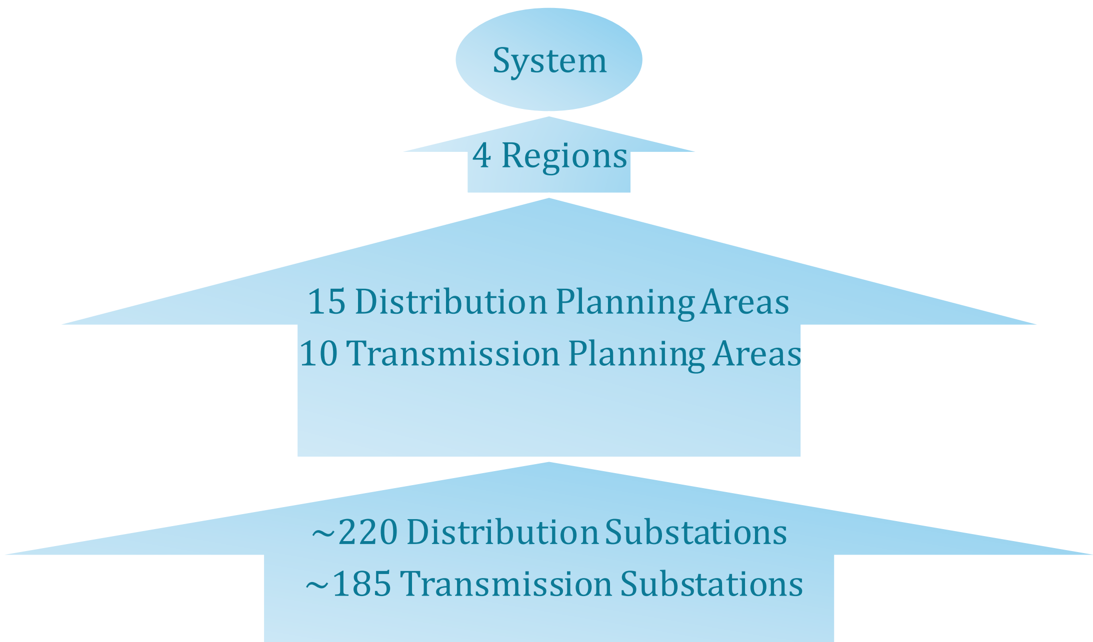
[15] The residential load segments we normalize are the heating and non-heating accounts in each of the four service regions, as such there are eight load segments (2 heating types and 4 regions).

[16] Because billing data of use per account is used in the temperature normalization process, the combined cooling and heating degree-days are weighted as percentages of the current and previous month to match the meter reading cycle for our residential customers. The weighting process is also an element of our SAE model.

Appendix D: Peak Demand Forecast Methodology

Figure D1.1 below shows that the bottom-up peak forecast methodology involves several steps for each of the distribution and transmission peak forecasts. The general description of the development stages in system peak forecast is provided following.

Figure D-1 Peak Demand Forecast Roll-up



The peak demand forecast is built up in three main stages, each incorporating several steps. First stage is the creation of the substation peak in MVA non-coincident[17], second, the four main service region peak forecasts in MW are determined on a region coincident basis and third, the system peak in MW on a system coincident basis.

Stage 1: Distribution Peak Demand Forecast

The distribution peak forecast is built up in three main sub steps:

a) the temperature normalized peak loads by substation/area are developed;

b) the distribution peak forecast guidelines are developed from an econometric model for each planning area;

[17] Non-coincident is defined in the glossary.

c) the guidelines are then used internally for the development of the substation forecast and the distribution peak demand forecast by rolling up to the 4 region level.

The appropriate equations and description of the sub steps are provided below.

(a) Temperature Normalized Substation Peaks

The simplified equation below is the basis for a linear regression model that estimates the relationship between substation peak demand and temperature:

Equation D1.1:

$$\mathrm{KVA} = \alpha + \beta * \mathrm{min}$$

Where:

- KVA is the metered peak load; and
- min is the minimum mean temperature for the coldest day during the metered period.
- α and β are the regression coefficients from a time series regression of peak substation demands on temperatures.

Using the estimated regression coefficients, the temperature - normalized peak is then calculated based on the design day temperature for that substation[18]:

Equation D1.2:

$$\mathrm{NKVA} = \alpha + \beta * \mathrm{designmin}$$

Where:

- NKVA is temperature -normalized peak; and
- designmin is the design temperature for the substation.

The first step involves estimating a relationship between substation peak demand and temperature. This is produced by equation D1.1.

In order to account for year to year variation in temperatures and other impacting factors, the historical substation peak demand data is ‘normalized’ to remove the impact of temperature variation from the mean temperature and, where possible, the impact of day of week,month, holidays, hours of darkness and other factors that may impact the peak demand. To account for temperature response often being non-linear, several models are created and the best fit model is used. Temperature independent factors, such as IPP generation impact are also removed before normalization. This is done through multivariable regression using MetrixND software.

Temperature data is obtained from Environment Canada using weather stations throughout BC to enable correlation between last year’s temperature at peak load and the design temperature (mean of the lowest daily mean temperatures over the past 30 years).

[18] A regression model using non-linear variables was also used for temperature normalization.

Temperature-normalized substation peak for each substation for the previous winter is determined by substituting the actual temperatures with the design temperature. This is depicted in equation D1.2.

(b) Distribution Peak Guideline Forecast

In the section sub step, a distribution substation peak guideline forecast is prepared for 15 planning areas using the following forecasting and (econometric model) equation:

Equation D1.3

$$SK_{it} = [\alpha_1 SFDHTG + \alpha_2 SFDNON + \alpha_3 MULTHTG + \alpha_4 MULNON + \alpha_5 U35E + \alpha_6 O35E]$$

Where:

- SK_{it} is the total substation peak for the i^{th} planning area;
- SFDHTG is the number of single-family electrically heated homes;
- SFDNON is the number of single-family non-electrically heated homes;
- MULTHTG is the number of multi-family electrically heated homes;
- MULTNON is the number of multi-family non-electrically heated homes;
- U35E is annual energy consumption General under 35 kW;
- O35E is annual energy consumption General over 35 kW;
- the coefficients $\alpha 1$, $\alpha 2$, $\alpha 3$, and $\alpha 4$ are kW contribution to the distribution peak per dwelling in area i, for the four dwelling types under normal temperature conditions; and the coefficients, $\alpha 5$ and $\alpha 6$ represent the increase in peak demand due to a one-kWh increase in the General rate class Under 35 and Over 35 kW energy consumption.

c) Substation forecast and distribution peak forecast.

The guideline forecast provides the expected total substation growth from the base year for each planning area. The drivers of the guideline forecast are based on regional economic information such as housing starts and employment. The guideline forecast is provided to BC Hydro Distribution Planners who are using it as a top-down anchor in developing an internal individual substation forecast. The Distribution Planners are taking inputs from the area guidelines provided by the Load Forecasting group and breaking them down to each substation service territory, and, where applicable to each feeder section. During this step, BC Hydro Distribution Planners may have additional and information or revised information from field engineers on expected increases or decreases on discrete customer loads as well as operational requirements for substations. The substation forecast is used for Capital Plan studies. In the past, the substation forecast would be averaged with the guideline forecast in developing the final distribution peak. However, due to the time differences between Load Forecast and Distribution Planning's cycles, only the guideline forecast was used in the development of the December 2020 Peak demand forecast.

The guideline forecast is summed up to the four main regions (Lower Mainland, Vancouver Island, North Region and South Region) on a non-coincident basis in MVA in preparation for the next stage.

Stage 2: Regional Peak Forecast

The regional peak is forecast developed using the following equation:

Equation D1.4:

$$RPKjt = \Sigma j\,[PKit * DCFj * PFj + TPj * TCFj * PFj + OPj * OCFj]$$

Where:

- DCF is the regional distribution peak coincidence factor;
- PF is the regional power factor for distribution and transmission;
- TP is the transmission peak; this is the aggregate of the transmission account peak forecast in each service region.
- TCF is the transmission coincident factor;
- OP is the other utility peak sales;
- OCF is the other utility coincident factor; and
- PK is the weighted average distribution substation forecast

A transmission peak forecast is prepared for each commercial and industrial transmission account using a bottom-up approach as described in section 6.0 Large Industrial Forecast. This involves using the historical peak data, information from Key Account Managers and market information and industry reports.

Stage 3: System Coincident Peak Forecast

Finally, system coincident peak is created as the sum of coincidence-adjusted regional peaks and it includes transmission losses:

Equation D1.4:

$$SPK = (1 + TL) * \Sigma j\, RPKjt * SCFj$$

Where:

- TL is the transmission loss factor; and
- SCF are the system coincidence factors for each of the four regions.

The Conference Board of Canada
September 15, 2020

Table of Contents

Introduction

As COVID-19 spread throughout the world in 2020, many countries mandated lockdowns to slow the transmission of the disease. As a result, economic activity around the globe ground to a halt, and Canada was no different. In the second half of March, provincial governments across the country began implementing emergency measures, such as physical distancing, to slow the spread of COVID-19, with many non-essential businesses ordered to close. Even though the measures were not in place until the second half of March, they had a devasting impact on the economy. Nationally, real gross domestic product (GDP) fell 7.5 per cent month over month in March, followed by an even greater drop of close to 12.0 per cent in April.[1]

The good news is that the gradual easing of restrictions since April has allowed the economy to rebound, though the recovery is expected to be gradual. After losing more than 3 million jobs between February and April, Canada has regained 1.66 million of those jobs as of July. This momentum is expected to continue into the fall as provinces carry out their reopening processes, easing social distancing requirements and allowing business, including dine-in restaurants, bars, gyms, and retail stores, to remain open. The success of these reopening plans and the country's ability to avoid a second wave will be crucial to the economy's recovery over the medium term. However, the need for people to continue to practice social distancing will keep many parts of the economy operating below potential until COVID-19 is no longer a domestic public health threat and a vaccine is available.

In this briefing, we examine the potential impact of the COVID-19 pandemic on the Vancouver census metropolitan area's (CMA)[2] economy from 2020 to 2040 to help inform BC Hydro's long-term projections of electricity usage in British Columbia. In the past, the Conference Board has provided BC Hydro with long-term economic forecasts for BC as a whole and for various sub-provincial regions. However, those past forecasts took months to complete, and due to the abrupt and significant negative impact of COVID-19 on Canada's economy in the first half of 2020, it was important to produce an informative forecast in a shorter period of time. The Vancouver model was used for this project because it is smaller than the BC model and can, therefore, produce outputs at a faster pace. More importantly, Vancouver accounts for the majority of economic activity in the province. In 2019, Vancouver's economy generated 60.5 per cent of BC's GDP, making the region's performance a good indicator of economic activity in the province overall.

[1] The Conference Board of Canada, "Uneven Recovery: Provincial Outlook," 3.
[2] The Vancouver CMA is composed of the City of Vancouver and surrounding municipalities, towns, townships, and Indian reserves as defined by Statistics Canada here. In this briefing, any mention of "Vancouver" refers to the "Vancouver CMA."

Methodology and Approach

The Conference Board has developed and refined a methodology to estimate economic activity at the CMA level, which has been used for this project to create long-term forecasts of key economic variables for the Vancouver CMA. Specifically, annual projections extending from 2020 to 2040 were provided for the following variables: total real GDP, total employment, total population, single housing starts, multiple housing starts, and total housing stock. Annual projections for employment by industry at the two-digit North American Industry Classification System (NAICS) was also provided, but only from 2020 to 2024.

The economic data used to inform the forecasts came largely from Statistics Canada and Canada Mortgage and Housing Corporation (CMHC). Projections for total employment and employment by industry are based on Statistics Canada's monthly Labour Force Survey results for the Vancouver CMA. Total population projections for Vancouver are based on demographic data released annually from Statistics Canada. Single and multiple-unit housing starts projections are based on data available from CMHC on a monthly basis. Total housing stock estimates are based on housing data from the 2016 Census available from Statistics Canada and housing completions data available from CMHC. Finally, real GDP forecasts for Vancouver were estimated using the Conference Board's own methodology, as historical GDP data at the CMA level is not available from any official source.

The Conference Board's Vancouver CMA model is typically used to create five-year economic forecasts on a quarterly basis. For example, in 2020 the model is designed to project economic variables over the period 2020-2024. To extend the forecast to 2040, we used the Conference Board's BC and Canada long-term forecasts as a guide. Because the most recent BC long-term forecast was published in December 2019, the Vancouver forecasts presented in this briefing are more in line with the Canada long-term forecast published in June 2020 that incorporates the impacts of COVID-19 on the national economy.

Conducting economic forecasts during the time of COVID-19 is a challenging exercise due to significant uncertainties. Because the economy is expected to operate below capacity until social distancing measures are no longer required, the economy is not anticipated to recover fully until COVID-19 is no longer a public health risk. As such, the speed of Vancouver's economic recovery is dependent on the development and availability of an effective COVID-19 vaccine or treatment. Other factors that could prolong the recovery include persistently low consumer and business confidence limiting consumption and investment, respectively, as well as slower international in-migration due to border closures and weaker economic prospects.

To accommodate for the uncertainty involved in forecasting the impact of COVID-19 on Vancouver's economy, we created three different scenarios and produced a forecast for each one based on different assumptions. The first scenario—the baseline case—is based on the assumptions used to conduct the Conference Board's June 2020 Canada forecast and presents a balanced expectation of Vancouver's economic performance. The second scenario—the high case—is based on the Conference Board's April 2020 Vancouver forecast and presents more optimistic assumptions and a much faster recovery than in the baseline scenario. Finally, the third scenario—the low case—presents a much slower recovery compared to the baseline scenario. For each scenario, the assumptions and results are presented in the next section, while detailed assumptions around the recovery path for employment by industry at the two-digit NAICS level is included in the appendix.

Forecasting Results

In the following section, we present the assumptions for and results of each of the three scenarios forecasted for Vancouver's economy: the baseline case, the high case, and the low case. In each case, Vancouver's economy eventually converges to the same long-run trend over the forecast period, albeit at different rates. This long-run trend is based on historical population and productivity growth and represents the average sustainable pace of growth for the economy. Because the COVID-19 pandemic is expected to be a temporary negative shock to the region's economy, its impact is anticipated to fade over time. The pace at which the economy converges to its long-run trend depends on the assumptions used in each forecast scenario.

Scenario 1: Baseline Case

Assumptions

- Social distancing measures will be relaxed only gradually until COVID-19 is no longer a domestic public health threat (i.e., until a treatment or vaccine is found).
- There is no second economy-wide shutdown. Regional or local shutdowns are still possible; but, nationally, restrictions are steadily relaxed.
- Global demand for resources and manufactured goods will remain weak as the Canadian and other economies do not operate at 100 per cent until an effective vaccine or treatment is available.
- Vaccine or treatment for the COVID-19 virus is found and widely available to Canadians by June 2021. COVID-19 is no longer an issue domestically.
- Wholesale and retail sales activity returns to normal by July 2021, although there could be a permanent shift to more online retailing.
- The vaccine is widespread globally by October 2021, prompting international travel to return to normal.
- Tourism, both outbound and inbound, is back to normal by the fall 2021.
- Adoption of telework is permanent for 5 to 10 per cent of the workforce, which has implications for commuter transportation, demand for automobiles, and gasoline, as well as for non-residential construction.
- Operating costs increase sharply for many businesses, so the federal wage subsidy is extended from April 2020 until June 2021 (i.e., until a vaccine available).
- Cost driven inflation starts to emerge despite excess capacity. However, this one-time transitory increase in prices does not sway the Bank of Canada to increase interest rates until 2022.

Results

In the baseline case, Vancouver's economy will largely recover from the COVID-19 pandemic over the short term (2020-2022). The end of social distancing measures, which have kept many sectors of the economy operating below capacity, are essential to this recovery. These measures are anticipated to be lifted once an effective COVID-19 vaccine or treatment is widely available to Canadians, which is assumed to be by June 2021.

After contracting by 5.0 per cent in 2020, real GDP is anticipated to rebound and push past 2019 levels in 2021 with a strong gain of 6.8 per cent. Employment, however, will take a bit longer to surpass pre-COVID-19 levels. In 2020, total employment is expected to contract by 7.1 per cent—a loss of 103,900 jobs. As a result of business closures and social distancing measures, the accommodation and food services and the arts, entertainment, and recreation industries are expected to post some of the largest job losses this year, shedding 27,700 and 11,800 positions, respectively. Although employment is anticipated to decline in nearly every industry this year, losses will be muted in sectors where work can be conducted remotely, such as in the professional and technical services industry and the education sector, which are expected to see declines of only 2,200 and 1,800 positions, respectively. In 2021, total employment is expected to rebound, but only regain about half of all jobs lost in 2020 with an expansion of 52,100 positions. Fortunately, Vancouver's labour market will rally further in 2022 and create another 81,000 jobs, pushing total employment past 2019 levels.

Meanwhile, the region's residential construction sector will log a solid performance in the short term thanks to steady population growth. Although border closures will limit international in-migration—a key component of Vancouver's demographic growth—weak job prospects across Canada will constrain out-migration from Vancouver, thus stabilizing the region's population growth to average 1.1 per cent annually between 2020 and 2022. After housing starts hit a record-high of 28,100 units in 2019, builders are expected to break ground on a further 20,900 units this year and an average of 21,700 annually over 2021-2022. This healthy level of new home construction will support average annual housing stock growth of 2.2 per cent between 2020 and 2022.

While the majority of COVID-19's negative impact will have dissipated by the end of 2022, the economy will continue to operate slightly below capacity over the medium term (2023-2029) as it rebuilds following the pandemic. Total real output is anticipated to grow at a steady average annual pace of 2.1 per cent, while employment is expected to advance at an average annual pace of 1.2 per cent—the equivalent of 18,900 jobs annually. Meanwhile, the economic recovery will begin to attract more domestic and international migrants to Vancouver, prompting population growth to accelerate to an average annual pace of 1.3 per cent between 2023 and 2029. These gains will support steady average annual housing starts of 18,300 units and average annual housing stock growth of 1.6 per cent over the same period. By the end of 2029, Vancouver's economy will have fully recovered from the COVID-19 pandemic and is set to grow at its long-run trend rate of growth over the remainder of the baseline forecast.

In the long term (2030-2040), Vancouver's economy will grow at a steady pace. Real GDP growth is expected to average an annual rate of 2.0 per cent over the period, while employment is anticipated to expand by an annual average of 1.0 per cent, or 17,100 jobs per year. These advances will be supported by healthy population growth, which is expected to average 1.0 per cent annually over the same period. This pace of population growth will also drive steady average annual starts of 14,300 units and an average annual increase in Vancouver's housing stock of 1.2 per cent between 2030 and 2040.

Please see Table 1 below for a more detailed look at the forecast results for the baseline case.

Table 1

Notes: f=forecast. Numbers in italics denote annual percentage change for each year between 2018 and 2024. For the periods 2025-2029, 2030-2034, and 2035-2040, the level values listed in the table denote the average value of each variable over that period, while the numbers in italics denote annual average percentage change over that period.
Sources: The Conference Board of Canada; Statistics Canada.

Scenario 2: High Case

Assumptions

- All non-essential business is closed, and borders remain closed to international travellers between mid-March and end of April 2020.
- Borders remain shut to personal travel, and the negative impact on demand for recreation, culture, accommodations, and restaurants continues from May to August 2020.
- Most industries will experience a negative shock to demand, with some such as accommodations and food services, travel, cultural industries, and many segments of retail experiencing a near-total collapse in activity from mid-March to April 2020.
- Manufacturing is mostly shuttered outside of essential items like pharmaceuticals, personal protective equipment and medical products, and food between mid-March and the end of April 2020.
- The construction industry slows significantly as some of its activities are deemed non-essential and forced to stop between mid-March and April 2020.
- Non-essential businesses gradually begin to re-open over the summer months, from May to August 2020.
- The financial fallout on households' balance sheets continues to weigh negatively on discretionary spending, particularly on pricier durable products like vehicle sales, from May to August 2020.
- The federal wage subsidy program positions businesses to quickly rehire as demand picks up, allowing the labour market recovery to begin between May and August 2020 and setting the foundation for stronger growth heading into the fall.
- Most aspects of the economy have returned to normal operations between September 2020 and February 2021.
- Borders re-open to international passengers between September 2020 and February 2021, but volumes remain well below pre-COVID-19 levels.
- Cultural events and recreation activities slowly resume from September 2020 to February 2021.

Results

In the high case, COVID-19's negative impact is assumed to be both weaker and shorter compared to the baseline case, with Vancouver's economy expected to make a full recovery by the end of the short-term (2020-2022). Unlike in the baseline case, social distancing measures are not as strict and allow the economy to recover more quickly. Most sectors of the economy are expected to return to normal by early 2021.

After contracting by a moderate 3.0 per cent in 2020, total real GDP is anticipated to post a strong recovery and expand by 6.5 per cent in 2021. At the same time, Vancouver's labour market is expected to contract by a similar 3.2 per cent—the equivalent of 47,800 jobs. The worst performances in 2020 are expected in the arts, entertainment, and recreation, the finance, insurance, and real estate, and the accommodation and food services industries with job losses of 11,300, 8,500, and 7,200, respectively, as people choose to limit their activities outside the home. Fortunately, employment is anticipated to bounce back and exceed 2019 levels by the end of 2021. While employment in some industries will still fall short of their 2019 levels next year, total employment is expected to rise by 4.9 per cent, or 70,000 jobs. In 2022, Vancouver's economy is expected to create a further 11,500 jobs as the region continues to move past the COVID-19 shock.

At the same time, population and housing growth will only face minor disruptions due to COVID-19. Population growth is expected to slow from 1.5 per cent in 2019 to 1.1 per cent in 2020 as a result of a significant drop in international in-migration due to international border closures. As international travel returns to normal after August 2020, the pace of population growth is anticipated to accelerate to 1.2 per cent in 2021 and 1.3 per cent in 2022. These gains will support healthy demand for new home construction. Although housing starts will fall from a record-high of 28,100 units last year to 21,000 units this year, they are expected to rebound to 24,100 units in 2021 before easing to 20,800 units in 2022. This level of residential construction will push Vancouver's housing stock to expand at an average annual pace of 2.3 per cent between 2020 and 2022.

By 2023, Vancouver is expected to recover fully from the COVID-19 shock. Therefore, the economy is anticipated to operate at capacity over the medium term (2023-2029) and is set to grow at its long-run trend rate of growth by 2025. Real GDP is projected to advance at an average annual pace of 2.0 per cent between 2023 and 2029, while employment is expected to grow an average annual pace of 1.2 per cent—the equivalent of 18,300 jobs annually. At the same time, Vancouver's healthy economic performance will attract more people to the region, driving average annual population growth of 1.3 per cent over the same period. These gains will support average housing starts of 18,200 units annually and average annual housing stock growth of 1.6 per cent between 2023 and 2029.

In the long term (2030-2040), Vancouver's economy in the high case will grow at the same pace as in the baseline case. Real output is expected to grow at an average annual pace of 2.0 per cent over the period, while employment is anticipated to advance at an average annual pace of 1.0 per cent, or 17,100 jobs annually. Meanwhile, population growth is expected to average 1.0 per cent annually. This steady influx of people will support average annual new home construction of 14,300 units and an average annual increase in the region's housing stock of 1.2 per cent between 2030 and 2040.

Please see Table 2 below for a more detailed look at the forecast results for the high case.

Sources: The Conference Board of Canada; Statistics Canada.

Scenario 3: Low Case

Assumptions

- Social distancing measures will be relaxed only gradually until COVID-19 is no longer a domestic public health threat (i.e., until a treatment or vaccine is found).
- There is no second economy-wide shutdown. Regional or local shutdowns are still possible; but, nationally, restrictions are steadily relaxed. Food services could see much slower growth as people decide not to go to bars and restaurants to avoid possible exposure to COVID-19.
- Global demand for resources and manufactured goods will remain weak as the Canadian and other economies do not operate at 100 per cent until an effective vaccine or treatment is available.
- Vaccine or treatment for COVID-19 virus is found and available, widespread globally by Summer 2022. (June 2021 in the baseline case).
- Adoption of telework and distance education is permanent for 25 per cent of the population, which has implications for commuter transportation, demand for automobiles, and gasoline, as well as for non-residential construction. (5 to 10 per cent of workforce in the baseline case).
- Operating costs increase sharply for many businesses, so the federal wage subsidy is extended until Summer 2022 (i.e., until a vaccine available).
- Cost driven inflation starts to emerge despite excess capacity. However, this one-time transitory increase in prices does not sway the Bank of Canada to increase interest rates.
- The economic shock resulting from the COVID-19 pandemic in the spring of 2020 has a long-term negative impact on consumer and business confidence, resulting in weak business investment and consumer spending through the rest of 2020 and 2021, both globally and domestically.
- Global and Canadian consumers are delaying the purchases of durable goods and other large investments, such as home, cars, furniture, and renovation spending.
- Depressed demand from both businesses and consumers results in significantly weaker demand for Canadian goods from the U.S. and China through the rest of 2020 through to the end of 2023.
- Weaker economic prospects combined with restrictions on international travel constrain international migration and thus slow population growth, impacting housing starts between 2020 and 2024.
- Domestically, we see a significant contraction in home prices (15 to 25 per cent) and housing starts over the next two years, impacting residential construction activity through the end of 2022.
- In addition to a permanent shift towards online shopping, depressed consumer spending will weigh further on the retail trade sector. As a result, retail employment will not return to 2019 levels within the five-year forecast (2020 to 2024).
- International tourism will gradually recover but will not go back to 2019 levels within the five-year forecast period (2020 to 2024).

- The employment recovery is much more subdued. Global and Canadian businesses are reluctant to re-hire all the staff let go during the height of the crisis. Total employment does not return to its 2019 level by the end of 2024.
- Vancouver's key economic series do not return to their long-run levels until 2035.

Results

In the low case, Vancouver's economy is projected to recover from the COVID-19 pandemic at a much slower pace compared to the baseline case. While the end of social distancing measures following the availability of an effective COVID-19 vaccine or treatment in summer of 2022 will help the economy recover, the pandemic's impact on consumer and business confidence, both domestically and internationally, will lead to a deeper and more prolonged recession. As a result, nearly every sector of Vancouver's economy will remain below pre-pandemic levels in the short term (2020-2022).

Following the economy-wide shutdown in in the spring, most of Vancouver's industries are expected to post little to no recovery over the rest of 2020 due to the persistence of COVID-19, weak international and domestic demand for goods and services, and a lack of confidence in the global economy. As a result, real GDP is expected to contract by 6.6 per cent overall in 2020. While output is expected to rebound and advance by 2.5 per cent in 2021 and 4.1 per cent in 2022, total GDP will still fall short of 2019 levels by the end of 2022.

Vancouver's labour market is expected to follow an even weaker recovery path. After falling by 9.6 per cent—the equivalent of 141,800 jobs—in 2020, employment is expected to contract by a further 1.2 per cent, or 16,200 jobs, in 2021, as businesses are reluctant to re-hire staff due to weak confidence in the economy. The accommodation and food services industry will suffer the greatest losses, shedding more than 30,000 jobs in 2020 and a further 10,000 jobs in 2021 due to depressed international visitor numbers and low domestic demand for dine-in restaurant meals. At the same time, weak business investment and a 15 to 25 per cent contraction in home prices will contribute to a loss of 18,400 jobs in the finance, insurance, and real estate industry in 2020. Finally, the retail trade industry will shed 15,600 jobs in 2020 in the face of low consumer spending, particularly on expensive durable goods. Although employment in every industry is expected to increase in 2022, the region's economy is only expected to reclaim 53,500 of the jobs lost over 2020-2021, leaving the labour market 104,500 short of 2019 levels by the end of 2022.

Vancouver's weak economic prospects will also impact the region's pace of population growth and residential construction over the short term. Slower international migration due to global travel restrictions will cool population growth from 1.5 per cent in 2019 to 1.0 per cent in 2020 before easing further to average an annual pace of 0.8 per cent between 2021 and 2022. This, along with weak consumer confidence and a significant contraction in home prices, will lead to much slower residential construction activity. After hitting a record high of 28,100 units in 2019, total housing starts are expected to drop to 19,300 in 2020 before cooling further to 17,300 units in 2021 and 16,000 units in 2022. In line with this slower pace of new home construction, housing stock growth is expected to ease from 2.3 per cent in 2019 to average 1.8 per cent annually between 2020 and 2022.

Despite the availability of an effective COVID-19 vaccine by the summer of 2022, Vancouver's economic recovery over the medium term (2023-2029) will be slow and subdued due to persistently weak consumer and business confidence at home and abroad. Real GDP is expected to advance at an average annual pace of 2.7 per cent between 2023 and 2029, with total output surpassing 2019 levels by the end of 2023. Meanwhile, employment is anticipated to grow by an average of 2.2 per cent annually—the equivalent of 32,400 jobs per year—over the same period. With businesses facing uncertainty around global and domestic demand, they are expected to rehire staff let go during the pandemic at a gradual pace. As a result, total employment is only anticipated to surpass 2019 levels by the end of 2025. At the same time, Vancouver's gradually improving economic prospects, along with the easing of international travel restrictions, will help population growth accelerate to an average annual pace of 1.3 per cent between 2023 and 2029 from 0.9 per cent over 2020-2022. Despite these gains, housing starts will only average 16,500 units annually over the medium term due to weak home prices, subdued international in-migration, and slowly recovering consumer confidence. This level of new home construction will drive average annual housing stock growth of 1.6 per cent between 2022 and 2029, though total housing stock will be lower compared to the baseline case.

Vancouver's recovery will continue over the long term (2030-2040), with the economy set to grow at its long-run trend rate of growth by 2035. Real GDP is expected to grow at an average annual pace of 2.1 per cent between 2030 and 2040, with output growing at a faster pace in the first half of the decade as the economy gradually operates closer to capacity. At the same time, employment is anticipated to expand at an average annual rate of 1.2 per cent, or 20,700 jobs annually. In line with the region's stronger job prospects, population is expected to grow at an average annual pace of 1.1 per cent. This steady influx of people into Vancouver will help support annual average new residential construction of 14,200 units and, in turn, increase the total housing stock at an average annual pace of 1.3 per cent between 2030 and 2040.

Please see Table 3 below for a more detailed look at the forecast results for the low case.

Navius Research Inc. (“Navius”) is a private consulting firm in Vancouver. Our consultants specialize in analysing government and corporate policies designed to meet environmental goals, with a focus on energy and greenhouse gas emission policy. They have been active in the energy and climate change field since 2004 and are recognized among Canada’s leading experts in modeling the environmental and economic impacts of energy and climate policy initiatives. Navius is uniquely qualified to provide insightful and relevant analysis in this field because:

- We have a broad understanding of energy and environmental issues both within and outside of Canada.
- We use unique in-house models of the energy-economy system as principal analysis tools
- We have a strong network of experts in related fields with whom we work to produce detailed and integrated climate and energy analyses.
- We have gained national and international credibility for producing sound, unbiased analyses for clients from every sector, including all levels of government, industry, labour, the non-profit sector, and academia.

We are proud to have worked with the following clients:

- **Provincial, territorial and municipal governments:** Alberta, British Columbia, New Brunswick, Newfoundland and Labrador, Northwest Territories, Nova Scotia, Ontario, Vancouver
- **Federal government:** Environment and Climate Change Canada, Natural Resources Canada, National Roundtable on the Environment and the Economy
- **Utilities and the energy sector:** Advanced Biofuels Canada, BC Hydro, Canadian Association of Petroleum Producers, Canadian Gas Association, Kinder Morgan Canada, National Energy Board, Ontario Energy Board, Powerex Corp, Power Workers' Union, Spectra Energy, Western Canada Biodiesel Association
- **Non-profit and research:** Carbon Management Canada, Clean Energy Canada, Climate Action Network Canada, David Suzuki Foundation, Ecofiscal Commission, Electric Power Research Institute, Équiterre, Environmental Defense Fund, Pembina Institute, Pacific Institute for Climate Solutions

Executive Summary

Introduction

The greenhouse gas (GHG) reduction policies implemented by the government of British Columbia and the Government of Canada will change the quantity and type of energy consumed in British Columbia (BC) in the future. Specifically, GHG reduction policy may result in significant electrification of some energy end-uses, allowing the substitution of fossil fuels with renewable energy (e.g. wind, hydro, solar power), delivered via the electricity system. Electricity consumption may increase for end-uses where that fuel is not currently widely used, such as transportation, or where there is significant share of other fuel fuels consumed, such as building space and water heating.

This potential change in electricity consumption is of interest to BC Hydro. Understanding the drivers of energy consumption will help with the utility's electricity system planning. The extent of electrification is largely a function of electric technology capital and energy costs compared with the cost of the conventional and alternative fuels that may compete or complement the use of electricity in a low-GHG future.

The goal of this project is to analyse the uncertainty in future electricity demand created by current and potential energy and GHG policies as well as the cost and performance of emerging energy technologies whose adoption will be incentivized by these policies. In doing so, this analysis will provide reasonable bookends for future electricity consumption in BC, while explaining the drivers of this consumption (e.g. technology market shares, fuel shares by sector, use of alternatives e.g. biofuels).

Methodology

In this analysis, we used a technologically detailed, full-economic equilibrium, energy economy model to simulate how different GHG policy portfolios will affect electricity consumption in BC from the present to 2040.

We tested the impact of:

- **"Current policies", that are legislated or have firm announcements.** These include the BC carbon tax, rising to \$50/tCO_2e by 2022 and other policies that generally date from the fist BC Climate Action Plan, released in 2008. This scenario also includes the announced light-duty (passenger) vehicle zero-emissions vehicle (ZEV) standard that requires a minimum fraction of sales be ZEVs and is trending towards a phase-out of conventional vehicles by 2040.

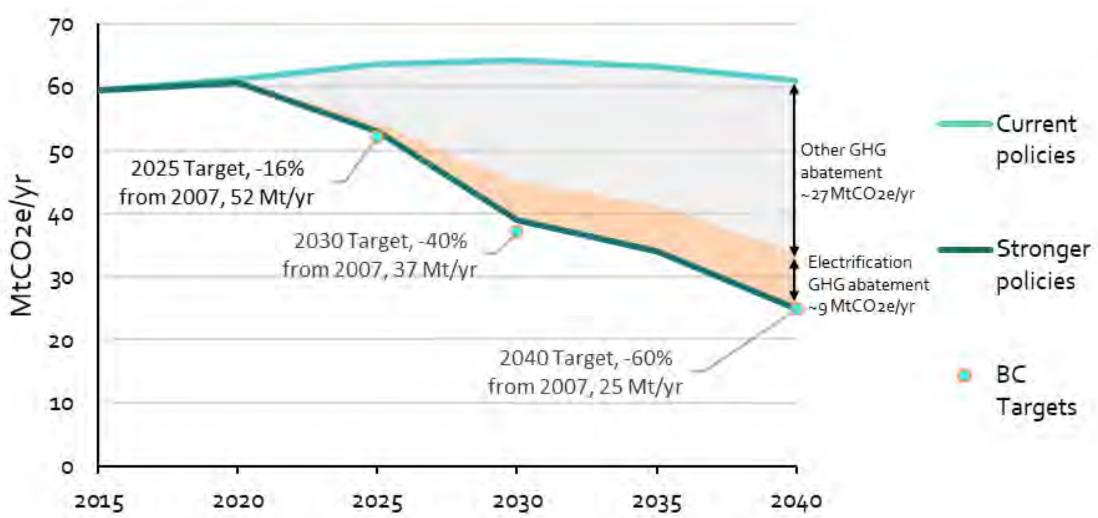
- **"Stronger policies", which include a range of stronger incentives and regulatory policies, plus an emissions cap that achieves BC's 2025, 2030 and 2040 GHG reduction targets**. These are a 16% reduction from 2007 emissions by 2025, a 40% reduction by 2030 and 60% reduction by 2040.

Using the stronger policy scenario as a reference, we also tested how the forecast of electricity demand is affected by a range of different technology costs assumptions, notably the cost of all classes of on-road battery electric vehicles. An additional sensitivity analysis looks at the impact of less stringent building regulations after 2030 (i.e. no requirement to retrofit building envelopes and no requirement for zero-GHG heating systems).

Results and Conclusions

The implementation of stronger policies substantially reduces British Columbia's total GHG emissions from the present and relative to a scenario with current policies. Electrification is an important GHG abatement action. With currently legislated policies, provincial GHG emissions are able the offset the growth of the population and the economy to keep GHG emissions roughly constant to 2040. By design, the stronger policy scenario hits the legislated GHG targets in 2025, 2030 and 2040 (Summary Figure 1). By 2040, electrification accounts for 25% of GHG abatement relative to the current policy scenario (about 9 of 36 $MtCO_2e$).

Summary Figure 1: BC GHG emissions by scenario and breakdown of GHG abatement



Of the dynamics tested, **BC's long-term electricity demand is most sensitive to the strength of climate policy**. In 2025, the difference in electricity demand between current policies and stronger policies is relatively small, just 1 TWh/yr more if BC achieves its GHG target. This difference grows to 10 TWh/yr in 2030 (+17%) and 12 TWh/yr in 2040 (+18%, with total electricity demand at 83 TWh/yr). (Summary Table 1).

Summary Table 1: BC electricity demand by scenario (TWh/yr)

	2015	2020	2025	2030	2035	2040
Current policies	51.4	53.5	56.9	61.3	65.5	70.7
Stronger policies	51.4	53.5	57.9	71.3	75.8	82.9

Most of this incremental growth in electricity demand comes from the natural gas sector and from buildings. In 2040, 45% of the incremental demand comes the electrification of compressors used for natural gas production and transportation. Another 38% of the incremental demand comes the electrification of space and water heating in buildings. 18% of incremental demand comes from transportation. Electricity demand for transportation must grow significantly in order to achieve deep GHG reductions in BC. However, much of this load growth is already included in the current policy forecast since it includes the light-duty vehicle ZEV standard.

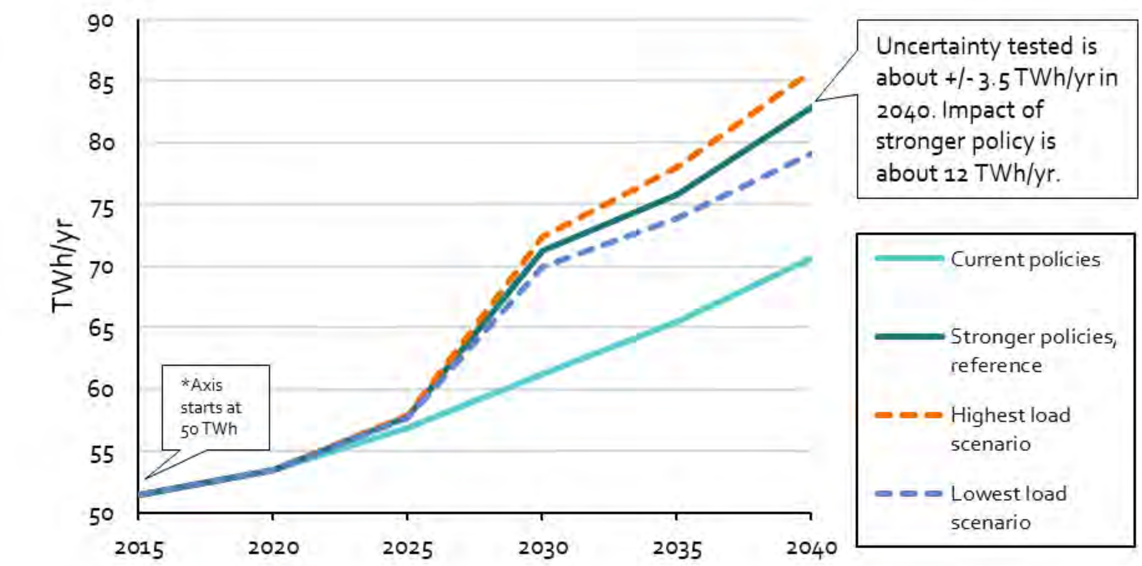
In contrast to the impact of GHG policy, **the other uncertainties tested in this analysis only shift total electricity demand in 2040 by a few TWh/yr relative to the reference forecast with stronger policies** (Summary Figure 2):

- **The future cost of plug-in electric vehicles (PEVS) is the largest uncertainty, but a wide range of assumptions only shifts electricity demand by around +/- 3.5 TWh/yr in 2040.** Two thirds of this range comes from greater or lesser adoption of light-duty PEVs after 2030, when low-cost PEVs combined with a strong carbon price drives sales beyond what the ZEV standard requires. The remaining third of this range comes from medium and heavy-duty PEVs. Even when assuming lower costs, PEVs are still a minority of these vehicle classes, used for at most 33% of medium-duty and 16% of heavy-duty travel in 2040. Given the additional potential to electrify these larger vehicles, the adoption of medium and heavy-duty PEVs could be significantly more important after 2040 and we recommend ongoing study of their electrification.
- **The cost and availability of direct air capture (DAC) and storage of CO_2 is a smaller uncertainty in these results.** DAC is a direct consumer of electricity, but it also changes the need for electrification in other sectors and reduces the strength of

policy required to achieve BC's targets, which may indirectly result in greater economic activity and electricity demand. Because these dynamics largely offset each other, DAC appears to have a limited impact on future electricity demand. However, this uncertainty could be larger: DAC could be deployed in an all-electric configuration (i.e. higher electricity demand in BC), or BC could fund DAC that occurs in another jurisdiction (i.e. lower electricity demand in BC) if these credits could be used as an offset to provincial GHG emissions.

- **Electricity demand through to 2040 is not sensitive to the production cost of 2nd generation biofuels or to more stringent building regulations.** A longer-term analysis, to 2050 for example, might find that these uncertainties become more important.

Summary Figure 2: British Columbia electricity demand in the stronger policy scenario with high/low range (note that the vertical axis starts at 50 TWh)



Note that **this analysis did not assess the impact of uncertainty in future natural gas production on electricity demand.** Including this dynamic would introduce more uncertainty into the electricity demand forecast. Based on the quantity of electricity used by the natural gas sector, this uncertainty could be at least as important to future electricity demand as is the uncertainty in PEV costs.

In summary, **this analysis shows that achieving BC's GHG reduction targets will result in substantially more electricity demand than would occur with current policies.** The results do not show a future where other potential low-GHG energy pathways out-compete electricity. Rather, these pathways, including bioenergy, energy efficiency and some use of hydrogen fuel cell vehicles, are complementary and all contribute to deep GHG reductions.

Table of Contents

1. Introduction

The greenhouse gas (GHG) reduction policies implemented by the government of British Columbia and the Government of Canada will change the quantity and type of energy consumed in British Columbia (BC) in the future. Specifically, GHG reduction policy may result in significant electrification of some energy end-uses, allowing the substitution of fossil fuels with renewable energy (e.g. wind, hydro, solar power), delivered via the electricity system. Electricity consumption may increase for end-uses where that fuel is not currently widely used, such as transportation, or where there is significant share of other fuel fuels consumed, such as building space- and water-heating.

This potential change in electricity consumption is of interest to BC Hydro. Understanding the drivers of energy consumption will help with the utility's electricity system planning. The extent of electrification is largely a function of electric technology capital and energy costs compared with the cost of the conventional and alternative fuels that may compete or complement the use of electricity in a low-GHG future. A further uncertainty is the design of the policy portfolios that will drive a reduction in GHG and emissions and may directly or indirectly require the use of low-carbon electricity.

The goal of this project is to analyse the uncertainty in future electricity demand created by current and potential energy and GHG policies as well as the cost and performance of emerging energy technologies whose adoption will be incentivized by these policies. In doing so, this analysis will provide reasonable bookends for future electricity consumption in BC, while explaining the drivers of this consumption (e.g. technology market shares, fuel shares by sector, use of alternatives e.g. biofuels).

While this is a forecast of electricity consumption in BC, it is independent of the BC Hydro load forecast. Nonetheless, within this analysis, the forecast of electricity consumption in the absence of new GHG policies has been approximately aligned with BC Hydro's 2020 December Reference load forecast to facilitate a comparison between the two. Similarly, while this is an analysis of how provincial GHG reduction policies will affect energy consumption and GHG emissions in the province, it is independent of the work the BC government has done in this regard. For example, this analysis uses a generic emission cap to achieve the provincial GHG targets in 2025, 2030, and 2040.

This report begins by describing the methodology, first with an overview of the energy-economy model used to produce the quantitative forecasts used in this analysis, which runs from the present to 2040. The methodology section then goes on to explain the scenarios we tested with that model. The scenarios include a forecast of provincial energy consumption and GHG emissions under the influence of currently legislated GHG reduction policies which is compared against a scenario with stronger GHG reduction policies that will achieve BC's legislated emissions targets for 2025, 2030 and 2040. Variations of this policy scenario are compared against each other to understand how future electricity consumption is affected by the use of technology neutral versus prescriptive policies, lower-cost electric vehicles, and higher cost biofuels. After the methodology section, we present and explain the scenarios results. This is followed by summary discussion of the key results and conclusions stemming form this analysis. The appendices include the detailed technology and fuel research conducted for this analysis and greater detail on the archetypal building energy technologies (e.g. building envelopes, mechanical systems etc.).

2. Methodology

This section first qualitatively describes gTech, the energy-economy model used for this analysis. This is followed by a description of the fundamental inputs to gTech as well as key indicators that describe the future forecasted by gTech. The methodology also includes an overview of the scenario design for this analysis as well as the specific GHG policy scenarios and uncertain parameters that are tested in these scenarios.

2.1. Introduction to the gTech model

The gTech model is designed to simulate the impacts of policy on both technological adoption and the broader economy. It simultaneously combines an explicit representation of technologies (everything from vehicles to fridges to natural gas extraction technologies) with key economic transactions within an economy, allowing it to provide insight about policy impacts on broader economic indicators such as GDP, industrial competitiveness and household welfare. This framework differs from most other models, which either exclude explicit technologies or are not intended to simulate full economic impacts.

Some of gTech's key features are highlighted below:

- **Over 50 unique energy end-uses and 200 unique technologies available to meet the end-use demand in all sectors of the economy.** For example, the model accounts for (1) the electricity consumption and hot water demand for different archetypes of clothes washers, (2) how changing the stock of clothes washers influences the demand for hot water and (3) the energy consumption of hot water heaters.
- **An explicit simulation of technology choice and capital stock turnover.** Each technology/end-use has a unique lifespan. The existing stock of technologies gradually retires over time, leaving a gap between the demand for end-use services and the supply from existing technologies. This gap is filled with new stock. New stock is determined using a technology choice algorithm that allocates market share to new technologies based on (1) capital costs, (2) energy costs, (3) discount rates, (4) an elasticity that accounts for heterogeneous decision-making among consumers and (5) non-financial factors that influence technology choice.
- **Technology choice in gTech is behaviourally realistic as opposed to prescriptive.** gTech seeks to be "descriptive", meaning that it tries to forecast how households and firms will respond to energy/climate policy or to changes in economic

conditions (e.g., change in the price for natural gas). Models that are “prescriptive” seek to tell the user the best path towards achieving a specific objective, with a typical objective being to minimize financial costs. While prescriptive models serve a purpose, they are not forecasting tools. The reason is that households and firms do not use financial costs as their only criteria for selecting technologies; rather, they use a myriad of criteria of which financial costs are just one consideration.

- **gTech has comprehensive coverage of energy consumption and energy-related GHG emissions in British Columbia.** The model aligns with Statistics Canada energy use data and the British Columbian provincial by economic sector and inventory category.

- **gTech is simultaneously a full economic model, in addition to a bottom-up technology model.** gTech is classified as a “computable general equilibrium” or CGE model. In a nutshell, gTech simulates:

  - **70 sectors of the economy.**

  - **10 regions.** The version of the model used for this project explicitly simulates the economies of British Columbia, Alberta, Saskatchewan, Manitoba, Ontario, Québec, New Brunswick, Nova Scotia, and the “rest of Canada” (i.e., Newfoundland, PEI and the territories) and the United States.

  - **The markets for commodities, factors and policy mechanisms in every region of the model.** gTech ensures that ALL markets simulated within the model arrive at an equilibrium. Equilibrium is defined as supply being equal to demand. gTech ensures equilibrium in all the following markets:

    - Over 78 commodity and service markets. These commodity and service markets include everything from energy products (e.g., oil, refined petroleum products, petroleum coke, electricity); resource commodities (e.g., wheat, soy, corn); manufactured goods (e.g., petrochemicals, cement); and services (e.g., trucking transport, wholesaling/retailing margins, other services).

    - Factors markets, including four different classes of labor based on productivity and capital goods.

    - Policy compliance mechanisms. Some policies generate a market for compliance mechanisms (e.g., allowances under a cap-and-trade program or credits under a low-carbon fuel standard). Under these policies, the allowances distributed, auctioned or purchased must equal the allowances required by the entities participating in the market. In gTech, the price for these policy compliance mechanisms adjusts to achieve equilibrium in these policy markets.

- gTech can simulate how:
  - **Policies affect the economy.** gTech reports economic impacts on both expenditure- and income-based GDP. The former reflects impacts on consumption, investment, government expenditures and exports and imports, while the latter reports impacts on GDP produced by each of the 70 sectors in the model.
  - **Policies affect industrial competitiveness.** As an economic model, gTech explicitly simulates how policies affect industrial competitiveness. For example, if the cost of products and services increases in Nova Scotia but not in other jurisdictions, demand for Nova Scotia's products and services will fall.
  - **Policies in jurisdictions outside of BC affect the province.** Policies implemented outside of BC may have an impact on the province (e.g. the federal vehicle emissions standards or carbon pricing).
- **gTech contains an electricity supply cost curve that has been calibrated to information provided by BC Hydro:** This cost curve shows an increasing average production cost (in real terms) for electricity as demand grow relative to current levels. There are limitations on the functional forms that can be used in gTech, so the cost curve does not replicate the information provided by BC Hydro exactly for large changes in electricity demand, for example a doubling of current demand. In this case, model is conservative in showing somewhat higher electricity costs and prices.

2.2. Fundamental drivers and reference scenario indicators

Fundamental inputs to gTech include forecasts of economic activity, oil and gas commodity prices, and specific assumptions for activity in the liquefied natural gas (LNG) sector (Table 1).

GDP growth in BC is based on the Parliamentary Budget Office's Fiscal Sustainability Report[1]. This long-term forecast average about 1.5% after 2020 and does not explicitly account for any ongoing impact of COVID-19 on the economy. Population growth can

[1] Parliamentary Budget Office, 2020 Fiscal Sustainability Report. Available from: https://www.pbo-dpb.gc.ca/en/blog/news/RP-1920-029-S-fiscal-sustainability-report-2020-rapport-viabilite-financiere-2020

be approximated by the labour growth contained within the GDP assumption which averages about 0.7%/yr over the forecast (Table 1).

The price of crude oil is based on the reference projection by the Canada Energy Regulator (CER)[2] with a long-term price of 70 USD/bbl (Table 1). Like GDP, this long-term forecast is not explicitly accounting for the impact of COVID-19. The price of natural gas is based on the same source, remaining low during the forecast, rising to just over 3 USD/mmbtu after 2030 (Table 1). This price is calibrated to the CER reference forecast by adjusting production costs assumption in the model rather than being a direct input.

Table 2 shows some key indicators that describe the future forecasted by gTech, including activity in the upstream natural gas sector, building floor area, housing starts and retail spending. These are modelled results that come from forecasting a continuation of current GHG reduction policies. The LNG production assumption is based on the 2020 reference load forecast.

Table 1: Fundamental drivers

	Unit	2015	2020	2025	2030	2035	2040
GDP growth	%/yr	n/a	2.42%	1.49%	1.40%	1.48%	1.55%
Labour growth	%/yr	n/a	1.30%	0.38%	0.52%	0.67%	0.77%
Natural gas price (Henry Hub)	2020 USD/mmbtu	2.4	2.1	2.5	3.0	3.2	3.4
Oil Price (WTI)	2020 USD/bbl	51	64	67	70	70	70

Table 2: Scenario indicators

	Unit	2015	2020	2025	2030	2035	2040
Natural gas production	bcf/day	4.1	5.4	7.9	9.1	9.3	9.3
Commercial and institutional floor area	Million m^2	102	119	127	137	149	161
Residential floor area	Million m^2	281	321	335	350	358	379
Housing starts*	New units/yr	33,683	40,918	21,149	21,759	18,252	29,742
Retail spending*	Billion 2020 CAD/yr	74	86	90	97	103	111

* Housing starts and retail spending are based on historic values indexed to growth in new residential floor area and activity in the wholesale and retail sector in gTech, respectively. The 2015 housing starts value is an average of 2013 to 2017.

[2] Canada Energy Regulator (2020). Canada's Energy Future 2020: Energy Supply and Demand Projections to 2050. Available from: www.cer-rec.gc.ca/en/data-analysis/canada-energy-future/2020/index.html

2.3. Scenario design and summary

This section explains the scenarios we tested in this analysis. These included several different policy scenarios based on current policies and stronger policies that can achieve BC's legislated GHG emission targets. Additional sensitivity scenarios explore the impact of varying technology assumptions that may lead to more or less electricity consumption in BC in a low-GHG future.

To test the impact of GHG reduction policies on electrification, we used three policy scenarios, summarized in Figure 1. The first is a representation of current legislated policies as well as firm policy announcements that are very likely to be implemented and are included in BC Hydro's load forecast (i.e. "current policies"). Of note, this scenario includes:

- A zero-emissions vehicle (ZEV) standard that requires sales of non-emitting light-duty vehicles (e.g. plug-in electric vehicles, PEVs, and fuel-cell electric vehicles). This policy is modelled directly from the legislation, where there is an annual requirement for ZEV sales credits each year and each ZEV sale produces credits as a function of its range.[3] While this policy could require 100% ZEV sales by 2040, the sale of longer range ZEVs generate more credits and could allow conventional car sales to continue to this date.

The second scenario include several incentive and regulatory policies paired with a hypothetical emissions cap that requires BC to achieve its s legislated GHG emissions targets: a 16% reduction in emissions from 2007 by 2025 (52 $MtCO_2$), a40% reduction by 2030 (37 $MtCO_2e$) and a 60% reduction by 2040 (25 $MtCO_2e$). Note that the 2030 target includes the assumption that 2 $MtCO_2e$ of forestry offsets will be available in that year so the actual emissions in the results will be 39 $MtCO_2e$. This is a somewhat ad hoc assumption that helps the model solve in 2030, though it is based on ideas

[3] Government of British Columbia (2020). ZERO-EMISSION VEHICLES REGULATION. www.bclaws.gov.bc.ca/civix/document/id/oic/oic_cur/0448_2020

expressed in the government's Forest Carbon Initiative[4] and analyses by Smyth et al. (2020)[5]. The incentives and regulatory policies include:

- A strengthening of the Renewable and Low-Carbon Fuel Requirement
- A ZEV standard that with some additional requirements for medium and heavy-duty vehicles
- A renewable natural gas (RNG) standard requiring a minimum blend of renewable fuel in the natural gas stream
- Incentives for the efficient electrification of buildings (e.g. with heatpumps)
- Requirement for building envelope energy retrofits from after 2030
- A zero-emissions building requirement, which affects new heating system installations after 2035

The final policy scenario is identical to the stronger policy scenario, except that excludes the additional building regulations (post-2030 retrofits and zero-GHG requirement).

Both stronger policy scenarios include more stringent GHG reduction policies in the rest of North America, added to mitigate "carbon leakage" where BC industrial activity declines and moves to other jurisdictions. Consequently, we assumed that in the stronger policy scenarios, GHG reduction policies outside of BC will be of a similar stringency to policies in BC. Specifically, the precent GHG reduction targets applied to BC were also applied to the rest of Canada and the United States for 2030 onwards.

The sensitivity analyses explore scenarios seven additional scenarios where different assumptions for technology cost, performance and availability might change future electricity demand (summarized in Figure 1):

- Lower and higher plug-in electric (PEV) vehicle costs, across all classes of vehicles
- Lower and higher 2nd generation bioenergy costs (for drop-in liquid and gaseous fuels made from woody or grassy feedstock)

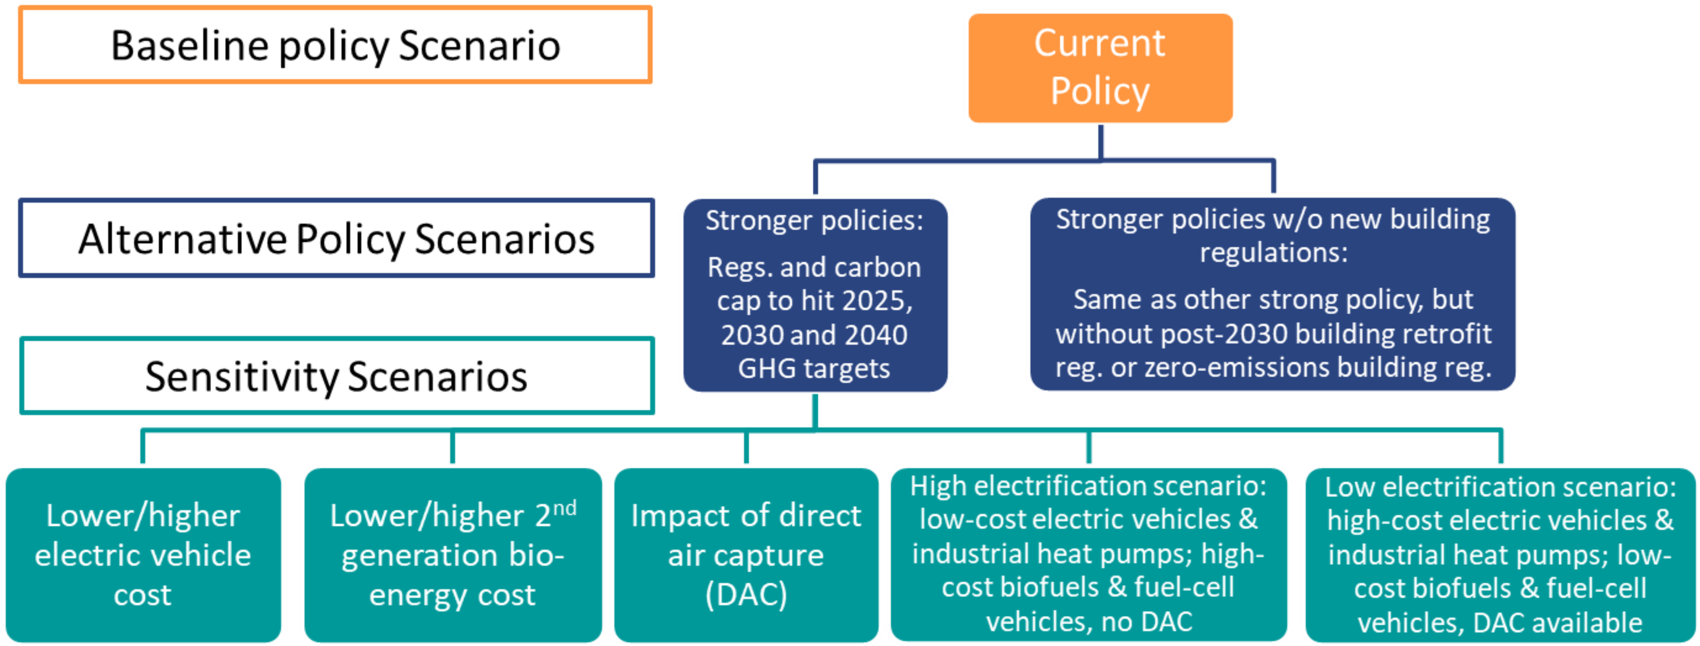
[5] Smyth, C.E.; Xu, Z.; Lemprière, T.C.; Kurz, W.A. (2020). Climate change mitigation in British Columbia's forest sector: GHG reductions, costs, and environmental impacts. Carbon Balance and Management, 15, 21. https://doi.org/10.1186/s13021-020-00155-2

- The availability of direct air capture (DAC) as a GHG abatement opportunity
- The combined impact of assumptions that are expected to lead to higher electrification: lower PEV costs and lower industrial heat pump costs, higher bioenergy costs and higher fuel-cell vehicle costs, no use of DAC.
- The combined impact of assumptions that are expected to lead to lower electrification: higher PEV costs and higher industrial heat pump costs, lower bioenergy costs and lower fuel-cell vehicle costs, DAC is used to reduce GHG emission.

Specific policy details by scenario are described in the next section (2.4). Specific sensitivity analysis assumptions are described in section 2.5.

Figure 1: Scenario Design Summary



2.4. Policy scenario inputs

Table 3 contains the detailed policy assumptions for each of the policy scenarios modelled in this analysis. Cells highlighted in green contain policy assumptions that are different from the previous column (i.e. the scenario to the left in the table).

Table 3: Detailed policy assumptions by scenario

Policy	1. Current policies - (no new policies except firm announcements)	2. Stronger policy scenario	3. Stronger policy scenario w. less building regulations
Carbon tax, price, or cap	\$50/tCO2e carbon tax (nominal) by 2022, with revenue recycled to cut labour taxes, provided as lump sum to households, and used to subsidize low-GHG industry	The same carbon tax as in the current policy scenario until 2030 with the use of GHG emission caps aligned with provincial GHG targets: -15% from 2007 in 2025; -40% in 2030, 37 Mt/CO2e ; -60% from 2007 in 2040, 25 Mt/CO2e	Same as 2
Clean Energy Act	98% renewable and zero-GHG electricity generation in 2030, 100% in 2040	Same as 1	Same as 1
Methane fugitive emission regulations	-	Oil and gas: ~45% reduction in fugitives for new equipment starting in 2020, with all equipment covered by 2025	Same as 2
Formation CO_2 carbon capture and storage	-	Capture and storage required for CO_2 removed from natural gas stream during processing	Same as 2
Renewable natural gas	-	15% by 2030	Same as 2
Landfill gas reductions	Organics diversion and landfill gas control: landfills reduce emissions by 35% by 2020, 30% of organic waste is diverted from landfills by 2025	75% of methane gas is captured from large landfills, 95% of organic waste is diverted from landfills by 2025	Same as 2

Policy	1. Current policies - (no new policies except firm announcements)	2. Stronger policy scenario	3. Stronger policy scenario w. less building regulations
Clean vehicle incentives	Existing Clean Energy Vehicles subsidy, ending in 2020	An additional $14 million per year until 2030 to incentivize the purchase of battery electric and plug-in hybrid vehicles. An additional $3.3 million per year until 2030 for zero emissions heavy-duty vehicles	Same as 2
Renewable and low-carbon fuel requirement	-10% GHG intensity by 2020	-20% GHG intensity by 2030, *not including electrification after 2021.*	Same as 2
Light-duty vehicle emission standards	119 gCO_2e/km fleet average for new sales by 2025 (approximately -40% relative to 2015)	105 gCO_2e/km by 2030, for which electric vehicles do not count as part of compliance	Same as 2
Light-duty zero-emissions vehicle (ZEV) mandate	Approximately 30% sales in 2030, and approaching 100% by 2040. Actual sales depend on the range of ZEVs that are sold (longer range allow less ZEV sales)	Same as 1	Same as 1
Heavy-duty vehicle emission standards	-10% reduction in of the GHG intensity for new vehicles from 2018 onward, relative to the 2015 model year vehicles	-24% in tailpipe CO_2 emissions for 2030 model year vehicles relative to 2015 model year vehicles	Same as 1
Medium and Heavy-duty vehicle ZEV mandate	-	Plug-in medium and heavy-duty vehicles: 10% sales by 2030 and beyond LNG-fueled vehicles: 16% sales in 2030 (no requirement thereafter)	Same as 2
Building codes for envelopes	Step code for new buildings, requiring net-zero ready after 2031	Same as 1	Same as 1
Heat Pump Incentive		$38 million annually through to 2030, used to incentivize the purchase of heat pumps for space and water heating	Same as 2

Policy	1. Current policies - (no new policies except firm announcements)	2. Stronger policy scenario	3. Stronger policy scenario w. less building regulations
Building envelope retrofits		Starting after 2030, 1.5%/yr of pre-2010 buildings are retrofitted to reduce heat load by 15-20%	Same as 1, no retrofit requirement
Zero-emissions building policy		Heat pumps are required for new/replacement space and water heating equipment after 2035	Same as 1, no zero-emissions requirement
North American policy outlook	No new policies (except firm announcements): Includes the federal carbon pricing backstop ($50/tCO2e carbon price equivalent (nominal) by 2022).	Stronger GHG policy is modelled as an emissions cap in the rest of the Canada and the US: The cap is equivalent to BC's in 2040 (-60% from 2007), but somewhat weaker when it starts in 2030 (-25% from 2007)	Same as 2

2.5. Sensitivity scenario inputs

The sensitivity scenario inputs below are all variations on the stronger policy scenario (scenario 2 in Table 3 above). The sensitivity analyses deal with:

- Lower and high PEV costs (across all classes of vehicles)
- Lower and high 2nd generation bioenergy costs (i.e. renewable gasoline, diesel, and natural gas produced from woody or grassy feedstock)
- The availability of direct air capture and storage of CO_2 (DAC)
- A combined look at assumptions that could lead to lower and higher electricity consumption: PEV and fuel-cell electric vehicle costs, 2nd generation bioenergy costs, industrial heat pump costs and the availability of DAC.

2.5.1. Plug-in electric vehicle cost sensitivity scenarios

The vehicle battery cost sensitivity scenarios affect the capital cost of all plug-in electric vehicle (PEV) technologies including light-duty vehicles, medium-duty vehicles, heavy-duty vehicles (represented archetypically as freight trucks) and buses.

PEV battery pack manufacturing costs are estimated at about 500 $/kWh (2020 CAD), backcasted based on the UBS bank's analysis of the Chevrolet Bolt.[6] The reference assumption is that battery costs may fall to $75/kWh (Table 4), based on Bloomberg New Energy Finance's 2020 outlook.[7] The higher cost assumption for a minimum cost of $105/kWh, is based on a 2017 outlook from BNEF.[8] The low cost assumption of $75/kWh is based on assumptions from the International Council on Clean Transportation (2019).[9]

The trajectory between the starting battery cost and the lowest cost is not assumed. Instead it is a function of the learning and the economies of scale that occur when the North American market for PEVs grows (assuming global production follows a similar trend). Therefore, the time when the lowest cost is reached is a model result rather than input, though it is included in Table 4 to illustrate how assumptions are affecting the scenario results.

Table 4: Battery pack manufacturing cost assumptions (2020 CAD/kWh)

	Starting cost (2015)	Lowest cost	Lowest cost reached:
Reference	$502	$84	After 2030
Low-cost	$502	$75	After 2030
High cost	$502	$105	After 2035

Battery manufacturing costs are only one component of total vehicle capital costs which include the cost of other components (e.g. vehicle glider, electronics, engine and transmission where applicable) and wholesale and retail markups (i.e. sales margins). Like batteries, many of these costs are function of the scale of PEV deployment. Therefore, vehicle costs throughout time are actually a model result. Nonetheless, these costs are included here to illustrate the effect of PEV cost model inputs. Table 5

9 International Council on Clean Transportation. (2019). Update on electric vehicle costs in the United States through 2030.

shows the light-duty vehicle retail prices for electric vehicles as a function of the sensitivity scenario, compared with the price assumptions for a conventional vehicle. Table 6 and Table 7 show those assumptions for medium-duty and heavy-duty vehicles. The development of vehicle prices as a function of potential battery pack manufacturing costs and other component costs is explained in detail in “Appendix A: Electrification Technology Research” as are energy intensity of the technology archetypes and rational for which technology archetypes are represented in the analysis.

Although, the focus of this section in on PEV costs, the model includes a range of other vehicle drivetrain archetypes. These include conventional vehicles of varying degrees of efficiency, hybrids (light-duty, buses, and medium-duty), and fuel cell-electric vehicles (FCEVs), compressed natural gas (buses and medium-duty) and liquefied natural gas (heavy-duty).

Table 5: Light duty-vehicle archetype capital costs by drivetrain and sensitivity scenario (based on sedan-sized vehicle, excluding any charging infrastructure) (2020 CAD)

	2020	2030	2040
Conventional high efficiency vehicle	22,923	22,923	22,923
Reference costs			
Plug-in hybrid (approx.64km)	33,729	27,451	26,962
Battery Electric (approx. 320 km)	39,072	24,680	23,162
Lower cost			
Plug-in hybrid (approx.64km)	32,942	26,771	26,182
Battery Electric (approx. 320 km)	38,141	23,433	21,594
Higher cost			
Plug-in hybrid (approx.64km)	29,649	28,928	28,810
Battery Electric (approx. 320 km)	39,932	28,306	26,885

Table 6: Medium-duty-vehicle archetype capital by drivetrain and sensitivity scenario (2020 CAD)

	2020	2030	2040
Diesel truck, high efficiency	75,439	75,439	75,439
Electric truck (approx. 200 km):			
Reference costs	105,825	72,085	68,320
Lower cost	104,094	69,321	64,759
Higher cost	107,423	79,852	76,641
Additional charge infrastructure			
Reference costs	49,822	49,380	37,293
Lower cost	49,822	49,158	24,584
Higher cost	49,822	49,463	46,227

Table 7: Heavy-duty-vehicle archetype capital costs by drivetrain and sensitivity scenario (based on class 8 freight truck) (2020 CAD)

	2020	2030	2040
Diesel truck, high efficiency	185,212	185,212	185,212
Electric truck (approx. 400 km):			
Reference costs	333,781	189,661	171,827
Lower cost	330,214	179,216	157,587
Higher cost	337,072	216,627	203,930
Additional charge infrastructure			
Reference costs	283,022	274,282	203,864
Lower cost	283,022	274,312	194,411
Higher cost	283,022	274,316	204,168

2.5.2. 2nd generation bioenergy cost sensitivity scenario

The bioenergy cost and potential sensitivity scenarios affect the price of all 2nd generation biofuels represented in gTech: cellulosic ethanol, renewable gasoline, diesel and natural gas, all of which have agricultural and forestry residue as feedstocks.

Biofuel costs

Given that 2nd generation biofuel plants are pre-commercial, their capital costs in the reference biofuel cost scenario are set at roughly 1.5 times the preliminary cost estimated found in the literature. In the pessimistic scenario, the capital costs are 25% than the reference costs, while in the optimistic low-cost scenario the capital cost is 25% lower. The resulting capital costs and wholesale fuel costs (net of any distribution margins or taxes) are in Table 8. For context, the wholesale price of gasoline and diesel have generally been between $0.60/L and $0.80/L over the past decade while the wholesale price of fossil natural gas has been in the range of $3/GJ. The characterization of 2nd generation biofuels in this analysis are explained in greater detail in "Appendix A: Electrification Technology Research".

Table 8: 2nd generation biofuel plant capital costs and production costs by sensitivity scenario (2015 CAD)

	Wholesale fuel cost (not including margins and taxes, long-term 2030-2040)
Reference Assumptions	
Renewable gasoline and diesel	$1.04/L
Renewable natural gas	$18/GJ
High Cost Assumptions	
Renewable gasoline and diesel	$1.16/L
Renewable natural gas	$21/GJ
Low Cost Assumptions	
Renewable gasoline and diesel	$0.9/L
Renewable natural gas	$15/GJ

Residue for 2nd generation biofuel feedstock

The reference assumption for the maximum residue available in Canada is 34 million oven dry tonnes per year (ODt/yr) based 2010 activity in the agricultural and forestry sectors (Table 9). This quantity includes roadside forest harvest residue and the crop residue produced for corn and grain production, not already used for other purposes (roughly 25% available, with the rest primarily left it in the field for soil sustainability).

The reference assumption does not include any urban wood waste, surplus wood waste from forest products mills (i.e. not used internally for energy), or purposely grown energy crops. Further detail on this quantity is explained in "Appendix A: Electrification Technology Research". To put this quantity in context, if the feedstock were converted to renewable gasoline and diesel (18 GJ/ODt at 63% energy conversion efficiency from feedstock), they could replace 15% of 2010 Canadian gasoline and diesel consumption. As well, the model includes the U.S. which can trade in residue and biofuels with Canada. Finally, first generation biofuels are and remain available in the model, where their production is constrained by a limited pool of land and crop prices.

Table 9: 2nd generation bioenergy feedstock availability (based on 2010 activity in the forestry and agriculture sector)

	Forestry residue (million ODt/yr)	Agriculture residue (million ODt/yr)	Total (million ODt/yr)
Reference	15.7	18.2	34.0

2.5.3. DAC availability

In the scenarios where DAC is available, the cost starts at $370 per tonne of CO_{2e} removed from the atmosphere during early commercialization. The costs may decline as experience with the technology increases to a price floor of $150/t$CO_{2e}$ (2020 CAD). In practice, this forecast shows costs declining to $325/t$CO_2$ by the end of the analysis in 2040. The technology archetype represented in the model uses natural gas combustion to provide the heat required to regenerate the sorbent that captures the CO_2, where the combustion emissions are also captured and stored. The DAC process uses about 0.28 MWh/tCO_2 of electricity to move air and compress and transport CO_2 and another 4 GH of natural gas for process heat (about 0.35 MWh/tCO_2 and 5 GJ/tCO_2 avoided since some of the captured gas comes from natural gas combustion). Costs and energy intensity are based on Faishi et al. (2019)[10] and Keith et al. (2018).[11] "Appendix A:Electrification Technology Research" contains more details on this technology and how it is parameterized in this analysis.

2.5.4. Low and high electrification scenarios

The high electrification scenario includes the low-cost PEV assumptions, the high-cost bioenergy assumptions and has no DAC available. Additionally, it includes more

---

[10] Fasihi et al. (2019). Techno-economic assessment of CO_2 direct air capture plants. *Journal of Cleaner Production*. 224. doi.org/10.1016/j.jclepro.2019.03.086

[11] Keith et al. (2018). A process for capturing CO_2 from the atmosphere. *Joule*. 2, 8. doi.org/10.1016/j.joule.2018.05.006

pessimistic assumptions for hydrogen consumption (Table 10) and lower-cost assumptions for industrial heat pumps (a minor assumption; +12.5% capital cost, where the reference cost is about $1000/kW (2020 CAD), or 3 times the cost of a gas-fired boiler or heater).

In contrast, the low electrification scenario has DAC as a GHG abatement action and includes the high-cost PEV assumptions, the low-cost bioenergy assumptions and the more optimistic assumptions for hydrogen consumption (Table 10). This scenario also has higher cost assumptions for industrial heat pumps (again, a minor assumption; -12.5% capital cost relative to the reference).

Table 10: Additional hydrogen and FCEV assumptions for the low and high electrification scenarios (as well as reference assumptions for other scenarios)

Assumption	High electrification scenario assumptions	Low electrification scenario assumptions	Reference Assumptions	Source
Cost of hydrogen electric vehicles	**High cost:** Fuel cell stacks and hydrogen tank costs may decline to $125/kW and $28/kWh, respectively. Fuel cell vehicles remain substantially more costly than other vehicle types.	**Low cost:** Steeper cost declines are assumed. Fuel cell stacks and hydrogen tank costs may decline to $39/kW and $9.9/kWh, respectively Light-duty vehicle purchase price can decline to be on par with conventional and electric vehicles ***if*** the scale of production grows big enough.	**Moderate cost:** Fuel cell stack system costs may decline from $306/kW to a minimum of $74/kW ($31/kWh to a minimum of $11/kWh for fuel tanks). Light-duty vehicle purchase price still $1000's higher than conventional vehicle in the long-term. The technology is more promising for heavy-duty vehicles.	SA Consultants (2016). Final report: Hydrogen storage system cost analysis. SA Consultants (2017). Mass production cost estimation of direct H2 PEM fuel cell systems for transportation applications. IEA (2020). Breakdown of cost-reduction potential for electrochemical devices by component category.
Cost of hydrogen production	**High cost:** Capital costs are about 25% to 35% higher, zero-GHG hydrogen production costs are in the range of 10-11 $/kg.	**Low cost:** Capital costs are about 25% lower, zero-GHG hydrogen production costs are in the range of 6-9 $/kg.	**Moderate cost:** Zero-GHG hydrogen produced from biomass gasification and electrolysis costs in the range of 8-10 $/kg.	NREL (2019). H2A Hydrogen Production Analysis. IEA (2019). The Future of Hydrogen.
Hydrogen blending limit	**Low blending:** Hydrogen can be blended into the natural gas stream to 2% by volume (0.5% by energy content).	**High blending:** Hydrogen can be blended into the natural gas stream to 20% by volume (5% by energy content).	**Moderate blending:** Hydrogen can be blended into the natural gas stream to 5% by volume (1.3% by energy content)	International Energy Agency. (2019). The Future of Hydrogen Atfeld K., Pinchbeck D. (2013). Admissible Hydrogen Concentrations in Natural Gas Systems. European Gas Research Group. National Research Council Canada (2017). Review of hydrogen tolerance of key Power-to-Gas (P2G) components and systems in Canada: final report.

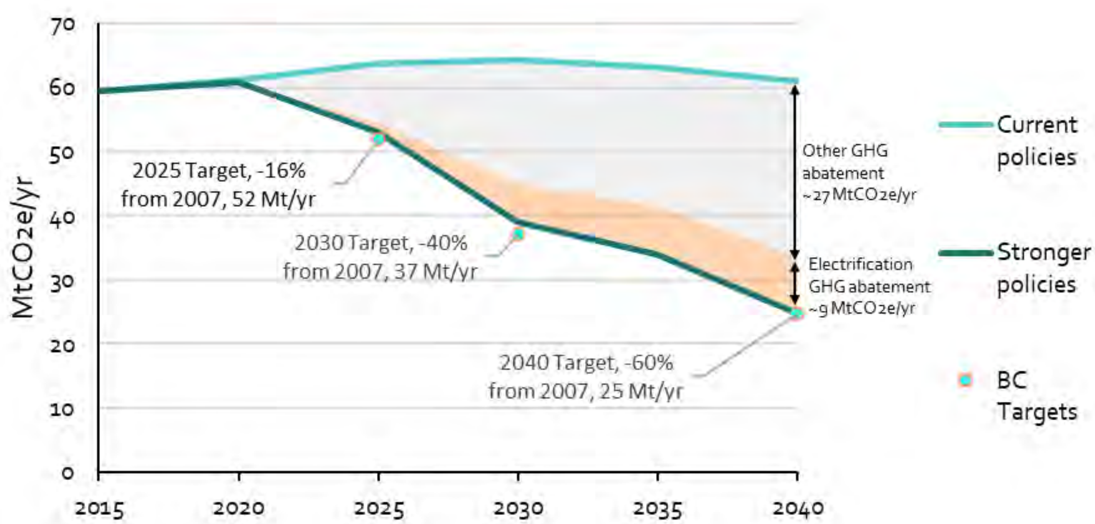
3. Results

The results chapter beings with a comparison of GHG emissions and electricity demand in the current policy scenario and the stronger policy scenario that achieves BC's GHG emissions targets. This is followed by explanatory results that describe the change in electricity demand in the stronger policy scenario in greater detail. The remaining section of this chapter assesses the sensitivity of this electricity demand forecast to a range of different technology assumptions and less prescriptive post-2030 building regulations (i.e. no retrofit or zero-GHG building regulation).

3.1. The impact of current and stronger GHG reduction policies

The implementation of stronger policies substantially reduces British Columbia's total GHG emissions from the present and relative to a scenario with current policies. Electrification is an important GHG abatement action. With currently legislated policies, provincial GHG emissions are kept roughly constant to 2040, despite a growing population and economy. By design, the stronger policy scenario achieves the legislated GHG targets in 2025, 2030 and 2040 (Figure 2). Recall that we assume 2 $MtCO_2e$ of forestry carbon offsets are available in 2030, but are not explicitly modelled. Therefore the results show that emissions in that year are 39 $MtCO_2e$ rather than 37. By 2040, electrification accounts for 25% of GHG abatement relative to the current policy scenario (about 9 of 36 $MtCO_2e$).

Figure 2: BC GHG emissions by scenario and breakdown of GHG abatement



*Provincial GHG emissions and targets exclude emissions resulting from international aviation and marine travel.

Stronger GHG reduction policies increase electricity demand in British Columbia. With current policies, future provincial electricity consumption matches the overall trend in load growth from the 2020 BC Hydro load forecast. There are differences by sector that cause a divergence in the forecasts around 2030 but total electricity demand in 2040 reaches roughly 71 TWh/yr in both the load forecast and the current policy scenario. The stronger policies increase electricity consumption relative to this baseline, initially by just over 1 TWh/yr in 2025, but with the difference growing to 10 TWh/yr in 2030 and 12 TWh/yr in 2040 (equivalent to +17% relative to the current policy scenario in that year) (Figure 3 and Table 11).

Figure 3: British Columbia electricity demand by scenario

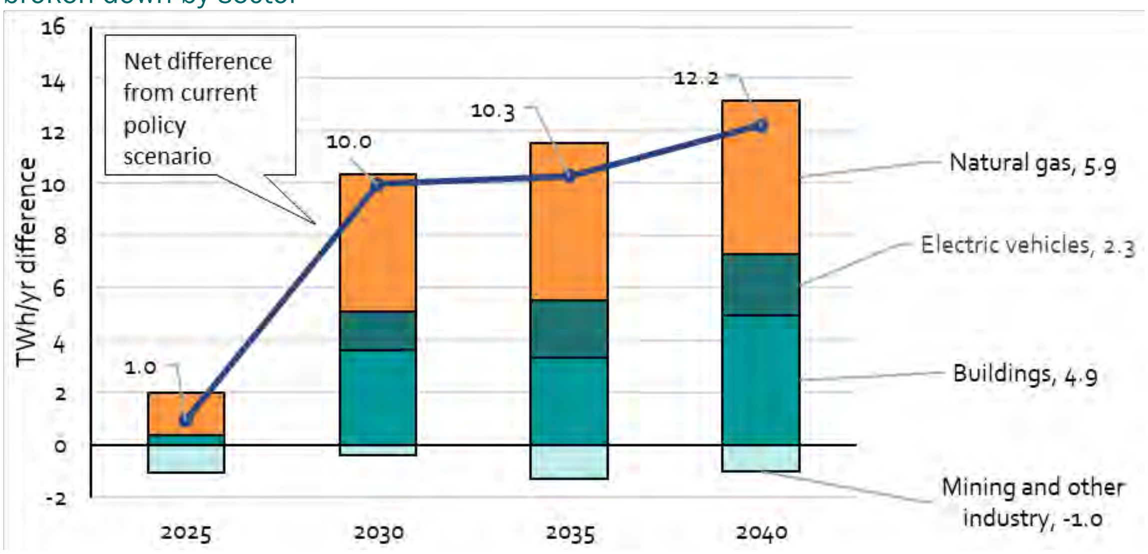
Current policies	51.4	53.5	56.9	61.3	65.5	70.7
Stronger policies	51.4	53.5	57.9	71.3	75.8	82.9

*Demand exclude electricity consumption for aluminum production and electricity consumed from cogeneration in forest products sectors, where this demand is supplied by industry owned generation.

Stronger GHG reduction policies result in much greater electricity demand relative to current policies, with the greatest differences in 2040 coming from the natural gas sector and buildings. To reach the legislated provincial GHG targets, both sectors must substitute even more electricity consumption for natural gas consumption. As such, the incremental electricity demand for gas compression and transport in the natural gas sector, relative to the current policy scenario, rises to about 5 TWh in 2030 and almost 6 TWh in 2040 (Figure 4). Similarly, additional electricity demand from buildings for space and water heating reaches almost 5 TWh by 2040. Incremental electricity demand from all classes of electric vehicles (light, medium and heavy-duty, including buses) is smaller because the current policy scenario already includes a significant amount of electrification driven by the light-duty vehicle ZEV standard. In contrast, slower economic growth results in somewhat less industrial and mining activity and less electricity demand. However, this reduction in industrial electricity demand, relative to the baseline, is a minor offset to the incremental load growth required to achieve provincial GHG targets.

Figure 4: Difference in electricity demand, stronger policies versus current policies, broken down by sector



3.2. Explanatory results for electricity demand in the stronger policy scenario

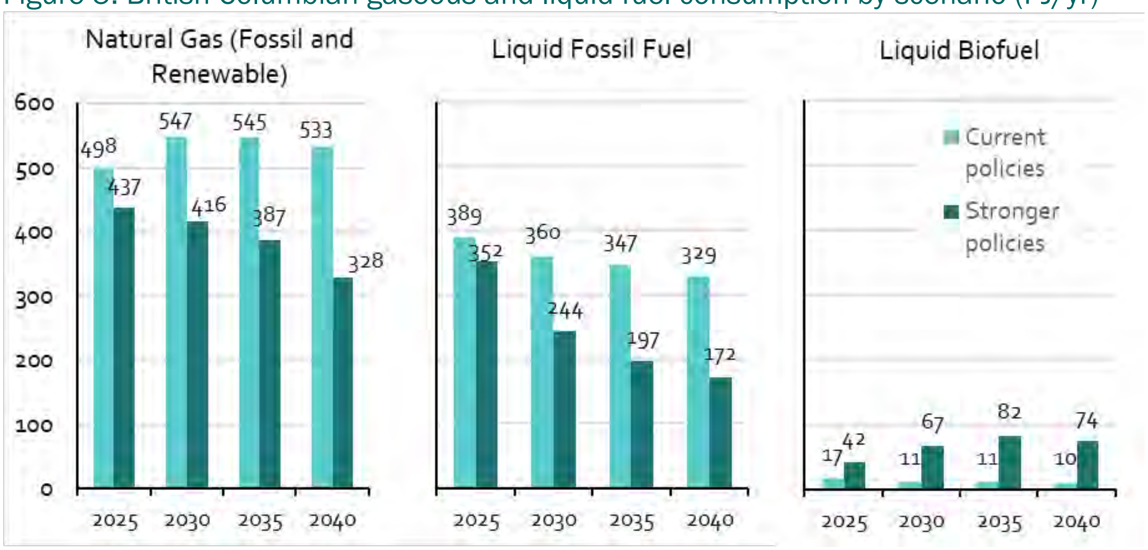
This section of the report goes into greater detail to explain the growth in electricity consumption required to achieve BC's GHG emissions targets. The details include an analysis of changes in other fuel consumption (e.g. gaseous and liquid fuels), changes in technology market shares (e.g. electric vs. non-electric technologies) and changes in activity and energy consumption by end-use in the relevant sectors.

3.2.1. Fuel Shares

Increased electricity demand occurs in response to GHG reduction policies when electricity, produced from low-GHG sources, is substituted for fossil fuels such as natural gas, gasoline and diesel.

The electrification that occurs in response to the strong policies results in substantially less liquid and gaseous fuel consumption by 2040, even when including biofuels. With current policies, gaseous fuel consumption (including what is used upstream by the natural gas sector) is about 25% larger in 2040 than it is in 2020 and all of that fuel consumption is fossil natural gas. In contrast, with strong policies, gaseous fuel consumption, which at minimum 15% renewable natural gas, declines by 25% relative to 2020 (Figure 5). Similarly, liquid fuel consumption declines relative to the current policy scenario to just 246 PJ/yr (fossil+biofuel), where one third of that is biofuel, much of it “drop-in” renewable diesel.

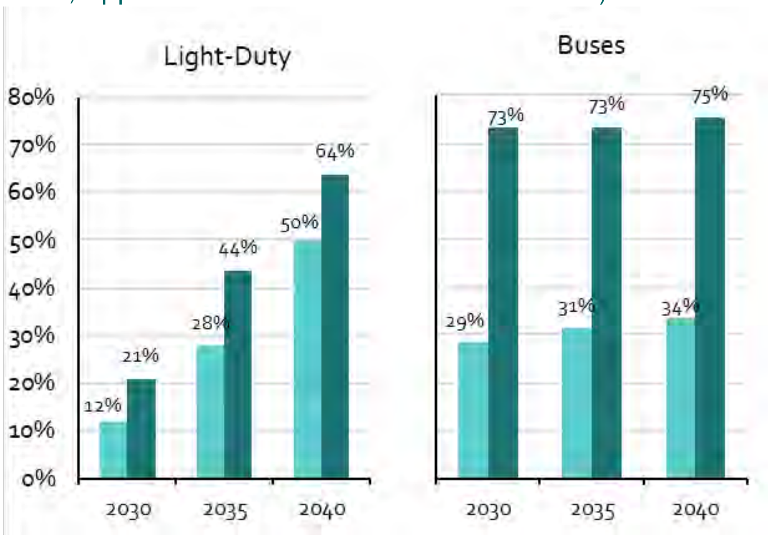
Figure 5: British Columbian gaseous and liquid fuel consumption by scenario (PJ/yr)



3.2.2. Transportation

The reduction in liquid fuel consumption and the increase in electricity consumption for transportation are both drive by the adoption of plug-in electric vehicles across all classes of on-road vehicles. In the current policy scenario, it is the light-duty ZEV standard is driving greater adoption of PEVs. However, this trend is accelerated to achieve provincial GHG targets in the stronger policy scenario where almost 50% of light-duty vehicles on the road are electric in 2035, reaching almost 65% in 2040 (Figure 6). This is equivalent to about 750,000 electric vehicles on the road in 2030 and 2.5 million in 2040.[12] Likewise, the switch to electric buses is also accelerated in the stronger policy scenario. After 2030, roughly 75% of buses are electric (vs. one third in the current policy scenario) (Figure 6). This is roughly equivalent to 12,000 transit, school and private electric buses operating in BC.[13]

Figure 6: Light-duty and bus PEV total market share by scenario (% of total travel by PEVs, approximates % of vehicles on the road)



There are also substantially more medium and heavy-duty ZEVs on the road in the stronger policy scenario. For medium-duty vehicles, most of these ZEVs are electric. The share of medium-duty travel activity using electric vehicles rises from about 12% in 2030 to 30% by 2040 (Figure 7Figure 6). Because the utilization and duty-cycles of medium duty vehicles is heterogeneous, it is difficult to equate this market share with a specific number of vehicles. However, Statistics Canada data indicates that there were approximately 135,000 medium-duty vehicles in BC in 2019[14] and that sector grows by 14% between 2020 and 2040 in the forecast. This market share and growth rate imply about 46,000 electric medium-duty vehicles on the road in 2040.

Heavy-duty ZEVs account for about 10% of travel activity in 2030, independent of the GHG policies are implemented. However, by 2040, this share rises to 24% with stronger policies. Heavy-duty ZEVs are a mix of both battery and fuel-cell electric

---

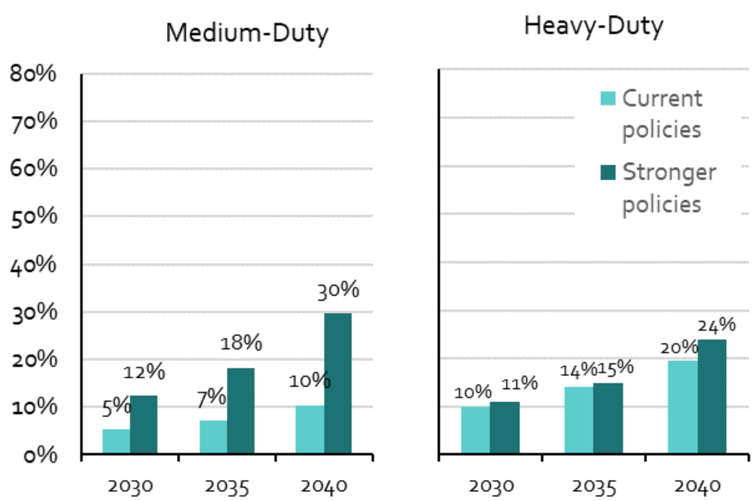
[12] Assuming 15,000 vehicle kilometers travelled per year by each light-duty vehicle

[13] Assuming 65,000 vehicle kilometers travelled per year by each bus with an average ridership of 12 passengers per km

[14] Statistics Canada. Table 23-10-0067-01 Vehicle registrations, by type of vehicle

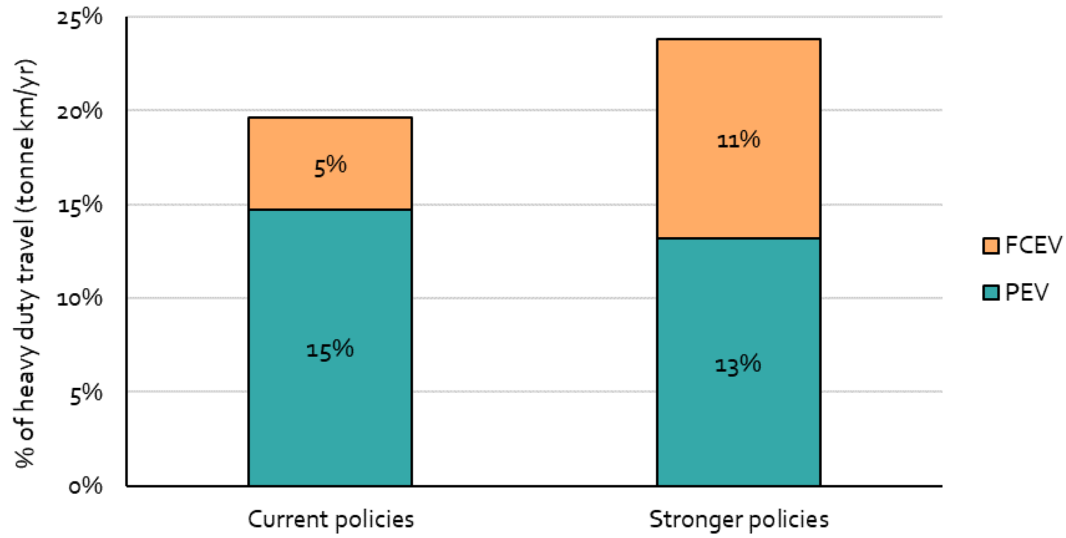
vehicles, where the relative share of each is sensitive to the GHG policy environment. Strong GHG reduction policies implemented across North America create a larger market for fuel-cell electric heavy-duty vehicles which in turn lowers their costs through economies of scale and learning. Consequently, there are more fuel-cell electric vehicles on the road in the stronger policy scenario. There is some competition between these two drivetrains and consequently there are fewer battery electric heavy-duty vehicles (Figure 8, 13% total market share compared to 15% in the current policy scenario). The utilization duty-cycles of heavy duty vehicles are also very heterogeneous, so calculating vehicles on-the-road from the modelled market share result is only a roughly approximation. Nonetheless, the stronger policy scenario indicates there would be about 5,500 battery electric heavy-duty vehicles on the road in 2030, and 12,000 in 2040.[15]

Figure 7: Medium-duty and Heavy-duty **ZEV** (electric ***and*** fuel cell vehicles) total market share (% of total travel activity by ZEVs)



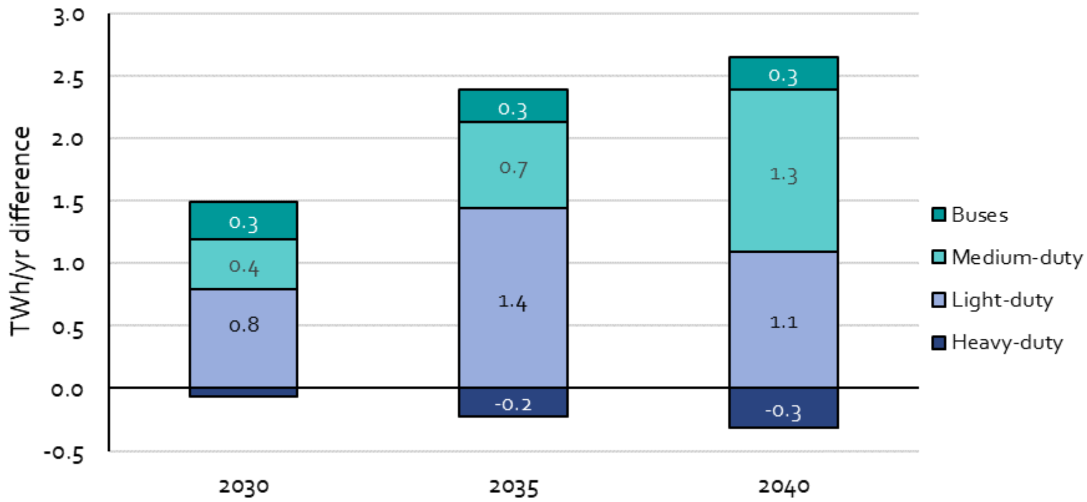
[15] Assuming each truck has an average payload of 10 tonnes, travelling 60,000 km/yr

Figure 8: Heavy-duty ZEV total market share by drivetrain type in 2040



By 2040, about half of the incremental electricity demand from transportation that occurs in response to stronger policies comes from medium-duty vehicles. Because the baseline current policy scenarios already includes a strong ZEV standard applied to light-duty vehicles, it already has substantial load-growth from these vehicles. As well. there are also fewer battery-electric heavy-duty vehicles in the stronger policy scenario (and more fuel-cell electric vehicles), hence less electricity consumption from those vehicles. In total, incremental electricity demand for transportation, relative to the current policy scenario, is 1.4 TWh/yr in 2030 (of which about 30% is from medium-duty vehicles). By 2040, the incremental load is 2.3 TWh/yr (of which about 50% is from medium-duty vehicles) (Figure 9).

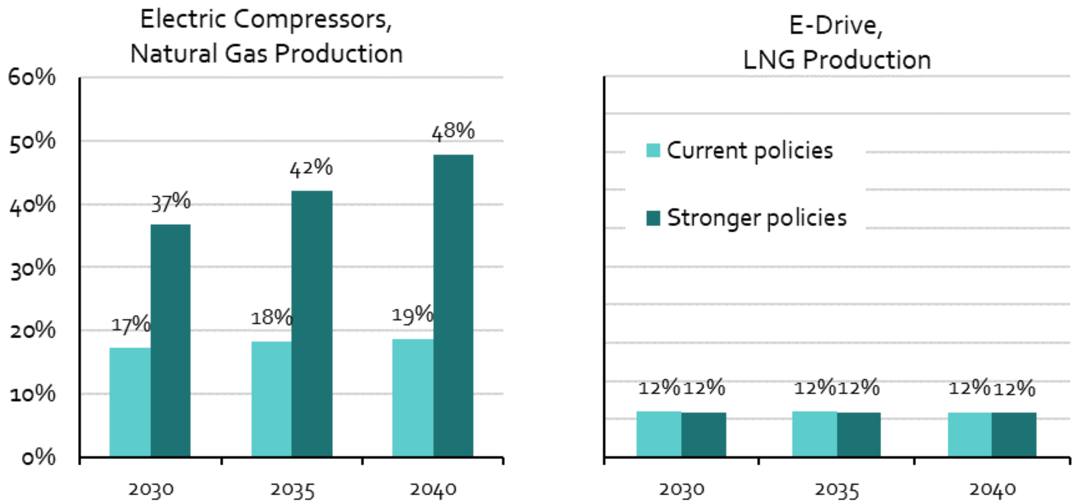
Figure 9: Incremental electricity demand from plug-in electric vehicles, stronger policies versus current policies, broken down by vehicle type



3.2.3. Natural gas

The change in electricity demand from the natural gas sector is largely a function of the adoption of electric compressors to transport natural gas. The stronger policies have no impact on electricity demand from the LNG sector within the time-horizon of this analysis. Electric compressors are used in place of gas-fired compressors, thus increasing electricity demand and reducing combustion GHG emissions. With stronger GHG policies, the incremental electricity demand from the natural gas sector, relative to the current policy scenario, grows from roughly 1.5 TWh/yr in 2025 to 6 TWh/yr in 2040 (total demand is roughly 7 and 11 TWh/yr in those years, respectively). The fraction of electric compressors is 37% in 2030 and almost 50% in 2040 (Figure 10). In contrast, the stronger policies have no impact on the drive technologies used for liquefaction in the LNG sector within the time horizon of this analysis (Figure 10).

Figure 10: Technology market share, % of natural gas and LNG production electrified by scenario



Reductions in natural gas production create a small offset to electrification. LNG production is not affected by GHG policies. The implementation of strong GHG reduction policies, which apply across all regions of North America (i.e. what is included in the model) suppresses demand for natural gas. Consequently, gas production in BC is somewhat lower in the stronger policy scenario, notably in 2040 when production is about 12%, or 1.1 bcf/day, lower (Table 12). Accordingly, electricity demand from the natural gas sector is slightly lower than it otherwise would be. However, it is important to note that the modelling includes some constraints that prevent a further reduction in natural gas production in BC and the corresponding reduction in the sector's electricity demand. Notably, we have assumed a fixed quantity of foreign demand for North American LNG, where 60% of the gas exported from BC must be produced in BC. If LNG demand were also reduced global GHG policies, then the activity and electricity demand in the BC natural gas and LNG sectors could be more sensitive to GHG policy than indicated in this analysis.

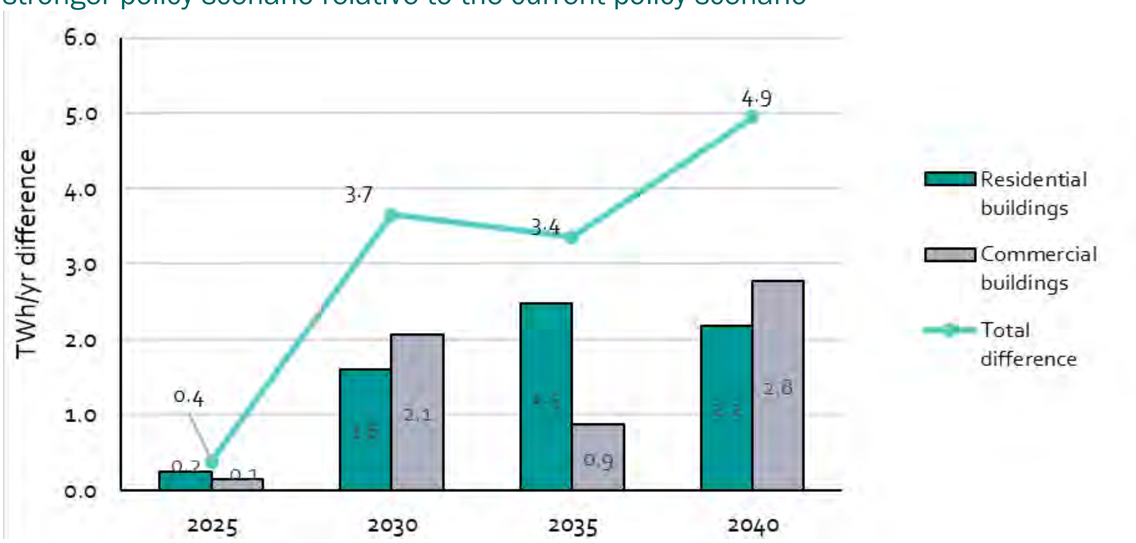
Table 12: Natural gas and LNG production in British Columbia by scenario

	2015	2020	2025	2030	2035	2040
Natural gas, bcf/day						
Current policies	4.1	5.4	7.9	9.1	9.3	9.3
Stronger policies	4.1	5.4	7.4	9.2	9.1	8.2
LNG gas, Mt/yr						
Current policies	0.0	0.0	8.4	19.0	19.0	19.0
Stronger policies	0.0	0.0	7.5	19.0	19.0	19.0

3.2.4. Buildings

Incremental electricity demand from buildings occurs in both residential and commercial/institutional buildings. With stronger GHG policies, the incremental electricity demand for buildings, relative to the current policy scenario, grows to about 3.5 TWh/yr for 2030 through to 2035, reaching almost 5 TWh/yr by 2040 (total demand is roughly 40 TWh/yr in 2030 and 44 TWh/yr in 2040) (Figure 11). The incremental demand from both commercial and residential buildings fluctuates over time depending on relative rates of electrification with current policies versus stronger GHG reduction policies.

Figure 11: Difference in building electricity consumption by building type in the stronger policy scenario relative to the current policy scenario



In response to stronger GHG reduction policies, there is a significant adoption of heat pumps for space heating in larger buildings (i.e. commercial) by 2030. By 2040, heat pumps are trending towards being a dominant space and water heating technology in

all BC buildings. Adoption of heat pumps through 2035 is a function of technology and energy costs (inclusive of carbon pricing) as well as some early incentives for heat pumps. This is most noticeable in commercial buildings starting in 2030, where the share of space heating provided by heat pump is over 50% (3x more than with current policies, Figure 13). After 2035, the adoption of heat pumps is further driven by the zero-emissions building policy, which requires new and replacement mechanical systems to use this technology. By 2040, 24% of residential space heating and 67% of commercial space heating is produced with heat pumps. There is a similar market penetration of heat pump water heating. Note that the model does not represent the potential for low-GHG biomass heating in commercial and institutional buildings, either through standalone systems or delivered by district energy. Therefore, the results may overestimate the electricity fuel share somewhat.

Figure 12: Residential space heating technology market share

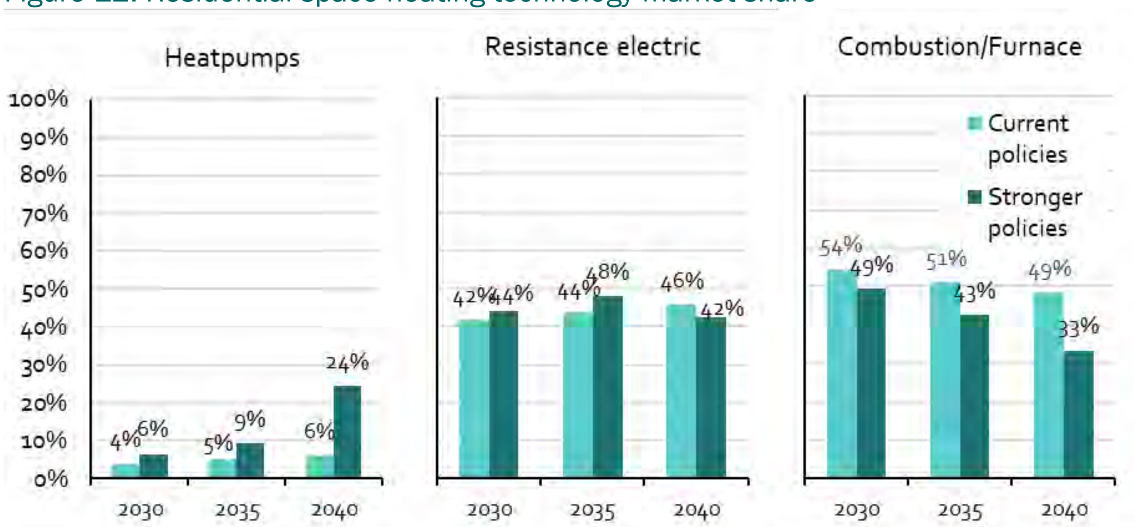


Figure 13: Commercial and institutional space heating technology market share

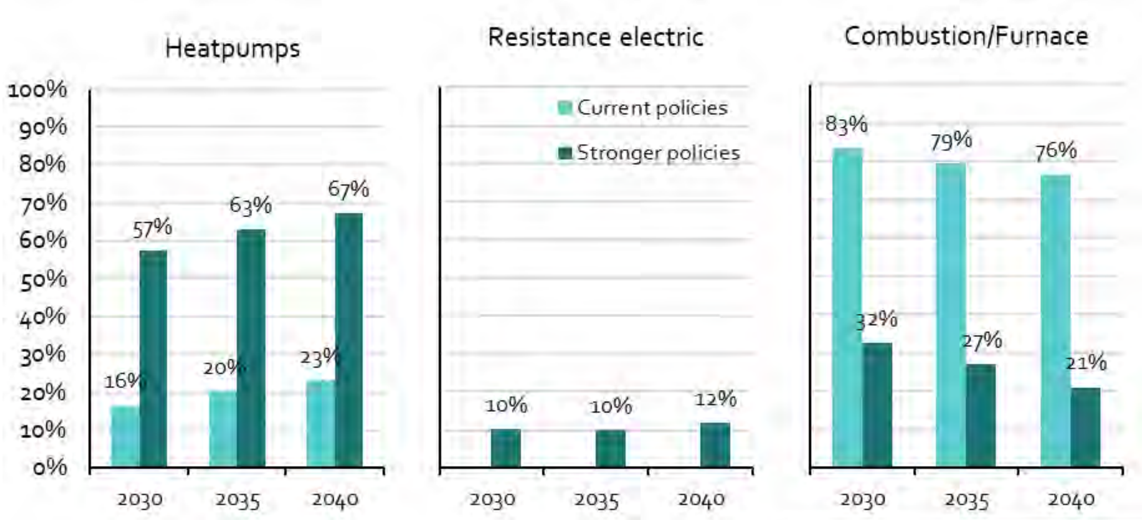
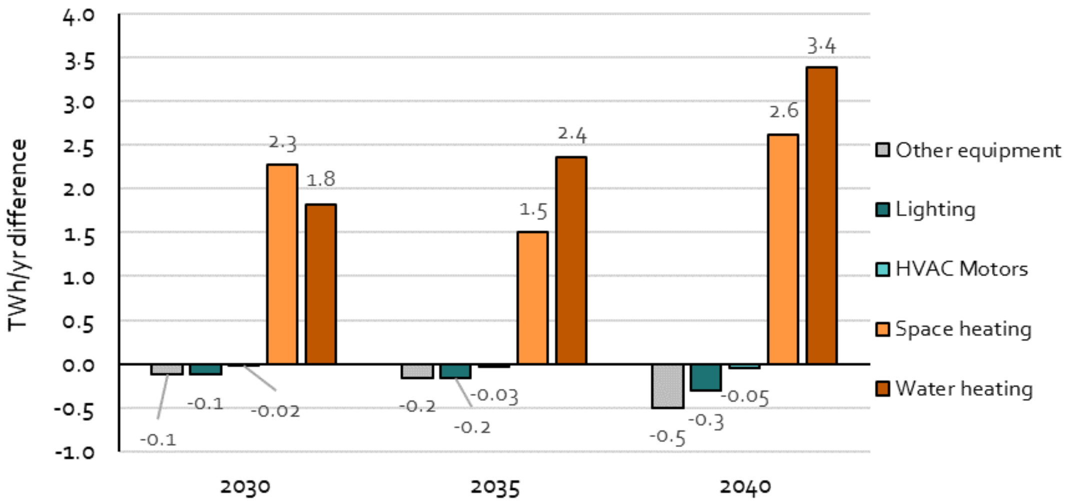


The electrification of space and water heating is offset by other energy efficiency slower growth in total building floor area. The stronger GHG policies result in more electricity consumption in buildings for space and water heating, relative to what would happen with current policies. However, some of this new load is offset by slower growth in electricity demand for lighting, plug-loads, motors used to for HVAC systems, and other equipment. In 2030 these changes offset about 7% of the incremental load growth. By 2040, they offset 14% of the incremental load growth (Figure 14). About half of this offset is a result of greater energy efficiency. The growth in provincial electricity consumption puts upward pressure on electricity prices, increasing the incentive to use more energy efficient equipment. The other half of the offset results from slower growth in floor area, a result of GHG reduction policies slowing economic growth (e.g. the services sectors grow more slowly and need less physical space).

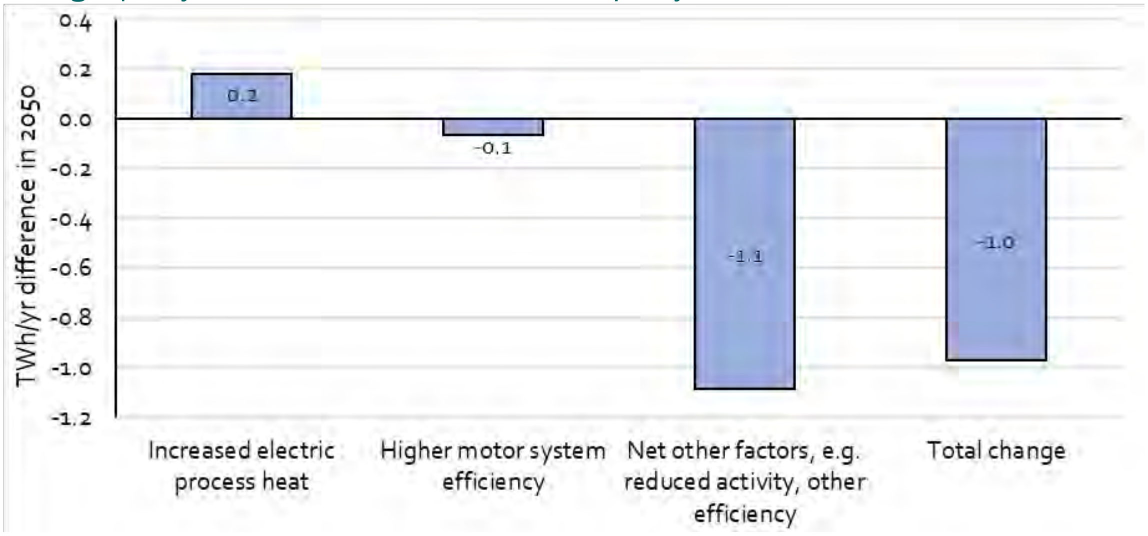
Figure 14: Difference in building electricity consumption by end-use in the stronger policy scenario relative to the current policy scenario



3.2.5. Mining and other industry

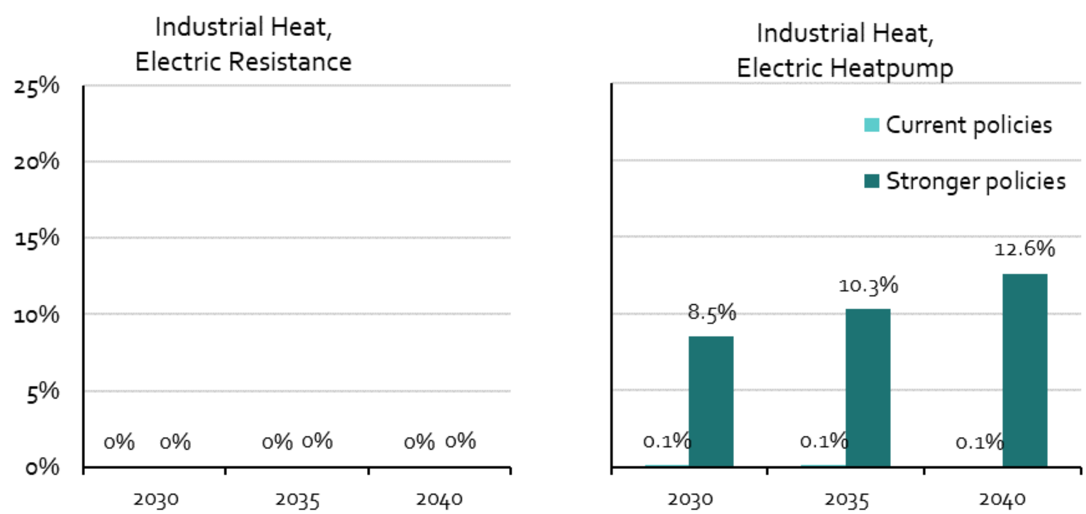
Electricity consumption from mining and other industry (i.e. not natural gas or LNG) is affected by several offsetting factors that ultimately result in less electricity consumption in response to stronger GHG policies. Electricity demand from mining and other industry is roughly 1 TWh/yr lower in 2040 than it would have been with a continuation of current policies (total demand is roughly 15 TWh/yr in 2030 and 16 TWh/yr in 2040). The offsetting drivers of industrial electricity demand are a switch to electricity for process heat, changes in sector activity, and other electrical efficiency. There is an increase in electric process heat, supplied by industrial heat pumps, equivalent to just 0.2 TWh/yr in 2040 (relative to current policies). However, this electricity consumption is more than offset by the adoption of more efficient motor systems (in response to higher electricity prices, -0.1 TWh/yr) and slower economic growth activity (-1.1 TWh/yr) (Figure 15). Note that any change in demand related to electric transportation within the industrial sectors is included with medium and heavy-duty vehicles.

Figure 15: Change in mining and other industrial electricity demand (2040) in the stronger policy scenario relative to the current policy scenario



The use of electricity for industrial heat increases in response to the stronger GHG reduction policies. Lower temperature process heat is supplied by industrial heat pumps drawing on ambient heat or providing active heat recovery from waste heat streams. By 2040, with the stronger GHG policies, heat pumps supply almost 13% of industrial process heat, which represents roughly 50% of the technical potential for this technology in the model (where we have limited heat pumps to supplying heat at 100 ºC or lower) (Figure 16). There is little use of electric resistance for industrial process heat by 2040, in even in response to the stronger GHG policies.

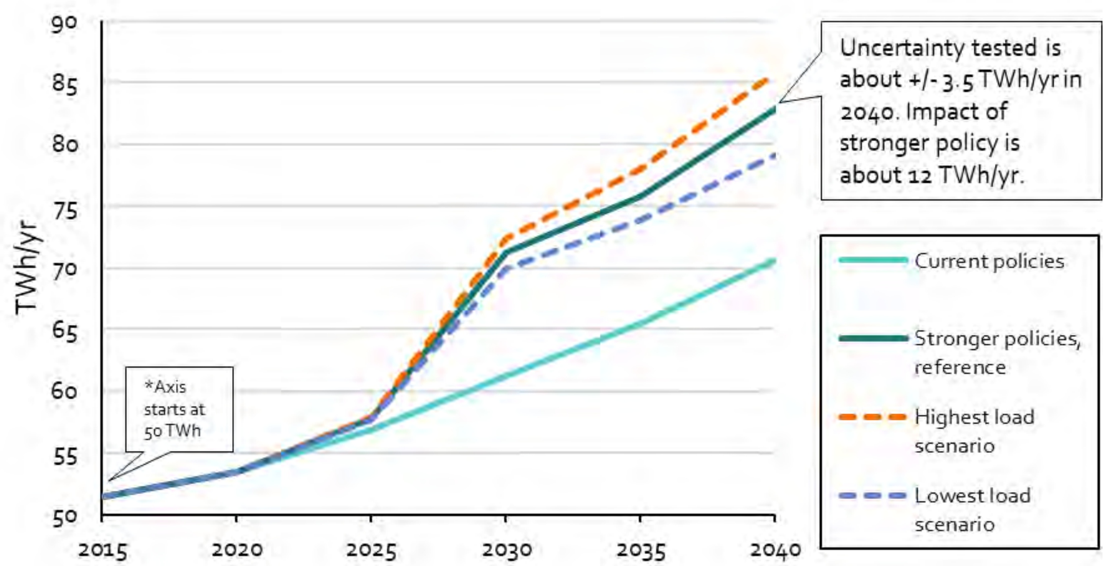
Figure 16: Electric industrial process heat technology market shares by scenario, % of total heat demand



3.3. Sensitivity analysis

Total electricity demand in BC is much more sensitive to the strength of GHG policy than it is to the technology uncertainties tested in the sensitivity analysis. Uncertainty in the future cost and performance of GHG reduction technologies create a band around the stronger policy electricity demand forecast of +/- 1.5 TWh/yr in 2030, growing to +/- 3.5 TWh/yr in 2040 (+/- 4%). In that year, provincial electricity demand could range from 79 to 86 TWh/yr (Figure 17). In contrast, strong GHG policy has an impact on electricity demand that is almost four times larger. Achieving the provincial GHG targets increases demand by 15 TWh/yr in 2040 compared to a future with a continuation of current policies.

Figure 17: British Columbia electricity demand in the stronger policy scenario with high/low range (note that the vertical axis starts at 50 TWh)



If BC achieves it's GHG targets, the largest uncertainty with respect to electricity demand is the future cost of PEVs. Lower and higher future for PEVs across of all vehicle classes can change electricity demand in 2040 by almost 7 TWh/yr (Figure 18, up to 8% of total demand with stronger policies). Two thirds of this variation comes from light-duty vehicles. While the ZEV standard puts applies a floor to light-duty ZEV sales, this policy is not binding from 2030 onwards when using the reference and lower PEV cost assumptions. PEV sales are instead driven by the implied carbon price required to achieve provincial GHG targets, meaning there are more sales than required by the ZEV standard. Just complying with the ZEV standard, as would occur if PEVs have higher costs, means half of all light-duty vehicles are be PEVs in 2040

(Figure 19). However, if PEV are less costly than expected, three quarters of vehicles on the road could be PEV by 2040 (Figure 19). The remaining variation in electricity demand comes from uncertainty in the stock larger vehicles, where the fraction of travel activity (i.e. tonnes km/yr) on PEVs in 2040 ranges from 18-33% for medium-duty vehicles and 10-16% for heavy-duty vehicles (Figure 19).

Interestingly, the high/low electrification scenarios that have multiple differences in assumptions relative to the reference stronger policy scenario produce a smaller net-change in electricity consumption than do the PEV cost scenario (Figure 18). This result indicates that uncertainties in future technology costs and performance may have offsetting impacts on electricity demand.

Figure 18: Difference from total electricity demand in the reference stronger policy scenario in 2040, all sensitivity scenarios

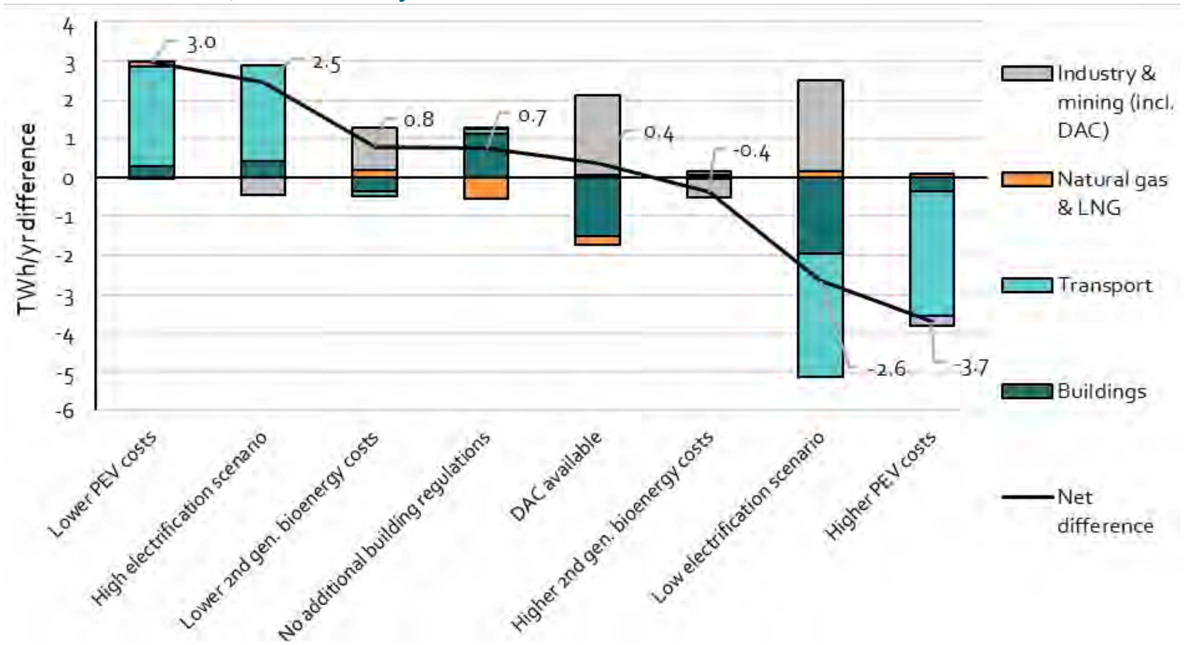


Figure 19: Uncertainty in PEV total market share (approximates % vehicles on the road for light-duty, approximates % of travel activity for medium and heavy-duty)

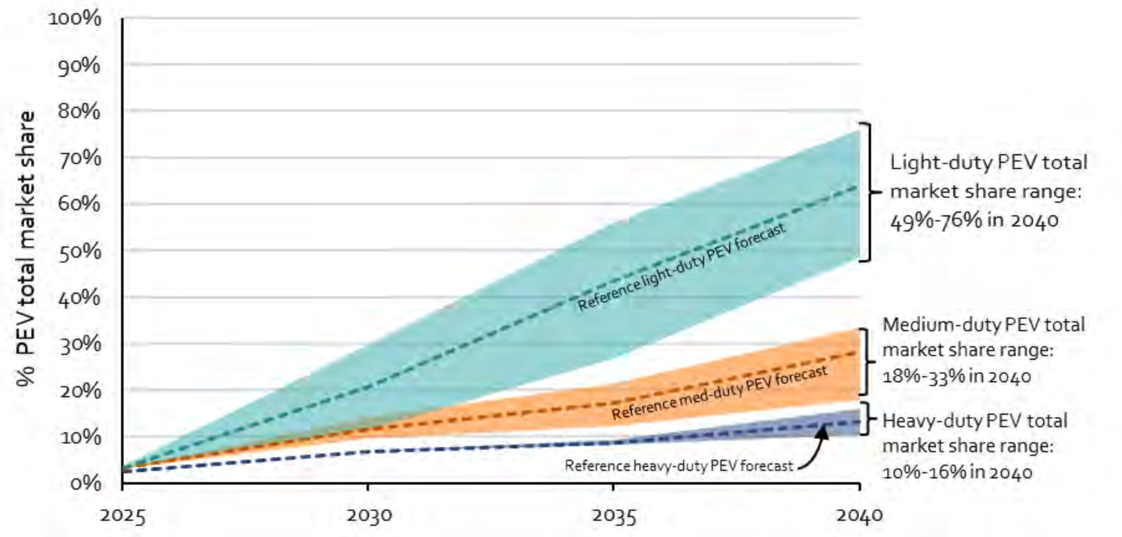

The cost and availability of direct air capture (DAC) and storage of CO_2 is a smaller uncertainty in these results. DAC and CO_2 storage affects electricity demand in three ways that partially offset each other. First, DAC and storage is a direct consumer of electricity. Although the DAC process characterized in this analysis uses natural gas for process heat (With carbon captured from the flue gas), it also uses a substantial amount of electricity, about 0.24 MWh/tCO_2. Second, DAC changes the extent to which other sectors must decarbonize, which changes the amount of electrification that occurs in those sectors. Third, more broadly, DAC changes the strength of policy (and policy cost) required to achieve BC's GHG target which can result in greater industrial activity and more electricity consumption. For example, if DAC is available, there is less electrification of buildings and the natural gas sector (-1.7 TWh/yr relative to the reference stronger policy scenario). DAC and storage uses an additional 1.2 TWh/yr, while the additional industrial activity indirectly caused by DAC consumes another 0.9 TWh/yr. On net, the use of DAC in response to stronger GHG policies in 2040 increases electricity demand by only 0.4 TWh/yr (0.5%) relative to a future without DAC (Figure 18).

The uncertainty of DAC in BC's future electricity consumption could be larger than it appears in this analysis, likely of similar magnitude to the uncertainty in PEV electricity consumption. First, DAC could increase electricity consumption if electricity is used to provide the process heat, though this approach would require abundant, low-cost and low-GHG electricity to make it cost competitive with gas-fuelled DAC. In a future with more extensive use of intermittent renewables, there could be daily or seasonal periods with excess generation when electricity is available at a low-price that would make all-electric DAC competitive. However, this analysis does not have the short-term resolution to explore this potential (i.e. hourly). Furthermore, all-electric DAC was not included in the model and even if it were, it would not be adopted with average-cost electricity prices. Second, DAC and storage could reduce electricity consumption in BC if the abatement occurs in another jurisdiction. Theoretically, BC could fund DAC and claim the emissions reductions credits, even if the physical process and electricity consumption occurs in another jurisdiction with lower-cost CO_2 storage. Both of these factors increase the uncertainty in BC's electricity consumption introduced by DAC, likely putting it in the range of +/- 2 TWh/yr in 2040.

Electricity demand through to 2040 is not sensitive to the production cost of 2nd generation biofuels or to more stringent building regulations. Lower and higher costs for renewable gasoline, diesel and natural gas produced from woody or grassy feedstocks have a small impact on industrial electricity consumption in 2040 (directly related to biofuel production) and an even smaller impact on electricity consumption for transportation (a minor substitution of biofuels for battery electric vehicles). Not implementing stronger building regulations after 2030 (the zero-emissions building regulation and building envelope retrofit requirement) increases electricity demand by 0.7 TWh/yr in 2040 (+0.8%) (Figure 18). Without these policies, buildings need on average more heating and there is more heating produced with electric resistance rather than heat pumps. Due to the slow turnover of building stock and mechanical systems, the impact of the additional building regulations should grow larger after 2040.

4. Discussion and Conclusions

In this analysis, we used a technologically detailed, full-economic equilibrium, energy economy model to simulate how different GHG policy portfolios will affect electricity consumption in BC from the present to 2040. We tested the impact of:

- "Current policies", that are legislated or have firm announcements
- "Stronger policies", which include a range of additional incentives and regulatory policies, plus an emissions cap that achieves BC's 2025, 2030 and 2040 and GHG emissions targets.

Using the stronger policy scenario as a reference, we also tested how the forecast of electricity demand is affected by a range of different technology and policy assumptions.

Of the dynamics tested, **BC's long-term electricity demand is most sensitive to the strength of climate policy**. In 2025, the difference between current policies and stronger policies is relatively small, just 1 TWh/yr more if BC achieves its GHG target. This difference grows to 10 TWh/yr in 2030 (+17%) and 12 TWh/yr in 2040 (+18%, with total electricity demand at 83 TWh/yr).

In response to stronger GHG reduction policies that will achieve the provincial GHG targets, **most of the incremental growth in electricity demand comes from the natural gas sector and from buildings**. 45% of the incremental demand comes the electrification of compressors used for natural gas production and transportation. Another 38% of the incremental demand comes the electrification of space and water heating in buildings. Just 18% of incremental demand comes from transportation. Electricity demand for transportation must grow significantly in order to achieve deep GHG reductions in BC. However, much of this load growth is already included in the current policy forecast since it includes the light-duty vehicle ZEV standard.

In contrast to the impact of GHG policies, **the other uncertainties tested in this analysis only shift total electricity demand in 2040 by a few TWh/yr relative to our reference forecast with stronger policies**:

- **The future cost of PEVS is the largest uncertainty, but a wide range of assumptions only shifts electricity demand by around +/- 3.5 TWh/yr in 2040.** Two thirds of this range comes from greater or lesser adoption of light-duty PEVs after 2030, when low-cost PEVs might drive sales beyond what the ZEV standard requires. The remaining third of this range comes from medium and heavy-duty PEVs. Even when assuming lower costs, PEVs are still a minority of these vehicle classes. By 2040, PEVs are used for, at most, 33% of medium-duty and 16% of heavy-duty travel. Given the additional potential to electrify these larger vehicles, the adoption of medium and heavy-duty PEVs could be significantly more important after 2040 and we recommend ongoing study of their electrification.

- **The cost and availability of direct air capture (DAC) and storage of CO_2 is a smaller uncertainty in these results.** DAC is a direct consumer of electricity, but it also changes the need for electrification in other sectors and reduces the strength of policy required to achieve BC's targets, which may indirectly result in greater economic activity and electricity demand. Because these dynamics largely offset each other, DAC appears to have a limited impact on future electricity demand. However, this uncertainty could be larger: DAC could be deployed in an all-electric configuration (i.e. higher electricity demand in BC), or BC could fund DAC that occurs in another jurisdiction (i.e. lower electricity demand in BC).
- **Electricity demand through to 2040 is not sensitive to the production cost of 2nd generation biofuels or to more stringent building regulations.** A longer-term analysis, to 2050 for example, might find that these uncertainties become more important.

In summary, **this analysis shows that achieving BC's GHG reduction targets will result in substantially more electricity demand than would occur with current policies.** The results do not show a future where other potential low-GHG energy pathways out-compete electricity. Rather, these pathways, including bioenergy, energy efficiency and some use of hydrogen fuel cell vehicles, are complementary and all contribute to deep GHG reductions.

However, this conclusion is subject to two limitations of this analysis. First, **This sensitivity analysis did not look at the impact of uncertainty in future natural gas production, yet this would introduce more uncertainty into the electricity demand forecast.** Electricity consumption in the natural gas sector is roughly 8 TWh in the stronger policy scenario in 2040 (almost 10% of total demand). Lower or higher natural gas prices, related to uncertainty in the North American natural gas supply curve (i.e. quantity available at a given production cost), could change BC's gas production and the related electricity demand substantially. Similarly, uncertainty in foreign demand for LNG, which is linked to gas production in BC within this analysis, would have the same impact. Based on the quantity of electricity used by the natural gas sector, this uncertainty could be at least as important to future electricity demand as is the uncertainty in PEV costs.

Finally, there are additional transportation modes that could electrify, but they are not included in this analysis. Consequently, electricity consumption for transportation could be higher than forecasted. Specifically, there will likely be niches for the electrification of marine and air transport. For example, Norled, a Norwegian ferry operator is already using a battery-electric ferry on one of its routes and has placed an order for more of these vessels.[16] For aviation, Harbour Air, based in BC, has announced that it plans electrify its short-haul seaplanes,[17] and Airbus is testing the electrification of one of its regional turbo-fan powered aircrafts.[18] The model results provide an upper bound on this uncertainty. If all domestic marine and air travel included in the analysis were to electrify, this would increase total electricity demand by 7 to 10 TWh/yr in 2040, depending on the growth of these sectors.[19] For context, total electricity demand from on-road PEVs grew to roughly 10 TWh/yr in 2040 in the stronger policy scenario. However, by analogy with the electrification of medium and heavy-duty vehicles observed in this study, actual electricity demand from marine and air travel would be a subset of the maximum. Given that electric boats and planes would likely be used for short and high-frequency routes, an approximate guess for that new load would be in the range of 2 to 3 TWh/yr by 2040.

Appendix A: Electrification Technology Research

This appendix describes research conducted for the electrification potential review and how this information was used in the analysis. It covers six topics:

- The cost and potential for 2nd generation biofuels a as low-carbon fuel that competes with, or complements, GHG abatement through electrification.
- Updated cost assumptions for light-duty electric vehicles and assumptions for the energy intensity of these vehicles.
- The cost and potential for battery electric vehicles for bus transit.
- The cost and potential for battery electric vehicles for heavy-duty truck transport.
- The opportunity for low-energy electric heating in industry with industrial heat pumps.
- The cost and energy intensity of direct air carbon capture.

2nd Generation biofuels

In this report, 2nd generation biofuels refer to liquid and gaseous fuels produced from ligno-cellulosic feedstocks. These are cellulosic ethanol and renewable gasoline, diesel and natural gas produced from wood or grassy organic matter. These contrast with first generation biofuels which include starch ethanol and biodiesel. Starch ethanol is produced from sugary and starchy crops such as wheat and corn. Biodiesel is produced from oilseeds (e.g. canola and soy) and can also be produced from a limited quantity of used cooking oil and tallow (fat by-products from animal production). We also include hydrogenation derived-renewable diesel as a first-generation biofuel given that it can be produced from the same feedstocks as biodiesel.

Currently, 2nd generation biofuels are pre-commercial and their production is more technically advanced and costly than the production of first-generation biofuels. However, 2nd generation biofuel feedstocks are more plentiful than those for first generation biofuels and the commercialization of 2nd generation biofuel is generally viewed as a necessary for the widespread substitution of fossil fuels with bioenergy.

The following section describes the feedstocks available for 2nd generation biofuels in the model in terms of their source, quantity, and cost. Feedstock quantities are always described in terms of dry mass (e.g. Oven dry tonnes or ODt). It then describes the fuel production pathways included in the model in terms of their capital and operating costs, their feedstock conversion efficiency and the lifecycle GHG intensity of the finished fuels. Based on these attributes, we can compare the quantity and cost of 2nd generation biofuels available within the model with the incumbent fuels: gasoline, diesel and natural gas.

Table 13 summarizes the feedstocks for 2nd generation biofuels represented in gTech. Table 14 summarizes the fuel production technologies. Production costs and GHG abatement costs are shown with the reference model inputs for biofuel plant capital costs (not necessarily the same as literature estimates). The fuel carbon intensities are calculated based on the 2010 GHG intensities for inputs like truck transportation and hydrogen production. If the GHG intensity of these inputs declines, so too will the biofuel carbon intensities and the abatement cost. The production potential (PJ/yr and fraction of gasoline/diesel or natural gas replaced) is only a snapshot for 2010 designed to give context to the quantity of fuel available.

Table 13: Summary of 2nd generation biofuel feedstock modelling assumptions

	Agriculture residue	Forestry residue	Total
Residue availability in 2010, million ODt/yr	18.2	15.7	33.9
Residue availability in 2010, PJ/yr	337	238	575
Plant-gate feedstock cost, 2010 CAD/ODt	76	88	74.5 (avg.)
Potential for greater future production	Modest: grows with food production	Modest: Forestry activity in 2010 was low, allowable cuts across Canada are higher, though future wood supply is constrained in BC as a result of the mountain pine beetle	-

Table 14: Summary of 2nd generation biofuel production modelling assumptions (reference inputs, not sensitivity scenario inputs). Costs in 2010 CAD.

	Renewable gasoline and diesel	Cellulosic ethanol	Renewable natural gas
Production costs, 2010 CAD assuming residue cost of $74.5/ODt	$1.04/L	$0.66/L	$18/GJ
Fuel lifecycle carbon intensity in 2010,[a] gCO_2e/MJ	20 (-77% from gasoline)	11 (-88% from gasoline)	6 (-90% from nat. gas)
Maximum production potential in 2010 if all feedstock available in 2010 were used for a given fuel, PJ/yr	384	263	453
Fraction of incumbent fuels replaced if all feedstock available in 2010 were used for a given fuel (% of 2010 Canadian consumption	15 % of gasoline and diesel	10% of gasoline and diesel	13% of natural gas
Abatement cost with model inputs (2015 CAD/tCO_2e)	142	104	247

[a] Accounts for energy used for feedstock extraction, transport and transformation to fuel, as well as additional fertilizer requirement for agricultural residue, based on 2010 GHG intensity of these activities in gTech

[b] Abatement cost for renewable gasoline and diesel and cellulosic ethanol measured relative to a gasoline lifecycle GHG intensity of 85.7 gCO_2e/MJ, and as assumed wholesale price of $0.70/L (roughly $70/bbl USD for oil). Abatement cost for renewable natural gas measured relative to a natural gas lifecycle GHG intensity of 58 gCO_2e/MJ, and as assumed wholesale price of $5/GJ (2010 CAD).

Feedstocks

The 2nd generation biofuel feedstocks included in the model are agricultural and forestry harvest residues. Agricultural residues are the remainders of plants after harvest such as corn stover and wheat straw. Forestry harvest residues are the branches and treetops that are piled and left at the side of forest roads during logging. Residue availability is defined for each source in 2010 as a function of agricultural and forestry activity and the quantity can grow or shrink as the activity of the associated sector changes (i.e. more forestry activity produces more harvest residue).

Agricultural Residue

In 2010, the model includes 18.2 Mt/yr of agricultural residue that is sustainably available as a feedstock (Table 15). At roughly 18 PJ/million ODt, this residue contains 328 PJ. This quantity was estimated by deriving the quantity of residue available from each of the primary grain crops in Canada using the Biomass Inventory Mapping and

Analysis Tool (BIMAT) and its corresponding data.[20] Other crops produce significantly less residue and are not included. Only a portion of all available agricultural residues can be sustainably harvested as biofuel feedstock since more than 50% of it is kept on the ground for tilling to prevent erosion and to maintain soil nutrients. Roughly 20% of residue is used for as animal bedding for livestock production leaving less than 30% of residue available for fuel production. The sustainable amount of residue available per tonne of grain was multiplied by total grain production in 2010[21] to yield total residue production in that year.

Agricultural residue supply is tied to agricultural production in gTech in Canada and the USA. Therefore, the supply can increase if total agricultural production increases or if there is a shift in the composition of crops (e.g. more corn and less wheat would yield more residue). However, agricultural production is constrained in gTech assuming a fixed land-base, so the model will not allow runaway residue production, nor does it allow runaway production of first-generation biofuel feedstocks.

Table 15: Summary of agricultural residue availability in Canada in 2010, as represented in gTech (reference scenario inputs)

Parameter	Units	Barley	Corn	Oat	Wheat	Total[a]
Residue yield[b]	$ODt_{residue}/t_{grain}$	0.90	0.67	1.52	1.22	1.13
Portion available for energy[b]	%	21.3%	72.9%	28.7%	18.9%	28.5%
Residue available for energy	$ODt_{residue}/t_{grain}$	0.19	0.49	0.44	0.23	0.32
Grain production in 2010[c]	Mt	7.6	21.0	2.5	23.3	54.4
Residue available for energy in 2010	Million ODt	1.5	10.3	1.1	5.4	18.2

a Flax data is not shown since no flax residue is available for energy

c Source is Statistics Canada

Forestry Harvest Residue

In 2010, the model includes 15.7 million ODt/yr of forestry harvest residue that is sustainably available as a feedstock.[22] At roughly 18 PJ/ million ODt, this residue contains 238 PJ. This quantity of biomass comes from roadside piles of branches and

[20] Agriculture and Agri-Food Canada. (2017). *Biomass Agriculture Inventory Median Values*. Available from: www.open.canada.ca

[21] Statistics Canada, CANSIM 001-0017

[22] Yemshanov D., McKenney, D.W., Fraleigh, S., McConkey, B., Huffman, T., Smith, S., 2014, *Cost estimates of post harvest forest biomass supply for Canada,* Biomass and Bioenergy, 69, 80-94

tree tops that are produced during whole-tree harvesting with clear-cut logging. It is net of residue that is not available due to technical reasons (e.g. too dispersed to be extracted) or sustainability reasons (i.e. must be left to maintain nutrients, habitat and forest carbon).

Forestry activity in 2010 was relatively low compared to the annual allowable cut, also known as the wood supply, which is an estimate of what can be sustainably harvested from Canadian forests each year. In 2010, the forestry sector harvested 138.6 million m^3 of wood, but the wood supply was 69% larger, at 234.9 million m^3.[23] The wood supply has been relatively stable in the past, ranging from 223 to 250 million m^3/yr between 1990 and 2015. However, the supply is constrained by natural factor such as the impact of the mountain pine beetle in BC. Notionally, if there is sufficient demand for Canadian wood products, then the quantity of forest harvest residue could about 50% larger (roughly 23 million ODt/yr).

Excluded Feedstocks

The analysis does not include forest product mills waste, urban wood waste and energy crops.

Forest product mill waste is a by-product of turning trees into forest products (e.g. lumber, panels). The quantity of mill residue is a function of demand for forest products and it similar in size to the harvest residue, estimated at 21 Mt/yr in 2005. However, it is generally already used for energy within the mills with some exported as wood pellets.[24] These other uses would compete against 2nd generation biofuels for wood feedstock, but the model does not currently account for this dynamic.

Urban wood waste primarily comes from deconstruction and urban silviculture. The supply is a function of the quantity produced per capita and the degree to which this waste is separated from the general waste stream for utilization. We estimate the quantity of urban wood waste available in Canada at 3 million ODt/yr based on a per capita production of 0.1 ODt/yr/person.[25] This quantity of wood is not insignificant, but because it is relatively small compared to agricultural and forest harvest residue, it is also not included in the analysis.

[23] Government of Canada, National Forestry Database, access May 28, 2018

[24] Bradley, D., 2009, Canada Report on Bioenergy 2009, Climate Change Solutions, NTL - IEA Bioenergy Task 40 - Biotrade

[25] Estimates for urban wood waste vary from 0.07 ODt/capita/yr (Tetra Tech (2015). *2015 Demolition, Land-clearing, and Construction Waste Composition Monitoring Program*, presented to Metro Vancouver), to 0.3 ODt/capita/yr (Agriculture and Agri-Food Canada (2018). *Biomass Inventory Mapping and Analysis Tool*)

Energy crops are excluded from the analysis due to the significant uncertainty in their potential and their GHG impacts. Energy crops will compete with other land-uses including agriculture, forests, prairies and pastures, so it is difficult to quantify how much land may be used for energy crop production. Furthermore, energy crop production can have a very large impact on soil carbon, both positive and negative, depending what crops are grown and where they are grown.[26] In other words, their production can emit or sequester significant quantities of carbon.

Feedstock costs and carbon intensity

The "at-the-plant cost" of agricultural residue in the model is $76/ODt (Table 16) (in 2015 CAD, as are all costs in the appendix). This cost is the sum of the residue's 'farmgate' and transportation costs. The farmgate cost is 69 $/ODt. based on a study crop residue extraction in Ontario.[27] Farmgate costs include harvest and nutrient replacement costs. Harvest costs come from chopping (for corn only), baling, collecting, and storing the residue. The nutrients in the residue that is removed from the fields must be replaced with fertilizers.

The transportation costs for agricultural residue are 7 $/ODt, informed by a study of corn stover transportation costs that are a function of distance travelled.[28] We used the BIMAT online tool to determine an average transportation distance of 40km. The distance is half the radius of an area that can produce roughly 0.72 million ODt/yr of residue (the input for an archetypal biofuel plant in gTech), measured at several locations across Canada using BIMAT.

The "at-the-plant cost" of forest harvest residue in the model is $88/ODt (Table 16). This is based on an assumed harvest cost of $57/ODt.[29] Yemshanov et al. (2014) estimated the transportation cost of forest residue to the nearest existing biomass cogeneration plants with costs ranging from $5/ODt to over 120 $/ODt. We use an average transportation cost of $31/ODt under the assumption that biofuel plants

could be located to mitigate transportation costs (e.g. co-located at existing forest products sites that do not have cogeneration and were not included in the analysis by Yemshanov et al. (2014)).

Table 16: 2nd generation biofuel feedstock production cost assumptions (2015 CAD/ODt)

	Agricultural residue	Forest harvest residue
Harvest/Extraction costs	$35	$57
Transportation to fuel plant	$7	$31
Nutrient replacement	$34	-
Total "at-the-plant" Cost	**$76**	**$88**

Note that the model is a general equilibrium model and all costs result from a corresponding demand for a good or service and will result in energy consumption and GHG emissions from that demand. For example, the transportation costs increase the activity in the truck transportation sector which increases energy consumption and GHG emissions in that sector. Likewise, nutrient replacement increases fertilizer production and the associated energy consumption and GHG emissions. Based on the gTech GHG intensity for truck transportation and fertilizer production in 2010, the carbon intensity of agricultural residue in 2010 is 0.09 $tCO_2e/t_{residue}$ (30% from extraction and transport, 70% from fertilizer). The carbon intensity of forest harvest residue in 2010 is 0.07 $tCO_2e/t_{residue}$ (100% from extraction and transport). The cost and GHG intensity of transportation and fertilizer production can change over time, meaning the feedstock production cost and lifecycle GHG intensity can change as well. These feedstock carbon intensities are further described in the context of biofuel lifecycle carbon intensity in the next section.

Fuel production cost and carbon intensity

The ligno-cellulosic feedstocks within the model (agriculture and forestry residue) can be used to produce three 2nd generation biofuels in gTech: Renewable gasoline and diesel, cellulosic ethanol, and renewable natural gas. The archetypal representations of these fuel production processes are based on plants that consume 0.72 Mt/yr of ligno-cellulosic feedstock.

Renewable gasoline and diesel are modelled as a single fuel pathway that is a perfect substitute for gasoline or diesel. The fuels are produced together via fast-pyrolysis of feedstock into a bio-crude and followed by treatment with hydrogen to upgrade the bio-crude to finished fuels. Model assumptions are in Table 17, which shows the literature estimate for an archetypal plant capital cost: $743 million (2015 CAD) for a plant producing 229 million L/yr. However, because this technology is pre-commercial and there is significant uncertainty in its capital cost, the technology has a 50% cost premium in this analysis, raising the capital cost to $1,114 million (2015 CAD). Renewable gasoline and diesel production is mostly energy self-sufficient, though it does require some electricity as well as hydrogen which can be produced from natural gas.

Table 17: Renewable gasoline and diesel production archetype assumptions

Attribute	Value	Source
Archetype production, million L/yr	229	Jones et al. 2013[30]
Capital cost (literature estimate for for commercial plant), million 2010 CAD	$743	Jones et al. 2013

Feedstock conversion efficiency, $GJ_{feedstock}/GJ_{fuel}$	63%	Derived from above assuming 18 $MJ/kg_{feedstock}$ and 35.5 MJ/L_{fuel}

The cellulosic ethanol fuel pathway in gTech is based on a biochemical process, using enzymes to produce ethanol from ligno-cellulosic feedstocks. The ethanol is functionally equivalent to ethanol produced from crops such as wheat or corn and it is not a perfect substitute for gasoline: We assume it can be blended at 15% by volume after 2020 once newer vehicles account for almost all vehicle stock. The capital cost assumption for cellulosic ethanol is $628 million (2015 CAD) for a 237 million L/yr plant, based on the observed cost of the first cellulosic ethanol plants (Table 18). The process is energy self-sufficient and produces a surplus of lignin which is assumed to be used for cogeneration of heat and power with some electricity export.

Feedstock conversion efficiency ($GJ_{feedstock}/GJ_{fuel}$)	43%	Derived from above assuming 18 $MJ/kg_{feedstock}$ and 35.5 MJ/L_{fuel}, not including electricity production

The 2nd generation renewable natural gas technology is based on the G4 Insights' pyrocatalytic hydrogenation process which produces natural gas from ligno-cellulosic material via fast pyrolysis and hydrogen treatment. The process is energy self-sufficient, meaning that the feedstock is used to produce the fuel, the required hydrogen and the energy for the process. The feedstock to gas conversion efficiency is 74% on an energy basis (Table 19). We assume the capital cost for a plant producing 9.6 PJ/yr is $1.064 million based on a proposal for using the technology and a review of literature sources indicating a much higher capital cost for biomethane production.[33]

2nd generation biofuels provide a significant reduction in lifecycle carbon intensity (Figure 20). The carbon intensity of renewable gasoline/diesel and cellulosic ethanol are 77% and 88% lower than gasoline, respectively (excluding the GHG associated with intermediate inputs to biofuels, e.g. chemicals and enzymes). The carbon intensity of renewable natural gas is 90% lower than fossil natural gas. The carbon intensity of the biofuels mainly comes from diesel consumption (feedstock extraction and transport), fertilizer production (CO_2 by product GHG emissions during ammonia production) and hydrogen production (CO_2 by product GHG emissions during steam methane reformation, renewable gasoline and diesel only). If GHG reduction policy reduces the GHG emissions from these sources, the lifecycle carbon intensity of biofuels can decline further.

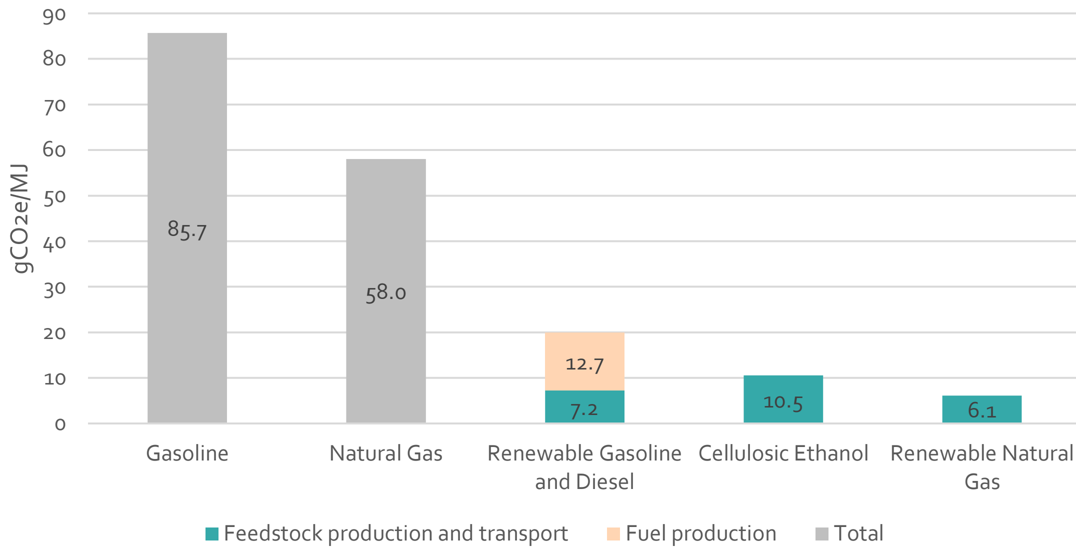
[35] G4 Insights, Our Technology, Accessed April 5th 2018

Figure 20: 2nd Generation Biofuel Carbon Intensity

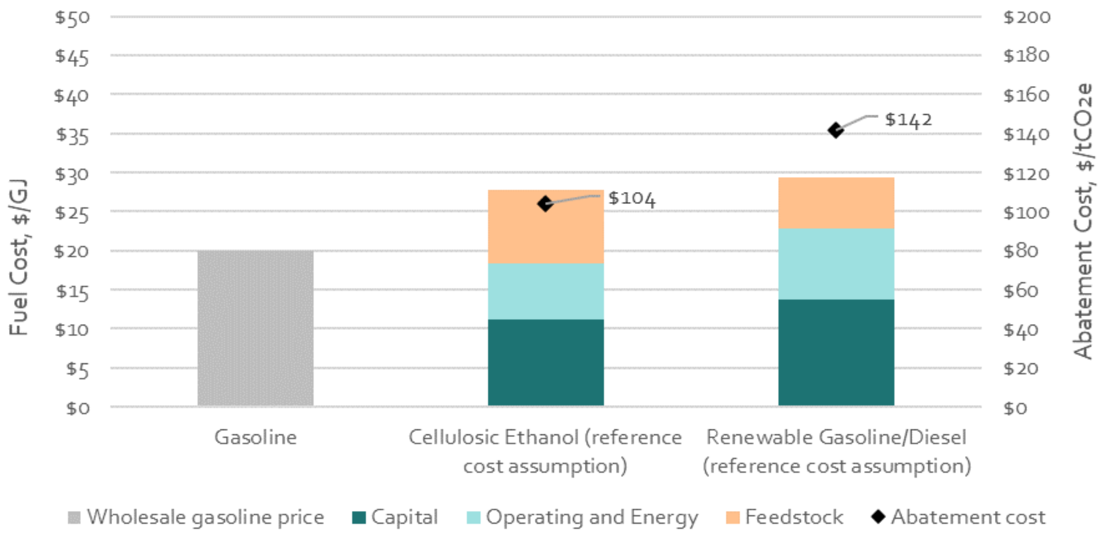


Gasoline and natural gas carbon intensity values from GHGenius 4.03a model, default Canadian values for 2016. Carbon Intensity of biofuels excludes GHG associated with intermediate inputs (e.g. chemicals). Electricity consumption GHG accounted assuming a 55% efficient natural gas-fired combined cycle power plant operating at 327 kg/MWh. Feedstock carbon intensity assumed 50% agricultural residue and 50% forest harvest residue.

With the reference biofuel cost scenario assumptions for 2nd generation biofuel production capital costs, the production cost for cellulosic ethanol is \$26/GJ (2010 CAD, equivalent to \$0.61/L). If the gasoline production cost is \$20/GJ (\$0.70/L, based on 70\$/bbl US oil), the GHG abatement cost is \$80/tCO_2e (Figure 21. With the reference biofuel cost scenario assumptions for renewable gasoline and diesel production capital costs, that fuel costs \$32/GJ (\$1.14/L), with an abatement cost relative to gasoline of \$185/tCO_2e (Figure 21).

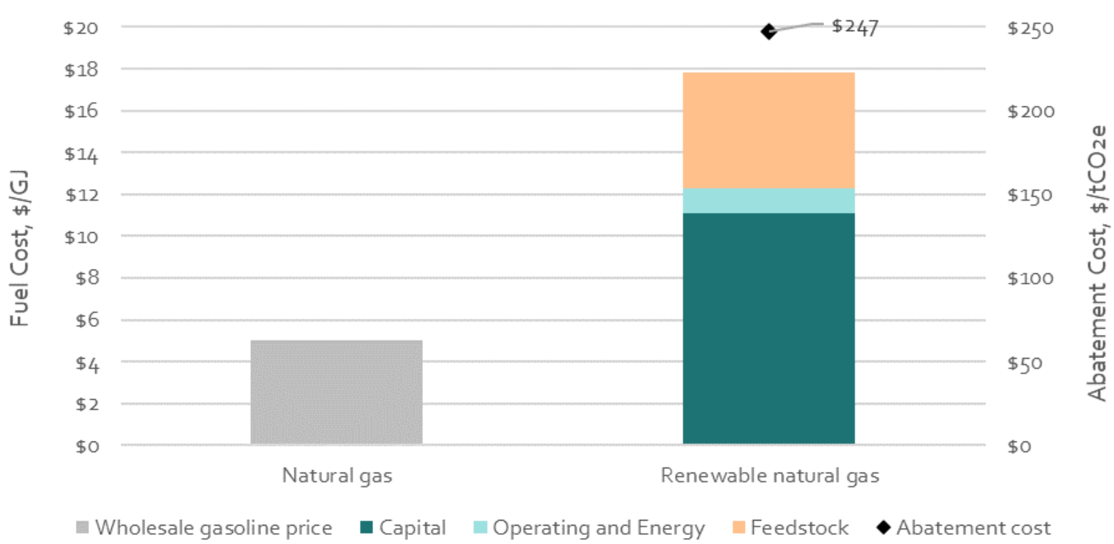
Similarly, the cost of renewable natural gas produced from ligno-cellulosic material is \$13.4/GJ with using the reference scenario assumptions for its capital cost (Figure 22). At this cost, the abatement cost is \$162/tCO_2e when the price of natural gas is \$5/GJ (2010 CAD).

Figure 21: 2nd Generation Liquid Biofuel Production and Abatement Cost (2010 CAD)



The cost of gasoline is calculated assuming a $70/bbl price, a Canada/US exchange rate of 1.25 and a refining margin of $0.15 2015 CAD/L. Ligno-cellulosic feedstocks are assumed to cost $74/ODt, an average of agricultural and forestry harvest residue supply costs in gTech. The abatement cost of cellulosic ethanol does not account for an improvement in the energy efficiency of the vehicle and or a reduction in the cost of gasoline blendstock it is blended with due to lower octane requirements.

Figure 22: 2nd Generation Gaseous Biofuel Production and Abatement Cost (2010 CAD)



The cost of natural gas is assumed at $5/GJ. Ligno-cellulosic feedstocks are assumed to cost $74/ODt, an average of agricultural and forestry harvest residue supply costs in gTech.

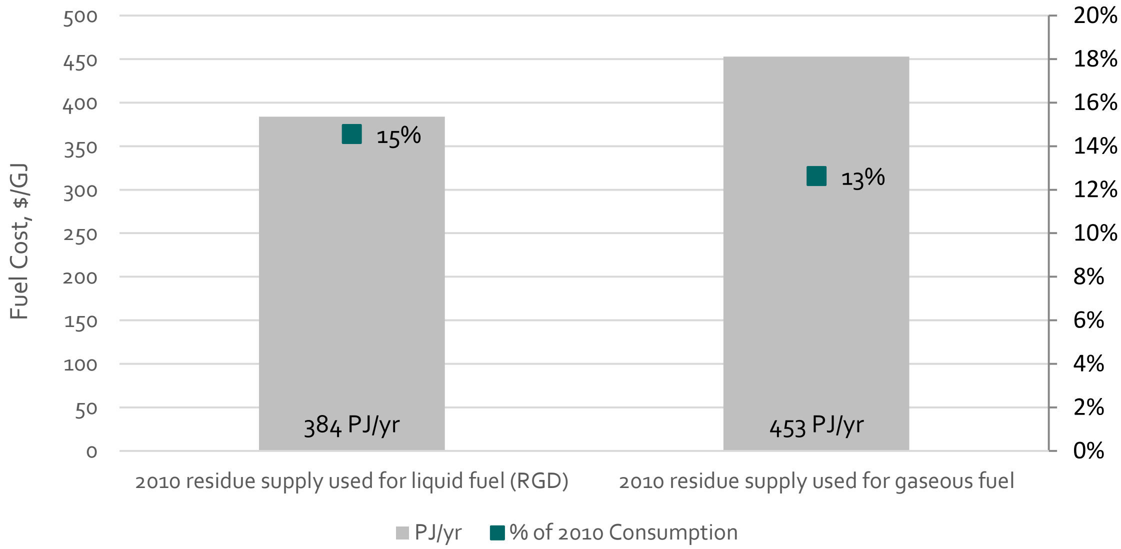
Production potential

If all residues available in 2010 calculated in the previous sections were used to produced renewable gasoline and diesel then the quantity of fuel produced would be 384 PJ/yr (15% of gasoline and diesel consumption in Canada in 2010) (Figure 23). If that residue were used to produce gaseous fuel, the quantity of natural gas produced would be 453 PJ/yr (13% of fossil natural gas consumption in 2010, including own use and consumption of natural gas to generate electricity.

This estimation of the 2^nd^ generation biofuel production potential is only meant to illustrate the magnitude available: it is a potentially significant low-carbon energy resource, but it cannot replace current fossil fuel consumption. There are some important caveats to keep in mind when interpreting this data:

- Residue production can increase: Somewhat more agricultural production is possible, though land is constrained in gTech, and potentially 50% more forestry activity is possible with a proportional increase in forestry harvest residue.
- Fossil fuel consumption will decline in most scenarios where 2nd generation biofuels are used: GHG reduction policy will drive more energy efficiency and electrification. These will reduce the total quantity of fossil fuel required, be it fossil or bio-derived. Therefore, the fraction of fossil fuel than can be substituted with 2nd generation biofuels will be larger than shown in Figure 23.
- The USA has a substantial supply of residue that could be used for fuel. However, if there is strong GHG reduction policy in the US, there would be substantial new demand for bioenergy. Therefore, the impact of US on the supply of feedstock available for Canadian fuel consumption is important.
- Other residues are available and could increase the production potential. For example, urban wood waste could increase the potential shown in Figure 23 by another: e.g. urban wood waste is available and could increase the production potential by another 50-60 PJ/yr.

Figure 23: Fuel production potential if the quantity of residue characterized in gTech in 2010 is converted to liquid fuels (renewable gasoline and diesel) or gaseous fuel: PJ/yr fuel (bars, left axis) and fraction of incumbent fossil fuel (points, right axis)



Assumptions for light-duty vehicles

The model includes two internal combustion engine vehicle technologies, and one of each hybrid, plug-in hybrid, battery electric, and fuel cell vehicle technologies in the light-duty sector. Archetypes are based on a midsize passenger car with a 150-kW power output. An intangible cost is added to represent perceived cost due to range anxiety as well as the actual cost of renting an internal combustion engine (ICE) vehicle for trips longer than the electric vehicle's assumed range.

The cost breakdown for the basic gasoline vehicle archetype is based on a 2015 Idaho National Laboratory report. The Energy Information Administration's National Energy Modeling System documentation is used to define the incremental cost and efficiency improvement for the efficient gasoline vehicle archetypes. The cost breakdown for battery electric vehicles is informed both from the UBS Bolt Teardown report and Bloomberg's battery cost assumptions. The cost breakdown for hybrid and plug-in hybrid vehicle costs is calculated using a combination of ICE and electric vehicle costs as reported in Argonne National Laboratory's 2016 Autonomie Model. The plug-in hybrid archetype in the modelling is based on Argonne's depiction of an extended range plug-in hybrid as opposed to a split drive plug-in hybrid. Battery energy density is assumed to improve by 2% per year between 2015 and 2025, after which it remains constant. Fuel cell vehicle cost components are based on a Strategic Analysis Consultants report prepared for the U.S. Department of Energy.

Table 20 through Table 23 contain the reference scenario breakdown of purchase prices for the various light-duty vehicle archetypes included in the analysis. Because component costs decline as a function of vehicle adoption, these values are in fact model results based on fundamental inputs about the cost of various vehicle components and the potential for those costs to change. Conventional vehicle costs are between $21,556 and $22,923, depending on the energy efficiency of the vehicle archetype. Table 24 shows the assumed energy intensity and Table 25 summarizes the sources used to characterize the vehicle archetypes.

Assumptions for medium-duty vehicles

The model includes four medium-duty vehicle archetypes that use internal combustion engines, three of which are diesel fueled, with the fourth fueled by compressed natural gas. It also includes archetypal hybrid, plug-in hybrid, battery electric, and fuel cell vehicles. A survey and literature review conducted in 2019 shows that most medium-duty vehicles fit within the smaller weight classes (3 to 5), which are characterized by power outputs close to 170 kW. The daily driving range is sourced from the same survey.

Most medium-duty vehicle costs are based on the National Renewable Energy Laboratory (NREL) FASTSim model inputs with some adjustments to the battery cost and fuel cell drivetrain cost. These larger commercial vehicles are expected to require more advanced charging infrastructure than personal light-duty vehicles. Costs are based on charging infrastructure costs for local operations as reported by the ICCT in 2019.

Medium-duty vehicle energy intensities are inferred from the energy intensities of heavy-duty vehicle technology archetypes. For example, if the heavy-duty fuel cell technology is 60% more efficient than the base heavy-duty diesel technology, then the same relative energy intensity is applied for the medium-duty fuel cell vehicle archetype.

Battery costs are based on Bloomberg's electric vehicle outlook publications, and battery energy density is assumed to improve by 2% per year between 2015 and 2025, after which it remains constant.

The energy consumption of freight vehicles is shown in megajoules per tonne kilometre (MJ/tkm). The energy consumed per vehicle kilometre is calculated by multiplying MJ/tkm by the tonnes of freight moved per vehicle. We assume that medium-duty vehicles move 1.3 tonnes of freight on average each, consistent with NRCan CEUD data. Therefore, a new diesel vehicle consumes 7.2 MJ/km (equivalent to around 19 L/100 km).

Table 26 through Table 30 contain the vehicle archetype price breakdown. Again, these are model results that are a function of battery and other component cost reductions that occur in the simulation. Table 31 presents the energy intensity of the medium-duty vehicle archetypes and Table 32 provides more detail on the information sources used to characterize these technologies.

Assumptions for heavy-duty vehicles

The model includes four internal combustion engine vehicle technologies, of which three are diesel, and one is natural gas, as well as a battery electric and a fuel cell vehicle technology each in the heavy-duty sector. The model's heavy-duty vehicle archetypes are mostly based on a 2017 ICCT report. The trucks are all assumed to have a 350-kW engine or motor, as per the publication. The daily driving range is inferred from the survey of British Columbia's medium and heavy-duty fleet that Navius conducted in 2019.

The vehicle cost breakdowns are estimated both using the ICCT 2017 report and a 2017 paper written by Fries M. et al. Battery costs and fuel cell system costs are based on Bloomberg and Strategic Analysis Consultants' work, respectively. Battery energy density is assumed to improve by 2% per year between 2015 and 2025, after which it remains constant.

The energy intensities for the heavy-duty vehicle technology archetypes shown below are all inferred from ICCT's 2017 report. As with medium-duty vehicles, advanced charging infrastructure costs are also included for plug-in technologies. We assume that 30% of heavy-duty vehicles are used for long-haul transport and 70% for local operations. The ICCT finds that long-haul operation will likely require higher infrastructure costs, hence the higher estimate relative to the exclusively locally operated medium-duty vehicle cost.

We estimate that a battery electric class 8 tractor weighs 11% more than a diesel tractor. Heavy-duty vehicles are restricted to a maximum weight for safety and infrastructure capacity limits, which means that any extra tractor weight reduces the hauling capacity. We therefore apply an 11% markup to the heavy-duty battery electric archetype to account for this disadvantage.

We use Natural Resources Canada's Comprehensive Energy Use Database and adjust it with the daily distance travelled estimated from our survey to infer that heavy-duty vehicles transport about 9.7 tonnes of freight on average over each km.

Table 33 through Table 35 contain the vehicle archetype price breakdown. As with other vehicle types, these are model results that are a function of battery and other component cost reductions that occur in the simulation. Table 36 presents the energy intensity of the heavy-duty vehicle archetypes and Table 37 provides more detail on the information sources used to characterize these technologies.

Industrial heat pumps

Heat pumps use energy to run a refrigeration cycle which is the compression and expansion of a fluid. This cycle moves energy in the form of heat from a lower-temperature source to a higher-temperature sink. Both thermal energy (e.g. waste heat, heat from combustion) and mechanical energy can drive the refrigeration cycle, where the quantity of energy transferred is typically much larger than the quantity of energy consumed by the heat pump. The focus of this research work is on mechanical heat pumps that use compression to drive the refrigeration cycle, with the compressor typically powered by an electric motor.

Although the most familiar application of heat pumps is for space and water heating in buildings, high capacity heat pumps can also be used in industry to provide heat for industrial processes. Industrial heat pumps can draw heat from several sources with a range of temperatures, from ambient air and water to process cooling water and process waste heat. Industrial heat pumps do not just provide passive heat recovery, but like their applications in buildings they take energy from a source and supply it at a higher temperature to the sink.

Currently, industrial heat pumps are not widely used. Barriers to their adoption include:

- **A lack of knowledge** about industrial heat pump technologies and a lack of attention to heat consumption within industrial facilities.
- **The high upfront costs** and long-payback periods. While heat pumps may reduce energy costs, their initial investment cost is higher than for a fossil fuel-fired boiler or heater. At current energy prices and with low (or no) cost for carbon emissions, industrial heat pumps are often not cost-competitive with gas-fired heat.

- **The limits on their supply temperature.**[36] Commercially available industrial heat pumps generally only provide heat at temperatures up to 100 ºC, though new technologies could raise this maximum to 140 ºC.[37]

Within the limits of their supply temperature, industrial heat pumps may be used for a range of end-uses that include drying, cooking, distillation, washing, and pre-heating. Case studies from Canada, Austria, Germany, France, and Denmark provide 42 examples of industrial mechanical heat-pumps used in a variety of manufacturing sectors (Table 38).[38] Each application is characterized by its coefficient of performance COP, which is a measure of how much heat is provided to the sink divided by the amount of energy used to move that heat from the source. The case studies are also characterized by their sink and source (i.e. supply) temperatures.

The COP depends the design of the heat pump and the on source and sink temperatures, with the difference in temperature know as the "lift".[39] The case studies provide examples that are currently economically viable, and they tend to have high COPs associated with smaller lifts and lower supply temperatures. Wider application of industrial heat pumps should see them used with larger lifts and higher supply temperatures (e.g. supply at 90-100 ºC, with a lift of 50-70 ºC). These conditions would result in lower COPs ranging from 2 to 3.[40] For example, commercially available heat pumps for lumber drying use ambient air to heat lumber kilns to temperatures as hot as 116 ºC. These systems use 40-60% less energy than a direct or steam heated kiln.[41] If the conventional system is 85% energy efficient, this energy savings implies a COP between 1.4 and 2.2.

The archetype of industrial heat pumps in gTech provides low-temperature heat for industry, based on a closed-cycle mechanical compression using electricity to drive the refrigeration cycle. The capital cost and COP of this archetype depend on the assumed temperature lift and supply temperature: larger lifts and higher supply temperatures will have higher capital costs and lower COP.[42] The archetype is based on a system that would apply across the broadest range of end-uses, with high supply temperatures (90-100 °C) and lift (70 °C). Under these conditions the COP is 2.5 and the capital cost is 840 $/kW (2010 CAD),[43] roughly three and a half times higher than for a natural gas combustion boiler (Table 39).

Table 39: gTech inputs for an industrial heat pump compared to a natural-gas boiler

Technology	Capital Cost (2010 CAD/kW)	Electricity, $GJ/GJ_{thermal}$	Natural gas, $GJ/GJ_{thermal}$
Industrial heat pump	838	0.4	-
Efficient gas boiler	233	-	1.1

We assume the industrial heat pump technology in gTech can supply heat to a maximum of 100 °C. Table 40 summarizes the share of heat demand that is 100 °C or less by sector. For most sectors, this share is based on a study of German industries that characterized heat consumption by sector and temperature.[44] Our assumption is that the temperature profile of heat demand by sector is the same in Canada (e.g. if 45% of the heat required for food and beverage manufacturing is at or below 100 °C in Germany, we assume that this fraction is representative for Canada). The fraction of

42 Ommen, T., Jensen, J.K., Markussen, W.B., Reinhold, L., Elmegaard, B. (2015) *Technical and Economic Working Domains of Industrial Heat Pumps: Part 1 - Single Stage Vapour Compression Heat Pump*, International Journal of Refrigeration, 55, 168-182

43 Ibid.

44 German Energy Agency (DENA) (2016), *Process Heat in Industry and Commerce: Technology Solutions for Waste Heat Utilisation and Renewable Provision*

heat below 100 °C in the forest products manufacturing sector (e.g. lumber and structural panels) is based on the fraction of thermal energy used for product drying estimated by Natural Resources Canada.[45]

Table 40: Modelling assumptions for the fraction of industrial heat demanded at less than or equal to 100 °C, by sector

Sector	% of heat demand <= 100 °C
Food & beverage manufacturing, agriculture processing	45%
Other manufacturing	30%
Chemical and biofuel manufacturing	15%
Forest products	85%
Pulp and paper	20%
Mineral and metal mining	100%

Direct-air carbon capture

Direct air capture (DAC) is a new negative emissions technology that extracts CO_2 directly from the atmosphere. DAC could play an important role in achieving future emissions reductions goals, such as the targets set out in the Paris Agreement.

Several DAC companies are currently in operation, such as Carbon Engineering in Squamish, BC. There are two technologies currently used for DAC. Air is either passed through a high temperature liquid sorbent, or a low temperature solid sorbent that both bind the CO2 from the air.[46] In both cases, DAC is currently an energy intensive process that requires both electricity, for fans and compressors, and heat, to regenerate the sorbet. While the heat may be electrified in the future, most current cost estimates assume the use of natural gas combustion, where the combustion emissions are captured along with atmospheric CO_2.

The future costs of DAC are uncertain, but all sources reviewed expect the cost of DAC to decline over time. In gTech, we estimate the cost of DAC using a declining capital cost function, where the upfront costs declines as a function of the cumulative deployment of the technology. The function was estimated from harmonizing cost estimates made by Fasihi et al. (2019), Larsen et al., (2019), and Keith et al.

[45] Natural Resources Canada (2009), *Status of Energy Use in the Canadian Wood Products Sector*

[46] IEA (2020). *Direct Air Capture*, IEA, Paris https://www.iea.org/reports/direct-air-capture

(2019).[47,48,49] While these sources use differing assumptions when calculating DAC costs, the costs communicated here and input to the model are based on the following assumptions:

- Discount rate of 15%
- 30 year lifespan
- 90% capacity utilization
- Natural gas price of $2.6/GJ (2015 CAD) and an electricity price of $95/MWh (2015 CAD) (for the sake of illustration in this report. Actual energy costs are determined for each region during the model simulation).

Figure 24 shows the cost of DAC per tonne of CO_2 reduced for each of the sources in with three different levels of technology deployment (first of a kind facility, early commercialization (8 $MtCO_2$ captured per year) and full commercialization (over 1.5 $GtCO_2$ captured per year). The figure disaggregates the cost of DAC into capital costs, fixed operating costs, variable operating costs, and fuel costs (natural gas and electricity). All sources examined expect DAC costs to decline over time with ongoing deployment. DAC cost estimates in the studies examined differ significantly, ranging from CAD 303 to CAD 1,295 per tonne of CO_2 reduced for a 1st of a kind plant in the reference case. In the long-term, estimates range from CAD 99 to CAD 142 per tonne of CO_2 reduced.

49 Keith et al., (2018). A process for Capturing CO2 from the Atmosphere. Joule, 2, 1-22.

Figure 24: Direct air capture abatement cost estimates from the literature

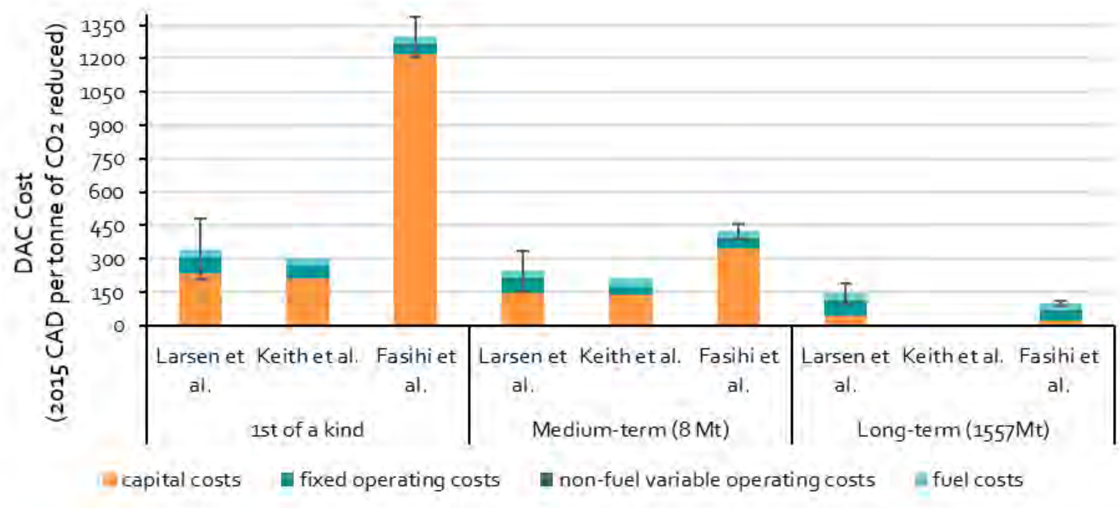

Figure 25 shows the DAC cost inputs used in this analysis. During early commercialization, the abatement cost is about \$370/tCO_2 (with about 30 Mt captured per year in North America). If the technology see substantial deployment, abatement costs may fall to as low as \$150/tCO_2 (e.g., with more than 600 Mt captured annually in North America). In all cases, costs are dominated by capital expenditures.

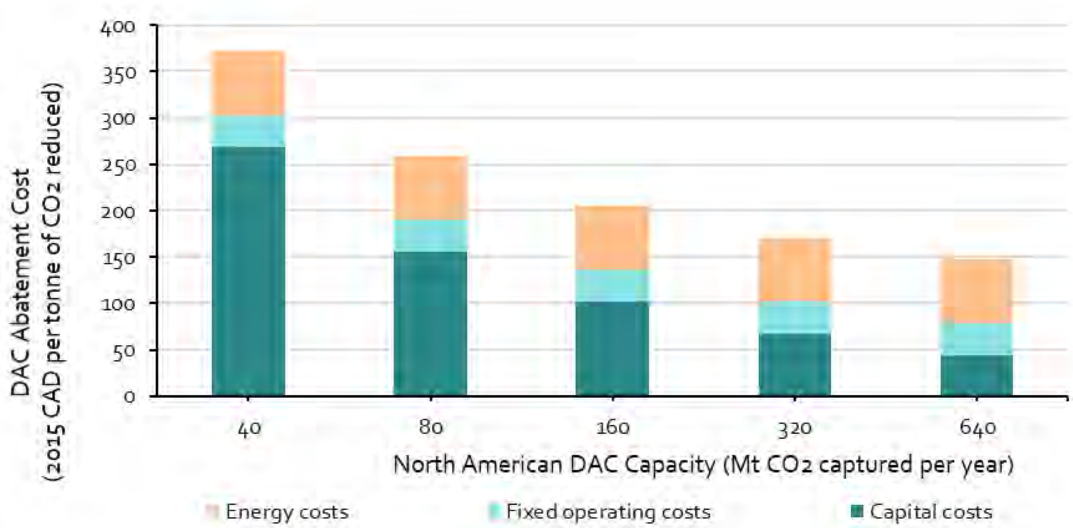
Figure 25: Direct air capture abatement cost inputs to the analysis



Appendix B: Building Sector Technology Assumptions

Building envelopes

The building envelope technology archetypes for the British Columbia (BC) region of the gTech model were developed in cooperation with RDH Building Science. The archetypes characterize BC's existing building stock and the thermal improvements associated with current and future building codes.

Building envelopes are disaggregated into nine building types, three vintages and three levels of new construction as shown in Table 41 and Table 42. Note that low-rise and high-rise apartment buildings are aggregated. RDH provided the data for these archetypes in three regions of BC (lower mainland, Kamloops and Prince George). These archetypes were aggregated to form a single representative region for use in gTech. Additional modifications to the archetypes were made to ensure that total floor space and demand for space conditioning aligned with Natural Resources Canada's Comprehensive Energy Use Database.

The costs are the portion attributed to the relevant elements of the building envelope and do not represent full construction costs. The costs for existing building envelopes are the cost to perform a comprehensive retrofit of the building envelope as would be required to meet new construction performance targets (i.e. a deep energy retrofit with a significant reduction, about 50%, in heating required). RDH's general description of their approach in developing the archetypes is in the Appendix. Additional detail by archetype can be provided upon request.

Building floor area by type

The share of building floor area by building type (e.g. apartment, single family detached home) is a result of gTech rather than an input. Nonetheless, this result can be calibrated to expectations, such as an increasing share of residential building floor area in higher density building types (Table 43). The fraction of commercial and institutional floor area by building type is constant over time as gTech does not disaggregate the services sector into subsectors and all segments grow at the same rate (Table 44, showing the trend to 2030).

Table 43: Residential building area by building type (%)

Mechanical systems

Space and water heating archetypes are based on data from the US Energy Information Administration[50] and National Renewable Energy Laboratory[51]. These archetypes are shown in Table 45, Table 46 and Table 47. Costs for the residential technologies are given as costs for a unit sized for an individual household. The output attribute of each archetype represents typical utilization of each technology: the quantity of heating provided, or the volume of hot water provided (with a 46.5 ºC temperature lift). Space cooling is a relatively small energy end-use in British Columbia and the space cooling technology archetypes are not currently included in this report.

Table 45: Residential space heating technology archetypes

End-use	Archetype	Capital cost (2018$)	Energy Efficiency (GJ_{out}/GJ_{in})	Output (GJ/yr)
Space heating*	Standard efficiency gas furnace	$4,746	90%	36.2
	Condensing gas furnace	$5,284	98%	36.2
	Electric baseboard	$3,040	100%	36.2
	Standard efficiency ASHP	$5,702	2.4	36.2
	High efficiency ASHP	$7,137	2.6	36.2
	High efficiency NGHP	$18,345	1.3	36.2

* equipment life is assumed to be 20 years for space heating

51 National Renewable Energy Laboratory. 2018. National Residential Efficiency Measures Database. Accessed from: https://remdb.nrel.gov/

Table 46: Residential water heating technology archetypes

End-use	Archetype	Capital cost (2018$)	Energy Efficiency (GJ_{out}/GJ_{in})	Output (m^3/yr)
Water heating*	Standard efficiency gas water heater with tank	$705	59%	82.0
	High efficiency gas water heater with tank	$819	67%	82.0
	Standard efficiency electric water heater with tank	$671	92%	82.0
	High efficiency electric water heater with tank	$739	95%	82.0
	Standard efficiency ASHP water heater	$2,274	2.0	82.0
	Standard efficiency tankless gas water heater	$1,706	82%	82.0
	High efficiency tankless gas water heater	$2,161	96%	82.0

* equipment life is assumed to be 9 years for water heating

Table 47: Commercial space and water heating technology archetypes

End-use	Archetype	Capital cost (2018$/$m^2$)	Energy Efficiency (GJ_{out}/GJ_{in})	Output (GJ/m^2/yr)
Space heating*	Standard efficiency gas boiler	$10.06	80%	0.35
	High efficiency gas boiler	$10.67	85%	0.35
	Condensing gas boiler	$11.29	98%	0.35
	Standard efficiency electric boiler	$5.46	98%	0.35
	High efficiency GSHP	$41.91	5.0	0.35
	High efficiency ASHP	$14.09	3.2	0.35
Water heating*	Standard efficiency gas water heater with tank	$1.47	80%	0.10
	Condensing gas water heater with tank	$1.73	99%	0.10
	Standard efficiency electric water heater with tank	$1.61	98%	0.10
	Standard efficiency ASHP water heater	$4.90	2.0	0.10

* equipment life is assumed to be 25 years for space heating and 10 years for water heating

Major appliances

Table 48 and Table 49 show the technology assumptions for fridges and freezers. The technologies are based on data from the National Renewable Energy Laboratory.[52] The archetype of "existing" technology stock is calibrated to the NRCAN Comprehensive Energy Use Database (CEUD).[53] The energy consumption of electric and gas ranges are also calibrated to NRCAN's estimate for total stock and new stock in the CEUD (Table 50). The energy consumption of the induction range is based on a doubling of the cooktop energy efficiency, but with the cooktop only accounting for 35% of a range's annual energy consumption (remainder from oven).

The energy intensity of the existing stock of dishwashers and clothes washers is calibrated to the NRCAN CEUD (Table 51, Table 52). New stock represents units that are compliant with regulations. New efficient archetypes are based on units that represent the most efficient models available. Note that most energy related to clothes washing is consumed by the clothes dryers, with the intensity of drying related to the amount of water removed in the clothes washer. gTech currently does not represent how a more efficient clothes washer also reduces clothes drying energy consumption. The energy intensity of drying is calibrated to the NRCAN CEUD and clothes drying energy consumption is roughly proportional to the number of households in a forecast.

Note that gTech also includes energy (primarily electricity) consumption for other appliances and electronics. The quantity of electricity consumed is roughly proportional to the number of households in a forecast.

Table 48: Residential refrigerator technology archetypes

End-use	Archetype	Capital cost (2018$)	Energy Consumption (GJ/yr)
Refrigeration*	Existing	$922	2.00
	Standard Efficiency	$922	1.80
	Medium Efficiency	$1,090	1.43
	High Efficiency	$1,247	1.35

* equipment life is assumed to be 17 years for refrigeration

53 Natural Resources Canada, Comprehensive Energy Use Database, http://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/menus/trends/comprehensive_tables/list.cfm

Table 49: Residential freezer technology archetypes

End-use	Archetype	Capital cost (2018$)	Energy Consumption (GJ/yr)
Freezers*	Existing	$519	1.46
	New	$524	1.35
	High Efficiency	$553	1.24

* equipment life is assumed to be 21 years for freezers

Table 50: Cooking range technology archetypes

End-use	Archetype	Capital cost (2018$)	Energy Consumption (GJ/yr)
Ranges*	Electric, high efficiency/induction	$1,300	1.54
	Electric, new	$600	1.88
	Electric, existing	$600	2.39
	Natural gas, existing	$700	4.43
	Natural gas, new	$700	4.41

* equipment life is assumed to be 20 years for ranges

Table 51: Dishwasher technology archetypes

End-use	Archetype	Capital cost (2018$)	Electrical Energy Consumption (GJ/yr)	Hot Water Consumption (m^3/yr)
Dishwashers*	Existing	$746	0.44	4.6
	New efficient, EF58	$756	0.29	3.4
	New most efficient, EF 94	$1,708	0.06	2.8

* equipment life is assumed to be 12 years for dishwashers

Table 52: Clothes washer technology archetypes

End-use	Archetype	Capital cost (2018$)	Electrical Energy Consumption (GJ/yr)	Hot Water Consumption (m^3/yr)
Clothes washers*	Existing	$613	0.32	8.2
	New, compliant with regulation (MEF~39)	$613	0.23	7.4
	New, efficient (MEF~67)	$764	0.07	1.4

* equipment life is assumed to be 12 years for clothes washers

Lighting

Table 53 shows the residential lighting technology archetypes. The archetypes are based on a 60W equivalent (roughly 850 lumens) serving 3.4 m^2 and operating for 652 hours/yr. The capital cost and energy consumption for commercial and institutional lighting is expressed per m^2 of floor area served (Table 54).

Table 53: Residential lighting technology archetypes

	Capital cost per 60W equivalent (2018$)	GJ/yr per 60W equivalent
Incandescent	0.25	0.041
Halogen	1.99	0.030
Compact fluorescent	2.74	0.009
LED	7.53	0.006

Table 54: Commercial and institutional lighting technology archetypes

	Capital cost per m^2 of floor space served (2018$)	GJ/yr m^2 of floor space served
Existing	14	0.15
New	14	0.10
New efficient	21	0.06

At Navius, we offer our clients the confidence to make informed decisions related to energy, the economy, and the environment.

We take a collaborative approach to projects, drawing on a unique suite of modeling, research and communication tools to provide impartial analysis and clear advice.

Notes:

1 Forecast values include load additions (EVs, Codes and Standards Overlap, LCE/Fuel Switching) and large industrial DSM persistence estimates.

2 Light Industrial/Commercial is the sum of the loads in the light industrial sector and commercial sector.

3 Domestic sales equals total firm sales less sales to BC Hydro own use.

4 Growth rates are computed over a five year period on an annual compound growth basis.

Vegetation Management Strategy (VMS)

Table of Contents

List of Figures

List of Tables

1 # 1 Definitions of Key Terms

2 There are a number of vegetation management-related trade terms used in this
3 document, which are set out below for ease of reference.

Term	Description / Definition
Edge Tree	Refers to a tree at the edge of the right-of-way that was identified as a potential risk as a result of its condition or other observable factors. Edge trees are removed to reduce the risk of them falling onto transmission assets.
Distribution Vegetation Management	Managing the vegetation on the distribution system. The vast majority of vegetation is on private or public land in proximity to the power system.
Hot-Spotting	Selective and targeted removal of a tall tree(s) or area within the transmission system to address an immediate risk or area of concern.
Hazard Tree	A tree that has a defect or adverse environmental condition that predisposes it to failure and that can cause damage if it falls (e.g., a power line, electrical equipment, buildings, people, etc.).
Light Detection and Ranging (**LiDAR**)	A LiDAR sensor uses infrared and ultraviolet light to map out the environment around it. It can get a sense of both the physical dimensions and motion (if any) of objects in its vicinity.
Rights-of-Way (**ROW**)	The legal right to the area below and surrounding transmission lines where BC Hydro is responsible for vegetation management and maintenance.
Riparian	The area of land adjacent to a water body that contains vegetation that is distinctly different from the vegetation of adjacent upland areas due to the presence of water.
Right-of-Way Clearing	Full clearing of vegetation within the right-of-way beneath and adjacent to the transmission system.
Transmission Vegetation Management	Managing the vegetation in proximity to high voltage transmission lines, including directly underneath and adjacent to conductors and structures.
Vegetation Management	The practice of reducing the risk of contact between vegetation (e.g., trees, shrubs, etc.) and electrical assets by proactively removing vegetation or reducing it in size or height.
VegNET	A mobile field application used to facilitate and spatially locate all tasks and activities related to transmission vegetation and access for BC Hydro staff, consultants and contractors.
On-Cycle Distribution Vegetation Management Work	Vegetation maintenance activities performed according to the standard work plan that aligns to vegetation growth rates and regional needs. Results in efficient area-based management and addresses vegetation risks in the area specified within the work plan.

Term	Description / Definition
Off-Cycle Distribution Vegetation Management Work	Off-cycle work often involves triage of required vegetation needs and highest risk areas receiving treatment versus full area maintenance. It results from a deviation from the optimal work plan in response to unplanned impacts. Average cost of off-cycle work is higher than on-cycle work.
Vegetation Accumulation	Vegetation growth on the system that has not been addressed within the current work plan and requires attention. Vegetation in this state constitutes an accumulation of vegetation material and work effort is necessary for removal.
High Voltage Transmission Circuits (**HVTC**)	Vegetation management description of transmission lines above 138 kV (but includes the 138 kV interties to Alberta) that are subject to the FAC-003 mandatory reliability standard due to system criticality.
Low Voltage Transmission Circuits (**LVTC**)	Vegetation management description of transmission lines at or below 138 kV.
Canadian Electricity Association (**CEA**)	The Canadian Electricity Association is national in scope and includes representation from all major Canadian utilities.
Program and Contract Management (**PCM**)	The Program and Contract Management KBU is responsible for the execution of capital and maintenance work programs on the generation, transmission and distribution systems as well as smaller scale projects on the BC Hydro system including distribution system improvement, major customer, substation and generation facility upgrades.
Site Prescription	A specific set of professional instructions developed by experienced foresters, biologists or other qualified vegetation personnel pertaining to the treatment plan for a specific site.

2 Version History and Revision Control

Version	Date / Version Notes
Version 1.0	July 12, 2021

Directive 10 of the BCUC's Decision on the Previous Application directed BC Hydro to file the new Vegetation Management Strategy and any revisions to it thereafter. The following defines the changes that would constitute a revision to the Vegetation Management Strategy:

Change	Description / Definition
Program Expenditures and Resource Variance	Annual vegetation expenditures and resources (FTEs) > 5 per cent.
Core Program Change(s)	Planned annual work volumes that are reduced below the minimum levels identified within the VMS.
Compliance Impacting Program Adjustments	Any deliberate program adjustment that would impact the ability to achieve mandatory compliance requirements.

The following occurrences do not constitute a revision to the Vegetation Management Strategy:

Event	Description / Definition
Uncontrollable Work Output Impacts	Variances to actual work outputs based on circumstances that are uncontrollable (e.g., work stoppage during drought, wildfires, labour disruption, etc.).
Non-Core Initiative(s) Scope, Schedule and Delivery	Beyond the core vegetation maintenance program, the VMS articulates a series of initiatives and pursuits. The scope, schedule and delivery of these will be adjusted regularly based on the requirements of the core maintenance program and would not constitute a revision of the VMS.
Continuous Improvements and Internal Organizational Structures	Over the course of the VMS delivery, it is expected that processes will be reviewed and enhanced, these would not require a formal revision of the strategy. Internal organization structures and accountabilities may also evolve over time and will not trigger a formal revision providing the impact to work output is not materially detrimental.

BC Hydro will file any revisions to the Vegetation Management Strategy with the BCUC.

3 Executive Summary

BC Hydro has an ongoing need to maintain vegetation surrounding the electrical system to ensure safe and reliable delivery of electricity. Vegetation management is a significant undertaking in British Columbia due to the size of the electrical system (approximately 18,500 kms of overhead transmission lines, over 48,600 kms of overhead distribution lines), the design of the system (primarily overhead), the climate (significant precipitation) and the extent of forestation (including fast growing and tall flora species).

Following an analysis in fiscal 2021 and summarized in the Fiscal 2022 Revenue Requirements Application, BC Hydro identified the need for incremental investment in vegetation management as a result of numerous exogenous cost pressures absorbed over the past decade while the program annual budget remained relatively stable. System performance was maintained by a prior period of extensive clearing and the benefits of this activity have been realized as the cost pressures were absorbed in the program. As a result of the recent vegetation accumulation adjacent to the electrical system, there is now a need to increase the overall annual vegetation program to sustain a regular maintenance cycle that is equal to regrowth levels.

BC Hydro has developed a new Vegetation Management Strategy (**VMS**) that defines the annual program that achieves a stable annual maintenance cycle while improving the capability to proactively identify emerging areas of need. Additionally, the strategy identifies a series of initiatives, pursuits and studies that will continue to enhance the overall ability for BC Hydro to deliver vegetation work and reduce the risk posed by vegetation (including encroachments, wildfires and similar hazards).

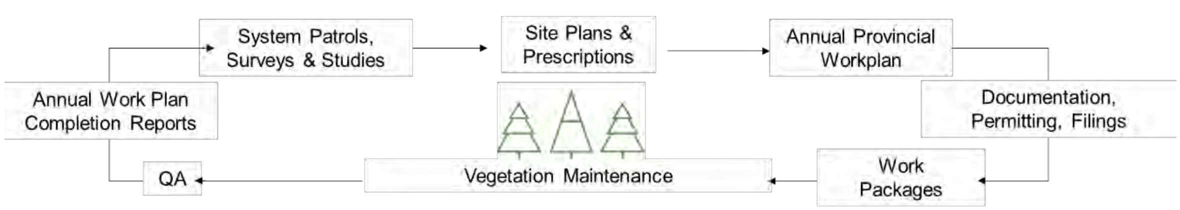
The annual expenditure for vegetation management will increase from the prior decade average of approximately $50 million per year to a new normal of approximately $90 million per year. The incremental investment is believed to be sufficient to identify and meet the required needs of the system including: maintaining compliance, improving reliability and achieving the stated goals of the new VMS under normal conditions. Following this increase, BC Hydro still continues to remain among the lowest cost utilities with respect to vegetation management expenditures on a per customer basis while delivering a vegetation program that meets industry standards and compliance requirements.

4 Background

BC Hydro's significant annual investment in vegetation management reflects the importance of this area to the safe and reliable operation of the BC Hydro system and the Western Bulk Electric System. Vegetation management is a core utility function for overhead power systems (both transmission and distribution), access areas (roads, helipads, bridges, etc.), stations and properties. Growing vegetation poses an ongoing risk to electrical assets in addition to representing an immediate safety hazard in instances of contact between vegetation and live conductors. Unmanaged vegetation can grow too close or into the power system, fall onto assets, bring overhead conductors to ground level or act as a source for fire ignition. A vegetation management program is essential to maintain adequate clearances between vegetation and electrical assets in addition to removing risks adjacent to the system.

Figure G-1 below outlines the high-level annual vegetation work cycle from planning to delivery.

Figure G-1 Annual High-Level Vegetation Work Cycle

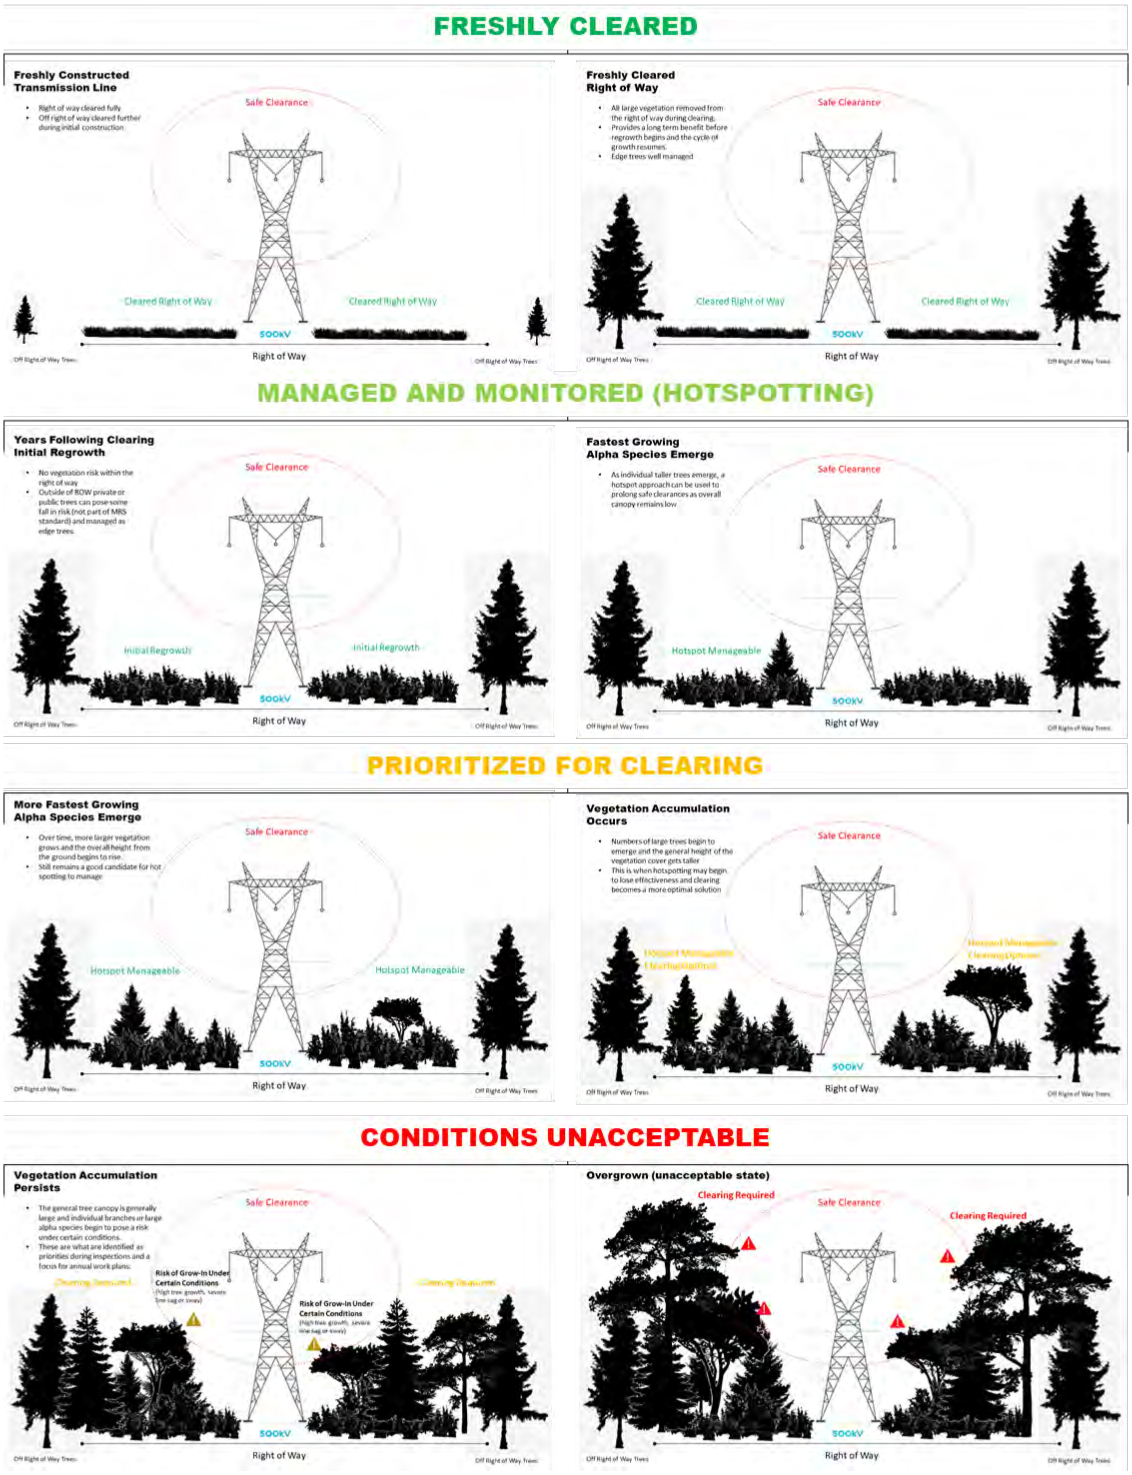


4.1 Background - Transmission System

For the transmission system, vegetation management involves three core practices: full clearing, hotspotting and edge tree management. **Full clearing** is when an area of a right-of-way (**ROW**) is cleared to the ground through various vegetation management techniques (e.g., mowing, brushing, falling, etc.). **Hotspotting** is when selective stands of trees or individual large trees are removed while the surrounding area is left untreated. This is used when only a small number of faster and larger species begin to emerge within an area that does not yet need full clearing to maintain clearances between conductors and the base vegetation canopy. **Edge tree removal** involves removing hazard trees at the edge of the ROW that pose a risk of falling into the ROW and onto a power system asset. The combination of these approaches preserves the clearances for the transmission system to safely operate as designed.

Figure G-2 below illustrates the various vegetation states around the transmission system in addition to the types of scenarios that maintenance approaches are used (e.g., clearing versus hotspotting). The figure also illustrates unacceptable states where growth is in excess of regular planned cycle work, inconsistent with planning standards and will be avoided through the defined execution levels within the VMS.

Figure G-2 Transmission Vegetation States Explained



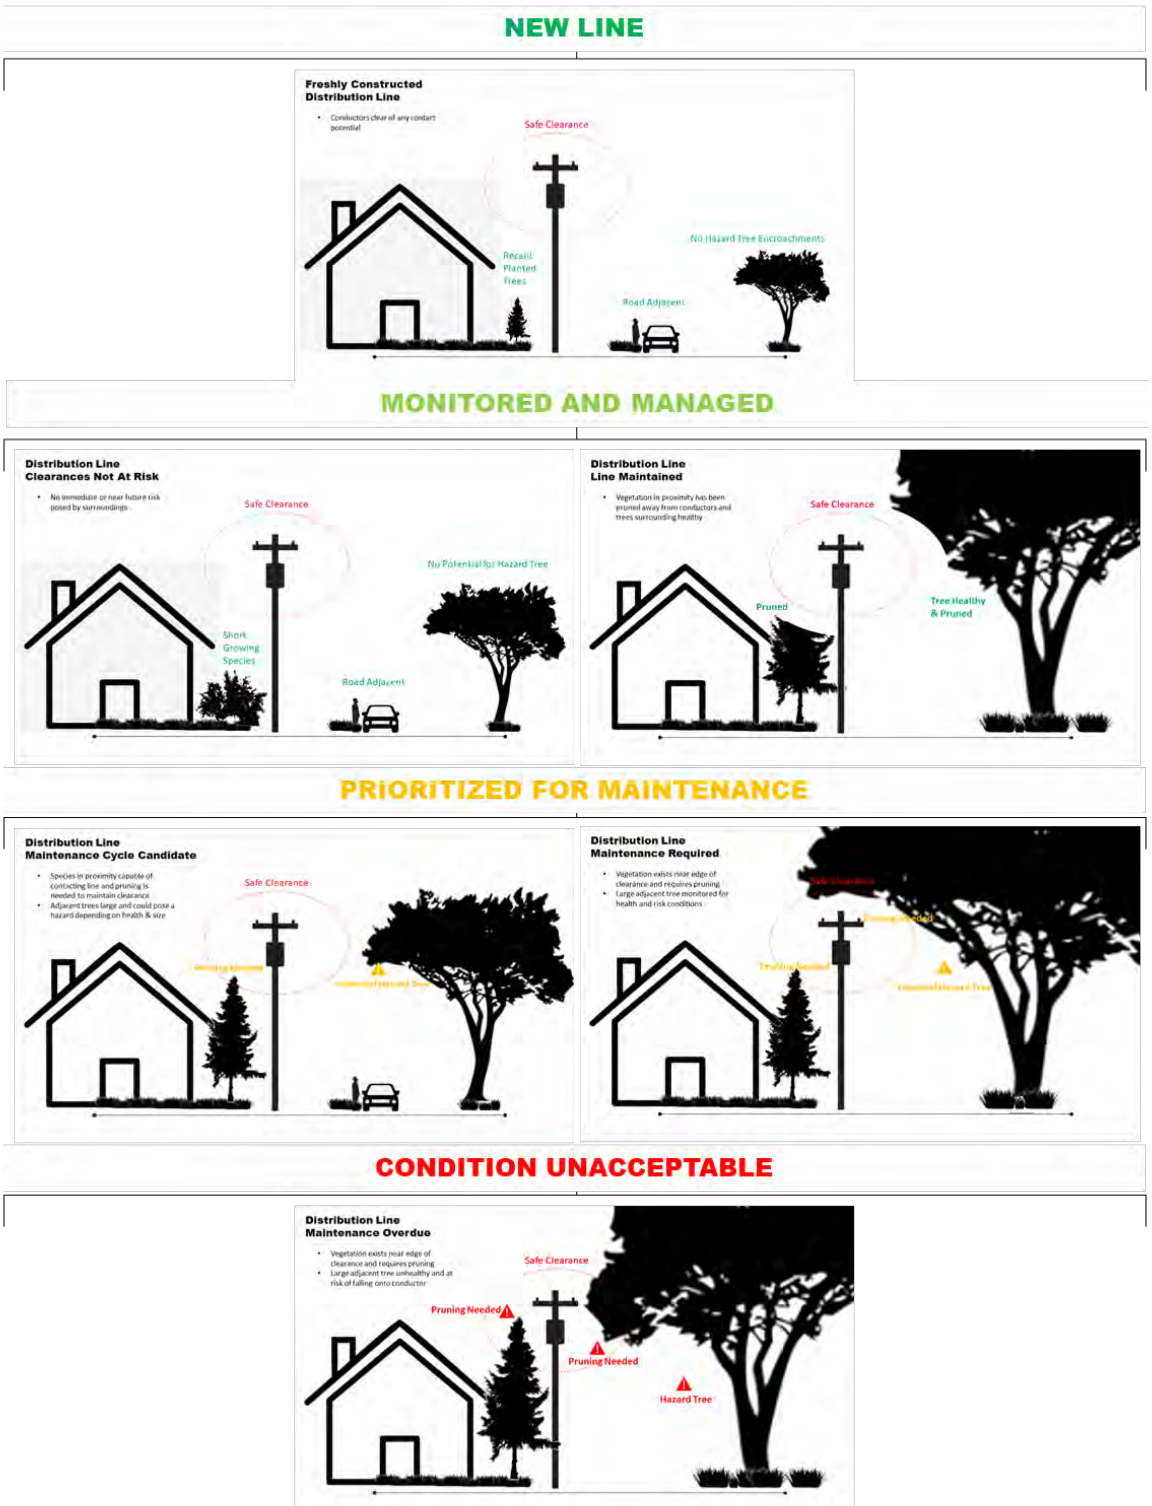
4.2 Background – Distribution System

For the distribution system, vegetation management involves two core practices; pruning and hazard tree removal. **Pruning** is the practice of cutting vegetation adjacent to the distribution system back and away from the conductors. Pruning also involves clearing of vegetation (by mowing, brushing, etc.) below the distribution lines that have the potential to grow up and into the lines over time. **Hazard tree removal** targets trees that pose a potential risk to the electrical system and often involve large specimens that are dead, dying or showing signs of instability. Although perfectly healthy trees can contact a line during a storm event, hazard trees represent a general risk outside of adverse weather conditions due to their general state.

Distribution vegetation management also involves working closely with landowners, municipalities and government to ensure appropriate selections of vegetation species near power lines. For example, when a homeowner plants a sapling in their yard under a power line, they may be unaware that it will grow up and into the line in future years, representing a reliability and safety risk. When identified, BC Hydro will work with them to ideally replace the tree with something that would not pose a future risk or prune the tree in such a way where future growth is mitigated below or around the conductors.

In Figure G-3 below, the various high-level states of distribution vegetation are illustrated in addition to the types of approaches for maintaining them. The illustration also shows unacceptable states that are avoided through the delivery of the regular work plan within the new VMS.

1 **Figure G-3 Distribution Vegetation States Explained**



5 Why a New Vegetation Management Strategy?

Three primary factors are contributing to the need for a significant increase in vegetation management investment, that in turn prompted the need for a new VMS, each of which was described in Fiscal 2022 Revenue Requirements Application and is restated below:

1. Vegetation growth across the system has regrown back to levels that existed prior to the significant clearing activities that took place a decade ago;
2. Cost pressures have increased with electrical system expansion, new regulatory requirements and general cost inflation associated with vegetation maintenance activities, and can no longer be absorbed; and
3. Climate change is impacting the growth rate and health of vegetation across the province.

Significant vegetation activities occurred a decade ago and created lasting benefits in the years following. This is reflected in Figure G-4 and Figure G-5 below, which shows that investment in vegetation management increased between fiscal 2002 and fiscal 2009 for transmission and until fiscal 2014 for distribution, before remaining largely static (in terms of real dollars) at a lower level until fiscal 2022. During this period and until fiscal 2020, system reliability and compliance was maintained annually. Regrowth of vegetation has occurred system wide to the extent that the benefits from the heightened vegetation maintenance period have been exhausted and additional effort is now required to sustain or improve system performance.

Figure G-4 Transmission Vegetation Maintenance Levels

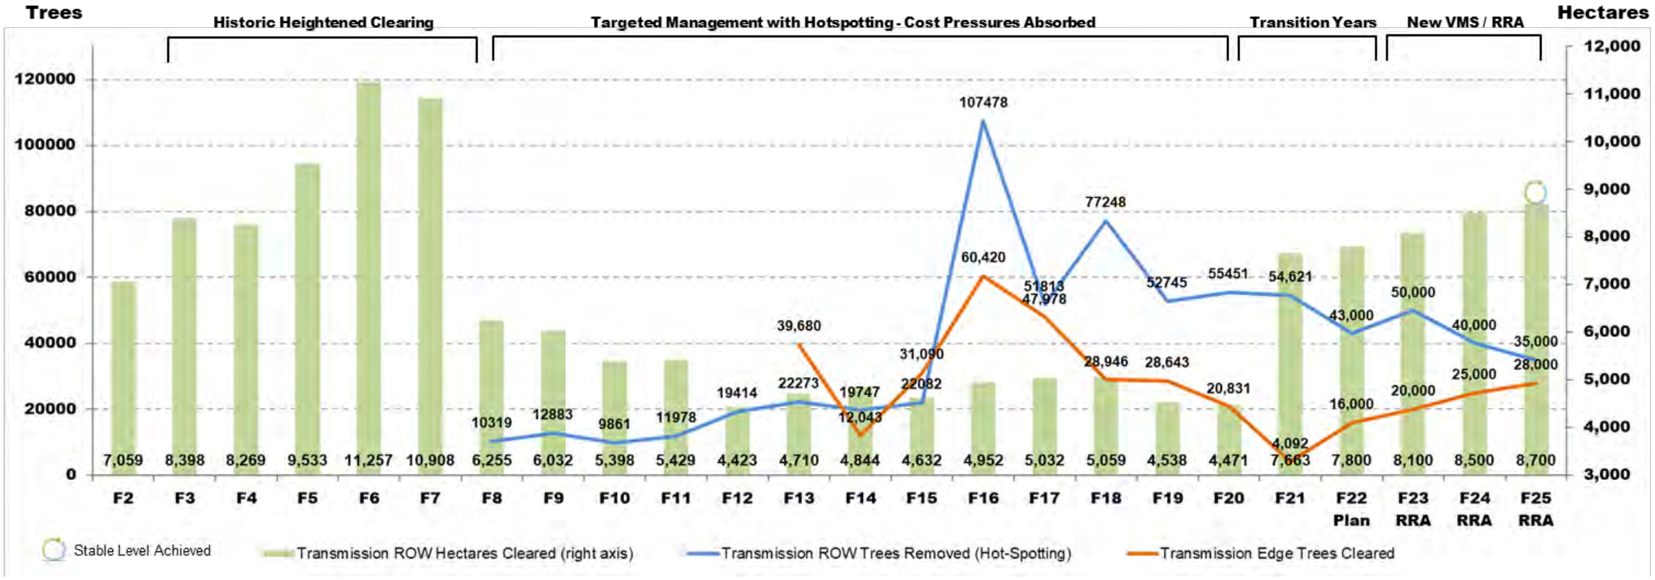


Figure G-5 Distribution Vegetation Maintenance Levels

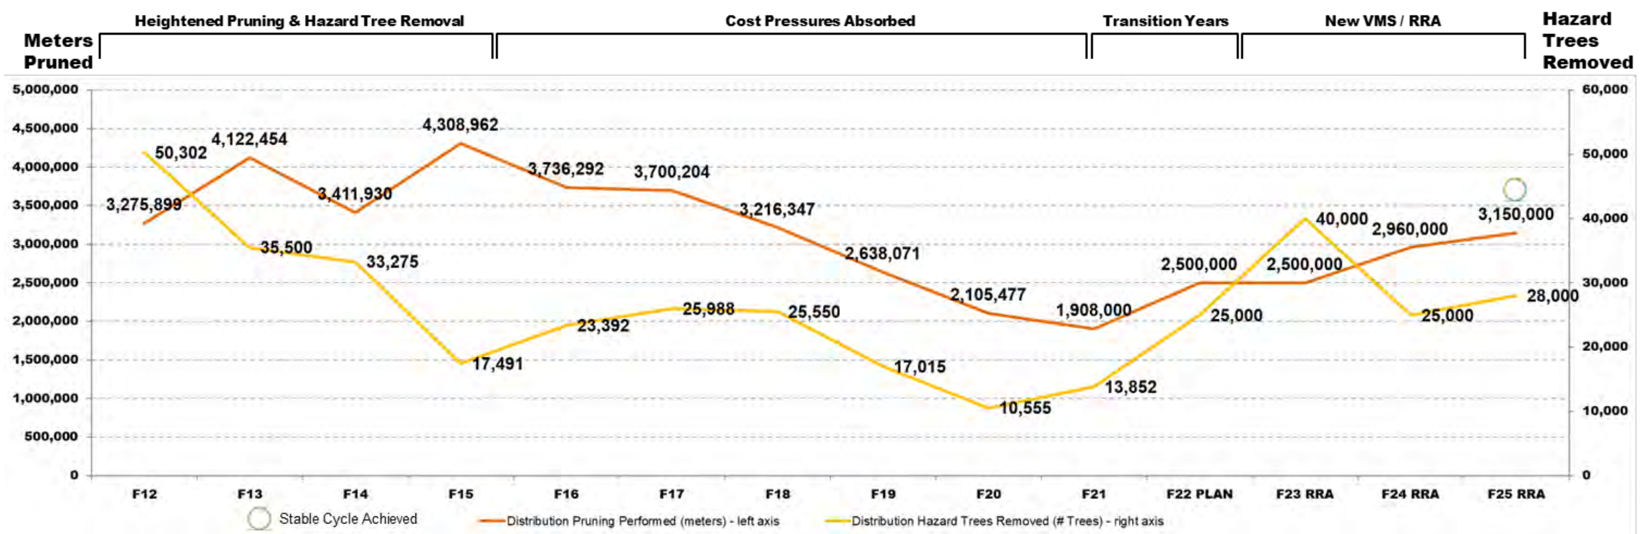


The direct impact of the vegetation regrowth and accumulation was minimized by other investments made by BC Hydro during this time (e.g., distribution automation, smart metering infrastructure). These investments contributed to key corporate outcomes, such as reliability performance metrics. A combination of reduced vegetation maintenance and these asset investments collectively preserved system reliability and safety in the latter years when vegetation regrowth had begun to accumulate on the system. This was evidenced by increased trouble costs as a result of vegetation originated system impacts. During fiscal 2020 and fiscal 2021, BC Hydro analyzed the increasing impact of vegetation regrowth and determined that the base level of vegetation effort now must increase in order to sustain the long-term objectives of the vegetation maintenance program and corporate reliability targets.

6 Determining the Right Approach for the VMS

BC Hydro analyzed four different potential approaches to shape the future vegetation management, listed and explained below. BC Hydro's analysis determined that the second approach – stable annual vegetation maintenance – was the best approach.

1. **Status Quo Preserved** (continue at the fiscal 2021 level of investment).
2. **Stable Annual Vegetation Maintenance** (stable year over year, size of program matches vegetation growth rate over a regular cycle).
3. **Cyclical** (cycles of heightened vegetation activity followed by reduced durations of low activity).
4. **Hotspotting / Triage Only** (focuses on removing vegetation two growing seasons before it is expected to become a challenge, dynamically targeted annually).

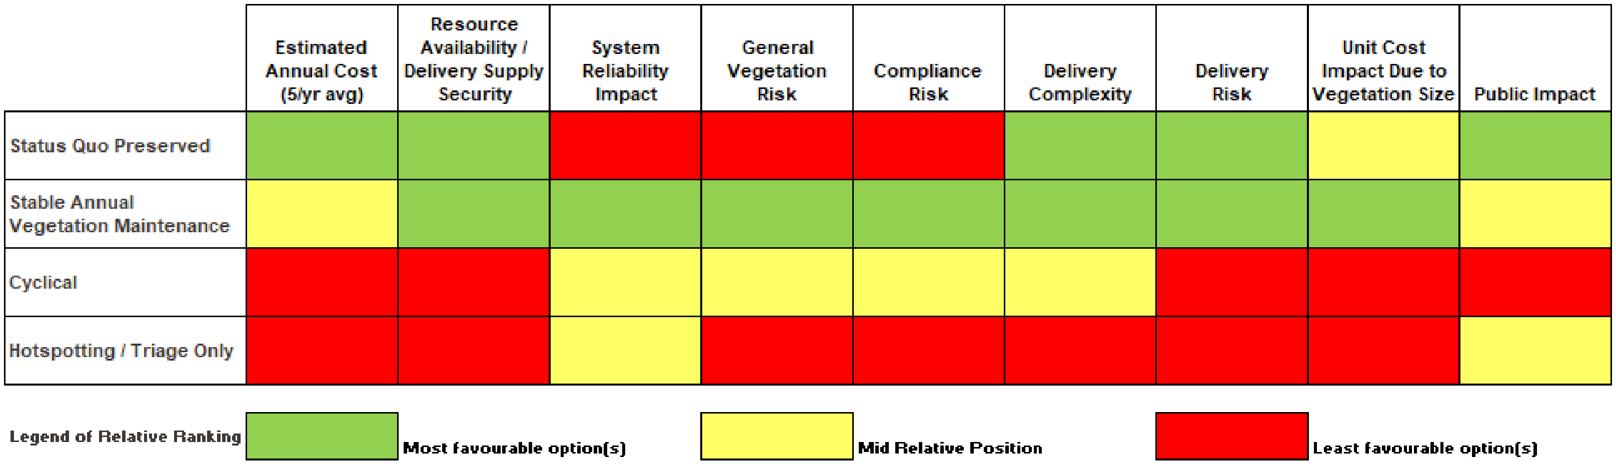
During this analysis, core criteria of the vegetation program were considered in addition to delivery factors (such as resource availability, cost of delivery, etc.). Each criterion has an individual preferred outcome, and all are balanced collectively to represent the single best option. The following were the criteria analyzed to support a decision on the overall strategic approach of the vegetation program.

- **Estimated annual cost (next five-year average)** – this examined the total cost to deliver the vegetation management program averaged over the next five-year period. A five-year average was selected to smooth cost variations annually across scenarios. A lower average cost is preferable within the analysis.
- **Resource Availability / Delivery Supply Security** – this examined the extent that BC Hydro would be able to ensure sufficient resources (both internal and external) to deliver on the vegetation program. Scenarios that had high resource variability translated into risk since acquiring resources, releasing them and then reacquiring in the future represents uncertainty for supply. Stable resourcing is preferred in the analysis since it allows long term supply security.
- **System Reliability Impact** – this examined the overall impact to reliability posed by vegetation with individual approach factors considered. Regularly treated vegetation is preferred due to lower impact than leaving vegetation untreated for any prolonged period of time (allowing it time to grow).
- **General Vegetation Risk** – this examined the other risk factors outside of reliability, such as safety and asset access. Leaving vegetation unmanaged for a period of time is viewed as higher risk due to regrowth and total size of vegetation (e.g., trunk and branch diameters). Large diameter vegetation is capable of obscuring access to assets and sufficient in size to bring a live conductor to the ground.

- **Compliance Risk** – this examined the extent that BC Hydro can sustain compliance with the required standards and legislated directives. Regular assurance for compliance is preferred within the analysis versus compliance based on just in time work.
- **Delivery Complexity** – this examined the complexity of the operation necessary to deliver on the annual work program. Regular, repeatable cycles are favoured over complicated delivery regimes that involve targeted work (hotspotting and triage).
- **Delivery Risk** – this examined the overall risk in delivering on the annual work plan each year. Delivery risk introduces regionalization of work effort and consistency in the types of work delivered. Low movement of resources and standardized delivery practices are preferred.
- **Unit Cost Impact Due to Vegetation Size** – this examined the cost per unit of work delivery, which is based on vegetation size. The larger the vegetation, the more expensive it is to remove due to the tools and procedures required. The same is true for pruning where smaller branches are easier and faster to remove than large ones. Low unit cost is preferred in the analysis.
- **Public Impact** – this examines the extent each approach has the potential to impact the public (aside from reliability and safety impacts that are covered in other criteria). More regular, small pruning of vegetation within a community has a lower public impact than large cuts after extended period of untreated growth. Lower public impact is preferred within the analysis.

To support a decision, the criteria were assigned a relative position to one another, ranging from most to least preferred. Figure G-6 below shows the relative ranking of each alternative approach for all of the criteria listed above. The analysis concluded that the most viable long-term approach for vegetation management would be to evolve the current program into a long-term stable model where a general cycle is established to address growth as it occurs. The new VMS was developed around this option where annual work volumes are directly related to the vegetation surrounding the transmission and distribution systems with additional considerations for access roads, properties and stations. Although the status quo was the lowest cost option, it is not capable of sustaining ongoing compliance due to regrowth and represents greater system impacts (namely reliability and safety) than deemed acceptable.

Figure G-6 Vegetation Approach Analysis Summary



7 Stable Annual Vegetation Maintenance – Goals and Objectives

Once BC Hydro decided on the stable annual vegetation maintenance approach, the remainder of the VMS was developed around this approach. This section will outline the goals and objectives of this approach. **Goals** are defined as the resulting outcomes sought by the VMS realized through the delivery of the vegetation management program, whereas the **objectives** are more focused on the specific actions that will be taken as part of the VMS to achieve the goals. Many of the goals in the new strategy are aligned with the vegetation management program goals in the past (e.g., safety, reliability, compliance, etc.). The VMS has further defined the extent of work required to meet the goals and added related areas of focus (e.g., access).

The primary goals of the new VMS are as follows:

Safety: Manage the ongoing and persistent risks posed from growing vegetation to the electric system to support both employee and public safety, with an additional focus on fire ignition prevention and mitigation.

Reliability: Ensure appropriate system reliability through the reduction of vegetation related contacts with utility assets.

Compliance: Manage ongoing compliance with all regulatory, statutory and legal requirements.

Access: Secure appropriate and safe access to assets and rights-of-way.

Stewardship: Act as responsible stewards of vast areas of vegetation within rights-of-way and across public and private property and continue to ensure social, environmental, financial and cultural perspectives are respected while balanced with vegetation management needs of the electrical system.

All of the above stated goals align with the core mandate of BC Hydro of providing safe, reliable and affordable electricity to the province of British Columbia. It is recognized by BC Hydro that vegetation management is an important maintenance program. The program is annually delivered provincially and has a direct relationship with reliability, safety and compliance when the necessary clearances between vegetation and the electrical system are maintained. Assuring vegetation is well managed and away from the electrical system reduces risks of system damage, fire ignition and other hazards. Another key tenet of vegetation management effort is ensuring unimpeded access to electrical and communications assets. Access is necessary to maintain and operate these assets safely for the duration of their operable life.

Furthermore, through the delivery of the vegetation management efforts, BC Hydro demonstrates appropriate stewardship of its maintenance duties to ensure social, environmental, financial and cultural perspectives are respected. These responsibilities are realized through ongoing consultation and cooperation with those who have a stake in the vegetation work being conducted across the province and the prudent management of all resources.

To meet the goals outlined above, the VMS includes a series of actionable objectives that translate the goals into business outcomes. The actionable objectives are as follows:

- Plan and implement an effective vegetation management program across the province that ensures sustainable mitigation of the risk posed by regular annual growth, notable events (infestations, droughts, climate impacts, etc.) and storms;

- Improve visibility of vegetation across the system and adopt a more dynamic approach of assessing annual workplans that take into account variable growth rates, system conditions and climate impacts;
- Strengthen compliance assurance within vegetation program delivery and processes;
- Manage climate change impacts and risks (e.g., wildfires, storm resiliency, tree health from drought, flooding, disease and other impacts);
- Secure vegetation management resources and ensure supply;
- Maximize efficacy of vegetation investment (e.g., treatment longevity, vegetation and access inspections combined, etc.); and
- Optimize vegetation management delivery.

Through the successful implementation of the VMS, the following business outcomes will be achieved.

Figure G-7 VMS Business Outcomes by Goal

The new Vegetation Management Strategy will deliver the following business outcomes:					
Removal of all vegetation accumulation on the system					
• Transmission accumulation removed between F25 and F27 (based on F22-F24 work outputs)	●	●	●	●	●
• Distribution hazard tree inventory addressed by end of F23	●	●	●	●	●
• Distribution pruning work secured on-cycle by F25	●	●	●	●	●
Improved system visibility					
• Enhanced patrol, survey and LiDAR capabilities – no surprises and imbedded quality assurance	●	●	●	●	●
• Improved metrics and reporting for proactive identification of issues	●	●	●	●	●
Compliance assurance					
• Improved compliance integration within work planning and delivery	●	●	●		
• Compliance delivery visibility in near real time (e.g. FastVeg reports, system imaging, etc.)	●	●	●		
Risk Reduction					
• Climate change and fire reduction activities	●	●	●	●	●
• Access assurance, inspections and clearing	●	●	●	●	●
• Secured resources to perform necessary work	●	●	●	●	●
Delivery Value					
• Improved cost stability through category management approach and contracts					●
• Internal optimization of resources					●
• Improved processes					●

8 BC Hydro’s Vegetation Program Fiscal 2023 to Fiscal 2025

Under the stable annual vegetation maintenance approach, BC Hydro’s vegetation management effort is expected to increase during the next three years and then remain stable by fiscal 2025, representing the new normal for vegetation activities. This is represented as the work output required to achieve the goals of the vegetation maintenance program, reflected as a range between minimum and optimal levels. Table G-1 below shows the minimum and optimal annual work levels for each activity by fiscal 2025. The minimum level represents the smallest work effort that would not result in incremental accumulation of vegetation on or around the electrical system and achieve mandatory compliance requirements only. The minimum level is vulnerable to unplanned events (e.g., work stoppages due to dry spells, external resource availability, wildfires, etc.), climate change impacts and work disruptions. To address these, the optimal level was developed and represents the amount of regular work that would both ensure achievement of the VMS goals while offering a degree of resilience to uncontrollable events.

Table G-1 Minimum and Optimal Work Levels

Category	Activity	Minimum Annual Work Level	Optimal Annual Work Level
Transmission Vegetation Maintenance	ROW Clearing (hectares)	**6,700**	**8,600** (adjusted to achieve VMS goals and address climate change uncertainty)
	Hotspotted Trees Removed (trees)	**40,000**	**30,000** (only optimal w hen clearing at optimal level)
	Edge Trees Removed (trees)	**25,000**	**30,000**
	LiDAR Scanned and Modelled (% of system)	**20%**	**20%**
	System Patrolled & Inspected (% of system)	**100%**	**100%**
Distribution Vegetation Maintenance	Vegetation Pruned (meters)	**3,100,000**	**3,300,000**
	Hazard Trees Removed (trees)	**26,000**	**30,000**
	System Patrolled & Inspected (% of system)	**33%**	**50%**
Access, Facilities and Properties	Access Patrolled & Inspected (% of system)	**33%**	**50%**
	Facilities Vegetation Assessment	**100%**	**100%**
	Priority Sites Maintained Post Assessment	**100% High Priority 50% Medium Priority**	**100% High and Medium**

To establish confidence that the volume of work being undertaken is consistent with industry practices and sufficient to meet the goals of the VMS, BC Hydro undertook an internal analysis and accessed a number of external sources. These are referenced and explained in the subsequent section of the strategy focused on investment justification.

To deliver this level of work to meet the needs of the system and achieve the goals of the program, the following are the planned expenditures with historical values for context. Table G-2 below shows the current and future cost estimates for delivery of the VMS.

The values used in Table G-2 are based on the established market rates for external work delivery and include foreseen cost pressures (e.g., inflation). Future cost pressures beyond fiscal 2025 (e.g., future inflation, standard labour rates, market price fluctuations, legislative requirement changes and other external influences) will need to be addressed in the future to maintain the level of work output necessary to achieve the stated goals of the program.

Table G-2 Historic and Planned Vegetation Management Costs[1, 2]

($ million)	F2012 Actual	F2013 Actual	F2014 Actual	F2015 Actual	F2016 Actual	F2017 Actual	F2018 Actual	F2019 Actual	F2020 Actual	F2021 Actual	F2022 Decision	F2023 Plan	F2024 Plan	F2025 Plan
Transmission Vegetation Maintenance	19.8	21.6	19.9	21.7	18.4	18.9	19.0	18.7	21.5	27.1	33.3	38.9	40.0	41.9
Distribution Vegetation Maintenance	35.5	34.8	30.1	32.2	32.7	32.4	31.2	31.8	28.4	31.9	36.1	40.1	43.3	46.9
Access Maintenance	1.0	1.2	1.1	1.3	1.0	1.0	1.0	1.2	1.0	0.9	1.0	3.7	3.9	3.9
Total Gross	**56.3**	**57.6**	**51.1**	**55.2**	**52.1**	**52.4**	**51.2**	**51.7**	**50.9**	**59.9**	**70.5**	**82.7**	**87.2**	**92.8**
Distribution Vegetation Recoveries (TELUS)	(10.3)	(8.2)	(7.0)	(5.5)	(6.2)	(6.7)	(6.5)	(6.4)	(5.5)	(6.4)	(6.9)	(7.2)	(7.7)	(8.5)
Total Net of Recoveries	**46.0**	**49.5**	**44.2**	**49.7**	**45.9**	**45.7**	**44.7**	**45.3**	**45.3**	**53.5**	**63.5**	**75.5**	**79.5**	**84.3**

Over the last decade, BC Hydro has maintained a relatively consistent annual expenditure for vegetation management effort, totalling approximately $50 million per year. This increased at the end of fiscal 2021 to address imminent vegetation risks on the transmission system and in fiscal 2022, as described in the Fiscal 2022 Revenue Requirements Application. The proposed fiscal 2023 to 2025 plan amounts are subject to BCUC approval in the Fiscal 2023 to Fiscal 2025 Revenue Requirements Application.

9 Vegetation Expenditure Justification

In support of the development of the new VMS, BC Hydro accessed and analyzed industry resources and benchmarks, and sought external validation of our approach. BC Hydro accessed the following sources to establish context for the VMS:

- Industry benchmarks from First Quartile Benchmarking;

1 F2012 to F2020 actuals are in real dollars and were adjusted using the B.C. Consumer Price Index with fiscal 2021 as the base year.

2 In the Fiscal 2022 Revenue Requirements Application, LiDAR was considered a planning operational cost as it was newly added to the vegetation management program. It has since been classified as Transmission maintenance, similar to all inspection expenditures, with the change having no impact on the overall O&M budget.

- Canadian utility vegetation study conducted by the Canadian Electricity Association (**CEA**);
- External review of BC Hydro's vegetation strategy by Guidehouse;
- Market procurement in BC for vegetation services;
- Publicly accessible utility regulatory filings from peers; and
- Internal analysis of current and historical vegetation performance and expenditures.

9.1 First Quartile Benchmarking

First Quartile Benchmarking is a utility industry resource for comparative analysis of operational areas, including vegetation management. Each year, approximately 40 utilities across North America and a small number of international utilities participate in the survey. The responses are anonymized and shared to show each participant their relative position in the industry and the quartile compared to others. Although each utility is different and varies in terms of geography, climate, vegetation species, system topography and customer composition, the large number of utility participants and normalizing factors built into First Quartile survey responses help ensure viable insight from the studies and relative comparisons. For vegetation management, factors are included in the survey related to financial expenditure, reliability and overall performance. Specific questions, such as the cost per customer to perform vegetation management work annually on the distribution system, help provide insight into overall levels of vegetation investment and delivery value. Other examples, such as reliability comparisons, provide a view into the overall outcome of vegetation management efforts. Overall, First Quartile Benchmarking was used by BC Hydro as a resource to establish a relative industry view and support context for decision making within the new VMS.

9.2 CEA 2021 Vegetation Management Benchmarking Report

Another input into the VMS was the recent 2021 Vegetation Management Benchmarking Report issued by the CEA. The CEA report provided valuable insight into specific vegetation management practices and common trends for utilities across Canada. The report covered key operational domains, including equipment usage, cycle durations, resourcing approaches and compliance categories. There also was a focus on inspection approaches where LiDAR was used by utilities of similar size to BC Hydro. The participating utilities in the CEA report included:

Table G-3 2021 CEA Vegetation Report Participants

CEA 2021 Vegetation Management Benchmarking Report Participants			
BC Hydro	Hydro Ottawa	Manitoba Hydro	FortisAlberta
Hydro Quebec	Yukon Energy	Maritime Electric	London Hydro
SaskPower	Toronto Hydro	Newfoundland Power	ENMAX
City of Medicine Hat	City of Summerside	Oakville Hydro	City of Lethbridge
ATCO	City of Red Deer	AltaLink	FortisBC
Hydro One	NB Power	NSPI	

9.3 External Review of BC Hydro's Vegetation Management Strategy by Guidehouse

BC Hydro also engaged a third-party to review the VMS and provide an independent review of the proposed program. BC Hydro selected Guidehouse to perform the review based on their demonstrable experience in utility strategy reviews and expertise in vegetation management strategy specifically. Guidehouse's approach was to review the current and proposed vegetation management strategies, interview key staff members (program managers, planners and operations), conduct a peer review and assess any notable differences between BC Hydro and other utilities. They examined specific areas within the vegetation program related to compliance requirements, cycle times, staffing, technology, clearances and overall objectives. Guidehouse also conducted a historical cost justification analysis to compare proposed expenditures to the cumulative impacts of cost pressures on the

BC Hydro vegetation program over the past decade. The study findings were detailed in a report to BC Hydro and used to inform the VMS.

9.4 Market Procurement in B.C. for Vegetation Services

Recent market procurements for vegetation services provided additional context for the VMS. The procurements established long-term, unit-based contracts that were competitively bid by external third parties. These provided assurance on the alignment of current delivery costs to market rates and ensured the necessary supply security of vegetation resources to deliver on the VMS. It also enabled accurate forecasting of unit costs over the upcoming years.

9.5 Publicly Accessible Utility Regulatory Filings from Peers

Beyond the explicit pursuits BC Hydro undertook to provide context and comparisons for the VMS, additional referenced materials included the regulatory filings of a number of utilities in Canada and the U.S. where vegetation programs were described. These were also used to ensure alignment of BC Hydro’s VMS to general industry practices.

9.6 Internal Analysis of Current and Historical Vegetation Performance and Expenditures

In 2021, BC Hydro conducted an internal analysis to review historical vegetation work activities, expenditures and cost pressures. This analysis was used to initially inform the Fiscal 2022 Revenue Requirements Application and subsequently updated to develop the VMS. The analysis also utilized the information and insight generated by the other sources mentioned in the section above. Based on the information obtained through this analysis, the following table shows the key findings supported by the referenced sources.

1 **Table G-4 Expenditure Justification Summary and**
2 **Key Findings**

Key Finding	Source(s)	Interpretation
BC Hydro's vegetation management efforts were subject to a number of exogenous cost pressures, many legislative in nature, that were also faced by the vegetation management industry in general. These include: *Mandatory Reliability Standards, Wildfire Act, Integrated Pest Management Act*, *Fisheries Act*, *Water Act*, *Migratory Bird Convention Act*, *Heritage Act*, *WSBC Requirements, Transportation Act*, *Industrial Roads Act*, *Motor Vehicle Act* and various municipal policies	BC Hydro internal analysis, Guidehouse	Exogenous cost pressures increased the unit delivery cost of BC Hydro's vegetation management program. Without incremental expenditures, total work output cannot increase
While the historical annual budget remained largely constant, increasing costs resulted in less work being completed	BC Hydro internal analysis	Reduced work volumes of vegetation management had resulted in incremental accumulation of vegetation on the system annually
BC Hydro's distribution vegetation expenditure over the last decade has been well below industry average and among the lowest in North America	First Quartile Benchmarking	Incremental distribution expenditures proposed in the Fiscal 2023 to Fiscal 2025 Revenue Requirements Application remain consistent with lowest quartile for utilities and are reasonable
BC Hydro's transmission vegetation expenditure over the last decade have been well below industry average	First Quartile Benchmarking	Incremental transmission expenditures proposed in the Fiscal 2023 to Fiscal 2025 Revenue Requirements Application remain consistent with industry averages and are reasonable
The current proposed expenditure is consistent with the magnitude of the historical cost pressures	Guidehouse	Each individual cost pressure, if funded when introduced historically, would have resulted in cost increases equal to or in excess of the current proposed expenditure on aggregate
BC Hydro's vegetation management activities and approach are consistent with industry practices	Guidehouse, 2021 CEA Vegetation Report	There are no anomalies in BC Hydro's vegetation approach that are driving incremental costs or representing an efficiency opportunity

Key Finding	Source(s)	Interpretation
BC Hydro would further benefit from incremental visibility to the state of vegetation on the system	Guidehouse, Canadian Electrical Association, NERC	BC Hydro will invest in improving inspections both manually and through LiDAR
BC Hydro's current contracts are consistent with market rates	BC Hydro market tenders	BC Hydro has validated market costs through a competitive process for delivery of external services
BC Hydro has fully realized the benefits derived from increased clearing that occurred a decade ago	BC Hydro vegetation analysis	Incremental vegetation management work is required to meet BC Hydro's goals
BC Hydro's vegetation management practices are aligned to those of Canadian peers with respect to: • Planning cycle and timing • Tree removal decision making criteria • Waste management • Environmental and wildlife impact mitigation • Tool and equipment usage	2021 CEA Vegetation Report	BC Hydro's methods for planning and delivering vegetation management work are consistent with industry standards in Canada

10 Vegetation Management Strategy – Elements and Measures of Success

This section describes how the VMS aligns with the stated goals and objectives and further defines what constitutes success.

Table G-5 Vegetation Management Strategy Elements and Measures of Success

Strategic Objective	Element(s) of Success	Measure(s) of Success	Goal(s) Supported
Plan and implement an effective vegetation management program across the province that ensures sustainable mitigation of the risk posed by regular annual growth, notable events (infestations, droughts, climate impacts, etc.) and storms	**Transmission:** • Full system inspection completed annually • 20 per cent of the full system maintained annually (clearing and hotspotting combined) • Maximum duration between vegetation management cycles is five years • Minimum of 6,700 hectares (minimum stable level) cleared annually in addition to 40,000 hotspotted trees removed by fiscal 2024 • Target 8,600 hectares (optimal stable level with climate uncertainty factor added and VMS goals) cleared annually in addition to 35,000 hotspotted trees removed by fiscal 2025 and this is maintained persistently thereafter • 25,000 edge trees removed per year minimum by fiscal 2024 and beyond	**Transmission:** • Percentage inspection completion • Percentage of system in annual workplan • Percentage of system maintained • No. of hectares cleared • No. of trees hotspotted • No. of edge trees removed	Safety, Reliability, Compliance, Access
	Distribution: • Minimum three-year system inspection cycle, optimally two-year • 17 per cent of the full system maintained annually (pruning) • Maximum duration between management cycles is 6 years • Minimum 3,100,000m of pruning per year by end of fiscal 2025 and persistent beyond • Reach a stable hazard tree removal level (~26,000 to 30,000 trees annually) by fiscal 2024	**Distribution:** • Percentage inspection completion • Percentage of system in annual work plan • Percentage of system maintained • No. of meters pruned • No. of hazard trees removed • maintained by priority	Safety, Reliability, Compliance, Access

Strategic Objective	Element(s) of Success	Measure(s) of Success	Goal(s) Supported
	Access and Facilities: • Access inspections covering 33 per cent of the system minimum annually • 50 per cent of facilities assessed for vegetation need annually • All priority sites identified post inspection maintained within one-year, secondary priority maintained within two years	**Access and Facilities:** • Percentage of access area inspected • KMs of roads maintained • Percentage of facilities assessed • Percentage of identified facilities	
Improve visibility of vegetation across the system and adopt a more dynamic approach of assessing annual workplans that take into account variable growth rates, system conditions and climate impacts	**Transmission:** • Annual LiDAR flights, modelling and analysis covering a minimum of 20 per cent of the system per year. • Adoption of a categorical prioritization approach to vegetation logging • Development of a formal annual transmission inspection report presented to planning and operational leadership teams **Distribution:** • Adoption of a categorical prioritization approach to vegetation logging (e.g., assigning priority to triage work plans) • Development of a formal annual distribution inspection report presented to planning and operational leadership teams	• Percentage of the system scanned with LiDAR • Percentage of the system modelled and analyzed • Transmission vegetation prioritization percentage and volume (e.g., No. of priority areas, percentage of priority areas on system) • Distribution vegetation prioritization percentage and volume (e.g., No. of priority areas, percentage of priority areas on system)	Safety, Reliability, Compliance

Strategic Objective	Element(s) of Success	Measure(s) of Success	Goal(s) Supported
Optimize vegetation management delivery	**Transmission:** • Removal of all historical vegetation accumulation by end of fiscal 2025 by maintaining > 20 per cent of the system annually from fiscal 2021 to 2025 • Annual work process review on a key vegetation process to seek improvement opportunities • Alignment of vegetation activities with the core vegetation management program and others (e.g., stations vegetation maintenance, NIA vegetation activities, etc.)	• Percentage of system cleared annually reaching target of 20 per cent • No. of processes reviewed • Confirmation of alignment	Compliance, Stewardship, Safety, Reliability
	Distribution: • Return to on-cycle distribution pruning by fiscal 2024 • Hazard tree inventory cleared by end of fiscal 2023, sustained thereafter at no accumulation (~26,000 to 30,000 removed annually)	• Percentage of annual work plan delivered on cycle • No. of hazard trees remaining in inventory	Stewardship, Safety, Reliability

Strategic Objective	Element(s) of Success	Measure(s) of Success	Goal(s) Supported
Strengthen compliance assurance within vegetation program delivery and processes	**Transmission:** • Maintain all adopted Mandatory Reliability Standards (**MRS**) for high voltage transmission lines and interties • Maintain all clearances on lower voltage transmission lines • Maintain compliance will all legislative requirements on BC Hydro's vegetation management activities • Sustain Fire Services Agreement with the Government of B.C.	• No. of MRS violations on the transmission system • Confirmed compliance with the following Acts (*Wildfire Act*, *Integrated Pest Management Act*, *Fisheries Act, Water Act*, *Migratory Bird Convention Act*, *Species at Risk Act*, *Provincial Wildlife Act* and the *Heritage Act*)	Compliance, Stewardship, Safety, Reliability
	Distribution: • Maintain compliance with all legislative requirements on BC Hydro's vegetation management activities (same as transmission) • Maintain compliance with respect to traffic control and road safety • Continue to work closely with municipalities and the public to mitigate public and social impacts during the completion of vegetation related activities	• Confirmed compliance with the *Transportation Act*, *The Industrial Roads Act* and the *Motor Vehicle Act*	Compliance, Stewardship, Safety, Reliability

Strategic Objective	Element(s) of Success	Measure(s) of Success	Goal(s) Supported
Maximize efficacy of vegetation investment (e.g., treatment longevity, vegetation and access inspections combined, etc.)	**Transmission:** • One patrol approach through combining vegetation and access inspections to increase overall coverage and a holistic view of vegetation and access needs • Continue annual reviews of pest management plans, herbicide applications and market scans for new and effective vegetation management approaches to preserve or extend longevity of vegetation maintenance activities	• Operationalization of integrated patrol approach • Annual reviews completed each fiscal	Access, Safety, Stewardship, Reliability
	Distribution: • Complete analysis of proactive vegetation maintenance versus reactive trouble activities (est. fiscal 2023/fiscal 2024)	• Completion of vegetation and trouble analysis in fiscal 2024 • Monitoring of percentage of outages that are vegetation originated	Stewardship, Safety

Strategic Objective	Element(s) of Success	Measure(s) of Success	Goal(s) Supported
Secure vegetation management resources and ensure supply	• Annually refresh a long-term vegetation resource requirement and fulfillment plan • Conduct active cost pressure monitoring and annual expenditure adjustments (within RRA cycles) to account for future cost pressures as they are introduced • Complete an internal labour analysis to determine the suitability and commercial impact of in-sourcing vegetation program delivery by end of fiscal 2024 (e.g., establishment of BCH certified utility arborists or extending the role of existing internal resources) • Ensure effective vegetation category management and procurement	• Confirmation of annual resource plans • Annual cost pressure analysis conducted • Completion of internal labour analysis by end of fiscal 2024 • Vegetation contracts secured until end of fiscal 2025 • Vegetation category management strategies (contract work & LiDAR) completed and implemented by end of fiscal 2023	Stewardship, Safety, Reliability, Compliance
Manage climate change impacts and risks (e.g., wildfires, storm resiliency, tree health from drought, flooding, disease and other impacts)	• Assess climate change impacts and notable trends emerging on the system province wide • Refresh of wildfire risk model • Continued adherence to fire prevention techniques	• Completion of climate change impact on vegetation report • Updated wildfire risk model • Power system related fire report	Compliance, Safety, Reliability, Stewardship

11 Vegetation Management Strategy – Capabilities Required

The following section will describe the core capabilities required by BC Hydro and the assessment of the current resources and processes in place to deliver on the VMS.

The core capabilities are broken into four categories:

- Vegetation visibility (BC Hydro's ability to inspect and assess vegetation);
- Executability (ability to deliver work in the field);
- Management and support (oversight, administration and ancillary functions); and
- Planning and strategy (program evolution in response of changes, certified professional oversight, compliance leads, workplan development, program leadership, etc.).

Within each of these capability categories, there are people, process and technology elements that were assessed. Each assessed capability was assigned one of three statuses:

1. Adequate based on fiscal 2022 levels to meet future needs;
2. Capability growth required for optimal outcome; or
3. Capability not performing as needed.

These were then assigned a colour (green, yellow or red, respectively), as summarized in Table G-6 below.

Table G-6 Vegetation Management Strategy Capabilities Assessment

	VEGETATION VISIBILITY	VEGETATION MAINTENANCE	MANAGEMENT & SUPPORT	PLANNING & STRATEGY

🟢 = Capability adequate based on F22 levels 🟡 = Capability growth required for optimal 🔴 = Capability not performing as needed

The proposed VMS will address the capabilities required to achieve the program goals between fiscal 2023 and fiscal 2025 and then sustain the full capability suite thereafter. The following is a summary of the incremental resources proposed and the affected capabilities.

Table G-7 Capability Growth Under the Vegetation Management Strategy

Change Category	Capabilities Reinforced
Incremental Vegetation Coordinators +6 FTEs (incremental coordinators in operations for fiscal 2023+)	**Vegetation Visibility:** Coordinators, Manual Patrols & QA **Vegetation Maintenance:** Coordinators, Field Plans & Delivery, Public Consultation and Engagement
Incremental Vegetation Specialists and Foresters +2 FTEs (incremental specialists in operations for fiscal 2023+)	**Vegetation Maintenance:** Site Prescriptions
Operationalization of the BC Hydro Vegetation LiDAR Program	**Vegetation Visibility:** LiDAR, Vegetation Data and Targeting
Vegetation Systems and Reporting Enhancement Roadmap	**All Technology Categories:** Business case development and investment justifications for enhancements within the annual IT capital and maintenance plans **Management & Support:** Reporting, Documentation and Records, Performance Management
Category Management Strategy & Market Procurements	**Management & Support:** Category Management, Vendor & Contract Management

In total, this represents eight incremental FTEs being added between fiscal 2023 and fiscal 2025, all within the Operations Business Group in BC Hydro. With these additions to the base complement, it is believed that the capabilities and internal resources required to delivery the VMS will be suitable for the next three years and further assessment is expected annually as enhancements are realized.

12 Performance Metrics and Evaluation

Vegetation maintenance is a significant undertaking for BC Hydro and involves considerable investment in both time and resources. In order to support the long-term successful delivery of vegetation management work, there is an ongoing need for performance metrics and program evaluation. This is required in order to both ensure appropriate management and oversight in addition to understanding key comparators to the industry and market. This information is used to shape the ongoing program, identify sources of business opportunity and communicate outcomes to both internal and external stakeholders.

Although there has been robust reporting in place for many years, an objective of the VMS is to formalize and improve visibility of performance metrics and program evaluation in addition to enhancing the overall complete suite of analytic capabilities. Moving from the status quo to the full operationalization of the proposed reporting and metrics will be undertaken in accordance with the initiative described as Vegetation Management Performance & Evaluation Enhancement Initiative (refer to Key Pursuits and Activities section for details on timing and scope). In addition to enhancing and formalizing reporting, the initiative will also focus on the integration of source data systems and reporting automation. This will ensure key information is identified without manual effort, delivering operational and planning insights in a regular and timely fashion to those that need it to inform decisions.

At the core of the Vegetation Management Performance & Evaluation Enhancement Initiative are three primary approaches to support performance and evaluation:

- Regular automated reporting and re-occurring studies or audits;
- Compliance reporting; and
- Planned analysis focused on specific areas of interest or improvement.

12.1 Regular Reporting

The regular automated reporting and re-occurring studies or audits are intended to cover a series of business needs. Shorter frequency, more detailed reports are in direct support of operational management and oversight, whereas higher level and more periodic reports are for senior audiences and executive reviews to assess general program performance towards stated outcomes. Additionally, annual benchmarking studies and regular audits (e.g., WECC Audit for Mandatory Reliability Standard FAC-003) are to understand context of performance relative to other utilities and compliance assurance, respectively. The cumulative effect of all these various reporting measures ensures both timely and contextual insight into how the vegetation management program for BC Hydro is performing and managed. The following is a summary of these reporting vehicles, inclusive of frequency.

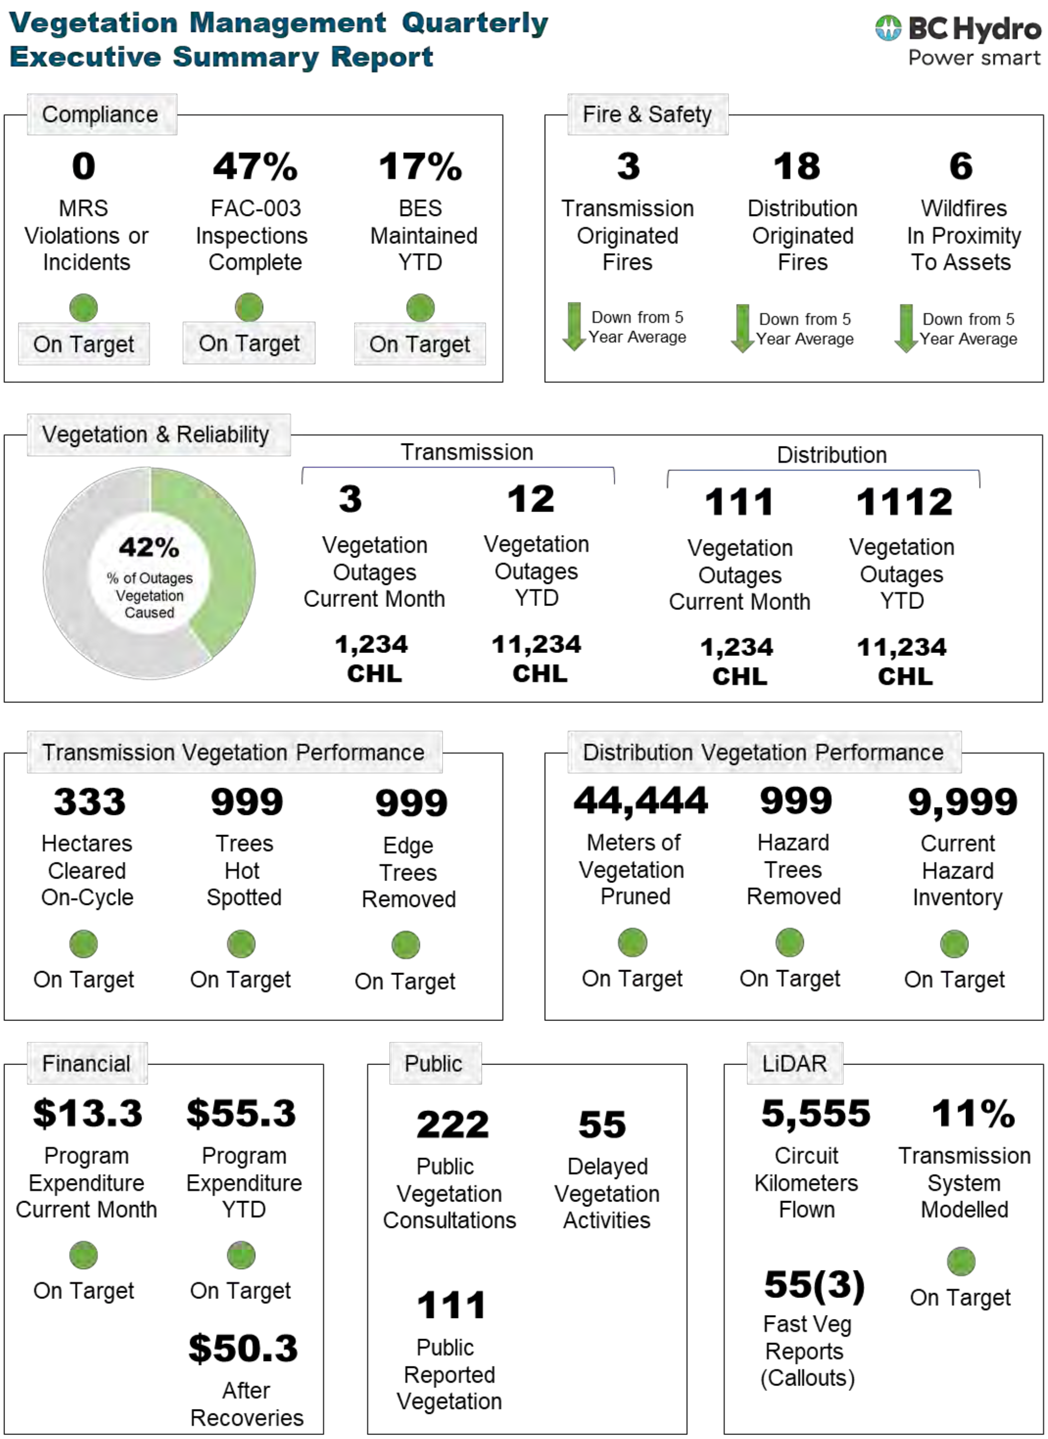
Table G-8 Summary of Vegetation Management Reports and Evaluation

Report / Study Name	Purpose	Audience	Frequency
Weekly Operations Report	The purpose of the weekly operations report is to provide front line managers with the information required to understand regular delivery activities in addition to ensuring regular and timely collection of data and insight	• Front line managers • PCM managers • Planning leads	Weekly
Monthly Vegetation Management Report (Detailed)	The purpose of the monthly vegetation management report is to provide broad awareness of the progress of the overall vegetation management effort to a broad audience at a detailed working level	• Front line managers • PCM managers • Planning leads • Responsible Directors • Compliance Leads • Cross Functional • Supporting Individuals • Responsible • Executives	Monthly

Report / Study Name	Purpose	Audience	Frequency
Quarterly Vegetation Management Executive Summary	The purpose of the quarterly vegetation management executive summary is to provide broad awareness of the progress of the overall vegetation management effort to senior level individuals	• Responsible Directors • Responsible • Executives	Quarterly
Asset Planning Monthly Dashboard	The purpose of this dashboard is for Asset Planning management and leadership to review key performance indicators from various programs, including the vegetation management program	• Asset Planning • Leadership Team • Integrated Planning • Leadership Team	Monthly
Executive Summary Presentations	The purpose of these presentations is to provide an overview of the vegetation program execution to the Executive Team	• Executive Team	As requested
Annual First Quartile Benchmarking Study	The purpose of the annual First Quartile Benchmarking Study is to understand BC Hydro's relative performance to industry peers and gain insight into industry themes and trends	• Planning Managers • Operations Managers • Responsible Directors • Responsible • Executives	Annual
WECC Audit Findings Report	The purpose of the WECC audit for vegetation management (FAC-003) is to ensure utility practices are suitable for maintaining compliance with Mandatory Reliability Standards	• Planning Managers • Operations Managers • Responsible Directors • Responsible • Executives	Every 36 Months

Figure G-8 below provides an illustrative example of the quarterly executive summary. The specific metrics and reported details will be developed during the course of fiscal 2022 as one of the initiatives completed as part of the VMS. The example is for illustration purposes only.

Figure G-8 Illustrative Example Quarterly Vegetation Executive Summary Report



* Actual report to be developed in fiscal 2022 as part of the delivery of the VMS. Illustration purposes only.

12.2 Compliance Reporting

Compliance reporting is crucial in order to provide the evidence necessary to validate ongoing achievement of compliance (e.g., FAC-003, Wildfire prevention, etc.). Reporting for the purposes of compliance is defined by the individual compliance requirements, inclusive of formats, timeframes and content. The general themes consistent with compliance requirements are as follows:

1. Eliminate grow-into outages and minimize risks from fall-into tree outages;
2. Implement a well-documented program that addresses all rated operating conditions taking into account line sag/sway and effects of line load, weather, vegetation growth, etc. to avoid vegetation encroachments;
3. Ensure a clear communication process in the event you have imminent risks;
4. Implement mitigation strategies to deal with work that may be deferred because of permits, disputes, etc.;
5. Complete annual documented patrols of the entire system; and
6. Implement documented annual work plan and tracking and quality reviews to assure that all planned work is completed and that no outstanding risks are left before next maintenance cycle.

12.3 Planned Analysis

Planned analysis is another method of performance management for vegetation maintenance. This approach relies on the identification of a potential opportunity or hypothesis for improvement and then a tailored analysis to understand the contemplated change. Each of these will be summarized with key findings and recommendations as completed. Examples of specific analysis undertakings include the following:

Table G-9 Planned Analysis – Initiative Based

Key Question	Initiative*	Timeframe
Are vegetation management external contracts cost effective?	Category Management Analysis	Fiscal 2022 and fiscal 2023
Are there financial and reliability benefits for proactive vegetation management work versus trouble response?	Proactive Vegetation Management Versus Trouble Cost Analysis	Fiscal 2022 to fiscal 2025
Are there financial and operational benefits to utilizing internal resources for vegetation management?	Internal Labour Utilization for Vegetation Management Analysis	Fiscal 2024
Are cost increasing faster than program resources?	Annual Cost Pressure Analysis	Annually

* Refer to the Key Pursuits and Activities section for additional details

Combining the use of multi-level regular reporting, re-occurring studies, compliance reporting and planned analysis, BC Hydro will be well positioned to ensure the effective delivery of vegetation management efforts. This suite of information directly enhances operational delivery oversight, long-term planning capabilities, quality assurance practices and compliance assurance. The range of activities also spans internal and external sources to ensure that there is a deep understanding of the insights produced in context of the broader utility industry. This will enable BC Hydro to maintain confidence in its delivery practices and ensure value for ratepayers in British Columbia.

13 Key Pursuits and Activities

BC Hydro recognizes that well performing vegetation management both requires ongoing, regular work programs to address growth and re-growth in addition to deliberate projects or work efforts to improve the overall capability to manage vegetation holistically. Evolving the program to take advantage of new technologies, market opportunities, process efficiencies and adapting to cost pressures and regulatory changes are all examples of changes that ensure long term efficacy. As such, beyond the delivery of regular vegetation management efforts, the VMS includes a series of key pursuits and incremental activities to the base work. These are each intended to be delivered in a project-based fashion and have scope, timing, resource and cost dependencies individually. Furthermore, as additional information becomes available and the new VMS is implemented, these pursuits will change and adapt to the needs present within each year's annual work plan.

The following are a summary of these pursuits as they are contemplated at this time:

Table G-10 Summary of Initiatives, Pursuits and Studies

Initiative	Description	Desired / Potential Outcome(s)
Integrated Vegetation Visibility Enhancement Initiative	There are currently several means in which BC Hydro gathers information on the state of vegetation across the electrical system. These include patrols, surveys, public reports and studies. The purpose of this initiative is to optimize the benefit and usefulness of the full breadth of information gathered by all means of collection to drive efficient realization of vegetation management goals. This initiative will span people, processes and technologies to manifest a deliberate ecosystem of inputs and outcomes that collectively represent an effective vegetation visibility and targeting capability.	Operationalization of an integrated vegetation visibility capability (including patrols, LiDAR, reports, studies, etc.) enabling the effective, efficient and prioritized targeting of vegetation management.
LiDAR Operationalization and Optimization	On ongoing LiDAR program covering a minimum of 20 per cent of the system per year will need to be operationalized across a number of internal BC Hydro teams and external parties. Geomatics, Engineering and Vegetation Planning will all require new processes and technology solutions to support the incremental LiDAR information and end use cases. Additionally, a category management strategy for vendor management will also be developed in support of this initiative.	A smooth operational process that receives cost effective LiDAR scan data and achieves the desired vegetation business outcomes post modelling and interpreting, enabling effective program targeting for transmission maintenance.

Initiative	Description	Desired / Potential Outcome(s)
Vegetation Management Performance & Evaluation Enhancement	Vegetation management represents a significant proportion of BC Hydro's annual operating and maintenance expense. As a key portfolio, it is regularly required to assess and communicate the efficacy of the end to end program effectiveness. This is done through the regular use and combination of internal metrics, external benchmarks (First Quartile, CEA, EPRI, etc.), industry resources (whitepapers, comparison studies, etc.), peer to peer engagement and consultants. The purpose of the vegetation management evaluation initiative is to develop an orchestrated regular suite of KPIs and comparators that will be used to communicate program details on a monthly basis, satisfying the need of both internal and external stakeholders. The goal is to enhance the current suite of metrics while improving the means in which information is gathered.	Improved awareness of vegetation management performance and accessibility of key performance indicators. Improved capability to manage the program in context and make determinations of where changes may be needed. Proactive insight about the overall program health and achievement of work.
Vegetation Management Longevity Study	The nature of vegetation management is an ongoing cycle between management efforts and regrowth. Growth rates are largely dependent on environmental and climate factors (precipitation, sun, temperature, etc.); however, there are means of extending the longevity of vegetation management efforts. Examples include the use herbicide, clearing techniques, landscaping, public engagement (preferential species selection, planting locations, etc.) and partnerships. BC Hydro will engage a study to assess the means of longevity extension and determine if any are favourable to implement into the regular delivery of vegetation work.	Longer persistence of vegetation management benefits resulting in incremental realization of the program's goals. Repeatable and reliable extensions of longevity could safely extend cycle times or reduce vegetation management needs in remote areas.

Initiative	Description	Desired / Potential Outcome(s)
Vegetation Work Consolidation Initiative	At present, in addition to the primary provincial vegetation management program, there are other vegetation related efforts occurring in isolation; namely at facilities (generation, substation, etc.), roads and access and non-integrated areas. Although small by comparison, there may be opportunities to realize benefits from alignment of these various efforts and ensure completeness for understanding the full breadth of vegetation management efforts across the company. Furthermore, there are robust linkages between roads and access and vegetation related work that will need to be studied to optimize both programs, improve access and reduce risk in remote areas.	Synergies in program deliveries, improve coordination of access with respect to vegetation, better prioritization capability, incremental utilization of manual patrols, reduced risk, improved reliability.
Vegetation Management Rights and Obligations Initiative	Over time, even the best designed structures, processes and systems experience gradual incremental changes as present needs drive minor changes into the business. Churn in particular roles, restructuring of teams, introducing new processes or systems, adding external compliance requirements and time are all examples of small, but cumulative changes that large-scale programs experience. After an extended period of time, organizational entropy can occur which leads to more effort being required to realize the optimal state of delivery. The goal of the rights and obligations initiative is to assess the status quo in terms of team structures and roles to either validate the current state as optimal or modify the current state to one that is optimal.	Improved inter-team collaboration, clarity of accountability and responsibility, reduction of potential gaps or overlaps.
Vegetation Management Work Process Review	Intended to follow the Vegetation Management Rights and Obligations Initiative, an annual process review focused on the key delivery areas will ensure alignment between roles and ensure they are optimal. Additionally, this initiative will assist in documenting how processes are delivered and aligned to the program goals, supporting future reviews, audits and regulatory proceedings.	Process efficiency, audit preparedness, delivery alignment and efficiency.

Initiative	Description	Desired / Potential Outcome(s)
Vegetation Resource Assurance Plan	Vegetation management is a resource intensive activity that requires a regular supply of qualified professionals to deliver. The purpose of this initiative is to establish a long-term sourcing plan that will align to the vegetation program needs. It is anticipated to include both an internal and external assessment that combined form a complete resource assurance plan.	Firm and cost-effective resource assurance for ongoing vegetation program delivery.
Proactive Vegetation Management Versus Trouble Cost Analysis	One of the contributing causes of outages and system damage is contact with vegetation. Proactive pruning, removal of hazard trees and other vegetation management efforts can reduce the potential for system contact during storms and weather events. The purpose of this initiative is to evaluate the cost effectiveness of incremental upstream vegetation management effort versus restoration efforts following a trouble event. The analysis will look at both the operational costs in addition to the system outcomes (e.g., improved reliability, safety, etc.) over a number of years to determine if a business case exists for broader proactive vegetation management efforts.	If a favourable relationship exists and can be repeatedly demonstrated, a business case will be developed for incremental upstream vegetation management efforts to proactively reduce the probability of trouble events.
Internal Labour Utilization for Vegetation Delivery Exploration	At present, all vegetation management delivery engaged by BC Hydro across British Columbia is conducted by external third parties, governed by a series of contracts with oversight from BC Hydro employees. There are utilities that utilize employees to perform vegetation management delivery and BC Hydro will explore the potential of this model. Furthermore, opportunities to expand existing field roles to include vegetation management elements may be a means of improving labour utilization in some areas of the province while also providing staff with additional opportunities to grow skillsets and diversify their working portfolios. It is recognized that this study will include a number of complex factors, including but not limited to engagement with employee relations, human resources, unions, existing employees and external parties to fully evaluate the potential benefits, detriments and scope of possibility for making a change of this nature.	Cost savings for the delivery of regular, localized and repeatable vegetation work. Potential opportunity for improved resource utilization (both equipment and labour). Efficiencies of work delivery for vegetation related system impacts.

Initiative	Description	Desired / Potential Outcome(s)
Vegetation Impacts from Climate Change Study	Vegetation across the province is highly susceptible to changes in environmental conditions and resulting occurrences (e.g., infestations, disease, etc.). It is globally recognized that climate change is occurring and to the extent that it impacts BC Hydro's system as a result of vegetation impacts has not been actively studied, although visible evidence of impacts is apparent. The purpose of this study is to formally assess the historic impacts and project impacts into the future to improve long term planning and guide actions in the present that can mitigate detriments from climate change.	Improved planning to mitigate climate change impacts, proactive preparation for broad scale climate events, improved program performance through future planning.
Fire Prevention and Mitigation Plan	One of the largest ongoing threats to public safety and the electrical system is fire. Fires originating naturally (e.g., wildfires caused by lightning strike) can damage remote electrical infrastructure and impact communities far away, all the while impeding restoration efforts. Fires can also be started by the electrical system where vegetation contact is a primary ignition driver. The purpose of this plan is to proactively address and mitigate fire related system risks and vulnerabilities. Activities ranging from ROW widening, incremental vegetation waste product removal, chemical fire retardants, line ratings and system enhancements (e.g., lateral reclosers) can all produce fire mitigation benefits for BC Hydro and for the public. This plan is intended to evaluate various options and advance a suitable suite of fire prevention and mitigation activities as they relate to vegetation.	Improved safety, reliability and compliance.

14 Proposed Workplan – Beyond Base Maintenance Work

The following is the proposed workplan covering the new VMS initiatives that extend beyond the scope of base work. The workplan and schedule below is at a higher level of detail than the initiatives and some initiatives have been represented by their individual scope below and shown in chronological order.

Table G-11 Proposed Workplan and Schedule

Workplan Item	Schedule	Business Units
LiDAR Operationalization & Optimization	Q1 F22 → ongoing	Integrated Planning, Supply Chain
New Vegetation Metric Suite	Q2 F22 → ongoing	Integrated Planning, Operations
Vegetation Reporting Automation	Q3 F22 → Q2 F23	Integrated Planning, Operations, Technology
Annual Process Review and Optimization	Annual (1 core process per year)	Integrated Planning, Operations
Access & Vegetation Inspections Consolidation	Q3 F22 – Q4 F23	Integrated Planning, Operations
Refresh Vegetation Long Term Resource Plan	Annual – Q4	Integrated Planning, Operations, Supply Chain
Vegetation Longevity Study	Q3 F23	Integrated Planning
Vegetation Category Strategy	F22 – F23	Supply Chain, Integrated Planning
Climate Impact on Vegetation Study	F24 – F25	Integrated Planning
Internal Labour for Vegetation Delivery Exploration	F23 – F24	Integrated Planning, Operations, Human Resources, Employee Relations
Integrated Vegetation Visibility Initiative	F23 – F24	Integrated Planning, Operations
Annual Benchmarking	Annual – Q4 F22 → Ongoing	Integrated Planning
Proactive Vegetation Versus Trouble Analysis	Monitored Annually	Integrated Planning, Operations
Vegetation Consolidation Initiative & Rights and Obligations	Q3 F22 – F23	Integrated Planning
Wildfire Prevention & Mitigation Plan	Q3 F22 – F23	Integrated Planning, Operations

Revenue Requirements Application

Appendix H

Fiscal 2022 to Fiscal 2031 Capital Plan

~~CONFIDENTIAL -~~ Discussion/Information

2.4 Annual 10 Year Capital Plan

Executive summary

This briefing provides a summary of BC Hydro's updated Capital Plan (Capital Plan) with an outline of the overall Capital Plan composition, excluding Site C, as well as retained risks and uncertainties across the portfolio. The Capital Plan is presented to the Capital Projects Committee of the Board of Directors annually and supports BC Hydro's Service Plan update and the upcoming Revenue Requirements Application (RRA).

The Enterprise Capital Planning process strives to balance affordability for BC Hydro customers with an appropriate level of retained risk and impacts to system performance. This Capital Plan achieves key strategic objectives including investing to address compliance, addressing our highest safety risks and preserving the reliability of the Key generating facilities and the bulk electric system. Since the approval of the Previous Plan, changes in the portfolio composition have increased the amortization and dismantling impacts. These changes include addressing increasing needs for the Supporting Portfolios (Technology, Properties, and Fleet Services) in the near-term years of the Capital Plan and increases to the customer driven capital expenditures net of contributions in aid. To address these changes while maintaining an appropriate level of risk within the Power System portfolio, there is a marginal increase to the rate impact of the Capital Plan in comparison to the Previous Plan.

To balance affordability with system performance and risk, some investments were deferred in the near years of the Capital Plan. The retained risks associated with the deferrals were evaluated and are considered to be manageable. These risks will be monitored, and adjustments will be made in the next capital planning cycle if appropriate. Funding levels for the Supporting Portfolios will also be re-evaluated as part of the next capital plan in support of initiatives such as the Greenhouse Gas (GHG) Management Plan and the Long-Term Workplace Strategy, as well as a level of funding in the Technology portfolio to manage risks and deliver on improvements to business capability over the longer term.

This Capital Plan has been developed in consultation with Project Delivery and Program and Contract Management. Resource risks and mitigation strategies have been identified and where required adjustments have been made to the capital investments to address potential near-term overloading of Engineering and Operations resources. Due to uncertainties related to ongoing COVID-19 protocols and Mandatory Reliability Standards (MRS) demands there will be an increased reliance on the 2 – 12 month resource forecasts and escalation process to monitor and adjust the detailed Operations work plans in the near term of the plan.

Background

Over the past year the capital planning schedule has been adjusted to accommodate the F2022 and F2023 – F2025 RRA filing schedules. Capital Planning activities to develop this updated Capital Plan began in February 2020, were put on hold in September 2020, and then were re-initiated in December 2020 including updating active project forecasts as of January 2021. This Capital Plan will form the basis of the capital expenditures included in BC Hydro's F2023 – F2025 RRA, expected to be filed in August 2021.

~~CONFIDENTIAL -~~ Discussion/Information

2.4 Annual 10 Year Capital Plan

Financial and Strategic Directions for the Capital Plan Process

The F2022 – F2031 Enterprise Capital Planning process began with defining business group level capital additions targets. Initial targets were set based on the strategic objective to maintain a rate neutral impact when compared to the Previous Plan in the front five years of the capital plan horizon. This includes consideration for amortization as well as OMA expense items related to capital, such as Capital Project Investigation funding and Dismantling.

Public and Worker safety continues to be the highest priority for capital investments, and re-direction of funding to the Supporting Portfolios in the near years of the plan was done in support of corporate wide priorities such as "Make it Easier to Get Work Done". This Capital Plan includes increased investment to support BC Hydro's MRS Program, and ensures sufficient funding for the investments required to meet the Federal Polychlorinated Biphenyl (PCB) Regulation deadline of December 31, 2025.

Main Investment Drivers

While the detailed investments within each portfolio change with every capital plan update, there are several key drivers across the enterprise portfolio:

Ageing Assets – A large portion of BC Hydro's system was built in the 1960s and 1970s and is reaching or exceeding expected end-of-life. A significant proportion of the risks facing BC Hydro's major assets can be attributed to their age. The physical condition, performance, maintenance history, and criticality of equipment and facilities are significant drivers for planning and prioritizing refurbishment or replacement.

Reliability – Capital investment is paramount to the total performance of the system, and the indicators of investment adequacy are consistent performance metrics over time and the number and impact of in-service failures on critical assets. The F2021 SAIDI and SAIFI results of 3.27 and 1.49 were slightly above (2 per cent and 6 per cent) their targets of 3.20 and 1.40, respectively. However, SAIDI and SAIFI measures within 10 per cent of targets are considered acceptable. The BC Hydro Service Plan sets targets for system performance measures based on longer-term trends and expected longer-term investment plans; these lagging indicators continue to indicate that BC Hydro is appropriately managing our service performance risks.

Compliance and Resiliency – The identification of capital investments to address environmental compliance, MRS and cybersecurity has continued over the past capital planning cycle. The Capital Plan includes investments to address the PCB Regulation deadline of December 31, 2025. In addition, the Capital Plan includes funding for the successful implementation of the latest version of Critical Infrastructure Protection (CIP) standards (NERC CIP-003 version 7), and physical security zone improvements at Key generation facilities. As key activities in the area of compliance progress in the coming fiscal year, additional capital investments may be identified that will need to be initiated as ex-plan or included in future capital plan updates.

Growth – While the overall level of investment in growth has moderated over the past few years, aligning with the trend in the load forecast, new investments continue to be required for both distribution and transmission infrastructure to meet regional customer demand growth. Investments within this Capital Plan are aligned with the System Load Forecast dated December 2020, and the Substation Load Forecast dated November 2019. Investments to address forecasted load growth now represent only a small proportion of the overall Growth expenditure portfolio.

BC Hydro
Power smart

~~CONFIDENTIAL -~~ Discussion/Information

2.4 Annual 10 Year Capital Plan

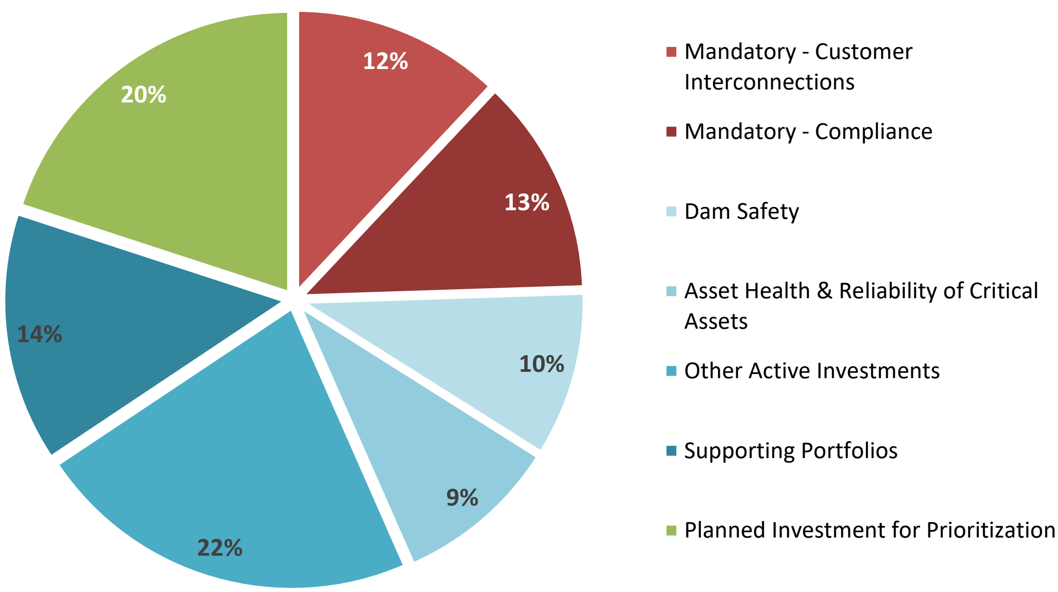
A significant proportion of the remaining Capital Plan growth expenditures are required to connect new supply of electricity based on customer requests and are considered Mandatory. The balance of the Growth portfolio is required to mitigate other system risks such as providing reliable service and/or allowing for the retirement of end-of-life assets. Examples include the construction of a new line to West Kelowna and a new substation in the West End of Vancouver to allow for the offloading of Dal Grauer substation. Even though these investments may be driven by the need to sustain the existing system, as is the case in the latter example, they are classified as Growth expenditures in the Capital Plan because they are adding new assets to the Power System.

Business Needs – The increasing prevalence of technology, particularly amidst the COVID-19 pandemic, changing employee needs, and the Vehicle Frontline Alliance Team (VFLAT) outcomes related to continued standardization, drive some of the investments associated with the Supporting Portfolios: Fleet Services, Technology, Properties, and Tools/Other.

Capital Plan Composition

The following chart outlines various components of the capital investments included in our updated Capital Plan after prioritization and are shown as the percentage of capital additions in the F2022 – F2027 period.

Figure 1: F2022 - F2027 Capital Plan composition by Prioritization Category

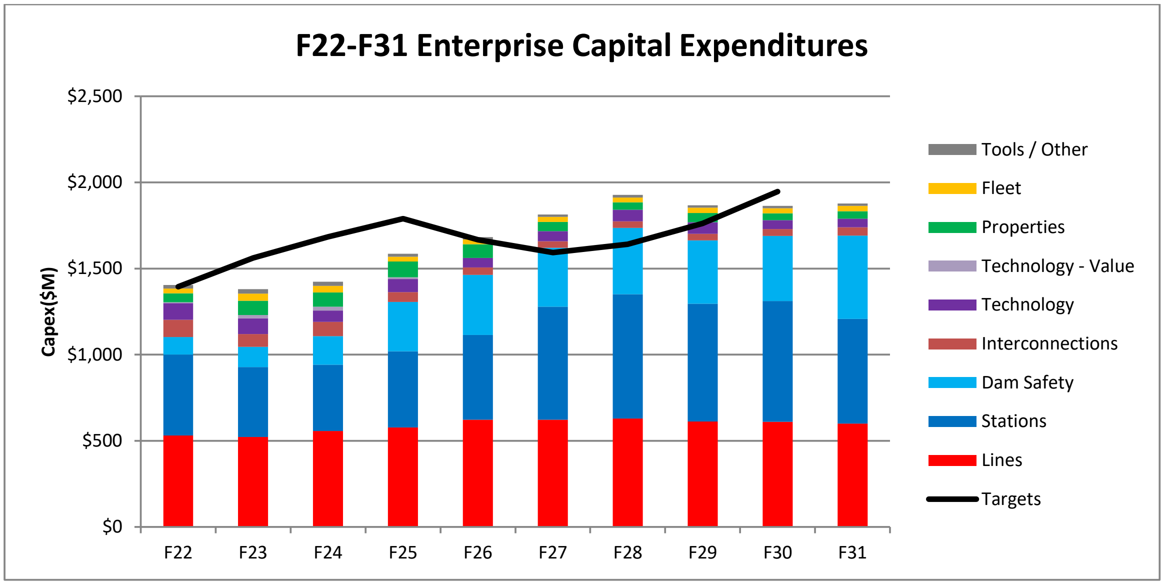


BC Hydro is forecasting net annual average capital expenditures of approximately $1.68 billion[1] per year or total net capital expenditures of $16.83 billion[1] over F2022-F2031. For capital additions, BC Hydro is forecasting a net annual average of approximately $1.63 billion[1] per year, or total net capital

[1] Excludes Site C and BC Hydro Subsidiaries

additions of $16.29 billion[1] over F2022-F2031. Figures 2 and 3 below show the capital expenditure and additions breakdown across the Enterprise Portfolio. A tabular representation of the capital expenditures and additions by category is included in the appendices.

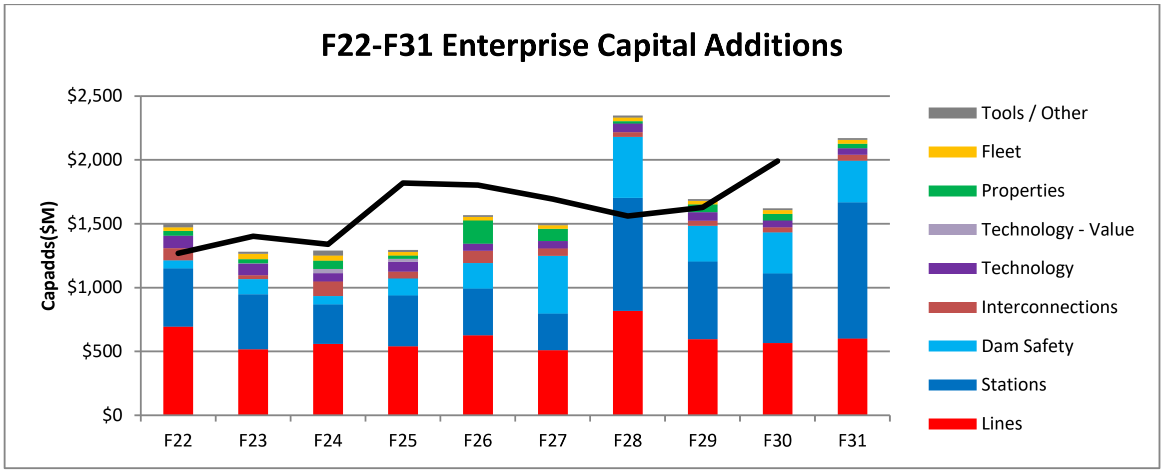
Figure 2: F2022 - F2031 Capital Expenditure



For the early years of the Capital Plan, BC Hydro is in a level of lower annual capital expenditures compared to levels seen in the past decade. Over the longer period, the increasing capital expenditure profile is driven by Project Delivery's forecasts for many large active projects that will be entering the Implementation phase in coming years, including the Strathcona Upgrade Discharge, John Hart Dam Seismic Upgrade, and Peace to Kelly Lake – Stations Sustainment projects. There are also a number of major projects expecting to have high capital expenditures after the F2027 period most notably the West End – Substation Construction and System Reinforcement and the La Joie Dam Improvement projects. While full investment level planning and prioritization was not completed for the F2028 – F2031 period, the updated forecasts for these larger active projects are indicating a need for sustained higher levels of investments in the latter years of the plan. Further discussion on the execution and resource risks associated with this Capital Plan are outlined below.

2.4 Annual 10 Year Capital Plan

Figure 3: F2022 - F2031 Capital Additions



The variations in the capital additions profile, shown in Figure 2, are driven by the in-service dates of large projects. In F2028, the capital additions include Peace to Kelly Lake – Stations Sustainment, Seton – Upgrade Unit and the System Wide – Bulk Electric System Telecom Equipment Replacement projects as well as the impact of the Project Delivery risk adjustment that is shifting forecasted additions from earlier years into F2028. The F2031 capital additions forecast is largely driven by the West End – Substation Construction and System Reinforcement forecast in-service date.

Uncertainties to Monitor

There are a number of uncertainties, within the Power System, Technology, Properties, and Fleet portfolios, that will need to be monitored for impacts on the Capital Plan. The base Capital Plan includes higher projected investments for Distribution Major Load and Transmission Interconnections but does not include all investments required to achieve BC Hydro's Electrification Plan or the Government of British Columbia's Clean BC Initiative. The incremental investments required to support BC Hydro's Electrification Plan are estimated to be between $25 to $75 million to connect new Transmission and Distribution Loads. Similar to the Previous Plan, expenditures related to the CleanBC initiative and the Revelstoke Unit 6 projects have been included in the Capital Plan to the current approved funding phase only. These investments will be added to the Capital Plan once firm load commitments are made by our customers. These investments will be offset by increased revenue projections to ensure the rate impacts of the Capital Plan remain neutral to the Previous Plan.

In addition, the level of growth investment has been moderated compared to previous plans. This means that higher than forecast load increases, where there are constraints on the system, will require offsets through mechanisms like demand-side-management and time of use rates. Otherwise higher levels of growth capital investment will be required to address system constraints. Electrification efforts and customer interconnections will also place demands on capital and resources as well as Capital Project Investigation (CPI) funds.

MRS and Cybersecurity activities may identify the need for additional capital investments on the Power System beyond what is currently included in the Capital Plan. This may also impact the demand for and prioritization of work for Technology.

2.4 Annual 10 Year Capital Plan

Finally, some strategies and plans were not approved as of the January 2021 currency date of the Capital Plan. The Long-Term Workplace Strategy has not yet been finalized and so the Properties portfolio does not include any investment related to a hybrid working environment. Also, the Capital Plan does not reflect the investments required to meet the CleanBC goals outlined in the Greenhouse Gas Management Plan, which was endorsed after the finalization of the Capital Plan. Investments to meet BC Hydro's Long-Term Workplace Strategy and CleanBC goals will be included in future capital plan updates.

Power System

After capital additions targets were set at the Enterprise Portfolio level, the Power System targets were set for each sub-portfolio. Cross portfolio reviews focused on ensuring the retained risks were comparable across the Power System.

Dam Safety

Dam Safety risk reduction targets remain as they were in previous Plans and align with the approach that was approved by the Board in 2014; to "manage the whole fleet of dams so that there is no significant deterioration in the risk position and that the overall level of risk is kept well within the limits considered to be tolerable." In practical terms, this Capital Plan aims to reduce the aggregated Vulnerability Index of issues identified in the Dam Safety Issues Database at a rate that will generally offset the historic (and expected) rate of additions to the Vulnerability Index through newly identified or understood issues.

This Capital Plan continues to prevent deterioration of the current risk profile related to BC Hydro's dams and reservoirs and will address several issues that significantly contribute to that risk. It provides for major seismic and spillway gate reliability upgrades to the Campbell River System and Mica Dam spillway, seismic upgrades to La Joie Dam and the Alouette-Stave tunnel and provides for flow control improvements and associated reduction of public safety risk along the Puntledge River.

While continuing to broadly meet the Dam Safety program's risk reduction targets, the size of the Dam Safety portfolio – specifically In-Service Additions in the period F2022 through F2027 – has been reduced by approximately ten percent within this latest version of the Capital Plan. This is primarily as a result of a number of deferrals of project releases. In some instances – such as at Duncan, Sugar Lake, Walter Hardman and Whatshan Dams – these deferrals accommodate the time required to complete precursor Dam Safety Investigations. Some other project releases have been deferred to reduce the number of concurrent projects in a region, such as the canal refurbishment and left dyke upgrade at Seton, or to reduce demands on a specific resource, such as the spillway gate system reliability upgrades at Seven Mile Dam. Finally, a handful of investments have been deferred by one or two years primarily for the purpose of balancing affordability with system performance and risk. These projects – at Bear Creek and Terzaghi Dams, on the Wahleach tunnel intake, and a second tranche of reservoir boom replacements at various sites – have relatively small impacts on the portfolio's risk profile that can be managed and/or tolerated in the interim.

Stations Asset Planning - Generation

The Generation portion of the Stations Asset Planning portfolio continues to focus on preserving a high level of reliability at our seven Key facilities which provide 90% of the average annual electricity generated by BC Hydro. These investments support BC Hydro meeting its forced outage factor service plan metric and include generator investments at Bridge River, G.M. Shrum, Revelstoke and Kootenay

Canal; and turbine overhaul projects at Mica, Seven Mile and G.M. Shrum. The Capital Plan also includes targeted investments at Strategic facilities, an increasing level of investment in physical security systems (non-MRS) and some provision for dismantling stations that are out of service.

The release dates of a number of projects have been deferred in the latest version of the Capital Plan. In some cases, such as with generator sustainment investments at G.M. Shrum (G5 and G9), this has been done considering the most recent condition information for those assets. In other cases, such as with cooling water piping system replacements at Mica and Seven Mile, investments were deferred to align with outages associated with other major projects (turbine overhauls in both of these cases).

Other investments have been deferred, where retained risks were determined to be manageable, to balance affordability with overall system risk and performance, these included reliability investments at select Strategic facilities such as Clowhom, Ladore and Puntledge. We continue to perform regular maintenance on these units, however, there is an increasing likelihood of unit failures prior to major re-investment which would primarily result in lost opportunity costs. Provisions for investing in out of service (OOS) facilities have also been limited within the period. Specifically, Elko (OOS 2014) has been deferred to while Alouette (OOS 2010) and Spillimacheen (OOS 2019) have been left outside of the period. To manage the regulatory/reputational risk associated with operating outside of our Water Licenses we have maintained open communication with the Comptroller of Water Rights and interested First Nations on BC Hydro's long-term plan to address these facilities.

Stations Asset Planning - Substations

The Substation portion of the Stations Asset Planning portfolio has an increased focus on sustainment investments, due to a moderation in the rate of load growth. The investment strategy focuses on the replacement of higher priority asset classes such as transformers, circuit breakers, and feeder section retrofits. A number of station rebuilds and upgrade projects are also planned that will facilitate the removal of end-of-life equipment. The portfolio includes the required funding to adhere to federal deadlines regarding the removal of PCB equipment that contains more than 50 parts per million (ppm) by the December 31, 2025 deadline and MRS Requirements.

There were some deferrals within the Substation portfolio, where retained risks were determined to be manageable, to balance affordability with overall system risk and performance. There were focused on the remaining major Sustain projects and programs without regulatory components, including the Port Alberni Refurbishment and the Patricia Upgrade. Reductions were also taken in recurring programs that do not have a regulatory compliance implications including: Instrument Transformer Replacements, Station Battery Bank Replacements, Station Insulator Replacements and 500 kV – 60 kV Disconnect Switch Replacements. As a result of these investment deferrals the portfolio anticipates an increased risk of end-of-life asset failures, and longer retention of end-of-life equipment with known limits of approach issues. These risks will be managed by normal station redundancy where possible but may require re-prioritization of the plan outside of the normal planning cycle. Risks associated with known limits of approach issues will continue to be managed through established operational work procedures.

Lines Asset Planning – Transmission

Investments under the Transmission portion of the Lines Asset Planning portfolio are focused on preserving the asset health and reliability of the bulk electric system, increasing capacity on the transmission system, meeting regulatory compliance requirements and mitigating the highest asset risks.

2.4 Annual 10 Year Capital Plan

Some deferral of investments was required, where retained risks were determined to be manageable, to balance affordability with overall system risk and performance. These deferrals included the dismantling associated with the 1X387AMX – Kitsault Transmission Line Hazard Mitigation project and the dismantling associated with the 2L146 (Horsey sub. to Goward sub.) - Cable Replacement project. Reductions were also taken in select recurring programs including ACSR2 Conductor Replacements, Spacer Damper Replacements, Access Program, and Disconnect Switch Replacements. Funding levels for high priority programs, such as wood pole replacements and metal structure civil and corrosion protection are in line with the amounts in the Previous Plan. Risks associated with these deferrals will be mitigated through monitoring of the health of the assets over time, through regular condition assessments and on-going maintenance and inspection activities. Where changes are observed, or risks emerge, decisions will be made with respect to the investment strategy and where necessary, short term operational changes.

Lines Asset Planning – Distribution

Investments under the Distribution portion of the Lines Asset Planning portfolio are focused on maintaining system safety and reliability, increasing capacity to meet customer demand, and grid modernization, which also supports system safety and reliability. The portfolio includes the required funding to adhere to federal deadlines regarding the removal of PCB equipment that contains more than 50 ppm by the December 31, 2025 deadline.

Reductions were taken in select sustainment programs and system improvement provisions, where retained risks were determined to be manageable, to balance affordability with overall system risk and performance. The programs reduced included Feeder Cable Replacements, Maintenance Access Hole Replacements, System Improvement projects to address New Feeders, and Voltage Conversions.

Decreasing voltage conversion and system expansion investment may lead to higher feeder and equipment loadings with a reduced ability to address existing overloaded feeders, which increased from 50 in F2019 to 163 in F2020 at current funding levels. Where changes are observed, or risks emerge, decisions will be made with respect to the investment strategy and where necessary, short term operational changes.

Lines Asset Planning – Protection & Control and Telecom

Investments under the P&C and Telecom portion of the Lines Asset Planning portfolio are focused on preserving the reliability of the telecom network and protection and control systems on the bulk electric system.

Some deferral of investments was required where retained risks were determined to be manageable, to balance affordability with overall system risk and performance, including the Jordan River – Communications System Upgrade project, which was deferred by two years, as well as reduction to the Leased Line Entrance Protection Replacement recurring sustainment program.

As a result of these investment deferrals, risks associated with ground potential rise (GPR) on high-voltage entrances of communication cables into substations that do not meet current BC Hydro design standards will remain on the system longer. Crews will continue to follow safe working procedures to mitigate some of the risk associated with working on or near this equipment. Preventative maintenance

[2] Aluminum core steel reinforced (ACSR) conductor.

inspections will continue, and critical emergent safety issues may be addressed by a corrective repair or through a minor capital project.

Technology

The capital plan funds Technology expenditures to enable and sustain business outcomes that help achieve our service plan objectives. This includes investments in cybersecurity and reliability compliance, data centre infrastructure, personal devices, networks, telephony, and a wide range of software platforms and applications. It also includes investments to enable and enhance business capabilities.

In addition to our service plan objectives, the key strategic drivers affecting the types of investments we make include government direction, regulation and compliance, desired business unit outcomes, utility industry direction, information technology (IT) asset health, IT market direction and IT trends. Specific drivers in the next five years include cybersecurity and regulatory compliance due to increasing cybersecurity threats and expanding NERC CIP and other MRS requirements; IT sustainment due to an aging IT asset base; modernization of IT supporting work planning, scheduling, and execution; and modernization and upgrade, or elimination of legacy IT systems that are out-of-support. Rapid advances in information technology allow our ongoing IT sustainment program to gradually introduce new capabilities such as data centre equipment modernization, mobility solutions, analytics and artificial intelligence (AI) to meet our business needs. Benefits include IT performance, capacity and mobility improvements; automation improvements for IT operations; and improved data-driven business decisions.

The Technology Capital Plan provides three years of investment level detail in the F2022 to F2024 period and portfolio level projections for the remaining years. In the F2022 to F2024 period, the Capital Plan includes appropriate investment to manage reliability compliance and cybersecurity, manage IT asset risk and sustain user productivity, and enhance existing business capabilities.

The Technology Capital Plan also includes funding in the F2022 to F2025 period for investment opportunity projects (value projects). These investments are to address key areas of IT obsolescence with the expectation that operating cost savings will offset capital amortization, ensuring that the investments are neutral to the rate impact of the Capital Plan. These include the Stations Work Management and Passport Decommissioning projects, and the enhanced capability portion of the Contact Centre Foundation project.

Funding declines sharply in F2025 to approximately 30% below expected requirements through F2031. This level of funding is expected to result in the following retained risks:

- Financial risk related to business application sustainment.
- Operational risk related to business enablement of safety, reliability and environment.
- Asset risk and productivity impacts due to delayed hardware and software platform improvements, delayed device replacements and reduced user provisioning.
- Cybersecurity risk due to delayed modernization of software platforms and applications.
- Business continuity risk due to delayed disaster recovery solutions

It is suggested that Technology capital funding in the F2025 to F2031 period be reviewed in the next planning cycle.

~~CONFIDENTIAL -~~ Discussion/Information

2.4 Annual 10 Year Capital Plan

Properties

The Properties capital plan continues to focus on mitigating Safety and Financial risks across the 100+ building portfolio, with emphasis on our larger and higher criticality facilities. Properties is continuing to invest in Building Development Projects (field building replacement projects) at the final high criticality large regional field office (Kamloops) and at the medium criticality facilities that are most in need of end-of-life asset replacement and operational upgrades. Properties will also continue to invest in upgrades to critical end-of-life building assets (e.g. roof replacements, HVAC upgrades) as well as a modest number of field building interior upgrades and construction/expansion of truck bay facilities to meet changing operational requirements. As the Long-Term Workplace Strategy has not yet been finalized, the Properties capital plan does not yet include any investment for a future hybrid work environment. In the short-term Properties' GHG specific investments will be managed opportunistically and then prioritized and included in future capital plans as appropriate.

In order to meet our capital additions targets, a number of Building Development projects continue to be delayed towards the back end of our 10-year plan or deferred beyond the 10-year plan. The annual spend on Building Improvement projects has also been reduced from historical levels. As a result of these investment deferrals and reductions, we anticipate continued deterioration of older buildings, with just over one third of building square footage being more than 40 years old, and asset deterioration or failures resulting in the need for additional repairs and maintenance expenditures as well as an impact on operations, safety, and employee satisfaction

These retained risks are being managed through the focus on larger and higher criticality facilities and systems where asset failure would have the greatest impact. Smaller and lower criticality facilities and systems will receive less investment, and assets will be allowed to deteriorate further than they have historically.

Fleet Services

The Fleet Services capital program is a continuous sustainment program to replenish fleet assets and support safe, efficient operations. Fleet assets are prioritized for replacement based on risk scores that measure variables such as maintenance costs, reliability, and condition of the asset. Under the current plan, approximately 731 end-of-life assets will be replaced by the end of F2026. This plan does not include capital to replace all fleet assets that are forecast to reach end-of-life. End-of-life assets that are deferred based on risk will grow from 102 units in F2021, to 361 units at F2026. The estimated replacement value of total deferred fleet assets will reach $39.3M by F2026.

BC Hydro is required to respond to emergency outages and operate in remote areas of the province. Most vehicle categories have limited alternative fuel products (i.e. electric) in the marketplace and/or are new to market. Another limitation is the small, but growing, volume of charging infrastructure across the province. Our near-term strategy to address greenhouse gas emissions includes small scale pilots of electric vehicle technology to evaluate viability. We anticipate increased adoption of electric vehicles in some light vehicle and equipment categories towards the end of the period.

We are currently funded to maintain the reliability of fleet assets, but forecast a need for escalated funding, starting in F2025. At the current funding levels, there is a risk that the Fleet Portfolio will see an increase in repair costs or an increase in vehicle downtime.

To manage these risks, Fleet is implementing Telematics[3] to assist in GHG emissions reduction while optimizing fleet asset life cycles, and is updating vehicle/financial policies such as: vehicle assignment criteria, re-allocation of low-utilization assets, and fleet standardization.

Resources and Execution of the Plan

This Capital Plan has been developed in consultation with Project Delivery and Program and Contract Management. Resource demand modelling was completed on critical Operations and Engineering resources. The resource modelling identified potential overloading of CPC technologists in the near term. In F2022 and F2023, the demand for these resources is largely driven by MRS Compliance initiatives and projects in Implementation. These types of non-discretionary investments offer minimal opportunity to reduce or defer as part of the enterprise wide prioritization framework for long term capital planning. This resource, as well as others impacted by COVID-19 protocols and MRS, may continue to present a delivery risk to the plan in the next one to two-year period. These resource risks will need to be monitored through the 2 - 12 month resource modelling, issues raised through the escalation process and adjustments made through this more detailed work planning process.

From a broader resource perspective, we have limited data to model the increasing demands on resources to complete capital and maintenance work in adherence to compliance standards. As this information evolves and the resource models account for these increased demands, it is possible additional Operations resource risks to the Capital Plan may be identified.

Telecom Engineering resource modelling also indicated a potential resource risk. The release of several projects in this portfolio have been deferred to ensure that resources can focus on supporting MRS compliance initiatives and higher priority projects.

Modelling and associated mitigation analysis indicate that other critical Operations and Engineering resources are balanced or can be balanced using resource augmentation and contracting strategies.

Overall, in the F2023-F2027 period, this Capital Plan includes funding for investments delivered by Program and Contract Management (PCM) that is a modest increase over the amounts delivered in F21. Expenditures at this level are considered low risk to the delivery of our small capital and recurring work programs.

As discussed above, the increasing capital expenditures profile is driven by Project Delivery's forecast for projects that are currently active and that will be entering the Implementation phase in the coming years. Modelling on associated resources such as senior level project managers and construction managers indicates a potential risk that is resolvable with appropriate resource planning strategies and does not require demand side adjustments by Integrated Planning at this time.

[3] Telematics: the installation of technology within Fleet vehicles to allow for the collection of vehicle data for analysis of key metrics such as good idling vs bad idling, hard/extreme breaking/acceleration, utilization and real time vehicle diagnostics.

Note A: ISA is in the fiscal year following the ISD because of a 3 month span between project in-service and finalization of the in-service additions by Finance.
Note B: Given the nature of the project, a definition phase was not undertaken.
Note C: $326M to $207M is the latest Pre-Implementation Cost Estimate that is reflected in the project's CPCN Application filed close to the submission date of this RRA.
Note D: Project was accelerated under the Project and Portfolio Management (PPM) scaling guidelines by combining the Feasibility Design Stage and Definition Phase, and as such does not yet have a published cost estimate. Project is considered low risk and low complexity and there is little to no Feasibility Design work required.

Notes:
(1) All information provided is current as of January 1, 2021.
(2) Some projects that are in-service or forecast to be in-service at the end of fiscal 2022 may have trailing expenditures that result in capital additions in the Test Period. These expenditures and associated capital additions have been aggregated and included in the line item "Programs and Projects Less than $5M".
(3) Project / Program dollars are generally capitalized starting either in the feasibility stage of Identification phase or in the Definition phase.
(4) Forecast ISD is the expected in-service date for the project.
(5) Start Date of Construction is the Implementation Approval Date. For projects in Definition, the Start Date of Construction is the forecast Implementation Approval Date.
(6) Definition Approval Date is the fiscal year that the project received Definition phase approval.
(7) Implementation Approval $ is the 'Authorized' total capital cost of the project when it was first approved by BC Hydro for Implementation.
(8) Pre-Implementation phases are: Initiation, Identification and Definition. Refer to Appendix N, Section 2.7 for further discussion on pre-Implementation phases. Pre-Implementation cost estimates are provided where an engineering estimate is available. N/A indicates that an engineering estimate is not yet available, or that the project is in Implementation phase.
(9) Authorized Amount is the 'Authorized' total capital cost of the project.
(10) Implementation Approval ISD refers to the in-service date identified when the project was first approved by BC Hydro for Implementation.
(11) An extension is a project that expands the service area or capacity of a utility plant or system, in accordance with paragraph 13 of BC Hydro's 2018 Capital Filing Guidelines filed with the BCUC on January 17, 2020.
(12) Project meets the current threshold for a CPCN or Section 44.2 Application based on the Project Authorized Cost Amount, or may meet the threshold, based on the planning cost allowance or cost estimate, or in accordance with BCUC Decision and Order G-47-18 and directive 29 of BCUC Decision and Order G-246-20.

Use of To Be Determined (TBD):
For projects in Future or Identification phase, To be Determined (TBD) is provided for the Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD), Start Date of Construction and Extension Project, for the following reasons:
For Future phase projects, a problem or opportunity has been identified, but the required response has not yet been determined. In Identification phase, a number of identified alternative responses are being investigated, and each alternative can result in very
different project scope, schedule and cost. As a result, Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start of Construction Date are generally only provided for projects in the Definition phase and later phases. For Extension Projects, TBD has been provided where both extension and non-extension alternatives are being investigated.

Appendix I - F2023-F2025 RRA - Transmission
Projects greater than $5 million with Capital Expenditures in the Test Period and/or Capital Additions in the Test Period (F23-F25) as at January 1, 2021 (1), (2)
$ Million

Note A: ISA is in the fiscal year following the ISD because of a 3 month span between project in-service and finalization of the in-service additions by Finance.
Note B: Project was accelerated under the Project and Portfolio Management (PPM) scaling guidelines by combining the Feasibility Design Stage and Definition Phase, and as such does not yet have a published cost estimate. Project is considered low risk and low complexity and there is little to no Feasibility Design work required.
Note C: Project was accelerated under the Project and Portfolio Management (PPM) scaling guidelines by combining the Feasibility Design Stage and Definition Phase, and as such does not yet have a published cost estimate.

Notes:
(1) All information provided is current as of January 1, 2021.
(2) Some projects that are in-service or forecast to be in-service at the end of fiscal 2022 may have trailing expenditures that result in capital additions in the Test Period. These expenditures and associated capital additions have been aggregated and included in the line item "Programs and Projects Less than $5M".
(3) Project / Program dollars are generally capitalized starting either in the feasibility stage of Identification phase or in the Definition phase.
(4) Forecast ISD is the expected in-service date for the project.
(5) Start Date of Construction is the Implementation Approval Date. For projects in Definition, the Start Date of Construction is the forecast Implementation Approval Date.
(6) Definition Approval Date is the fiscal year that the project received Definition phase approval.
(7) Implementation Approval $ is the 'Authorized' total capital cost of the project when it was first approved by BC Hydro for Implementation.
(8) Pre-Implementation phases are: Future, Identification and Definition. Refer to Appendix N, Section 2.7 for further discussion on pre-Implementation phases. Pre-Implementation cost estimates are provided where an engineering estimate is available. N/A indicates that an engineering estimate is not yet available, or that the project is in Implementation phase.
(9) Authorized Amount is the 'Authorized' total capital cost of the project.
(10) Implementation Approval ISD refers to the in-service date identified when the project was first approved by BC Hydro for Implementation.
(11) An extension is a project that expands the service area or capacity of a utility plant or system, in accordance with paragraph 13 of BC Hydro's 2018 Capital Filing Guidelines filed with the BCUC on January 17, 2020.
(12) Project meets the current threshold for a CPCN or Section 44.2 Application based on the Project Authorized Cost Amount, or may meet the threshold, based on the planning cost allowance or cost estimate, or in accordance with BCUC Decision and Order G-47-18 and directive 29 of BCUC Decision and Order G-246-20.

Use of To Be Determined (TBD):
For projects in Future or Identification phase, To be Determined (TBD) is provided for the Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD), Start Date of Construction and Extension Project, for the following reasons:
For Future phase projects, a problem or opportunity has been identified, but the required response has not yet been determined. In Identification phase, a number of identified alternative responses are being investigated, and each alternative can result in very different project scope, schedule and cost. As a result, Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start of Construction Date are generally only provided for projects in the Definition phase and later phases. For Extension Projects, TBD has been provided where both extension and non-extension alternatives are being investigated.

Appendix I - F2023-F2025 RRA - Distribution
Projects greater than $5 million with Capital Expenditures in the Test Period and/or Capital Additions in the Test Period (F23-F25) as at January 1, 2021 (1), (2)
$ Million

Note A: ISA is in the fiscal year following the ISD because of a 3 month span between project in-service and finalization of the in-service additions by Finance.
Note B: This project was approved directly to Implementation and the Definition Phase Activities were completed under the overall Program Management.

Notes:
(1) All information provided is current as of January 1, 2021.
(2) Some projects that are in-service or forecast to be in-service at the end of fiscal 2022 may have trailing expenditures that result in capital additions in the Test Period. These expenditures and associated capital additions have been aggregated and included in the line item "Programs and Projects Less than $5M".
(3) Project / Program dollars are generally capitalized starting either in the feasibility stage of Identification phase or in the Definition phase.
(4) Forecast ISD is the expected in-service date for the project.
(5) Start Date of Construction is the Implementation Approval Date. For projects in Definition, the Start Date of Construction is the forecast Implementation Approval Date.
(6) Definition Approval Date is the fiscal year that the project received Definition phase approval.
(7) Implementation Approval $ is the 'Authorized' total capital cost of the project when it was first approved by BC Hydro for Implementation.
(8) Pre-Implementation phases are: Future, Identification and Definition. Refer to Appendix N, Section 2.7 for further discussion on pre-Implementation phases. Pre-Implementation cost estimates are provided where an engineering estimate is available. N/A indicates that an engineering estimate is not yet available, or that the project is in Implementation phase.
(9) Authorized Amount is the 'Authorized' total capital cost of the project.
(10) Implementation Approval ISD refers to the in-service date identified when the project was first approved by BC Hydro for Implementation.
(11) An extension is a project that expands the service area or capacity of a utility plant or system, in accordance with paragraph 13 of BC Hydro's 2018 Capital Filing Guidelines filed with the BCUC on January 17, 2020.
(12) Project meets the current threshold for a CPCN or Section 44.2 Application based on the Project Authorized Cost Amount, or may meet the threshold, based on the planning cost allowance or cost estimate, or in accordance with BCUC Decision and Order G-47-18 and directive 29 of BCUC Decision and Order G-246-20.

Use of To Be Determined (TBD):
For projects in Future or Identification phase, To be Determined (TBD) is provided for the Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD), Start Date of Construction and Extension Project, for the following reasons:
For Future phase projects, a problem or opportunity has been identified, but the required response has not yet been determined. In Identification phase, a number of identified alternative responses are being investigated, and each alternative can result in very different project scope, schedule and cost. As a result, Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start of Construction Date are generally only provided for projects in the Definition phase and later phases. For Extension Projects, TBD has been provided where both extension and non-extension alternatives are being investigated.

Notes:
(1) Information provided is current as of the established 'Currency Date' which is January 1, 2021.
(2) Some projects that are in-service or forecast to be in-service at the end of fiscal 2021 may have trailing expenditures that result in capital additions in the Test Period. These expenditures and associated capital additions have been aggregated and included in the line item "Programs and Projects Less than $5M".

(3) Project / Program dollars are generally capitalized starting either in the feasibility stage of Identification phase or in the Definition phase.
(4) Forecast ISD is the expected in-service date for the project.
(5) Start Date of Construction is the Implementation Approval Date. For projects in Definition, the Start Date of Construction is the forecast Implementation Approval Date.
(6) Definition Approval Date is the fiscal year that the project received Definition phase approval.
(7) Implementation Approval $ is the Authorized total capital cost of the project when it was first approved by BC Hydro for Implementation.
(8) Pre-Implementation phases are: Future, Identification and Definition. Refer to Appendix S-2, pp. 6-65 to 6-67 for further discussion on pre-Implementation phases. Pre-Implementation cost estimates are provided where an engineering estimate is available. N/A indicates that an engineering estimate is not yet available, or that the project is in Implementation phase.

(9) Authorized Amount is the Authorized total capital cost of the project.

(10) Implementation Approval ISD refers to the in-service date identified when the project was first approved by BC Hydro for Implementation.
(11) An extension is a project that expands the service area or capacity of a utility plant or system, in accordance with paragraph 13 of BC Hydro's 2018 Capital Filing Guidelines filed with the BCUC on January 17, 2020.
(12) Project meets the current threshold for a CPCN or Section 44.2 Application based on the Project Authorized Cost Amount, or may meet the threshold, based on the planning cost allowance or cost estimate, or in accordance with BCUC Decision and Order G-47-18 and directive 29 of BCUC Decision and Order G-246-20.

Use of To Be Determined (TBD):
For projects in Future or Identification phase, To be Determined (TBD) is provided for the Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD), Start Date of Construction and Extension Project, for the following reasons:
For Future phase projects, a problem or opportunity has been identified, but the required response has not yet been determined. In Identification phase, a number of identified alternative responses are being investigated, and each alternative can result in very different project scope, schedule and cost. As a result, Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start of Construction Date are generally only provided for projects in the Definition phase and later phases. For Extension Projects, TBD has been provided where both extension and non-extension alternatives are being investigated.

*****this will be confusing as we were approved in June with a new budget of approximately $15,240.0, but the data date is April 1, 2021**

Notes:
(1) Information provided is current as of the established 'Currency Date' which is April 1, 2021.
(2) Some projects that are in-service or forecast to be in-service at the end of fiscal 2021 may have trailing expenditures that result in capital additions in the Test Period. These expenditures and associated capital additions have been aggregated and included in the line item "Programs and Projects Less than $5M".
(3) Project / Program dollars are generally capitalized starting either in the feasibility stage of Identification phase or in the Definition phase.
(4) Forecast ISD is the expected in-service date for the project (as at the Currency Date).
(5) Start Date of Construction is the Implementation Approval Date. For projects in Definition, the Start Date of Construction is the forecast Implementation Approval Date.
(6) Definition Approval Date is the fiscal year that the project received Definition phase approval.
(7) Implementation Approval $ is the 'Authorized' total capital cost of the project when it was first approved by BC Hydro for Implementation.
(8) Pre-Implementation phases are: Future, Identification and Definition. Refer to Appendix S-2, pp. 6-65 to 6-67 for further discussion on pre-Implementation phases. Pre-Implementation cost estimates are provided where an engineering estimate is available. N/A indicates that an engineering estimate is not yet available, or that the project is in Implementation phase.
(9) Authorized Amount is the 'Authorized' total project cost including the present value of future operating payments and costs deferred to the Site C Regulatory Account as of as of July 1, 2021.
(10) Implementation Approval ISD refers to the in-service date identified when the project was first approved by BC Hydro for Implementation.
(11) An extension is a project that expands the service area or capacity of a utility plant or system, in accordance with paragraph 13 of BC Hydro's 2018 Capital Filing Guidelines filed with the BCUC on January 17, 2020.
(12) Project meets the current threshold for a CPCN or Section 44.2 Application based on the Project Authorized Cost Amount, or may meet the threshold, based on the planning cost allowance or cost estimate as of the Currency Date (See Note 1), or in accordance with BCUC Decision and Order G-47-18 and directive 29 of BCUC Decision and Order G-246-20.

Use of To Be Determined (TBD):
For projects in Future or Identification phase, To be Determined (TBD) is provided for the Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD), Start Date of Construction and Extension Project, for the following reasons:
For Future phase projects, a problem or opportunity has been identified, but the required response has not yet been determined. In Identification phase, a number of identified alternative responses are being investigated, and each alternative can result in very different project scope, schedule and cost. As a result, Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start of Construction Date are generally only provided for projects in the Definition phase and later phases. For Extension Projects, TBD has been provided where both extension and non-extension alternatives are being investigated.

BC Hydro Fiscal 2023 to Fiscal 2025
Revenue Requirements Application

Appendix J

Capital Expenditures > $20 million

Appendix J Summaries

Appendix J, Attachment 1 provides descriptions for capital projects and programs of projects with planned capital expenditures or additions in the test period, with planned total capital expenditures greater than $20 million.

Consistent with our Previous Application, the Appendix J project summaries include information on the key drivers of the capital projects. In this application these key drivers are aligned with the consequence types identified in BC Hydro's Corporate Risk Matrix.

The Corporate Risk Matrix identifies the following "consequence types" or risk impacts:

- Safety – This includes the safety of both the public and BC Hydro workers;
- Environmental – This includes impacts to habitats and species;
- Financial Loss (Financial) – This includes direct financial loss or costs;
- Reputational – This includes responses from the public, media and public officials as well as impacts to projects, programs, plans and operations as a result of these responses; and
- Reliability – This includes customer reliability (hours lost per event) and reliability of supply.

The Appendix J capital project summaries identify which of these five categories of consequence types are the key drivers for investments that are risk driven.

Also consistent with our Previous Application, the Appendix J summaries provide Implementation Phase risks and risk treatment for those projects in the Implementation Phase with risks identified as high severity and/or high probability consequences, or a combination of moderate severity and probability consequences. The assessment is based on BC Hydro’s Project Delivery Risk Matrix (derived from the Corporate Risk Matrix).

<tr><td colspan="3">Description:
The purpose of this project is to address seismic deficiencies of the Alouette water conveyance system to ensure it can be relied upon to pass reservoir inflows to Stave Lake after a large earthquake event.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Environmental
• Financial Loss
• Reputational</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Alouette Dam is classified as an “Extreme” consequence dam based on the BC Dam Safety Regulation. As such the expected seismic performance is for no uncontrolled release for the Maximum Design Earthquake (MDE) with an annual exceedance frequency of once in 10,000 years. A seismic performance deficiency investigation of the dam and power tunnel was completed in 2011, and it concluded that the spillway would be damaged in the MDE and could not be relied upon to pass the inflow of water afterward. Spilling water through the damaged spillway could lead to its failure and an uncontrolled release of water from the reservoir, with significant risk to life, financial loss, environmental consequences and reputational impact.
Should the spillway not be available following a MDE, the only means to control the reservoir elevation would be to use the Alouette power tunnel and adit to allow a controlled discharge into Stave Lake. The seismic assessment indicated that in the event of a MDE, damage to structures associated with the power tunnel is expected, which could result in the inoperability of the power tunnel and/or adit. As such, a decision was made to upgrade the power tunnel and related structures, to ensure safe and reliable operation of the Alouette Dam after a MDE.</td></tr>
</table>

1 Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:	
BC Hydro is considering three alternatives: i. **Do nothing:** defer, either temporarily or permanently, the correction of the seismic deficiencies, ii. **Upgrade the power tunnel and related structures**, and iii. **Demolish and replace the structures associated with the power tunnel**. Alternative ii is the current leading alternative to achieve the project objectives. The project is currently in the Feasibility Design Stage. BC Hydro is consulting First Nations and conducting stakeholder engagement on construction period impacts to the reservoir and Alouette River flows to determine the preferred means of implementing the project.	
Project Impacts and Benefits: • Improve safety by addressing seismic deficiencies of the power tunnel and related structures, so that this water conveyance system can be relied upon to pass reservoir inflows to Stave Lake after a MDE. • Reduce potential for fatalities, financial loss, environmental consequences and reputational impact due to an uncontrolled release of water from Alouette Reservoir, in the event of a MDE.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: N/A	

Investment Planning ID:	Project Name:	
G000042	Ash River Extend Life of Steel Penstock	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-95 • Appendix I - Generation, line 50; Appendix K, pages 5 and 31 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-27 • Appendix I - Generation, line 43	

Description:

The purpose of this project is to ensure safe and reliable operation of the steel penstock at the Ash River Generating Facility and extend the life of the penstock, by addressing the active corrosion which is resulting in loss of metal thickness and strength on the interior and exterior of the steel penstock, and three tunnel portal steel liners.

Key Drivers:

- Environmental
- Reliability
- Safety
- Financial

Issues Being Addressed:

The Ash River Generating Station is categorized as a Strategic facility based on BC Hydro's Facility Asset Plans. It is downstream of Elsie Lake which is impounded by the Elsie Lake Dam.

The internal coating system on the steel penstock and tunnel portal liners at Ash River are failing with significant defects throughout the coated surfaces and signs of corrosion. The external steel penstock shows small isolated areas of coating failure. The Asset Health Rating for the penstock is Poor. Addressing the penstock internal coating system failure will extend its useful life. If no action is taken, the penstock surfaces will continue to corrode. Over time, this will undermine the structural integrity and safety of the penstock. The penstock would then need to be replaced when it is no longer safe to operate.

Discussion of Alternatives:

The following alternatives were evaluated:

i. **Defer recoating;**

ii. **Fully Strip and recoat the steel penstock interior and the tunnel portal liner surfaces, and only partially over-coat the steel penstock exterior;**

iii. **Fully Strip and recoat the steel penstock interior and the tunnel portal liner surfaces;**

iv. **Fully Strip and recoat the steel penstock interior and exterior and the tunnel portal liners.**

Alternative ii was selected as the Single Viable Alternative, as it was lowest cost alternative that would meet the requirements for safety, reliability and extended penstock life. Alternative i was not considered viable due to the risk that, if left for too long, the steel penstock may require replacement as the window of

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">opportunity for re-coating will have passed. Alternative iii was not considered viable, because if the exterior over-coating is deferred the condition will worsen to the point that over-coating is no longer possible, and a full external strip and re-coat (at higher cost) would be required in the future. Alternative iv was not considered viable as it would achieve the same outcome of extended penstock life, yet at a significantly higher cost.</td></tr>
<tr><td colspan="2">• Project Impacts and Benefits:
• Improve equipment reliability and safety.
• Extend penstock life.
• Reduce potential for fatalities, financial loss, and reputational damage due to uncontrolled release of water from the reservoir.</td></tr>
<tr><td>Project Implementation Phase Risk:

Investment Planning ID: G004327	Project Name: Bridge River 1 - Penstock Concrete Foundation Refurbishment	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** New	

Description:

The purpose of this project is to ensure safe and reliable operation of the four steel penstocks at the Bridge River 1 Generating Facility for another 40 years by refurbishing the concrete penstock foundations that have deteriorated over time.

Key Drivers:

- Reliability
- Safety
- Financial

Issues Being Addressed:

There are four steel penstocks at Bridge River 1 that supply power to four 50 MW generating units. Inspections have found that the fixed concrete foundations and the sliding concrete foundations in some locations for each penstock have visible defects such as cracking and are undermined due to erosion. The foundations are also buried in many sections due to accumulation of rockfall debris which prevents a full inspection from being completed. It is assumed that the observed defects in the visible foundations would be of a similar level in the buried sections.

The identified damaged sections, as well as the potential damage to uninspected sections, present an increased risk of failure of the concrete foundation. Failure of the concrete foundation could lead to penstock failure that would impact the switchyard, powerhouse, staff on site, CN Rail, and the local community.

Discussion of Alternatives:

BC Hydro is considering three alternatives:

i. **Do nothing** and monitor the condition;

ii. **Replace** penstocks and foundations; and

iii. **Refurbish** concrete foundations and replace or add retaining walls to control future rockfall.

Alternative iii. was selected as the single viable alternative as it would address safety and reliability objectives with the lowest life cycle cost. Alternative i. would not address the risk to the overall penstock, nor does it reduce the impacts a failure could have on personnel, infrastructure, and equipment downstream of the penstocks. Alternative ii. would be a magnitude higher cost than refurbishment and is not warranted as the penstock steel is in good condition and planned to be recoated.

Project Impacts and Benefits:

- Improve worker and public safety by addressing deteriorating condition of the penstock concrete foundations that could lead to a penstock failure.
- Reduce potential for fatalities, financial loss and reputational damage, due to an uncontrolled release of water from the reservoir.
- Improve equipment reliability and safety.
- Extend asset life.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Investment Planning ID: G000776	Project Name: Bridge River 1 Replace Units 1-4 Generators / Governors	
Forecast Capital Cost: $333 million to $202 million	**Forecast In-Service Date:** Fiscal 2031	**Start Date of Construction:**[1] Fiscal 2024
Development Phase: Definition	**Filing Reference:** BC Hydro 2014 Annual Report to the BCUC • Attachment to Section 8 – Part 2 Appendix I, page line 139 Appendix J, page 2 F17-F19 RRA • Appendix I, Appendix J, page 28 • BCUC IRs 1.70.3, 2.249.8, 2.260.4 • BCOAPO IR 1.36.1 F20-F21 RRA: • Chapter 6, page 6-95 • Appendix I - Generation, line 52; Appendix J, page 50; Appendix K, page 7 • BCOAPO IR 1.62.1 PUBLIC Attachment 1 • BCUC IR 1.115.2 • BCUC IR 1.133.1 Confidential F22 RRA: • Chapter 6, page 6-27 • Appendix I - Generation, line 44 • BCUC IR 1.45.2	
Description: The purpose of the project is to improve generation reliability of the Bridge River 1 Generating Facility Units 1 to 4 generators and related equipment, and to provide reliable water conveyance capacity within the Bridge River system.		
Key Drivers: • Reliability • Environmental • Reputational		
Issues Being Addressed: The four generators and related equipment in the Bridge River 1 Generating Facility have an Asset Health Rating of either Unsatisfactory or Poor. Unit 4 was re-wound in 1977 but was de-rated after a stator winding failure during testing in 2011. The de-rating of Unit 4 restricts the water flow through the unit, limiting water conveyance capabilities.		

1 Start Date of Construction is the Implementation Approval Date.

In addition to the loss in operating capability due to the de-rating of Bridge River 1 Unit 4, the operating regime for both Bridge River 1 and 2 has been impacted by a Dam Safety requirement from February 2015 to lower the maximum elevation of the upstream Downton Reservoir to manage LaJoie Dam seismic safety risks. This change in operations means there is 50 per cent less storage in Downton Reservoir, resulting in increased seasonal inflow to Carpenter Reservoir. Reduced capability to divert water from Carpenter Reservoir to Seton Lake, via the Bridge River generating stations, has increased the likelihood and magnitude of spills from Terzaghi Dam to the Lower Bridge River beyond the Water Use Plan Order (**WUP Order**) targets for annual average flows and those same targets set forth in settlement agreements with the St'át'imc Nation. BC Hydro has been, and currently is, operating under a variance to our WUP Order, approved by the Comptroller of Water rights (February 16, 2017).

Discussion of Alternatives:

Four alternatives were evaluated during the Identification Phase:

i. **Do Nothing:** maintain the existing units and replace the generators and other related components upon failure;

ii. **Rewind** the generator stators and replace or refurbish other components, as needed, to ensure each unit can maintain its original 50 MW rating;

iii. **Refurbish** the generators and replace the exciters and governors to match the current capacity of the turbines, and operate within the limitations of the existing physical plant and constraints of the existing WUP Order; and

iv. **Replace** the generators, exciters and governors to match the current capacity of the turbines and operate within the limitations of the existing physical plant and constraints of the existing WUP Order.

Alternative iv, Replace the generators, exciters and governors, was selected as the leading alternative because it offers improvements to generator reliability and water management capabilities. Compared to alternatives i, ii, and iii this alternative maximizes unit reliability, minimizes impacts to the environment and St'át'imc Nation interests, enhances BC Hydro's relationship with the St'át'imc Nation, minimizes cost and cost risks, and minimizes overall safety risks.

Project Impacts and Benefits:

- Improve generation reliability by replacing the Units 1 to 4 generators and related equipment.
- Provide reliable water conveyance capacity within the Bridge River system.
- Reduce the likelihood and magnitude of spills from Terzaghi Dam to Lower Bridge River, in order to minimize potential effects on fish, riparian habitat, and First Nations values.
- Maintain BC Hydro's relationship with the St'at'imc Nation.
- Reduce potential reputational impact due to spill events.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase	To be determined when the project reaches Implementation.

Additional Information:

BCUC Order No. G-246-20 directed BC Hydro to file a joint CPCN application for this project and the Bridge River Transmission Project.

The planning level estimate for this project is over $100 million. $326.3 million to $207.1 million is the latest Pre-Implementation Cost Estimate that is reflected in the project's CPCN application.

Investment Planning ID: G000489	**Project Name:** Bridge River 2 – Strip and Recoat Penstock 2 Interior	
Forecast Capital Cost: $35.3 million	**Forecast In-Service Date:** Fiscal 2023	**Start Date of Construction:**[1] Fiscal 2021
Development Phase: Implementation	**Filing Reference:** F20-F21 RRA: • Appendix I: Generation - line 53 • Appendix K: pages 7 and 31 • Chapter 6, page 6-97 • BCOAPO IR 1.59.1 • BCOAPO IR 1.62.1 PUBLIC Attachment 1 • BCUC IR 1.133.1 Confidential F22 RRA: • Chapter 6, page 6-27 • Appendix I - Generation, line 46 • BCUC IR 1.43.1 • BCUC IR 1.46.3	

Description:

The purpose of this project is to ensure safe and reliable operation of Penstock 2 at the Bridge River 2 (**BR2**) Generating Facility and extend the life of the penstock, by addressing the active corrosion of the interior which is resulting in loss of metal thickness and strength.

Key Drivers:

- Reliability
- Safety
- Financial

Issues Being Addressed:

The Bridge River Generating Station is classified as a 'key' facility according to BC Hydro's Facility Asset Plans. It is located downstream of Carpenter Lake, which is impounded by Terzaghi Dam. The internal coating system on Penstock 2 at BR2 is failing with significant defects identified throughout the coated surface; there are signs of coating failure and corrosion. The Asset Health Rating for the penstock is rated as Unsatisfactory. Stripping and recoating the penstock will extend its useful life.

If no action is taken, the interior penstock surface will corrode. Over time, this will undermine the structural integrity and safety of the penstock. The penstock would then need to be replaced when it is no longer safe to operate.

Discussion of Alternatives:

BC Hydro considered three alternatives:

i. **Defer Recoating**;
ii. **Complete a Full or Partial penstock replacement**, and
iii. **Strip and recoat the penstock interior during a planned outage**.

[1] Start Date of Construction is the Implementation Approval Date.

Alternative iii, strip and recoat the penstock interior during a planned outage, was selected as the preferred alternative as it was the lowest cost alternative that would meet the requirements for safety and reliability and extend the life of the asset. Alternative i was not considered viable due to the risk that, if left for too long, the steel penstock may require replacement as the window of opportunity for re-coating will have passed. Alternative ii was not considered viable due to the much higher cost.	
Project Impacts and Benefits: • Improve equipment reliability and safety. • Extend penstock life. • Reduce potential for fatalities, financial loss, and reputational damage due to an uncontrolled release of water from the reservoir.	
Project Implementation Phase Risk: The work will be carried out on a steep slope and inside a penstock. As such, there is significant risk to worker safety due to fall hazards and confined space issues.	**Risk Treatment:** The project will use unmanned robotic technology to complete many of the most hazardous tasks such as water jetting, abrasive blasting and relining the interior of the penstock.
Additional Information: N/A	

Investment Planning ID: G000052	Project Name: Cheakamus - Dam Improvements	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** New	

Description:

The purpose of this project is to address internal erosion and seismic deficiencies of the Cheakamus Dam so that this facility can be relied upon for passing floods and post-earthquake operation.

Key Drivers:

- Safety
- Reputational
- Environmental
- Financial

Issues Being Addressed:

The Cheakamus Dam is classified as an Extreme consequence dam. Investigations have identified that various components of the dam – notably spillway piers, several zones of the earthfill dam and a retaining wall at the contact between the concrete and earthfill dams – could fail or deform excessively when subjected to earthquake ground motions expected to occur at the site once every 500 to 1,500 years. This is less than the target "withstand" of one in 10,000 years for an Extreme consequence dam.

In addition, the earthfill dam has a history of seepage along the downstream slope above the downstream rockfill berm when reservoir levels are high. In response, the normal maximum reservoir elevation was lowered by 1.45 m from its original elevation to reduce the risk of internal erosion of the upper dam core. Under a sustained extreme flood, however, the higher reservoir elevation that would result could initiate internal erosion in the dam core.

Failure of the dam could lead to uncontrolled release of water from the reservoir, potentially resulting in fatalities, reputational risks, environmental damage, and significant financial loss.

Discussion of Alternatives:

BC Hydro is considering four alternatives:

i. **Do nothing:** defer, either temporarily or permanently, the correction of the deficiencies of the dam;

ii. **Decommission the dam**;

iii. **Decrease downstream consequences**: lower the reservoir, protect inundation areas, and implement an early warning system; and

iv. **Upgrade the dam, spillway and retaining wall:** This may include a seismic upgrade of the spillway, treatments to strengthen existing soils, construction of a downstream berm to buttress the slopes, and anchoring of Retaining Wall No. 1.

Project Impacts and Benefits:

- Improve public safety by addressing seismic deficiencies and internal erosion potential of the Cheakamus Dam, so that this facility can be relied upon for passing floods and post-earthquake operation.
- Reduce potential financial loss and reputational impact due to an uncontrolled release of water from the reservoir, in the event of a Maximum Design Earthquake or Probable Maximum Flood.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.
Additional Information: There is an ongoing Deficiency Investigation at Cheakamus Dam to update flood parameters and conduct a performance assessment of the dam and discharge structures. The scope of the Dam Improvements project may be affected by the findings of the Deficiency Investigation.

• Environmental</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Cheakamus Generating Station is categorized as a ‘Strategic” facility according to BC Hydro’s Facility Asset Plans. The Station is located downstream of Daisy Lake which is impounded by the Cheakamus Dam.
The protective coatings on the exterior and interior of the Cheakamus steel penstocks and steel tunnel liner are exhibiting signs of coating failure. The Asset Health Rating is rated as Unsatisfactory.
Without recoating, the extent of corrosion will increase to the the point where recoating is no longer an option and a penstock replacement is required. Over time, continued corrosion will impact the structural integrity of the steel material, impacting the penstock’s ability to reliably and safely convey water to the Cheakamus generating units.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:	
BC Hydro considered four alternatives: i. **Do Nothing and Monitor**; ii. **Strip and Recoat Exterior Surface of Steel Penstocks**; iii. **Strip and Recoat Exterior and Interior Surfaces of Steel Penstocks**; and iv. **Complete Replacement of Steel Penstocks**. Alternative iii, strip and recoat exterior and interior surfaces of steel penstocks, was selected as the preferred alternative as it would address safety and reliability objectives and extend the penstock life. Alternative i or Alternative ii would not deliver a significant overall penstock life extension because corrosion of the uncoated and unprotected steel penstock sections would not be achieved. Loss of steel would persist, potentially undermining the structural integrity of the penstock, which are considered high pressure vessels conveying significant volumes of water and are key water passage components used for generation. Penstock failures may cause extensive damage to the Cheakamus Generating Station. Alternative iv was not selected as it would be too costly compared to Alternative iii which also addresses the project objectives.	
Project Impacts and Benefits: • Improve equipment reliability and safety. • Extend asset (penstock and steel tunnel) life. • Reduce potential for fatalities, financial loss, and reputational damage due to an uncontrolled release of water from the reservoir.	
Project Implementation Phase Risk: The interior coating work requires power generation outages. The project schedule could extend if the outage windows available to the project are shorter than planned or if the contractor underperforms.The work will be carried out on a steep slope and inside a penstock. As such, there is significant risk to worker safety due to fall hazards and confined space issues.	**Risk Treatment:** Accept – There are escalation clauses within the contract should the work be extended. There will be additional overhead costs that will have to be covered by project contingency.The project will use unmanned robotic technology to complete many of the most hazardous tasks such as water jetting, abrasive blasting and relining the interior of the penstock.
Additional Information: N/A	

Investment Planning ID: G000657	Project Name: Comox – Puntledge Flow Control Improvements	
Forecast Capital Cost: $56.7 million to $33.9 million	**Forecast In-Service Date:** Fiscal 2025	**Start Date of Construction:**[1] Fiscal 2022
Development Phase: Definition	**Filing Reference:** BC Hydro's F2014 Annual Report to the BCUC • Attachment to Section 8 – Part 2 Appendix I, line 109 Appendix J, page 9 F17-F19 RRA: • Appendix I - Generation, line 15, Appendix J page 16 • BCUC IRs 1.70.3,2.249.8, 2.260.4, BCOAPO IR 1.36.1 F20-F21 RRA: • Chapter 6, page 6-98 • Appendix I - Generation, line 8; Appendix J, Page 9; Appendix K, Page 33 • BCOAPO IR 1.62.1 PUBLIC Attachment 1 • BCUC IR 1.133.1 Confidential F22 RRA: • Chapter 6, page 6-25 • Appendix I - Generation, line 14 • BCUC IR 1.53.1	

Description:

The purpose of this project is to improve the ability to manage water conveyance at Comox-Puntledge in a controlled and safe manner.

Key Drivers:

- Safety
- Reliability
- Environmental
- Financial Loss
- Reputational

Issues Being Addressed:

The Comox Dam and downstream Puntledge Diversion facilities are rated as "Extreme" and "Very High" consequence dams, respectively, based on the BC Dam Safety Regulation. The water passing through Puntledge Dam enters one of two parallel watercourses:

- Generation water is conveyed through the power intake and penstock. Most of the water is conveyed through the single turbine to produce power; and
- The balance of the water overflows Puntledge Dam into a public watercourse which is heavily used for recreation, especially in summer.

[1] Start Date of Construction is the Implementation Approval Date.

Appropriate control of both watercourses is imperative for public safety, dam safety, reliable generation and downstream fish migration and habitat. Uncontrolled flows pose a risk to life, and could result in financial loss, environmental and reputational damage.

The principal risk to be managed through this project is the potential for unintended and sudden increases in flows down the Puntledge River that could lead, without warning, to injury or fatality for exposed downstream recreational users. There are a number of deficiencies within the flow control system which could cause such a surge in flow, and these deficiencies are to be addressed within this project.

Discussion of Alternatives:

BC Hydro considered eight alternatives that consisted of various combinations of the following nine “Concept Groups”:

i. **Improve Support for Operational Decisions:** improve the clarity and certainty in making operational decisions to avoid incidents (such as providing additional tools, training, and data collection and monitoring capability to personnel on site);

ii. **Comox Sluiceway Reliability Improvements:** improve the reliability of the gate controls (such as additional protection and controls equipment and improving the current mechanical gate hoist);

iii. **Generation Conveyance Control System Upgrades:** reduce the probability of a malfunction, lack of function, or other error on the equipment and control systems from the Puntledge intake to the powerhouse (such as improvements to intake trashrack, intake operating gate, fish screen, penstock protection, turbine inlet valve, communication monitoring and control);

iv. **Provide Storage Buffer at Puntledge Diversion Dam:** attenuate the impacts of a stoppage of flow by using available storage in the low gradient Puntledge headpond (such as providing control of discharge at Puntledge Dam in real-time and strengthening the diversion);

v. **Comox Dam Safety Upgrades:** reduce the probability of unusual, very rapid flow increases due to right abutment failure (such as addressing concerns with sloughing of the right bank upstream from the sluiceway and with the robustness to resisting overtopping and piping during extreme floods),

vi. **Modify Puntledge Intake Layout:** Reduce the likelihood of flow control failures in the Puntledge intake and fish screens (such as construction of new fish bypass facilities, new intake bays and penstock work);

vii. **Puntledge Powerhouse By-pass:** Provide flow continuity around the powerhouse (such as construction of a new valve with emergency submerged discharge on the upstream side of the powerhouse);

viii. **Restrict Summer Generation:** Reduce flow control risks; and

ix. **Fully Restrict Generation:** Eliminate flow control risks.

The alternative selected is comprised of Concept Groups i, ii and iii above. It was selected as the preferred alternative because it meets the project objectives regarding public safety and because it provides the best balance of flow and incremental risk improvement versus cost to implement. Other combinations of concept groups including ix Fully Restrict Generation are either higher cost than other alternatives that provide an equal or better flow control improvement benefit, or provide less flow control improvement benefit than alternatives of similar cost.

Project Impacts and Benefits:

- Improve safety by addressing uncontrolled flow at Comox-Puntledge, so that safe downstream recreation can continue.
- Reduce potential for fatalities, financial loss and reputational impact due to uncontrolled flow events.
- Provide long-term operability and maintainability at Comox-Puntledge, at a high level of reliability.
- Reduce environmental risk associated with uncontrolled flow impacts on upstream and downstream fish migration and habitat.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase, further developed during Definition Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

<tr><td colspan="3">Description:
This purpose of this project is to modernize Units 1 to 10 control systems, replace Units 6 to 10 governor control systems, replace Units 9 and 10 exciters, replace the controls for plant auxiliary systems, and replace the control room controls at G.M. Shrum (GMS) Generating Facility.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The GMS Units 6 to 8 governors have an Asset Health Rating of Poor due to the tendency of the analog controls to drift out of calibration, limited technical support, governor frequency control being out of specification during standardized tests, and limited availability of spare parts. The Unit 9 analog governor has an Asset Health Rating of Poor due to the forced outages attributed to the governor, limited technical support and limited spare parts availability. The Unit 10 analog governor, which is from the same manufacturer as Unit 9, has an Asset Heath Rating of Fair.
The GMS Units 9 and 10 Westinghouse Rapcon exciters have analog controls and are based on obsolete technology. Unit 9 has an Asset Health Rating of Fair, and Unit 10 has a rating of Poor. Concerns include component failures, limited availability of spare parts, and limited technical support.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date for all Tranches of this project.

Concerns on all the equipment to be replaced include lack of vendor support due to system age, limited or no availability of spare parts, units drifting off settings due to control deficiencies, and unit outages caused by component failure or mis-operation.

Discussion of Alternatives:

BC Hydro considered three alternatives:

i. **Full-scope**;

ii. **Controls-only scope**; and

iii. **Deferral** - continue to operate GMS (and Peace Canyon) Generating Facility in their current condition

Alternative i, full-scope, was selected as the preferred alternative because it minimizes the total outage time and avoids the need to design and implement interfaces between new and old technology. The project is partitioned into three tranches of work, with a separate approval for each tranche.

- Tranche 1: Units 1 to 5 controls and plant Local Area Network (completed);
- Tranche 2: Units 6 to 10 controls, Units 6 to 10 governor controls, and Units 9 to10 exciters (in Implementation); and
- Tranche 3: Spillway, switchyard and intake controls, and GMS control room (in Implementation).

This approach allows lessons learned on earlier tranches to be adopted in subsequent tranches. More importantly, each tranche will be estimated and scheduled shortly before it enters Implementation Phase, based on current supplier and market understanding, and avoids a commitment to cost and schedule targets over a decade in the future.

It was recognized that due to the long duration of the project, control improvements could be available during the course of the project. BC Hydro has implemented a strategy of evaluating the benefits of any changes in controls, and if warranted, adopts a new control approach both prospectively and retrospectively, updating completed work to match any newly adopted designs. This strategy balances the advantages of new or improved technology with the benefits of standardization across all units in the plant.

Alternative ii was not selected due to inefficiencies with executing the three scope packages (controls 1-10, exciters 9-10, and governors 6-10) as separate projects in the areas of project delivery and engineering, outage coordination, and ability to avoid stranded costs. Alternative iii was not selected due to inferior risk reduction and economic benefits as compared to Alternative i.

Project Impacts and Benefits:

- Allows both local and remote operation of both GMS and the Peace Canyon Generating Facilities.
- Governors on Units 6 to10 and exciters on Units 9 to10 will be new, improving availability of both spares and vendor support.
- New controls and control room will improve the operators' situational awareness and ability to respond to problems.

Project Implementation Phase Risk:	**Risk Treatment:**
There is a risk that the equipment currently deployed by the Generating Operational Asset Architecture Logic standard will not provide the functionality to support the required plant control room alarm management features	This is being avoided by deploying a Supervisory Control and Data Acquisition control packages for the new plant control room design with the intention of including this alarm management capability in the Generating Operational Asset Architecture Logic standard

<tr><td colspan="3">Description:
The purpose of the G.M. Shrum Upgrade HVAC System project is to address degrading conditions of the Heating, Ventilation and Air Conditioning (HVAC) system at the G.M. Shrum (GMS) Generating Facility.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Safety</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The project will address the reliability risk of forced unit outages due to HVAC system failures. Recent forced outage reports have indicated that heating systems in the Circuit Breaker Buildings may be a contributing cause to improper operation of the unit circuit breakers. In addition, the cooling coils and related piping for the Low Voltage Lead Shaft powerhouse supply fans are nearing end of life and have been a source of water leaks. Although the HVAC system is classified as an ancillary system, it has impacts to the reliable and safe operation of units at the GMS Generating Facility.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
BC Hydro considered three alternatives:
i. Limited Refurbishment of HVAC System;
ii. Modernization of HVAC System; and
iii. Modernization and Selected Upgrades of HVAC System.
Alternative iii, Modernization and Selected Upgrades (upgrade to improve performance of certain components) of the HVAC System, was selected as the preferred alternative as it will meet the project objectives of improving reliability, and reducing worker safety risks. Alternative i was not selected because of the negligible difference between the incremental costs associated to refurbishment</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

compared to Alternative iii with residual reliability, maintainability, and safety risks. Alternative ii was not selected because of lower maintainability, flexibly, safety and energy efficiency than Alternative iii.	
Project Impacts and Benefits: • Improve reliability by reducing outages due to HVAC component failure. • Improve Worker Safety by facilitating safe egress in an emergency situation by pressurizing escape routes and ensuring fresh air is supplied to workers in the underground powerhouse.	
Project Implementation Phase Risk: The HVAC systems work requires multiple outages for different generating units. There is a risk of changes to required planned outages which may result in schedule delay and additional cost.	**Risk Treatment:** The treatment plan is to align the outages with generator maintenance outages to reduce the probability of changes to the planned outages.

Investment Planning ID: G003336 G000131	Project Name: G.M. Shrum – Intake Operating Gate Hydraulic Upgrade G.M. Shrum – Intake Operating Gate and Intake Mainenance Gate Refurbishment	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-96 • Appendix I - Generation, line 72 and 73; Appendix J, page 63; Appendix K, Page 13 • BCOAPO IR 1.62.1 PUBLIC Attachment 1 • BCUC IRs 1.116.8; 1.133.1 Confidential; 2.253.3 F22 RRA: • Chapter 6, page 6-28 • Appendix I - Generation, line 60 and 61	

Description:

The purpose of this project is to recoat and refurbish the 10 intake operating gates and two intake maintenance gates and to address reliability risks associated with operating the hydraulic systems used to raise and lower the 10 Intake Operating Gates.

Key Drivers:

- Reliability

Issues Being Addressed:

G.M. Shrum Generating Facility has 10 intake operating gates and two intake maintenance gates. The gates have been in use since the 1970's and the coatings on all 12 gates have an Equipment Health Rating of Poor or Unsatisfactory. Based on available inspection reports, the gates are suitable for refurbishment in the near term. If left untreated for an extended period, the opportunity to recoat and refurbish could be missed, requiring a higher cost investment such as replacement.

The ten Intake Operating Gates are opened and closed by hydraulic systems which consist of hydraulic cylinders, hydraulic power units (**HPUs**) and hydraulic lines. These are all original plant equipment from the 1970's. Issues being addressed include: insufficient emergency close hoist capability, pitting corrosion of the hydraulic lines and lack of fail-safe and redundancy for the HPUs.

Discussion of Alternatives:

BC Hydro is considering three alternatives for the gate refurbishment:

i. **Life Extension:** prioritize work on the 12 gates based on severity and/or availability. Some coating, structural and mechanical deficiencies would be deferred to a later date;

ii. **Refurbishment:** fully refurbish the gates to maximize their life expectancy; and

iii. **Replacement:** replace gates with new gates that have a minimum design life of 75 years.

BC Hydro is considering two alternatives for the gate hydraulic upgrade:

i. **Partial upgrade** of targeted hydraulic components: Upgrade the hydraulic hoisting systems to provide sufficient capacity for emergency closure of the operating gates and refurbish the hydraulic cylinders. This alternative would not address the issue of HPU redundancy; and

[1] Start Date of Construction is the Implementation Approval Date.

ii. **Complete upgrade** of hydraulic components: A complete upgrade of the hydraulic hoisting system on Units 1 to 10 including the hydraulic cylinders, the hydraulic lines and individual HPUs for each unit.	
Project Impacts and Benefits: • Extend life of intake operating gates and intake maintenance gates by restoring the protective coating. • Improved reliability of the intake operating gates.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: As of the currency date of the Capital Plan, IPID G003336 and G000131 were expected to be released as two projects. At the time of initiation, it was determined that these investments should be released and executed under one IPID. This appendix J summary addresses the combined scope of the two investments.

<tr><td colspan="3">Description:
The objective of the project is to provide a safe and reliable unwatering system at the G.M. Shrum (GMS) Generating Facility to facilitate unit outages, as well as regular maintenance and inspections of the generating units.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Environmental
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
Due to the deteriorating condition of the unwatering system at the GMS Generating Facility, there are safety, environmental and reliability risks with the equipment. If the pumps are not working properly and the water cannot be evacuated adequately, the powerhouse could potentially be flooded. In addition, if there is a failure of the components responsible for decontaminating the water, the waterway could become contaminated. There have also been delays to operation due to the draft tube drain valves failing to close when attempting to get a unit back online.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
BC Hydro considered three alternatives:
i. Unwatering System Replacement/Upgrade;
ii. Unwatering System Refurbishment; and
iii. Do Nothing.
Alternative i, unwatering system replacement/upgrade, is the preferred alternative because it is the most cost-effective solution to address the reliability risks by replacing all critical system components of the equipment. Alternative ii was not selected as it would not meet the technical requirements of the project. Alternative iii was not selected as it does not address the risks nor meet the project objectives.</td></tr>
<tr><td colspan="3">Project Impacts and Benefits:
• Reduced environmental and safety risks by ensuring water can be evacuated adequately to minimize the risk of powerhouse flooding.
• Reduced environmental risk by minimizing potential failure of unwatering system components responsible for decontaminating the water.
• Improves the reliability of the unwatering system by reducing the likelihood of unplanned outages, as well as facilitating outages for maintenance, inspections and planned projects.</td></tr>

<tr><td colspan="3">Description:
The objective of this project is to upgrade damaged concrete structures in the Hugh Keenleyside Dam's spillway and low-level outlets, restoring them to near-original condition. This upgrade will extend these structures' service lives and permit a wider range of operational options relating to the passage of water over the spillway and through the dam.
Refer to Appendix K – Hugh Keenleyside Facility Asset Plan for additional information.</td></tr>
<tr><td colspan="3">Key Drivers:
• Financial
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Hugh Keenleyside Dam has been classified as an Extreme consequence dam based on the BC Dam Safety Regulation.
Since the dam was put into operation in 1968, there has been localized loss of concrete to the spillway and low-level outlets due to erosion, abrasion and cavitation to the extent that the concrete reinforcing steel is exposed in a number of locations. Low Level Outlets 1 and 4 have sustained the largest amount of damage.
The rate of progression of concrete damage is unpredictable, and there is the potential need for a portion of the spillway or low-level outlet to be taken out-of-service with little or no advance notice. In this event, immediate repairs implemented under urgent or emergency conditions would be required.
With the benefit of modern numerical hydraulic modelling, BC Hydro implemented operational changes that restrict use of the low-level outlets which are expected to slow (but not stop) the progression of damage. The operational changes, however, have reduced operational flexibility in passing flows.
Maintenance and repairs to the concrete have been carried out over the years, but with limited success. Due to the progression of damage, the required frequency, extent, and cost of repairs (largely underwater) is expected to grow with diminishing effectiveness.</td></tr>
</table>

1 Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

BC Hydro considered three alternatives:

i. **Do nothing,** this alternative involves temporarily or permanently foregoing the repair to the damaged concrete structures;

ii. **Upgrade structural concrete in the dry,** with complete isolation of the structures from the downstream tailwater; and

iii. **Upgrade structural concrete under water,** with divers utilizing customized procedures and concrete mixes developed for this specific task.

Alternative iii, upgrade structural concrete under water, was selected as the Single Viable Alternative that will meet the reliability and financial objectives of the Project. Alternative i is not viable as there is a reasonably high risk that a rapid progression of damage could occur which may result in severe financial, environmental, and reputational impacts. Repairs are expected to become increasingly expensive and decreasingly effective over time and the point at which these structures will no longer be fit for safe use cannot be accurately predicted. Alternative ii is not viable due to the significant operational and environmental impacts that would occur due to the large size of the cofferdam needed to isolate the tailwater. Also, building the cofferdam would prevent the use of the Hugh Keenleyside Dam spillways for water conveyance and potentially impact BC Hydro’s obligations under the Columbia River Treaty.

Project Impacts and Benefits:

- Extended life of the spillway and low level outlet structures.
- Reduction of anticipated maintenance costs and outages.
- Elimination of concerns that a sudden progression of damage will force some or all of these discharge facilities to be taken out of service, requiring even more costly interventions under urgent or emergency conditions.
- Increased flexibility of operations to pass flows that preserve the integrity and service life of the structure while mitigating environmental impacts.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

Operations at Hugh Keenleyside Dam have international impacts on flow regulation, power generation and flood control under the terms of the Columbia River Treaty.

Investment Planning ID: G000585	Project Name: John Hart Dam Seismic Upgrade	
Forecast Capital Cost: $738.7 million to $432.3 million	**Forecast In-Service Date:** Fiscal 2030	**Start Date of Construction:**[1] Fiscal 2023

Description: The purpose of this project is to address seismic deficiencies of the John Hart Dam so that this facility can be relied upon to withstand the effects of a major earthquake and to operate post-earthquake. The selected alternative will make improvements to the operational reliability of the spillway gates and will reduce the potential for dam overtopping due to flow imbalances between the John Hart and upstream facilities and is consistent with the continued operation of the John Hart Generating Station. Refer to Appendix K – Campbell River Systems Engineering Assessment for additional information.		

1 Start Date of Construction is the Implementation Approval Date.

Key Drivers:

- Safety
- Financial
- Reputational
- Environmental

Issues Being Addressed:

The John Hart Dam is classified as an Extreme consequence dam based on the BC Dam Safety Regulation. As such the expected seismic performance is for no uncontrolled release for the Maximum Design Earthquake (**MDE**) with an annual exceedance frequency of once in 10,000 years. A seismic performance investigation was carried out and it was determined that the withstand of the various component dams and spillway gate system is less than the MDE. Damage from a seismic event could lead to uncontrolled release of water from the reservoir, with significant risk to life, financial loss and reputational damage. Therefore, seismic upgrades to the dam and spillway gates system are required.

In addition to the seismic-related deficiencies, there is a risk of overtopping the John Hart Dam due to unplanned generation flow imbalance between John Hart and the upstream Ladore facility. A free overflow spillway is planned to address this concern.

The scope of this project includes the design and construction of the following:

- Upgrades to the Middle Earthfill dam and Power Intake Dam;
- Upgrades to the North Earthfill dam;
- Upgrades to the concrete dam, including incorporation of a free overflow spillway; and
- Upgrades to the spillway gates system.

Discussion of Alternatives:

BC Hydro considered four alternatives:

i. **Do nothing:** defer, either temporarily or permanently, the correction of the seismic deficiencies of the John Hart Dam. Could include an interim response plan such as: including availability of 24/7 electricians post-earthquake to control operation of the dam or improving instrumentation at the dam such as addition of cameras in an effort to be able to provide a more rapid evaluation of the state of the dam post-earthquake;

ii. **Decommission** the John Hart Dam;

iii. **Permanently lower the reservoir** to reduce loading on the dam; and

iv. **Upgrade the John Hart Dam,** to ensure: a) no uncontrolled release of reservoir following a MDE; and b) the dam suffers only minor damage such that an immediate deep or prolonged drawdown is not required to maintain post-seismic river flow control.

Alternative iv, upgrade the John Hart Dam, was selected as the preferred alternative as it is the only alternative that satisfies the dam safety objectives. Alternative ii is not consistent with the implementation of the John Hart Replacement Project. Alternative iii would not satisfy dam safety requirements as it would not improve the seismic withstand nor materially improve the consequences of dam failure. Further Alternative iii would have unfavourable economic and environmental consequences, as it would reduce generation at the John Hart Generating Station due to the reduced head and would expose currently inundated reservoir areas.

Project Impacts and Benefits:

- Improve safety by addressing seismic deficiencies of the John Hart Dam so that this facility can be relied upon for post-earthquake operation.
- Avoid potential for fatalities, financial loss and reputational impact due to an uncontrolled release of water from the reservoir, in the event of an earthquake up to and including the MDE.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

As the planning level estimate for this project is over $100 million, BC Hydro expects to submit an application to the BCUC under Section 44.2 for this project.

Planning is currently underway for upgrades at the upstream Strathcona and Ladore facilities (Strathcona Discharge Upgrade Project, G000525; and Ladore Spillway Seismic Upgrade Project, G000668). Planning for these two projects is being considered in conjunction with the John Hart Dam Seismic Upgrade project for the following reasons:

- The projects are planned with similar and potentially overlapping construction schedules;
- The projects are relatively close geographically to one another;
- The projects have some similar scope elements that will require similar contractor expertise; and
- The projects all reside on the Campbell River and the work will need to be considered from a river system management perspective and coordinated accordingly.

Investment Planning ID:	Project Name:	
G003811	Kootenay Canal - Canal Concrete Liner Joints Upgrade	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** New	

Description:

The objective of this project is to significantly reduce water leakage from the Kootenay Canal and reduce the risk of sudden collapse of the Kootenay Canal concrete slab liner and potential breach of the Canal by installing functioning water stops at all slab to slab and all slab to plinth curb joints.

Key Drivers:

- Safety
- Reliability

Issues Being Addressed:

Kootenay Canal starts at the downstream end of Kootenay Lake, paralleling a stretch of the Kootenay River and conveys water some 4.5 km downstream. On the North side of the Canal, concrete faced rockfill has been constructed to form the Canal where the bedrock is lower than the Canal's design elevation. The inner surface of this rockfill was made watertight by placement of concrete liner slabs. There are in excess of 500 slabs along the full length of the Canal. The slabs are separated by an equal number of joints that are nominally one inch wide. The key feature of the joints is a PolyVinyl Chloride (**PVC**) water stop that spans across the joint between adjacent slabs. The vast majority of the Canal's liner slab joints are original and have suffered considerable degradation and increased leakage. If left untreated, the leaks could eventually be sufficient to suddenly wash out the bedding fill that underlies a slab, which could in turn lead to the sudden collapse of Kootenay Canal.

A similar defect that led to a previous leakage event and other potential defects in the canal's forebay segment was previously treated by the widespread application of Carpi membrane in 2014. This project will treat degraded liner slab joints in the upstream portions of the canal.

Discussion of Alternatives:

BC Hydro is considering three alternatives:

i. **Do Nothing:** continue to monitor leakage;

ii. **Apply External Waterstops to Slab joints:** this could be achieved by application of a Carpi membrane or similar technology as was done in 2014; and

iii. **Partial Demolition:** and reconstruction of joints using conventional waterstops.

The "Do Nothing" alternative does not address the continued degradation and leakage of the canal joints. The failure mechanism of a sudden washout of bedding fills under a slab cannot be effectively managed by surveillance in the long term.

The partial demolition and reconstruction of the slab liner joints using conventional waterstops, would have a significantly higher cost and potentially create new joints where leakage could occur.

Applying external waterstops at all degraded or potentially degraded slab joints addresses the issues identified above and is expected to be the preferred alternative, but this will be confirmed when the project is initiated.

1 Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits: • Extended life of the Kootenay Canal structure. • Reduction of anticipated maintenance costs and outages. • Improved worker and public safety by preventing the breach of the Canal and an uncontrolled release of water.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: N/A	

Investment Planning ID:	Project Name:	
G003058	Kootenay Canal - U1 - U4 Generators Refurbishment	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** New	

Description:

The purpose of this project is to address the reliability issues associated with the four generator units at Kootenay Canal (**KCL**) Generating Facility.

Key Drivers:

- Reliability

Issues Being Addressed:

The KCL Generating Facility Unit 1 to 4 generators have been in-service since 1976 and have reached their end of life. The latest Asset Health Rating of Unit 1, 3 and 4 generators is Poor and Unit 2 is Unsatisfactory. Due to the condition of the generators, there is an increased risk of an in-service failure, resulting in a long duration forced outage at KCL Generating Facility, a key generating facility in BC Hydro’s fleet.

Discussion of Alternatives:

BC Hydro is considering four alternatives:

i. **Replace Generator**, which includes replacement of stator, rotor and other major components;

ii. **Partial Replacement**, which includes replacement of stator, rotor pole re-insulation or replacement, refurbishment of other major equipment;

iii. **Refurbishment**, which includes re-wind of the stator, and may include refurbishment of other major components; and

iv. **Defer Major Intervention**.

The project is in Identification phase and in the process of further assessing alternatives. The alternatives will be assessed on a unit by unit basis. The preferred alternative has not yet been determined.

Project Impacts and Benefits:

- Improve the reliability of the Units 1 to 4 generators

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	To be determined as the project reaches Implementation Phase.

Additional Information:

N/A

[1] Start Date of Construction is the Implementation Approval Date.

<tr><td colspan="3">Description:
The purpose of this project is to improve the long-term reliability, maintainability, operability and safety of the control systems, exciters and select governor mechanical components for all four generating units at Kootenay Canal Generating Station.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Maintainability
• Safety</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Kootenay Canal Generating Station is categorized as a Key facility according to BC Hydro’s Facility Asset Plans. The facility has been operating with high reliability since 1975. However, the unit transformers and turbines are the only major water-to-wire components that have been replaced. The exciters, governors, unit auxiliary control Alternating Current (AC) distribution panels and controls systems are all original and have reached end-of-life.
Risks to be addressed by this project include technical expertise in the marketplace and within BC Hydro is no longer readily available to maintain this equipment; spare parts are increasingly unavailable; mechanical components have worn out; and, decreased control systems reliability. In addition, the AC distribution panels do not meet current arc flash protection standards or Worker Protection Practices for switching and lock-out. Over the past 12 years, Kootenay Canal has experienced 23 forced outages due to the failures of the aged exciters, governors, and unit control relays.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
BC Hydro considered four alternatives:
i. Base scope only – replace controls (unit controls, exciter controls, and governor controls) and replace exciters;
ii. Base scope, plus replace unit AC distribution panels and select governor mechanical components;</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

iii. Base scope, plus replace unit AC distribution panels and full governors; and

iv. Do nothing – continue to maintain and operate as currently done.

Alternative ii is the preferred alternative as it is the lowest cost alternative that addresses the reliability, maintainability, and safety risks associated with the controls, exciters, governors, and unit AC distribution panels.

Alternative i is inferior to Alternative ii because it would cost more in the long-term to address the reliability, maintainability and safety risks associated with the equipment, and would expose BC Hydro to retained risks associated with the governors and AC power distribution panels until these are replaced.

Alternative iii is not cost effective. The remaining industry life expectancy of the governors is more than 50 years, and replacement of this equipment can be deferred until that time.

Alternative iv is not viable because it would not meet the Project objectives. The reliability, maintainability and safety risks of the equipment cannot be mitigated to an acceptable level through maintenance, and these risks will continue to increase over time.

Project Impacts and Benefits:

- Improve the long-term reliability, maintainability, operability and safety of the control systems, exciters, governors and the AC distribution panel.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

Investment Planning ID: G000459	Project Name: La Joie – Dam Improvements	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F22 RRA: • Chapter 6, page 6-25 • Appendix I: Generation - line 10 • BCUC IRs 1.43.1; 1.45.2	
Description: The La Joie Dam Improvements Project has been initiated to mitigate Dam Safety risks related to seismic and static deficiencies associated with the dam, intake structure, and flow passage.		
Key Drivers: • Safety • Environmental • Financial Loss • Reputational • Reliability		
Issues Being Addressed: The La Joie embankment dam, which impounds Downton Reservoir, is classified as an Extreme consequence dam based on the BC Dam Safety Regulation. The dam is expected to deform during a seismic event resulting in increased seepage through the dam and potentially escalating to an uncontrolled release of the reservoir following an earthquake with a return period of about 2,200 years. Significant damage to the power intake tower that could lead to failure is expected following an earthquake with a return period of about 1,000 years, and the water passage system cannot be relied upon to operate following an earthquake further limiting BC Hydro's ability to manage the post seismic condition. Uncontrolled release of the reservoir would result in financial damage, reputational damage, environmental impact, and possible fatalities. The identified Dam Safety risks are currently being managed through operational changes where the Downton Reservoir is operated at a reduced level, and other monitoring and maintenance efforts. However operating Downton Reservoir at a reduced level creates operational constraints for the Bridge River System which can necessitate discharges down the Lower Bridge River that exceed water use plan targets and have environmental impacts. The La Joie Dam is the uppermost dam in the Bridge River System and the Downton Reservoir impounded by the dam provides significant storage and inflow buffering capacity for the downstream generating facilities. As such, decisions relating to the La Joie facility must also consider potential impacts on the full Bridge River System.		
Discussion of Alternatives: BC Hydro is considering four alternatives: i. **Do Nothing:** this is to maintain the status quo and should be considered as a deferral as the condition of the shotcrete face is approaching end of its serviceable life. Operating the reservoir at a lower level reduces operational flexibility for the system and increases the likelihood of downstream impacts;		

[1] Start Date of Construction is the Implementation Approval Date.

ii. **Decommissioning of La Joie Dam:** this would naturalize flows at Upper Bridge River and eliminate the operational buffer associated with Downton Reservoir. Loss of the buffer increases the likelihood of downstream impacts but does naturalize terrestrial areas upstream of La Joie; iii. **Improve the Existing Dam to Operate at Normal Reservoir Level:** improve the dam to, generally, operate as originally intended. This provides the maximum operational flexibility on the Bridge River System minimizing downstream impacts. Upstream impacts (i.e., reservoir inundation) remain unchanged from the original; and iv. **Improve the Existing Dam to Operate at a Reduced Operating Level:** the reduced operating level is to be determined and would, presumably, be at a level to balance impacts and benefits. The project is currently in Identification and the alternatives are being evaluated.
Project Impacts and Benefits: • Mitigate or eliminate Dam Safety risks related to seismic and static deficiencies associated with the dam, intake structure, and flow passage.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:
Regardless of which alternative is selected (except for the Do Nothing Alternative), BC Hydro expects to submit an application to the BCUC under Section 44.2 of the *Utilities Commission Act* for the project.

Investment Planning ID: G002326	**Project Name:** La Joie - Governor Pressure Regulating Valve Replacement	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** New	

Description:

The purpose of this project is to address the operating risks with the deteriorating governor, turbine inlet valve (**TIV**) and pressure relief valve (**PRV**) at the La Joie generating station. The project will upgrade these assets to restore long-term reliability and address risks with common points of failure across the systems.

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

The penstock at La Joie was originally built prior to the powerhouse and was used to pass water from the Downton Reservoir into Carpenter Reservoir via a hollow cone valve (**HCV**). As such, the penstock has relatively thin walls because it wasn't designed for pressure transients associated with relatively fast wicket gate operation on a turbine. When the unit was added in 1956 a pressure relief valve (**PRV**) was required to ensure pressure transients associated with relatively fast wicket gate operations would not damage the penstock.

This project will address reliability issues with the governor and mitigate the risk associated with the current common low-pressure hydraulic power unit (**HPU**). The project will also upgrade the PRV to ensure the PRV can be operated for up to six-months continuously to support water management during the La Joie Dam Improvements project.

The governor is over 60 years old, most of its components are original, and have exceeded their expected service life. The current Asset Health Rating of the governor is Poor. The governor and the PRV are mechanically linked and have a common hydraulic system that is also shared with the TIV. The PRV and its discharge pipe have suffered from severe cavitation and fatigue damage in the past. The PRV underwent major repairs in 2000, 2004, 2013, 2014 and 2016 and several major repairs have also been undertaken on the discharge pipe. Failure of either the governor or PRV would result in a loss of generation and the inability to manage the Downton Reservoir levels which would pose an unacceptable dam seismic risk.

Discussion of Alternatives:

As stated above the governor and the PRV are mechanically interlocked and share a common low pressure HPU and accumulator. The TIV also share the same low pressure HPU and accumulator with both the governor and PRV. Due to the interconnectivity of the equipment there are many technical options and three key alternatives were identified.

Replacing the governor and upgrading the hydraulic system is a common scope item for all alternatives due to the assets poor condition.

BC Hydro is considering three alternatives:

i. **PRV refurbishment, and governor/hydraulic system upgrade**;

ii. **PRV replacement and governor/hydraulic system upgrade**; and

1 Start Date of Construction is the Implementation Approval Date.

iii. **PRV refurbishment and Auxiliary Bypass Valve (ABV) and governor/hydraulic system upgrade**: This involves replacing the ABV (a valve that has not been used since construction of the dam) with a new valve that will function as the PRV and using the old PRV with some modifications as a standby PRV.	
Project Impacts and Benefits: • Improved reliability of governor system, PRV and TIV • Ability for the unit to run remotely • Provide reliable water conveyance during normal operations • Ability for six months of water conveyance to enable the La Joie - Dam Improvements project	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: N/A

<tr><td colspan="3">Description:
The purpose of this project is to implement seismic and system reliability upgrades to the structures, gates, mechanical systems, controls and power supplies for the spillway of the Ladore Dam so that this facility can be relied upon for post-earthquake operation as well as for reliable operation under normal and flood conditions.
Refer to Appendix K – Campbell River Systems Engineering Assessment for additional information.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Financial
• Reputational</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">

Issues Being Addressed:

The Ladore Dam is classified as an Extreme consequence dam based on the BC Dam Safety Regulation. As such the expected seismic performance is for no uncontrolled release for the Maximum Design Earthquake (**MDE**) with an annual exceedance frequency of once in 10,000 years. A seismic performance investigation was carried out, and it was determined that the withstand of the spillway gates and hoist structure is less than the MDE, and damage could lead to an uncontrolled release of water from the reservoir. Failure of the Ladore gates could lead to a flow imbalance at John Hart Dam, located about 1 km downstream, with potential for overtopping of the John Hart Dam, potentially resulting in fatalities, financial loss and reputational damage.

The scope of this project includes upgrades to the Ladore spillway to ensure that:

- In the event of an MDE, the spillway and water conveyance system act as an integral water barrier to retain the Ladore Reservoir;
- The spillway can release water in a controlled manner after a seismic event up to MDE; and
- Electromechanical systems that operate the spillway have an acceptable level of reliability, in both post-earthquake and normal service, including during high inflows and floods.

</td></tr>
<tr><td colspan="2">

Discussion of Alternatives:

BC Hydro considered three alternatives:

i. **Refurbishment** of gates, towers and hoists;

ii. **Replacement** of gates **and refurbishment** of towers and hoists; and

iii. **Replacement** of gates, towers and hoists.

Alternative iii, replacement of gates, was selected as the preferred alternative because it provides the best long term solution as compared to Alternatives i and ii, due to a more reliable and robust design, increased ease of maintenance and safety for BC Hydro operation staff, and reduced environmental impacts during and after construction.

</td></tr>
<tr><td colspan="2">

Project Impacts and Benefits:

- Improve safety by addressing seismic deficiencies of the Ladore Dam spillway, so that this facility can be relied upon to safely retain the reservoir through an earthquake to and including the MDE and for post-earthquake operation.
- Improve safety by improving the operational reliability of the Ladore Dam spillway gates to control the discharge of reservoir inflows over the spillway.

</td></tr>
<tr><td>

Project Implementation Phase Risk:

Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.

</td><td>

Risk Treatment:

To be determined when the project reaches Implementation.

</td></tr>
<tr><td colspan="2">

Additional Information:

As the planning level estimate for this project is over $100 million, BC Hydro expects to submit an application to the BCUC under section 44.2 for this project.

Planning is currently underway for upgrades at the upstream Strathcona facility and downstream John Hart facility (Strathcona Discharge Upgrade Project, G000525; and John Hart Dam Seismic Upgrade Project, G000585). Planning for these two projects is being considered in conjunction with the Ladore Spillway Seismic Upgrade project for the following reasons:

- The projects are planned with similar and potentially overlapping construction schedules;
- They are relatively close geographically to one another;
- They have some similar scope elements that will require similar contractor expertise; and
- They all reside on the Campbell River and the work will need to be considered from a river system management perspective and coordinated accordingly.

</td></tr>
</table>

Investment Planning ID: G000168	Project Name: Lake Buntzen 1 – Generator Replacement	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-96 • Appendix I - Generation, line 78; Appendix J, page 65; Appendix K, page 24 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-27 • Appendix I - Generation, line 48	

Description:

The purpose of this project is to improve the reliability of the generator at the Lake Buntzen 1 (**LB1**) Generating Facility.

Refer to Appendix K – Coquitlam-Buntzen System Facility Asset Plan for additional information.

Key Drivers:

- Reliability

Issues Being Addressed:

The LB1, generator one (60 MW) was assessed in 2016 and the Asset Health Rating is Poor. The main issues leading to this health rating include the poor condition of the stator windings, stator core, and rotor windings, as confirmed by poor electrical test results, visible signs of deterioration and deformation, and a stator winding insulation failure which resulted in two coils cut-out in 2005.

Discussion of Alternatives:

BC Hydro considered four alternatives:

i. **Do Nothing**;
ii. **Rewind generator** (stator and rotor only);
iii. **Refurbish some components of the generator system**; and
iv. **Replace most of the components of the generator system**.

Alternative iv, “Replace most of the components of the generator system”, was selected as the single viable alternative. Alternative i was not considered viable given the deteriorated condition of the generator that will eventually lead to its failure. Alternative ii and Alternative iii were not considered viable as they would only improve asset condition in the short-term, but would not achieve the project objective of extending the asset life by at least 40 years and therefore would likely result in additional future projects to achieve the project benefits.

Project Impacts and Benefits:

- Extend the generator life by at least 40 years.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	To be determined when the project reaches Implementation.

<tr><td colspan="3">Description:
The purpose of this project is to address water conveyance reliability risks associated with the tunnel from Coquitlam Reservoir to Lake Buntzen Reservoir.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Safety</td></tr>
<tr><td colspan="3">Issues Being Addressed:
There are two Intake Operating Gates located in the tunnel to control flow. In addition, one Intake Maintenance Gate is provided for Single Device Isolation of the two Intake Operating Gates and the tunnel. Tunnel isolation is required to complete inspections and maintenance of the tunnel and Intake Operating Gates.
The Intake Operating Gates are original equipment (1908 and 1911) and are in poor condition. The operating gates have experienced failures due to broken rollers and wire ropes, and have experienced difficulties opening under high head conditions. Failures of these gates impact BC Hydro’s ability to
• Convey water between the Coquitlam Reservoir and Lake Buntzen;
• Generate at Lower Buntzen 1 Generating Station;
• Manage levels in the Coquitlam Reservoir, potentially affecting the public drinking water supply;
• Regulate and manage flows into Lake Buntzen, with potential for overtopping of the spillway at Buntzen Dam and consequent damage to the Lower Buntzen 1 Generating Station; and</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

- Regulate and manage flows into the Coquitlam River which, during extended periods of high inflows, could contribute to incremental flooding along the Coquitlam River.

Discussion of Alternatives:

BC Hydro considered five alternatives:

i. **Do nothing:** continue to repair the gates as they fail;

ii. **Replace Gates:** Replace two Intake Operating Gates at the existing location and install the Intake Maintenance Gate at a new location;

iii. **Replace Gates in New Location:** Enlarge the Intake Operating Gates vertical access shaft, replace the concrete pier to provide a new location for two new Intake Operating Gates, and replace the Intake Maintenance Gate with two new gates at the existing location of the two Intake Operating Gates;

iv. **Replace Operating Gates and Maintenance Gate:** Replace the two Intake Operating Gates and the Intake Maintenance Gate at their existing locations and refurbish the existing Intake Maintenance Gate concrete gate wall; and

v. **Refurbish:** Refurbish the mechanical parts of the two Intake Operating Gates at their existing locations to achieve a 15-year service life, including re-use of gate system components. Replace the Intake Maintenance Gate at its existing location and refurbish the concrete wall for this gate.

Alternative ii, replace gates, was selected as the preferred alternative. The Intake Maintenance Gate is being replaced in a new location to eliminate underwater construction hazards and the Intake Operating Gates will be replaced in the original location. All gates will receive seismic upgrades and remote control with a new local power supply. Alternative i is not considered viable given the deteriorated condition of the gates that will eventually lead to their failure. Alternatives iii was not selected as it was less cost-effective in achieving a long-term solution as compared with Alternative ii. Alternative iv was not selected because it was a higher cost compared with Alternative ii, had a greater potential for cost overruns, had a higher quality risk and had the highest underwater construction safety hazard for divers. Alternative v was not selected because it did not meet the user requirements for a 50-year service life or for seismic withstand, post event tunnel gate operability.

Project Impacts and Benefits:

- Improve reliability of the Coquitlam-Buntzen Tunnel gates.
- Reduce public and worker safety hazards.
- Provide seismic withstand capability for the tunnel gates
- Provide remote control for the gates from Fraser Valley Office.

Project Implementation Phase Risk:	Risk Treatment:
Risk of delays due to unfavourable weather conditions.	The schedule has been designed to complete the work in three two-month outages over a one-year period to align with summer low inflow periods, and reservoir drawdowns will be undertaken in the winter months.

Additional Information:

There is no Asset Health rating for gates, as there are for generating equipment; however, their condition is poor as described.

Investment Planning ID: G003234	Project Name: Lake Buntzen 1 - Penstock Interior Restoration	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** New	

Description:

The purpose of this project is to ensure safe and reliable operation of the Lake Buntzen 1 steel penstock for another 25 years at the lowest lifecycle costs by mitigating the risks due to active corrosion.

Key Drivers:

- Reliability
- Safety
- Financial

Issues Being Addressed:

The Lake Buntzen 1 steel penstock has been in service since 1952 and has an Equipment Health Rating of Unsatisfactory. The penstock interior is exhibiting signs of coating failure and surface corrosion, particularly in the sloped section leading to the downstream Turbine Inlet Valve where general corrosion is occurring over 50 per cent of the surface area.

The penstock's protective coating is intended to prevent corrosion of the steel which can result in reduced material thickness and strength. Without recoating, the extent of corrosion damage will increase and over time will impact the structural integrity of the steel to the point where recoating is no longer viable, and a significantly more costly penstock replacement would be required. Left unaddressed, corrosion damage could result in the penstock being removed from service if no longer safe to operate.

Discussion of Alternatives:

BC Hydro is considering three alternatives:

i. **Do Nothing** and monitor the condition;

ii. **Install Cathodic Protection** to arrest ongoing corrosion; and

iii. **Restore Coating (Interior)** to protect from further corrosion.

The Alternative i, to do nothing, does not address the issues identified above and continued corrosion would impact the structural integrity of the steel to the point where recoating is no longer viable and replacement costs are expected to be significantly higher than recoating the existing penstock. The corrosion rate is unknown and difficult to estimate given the available information.

Alternative ii, installing a cathodic protection system is also not recommended because it is not typically used as corrosion protection of penstock interiors. It could increase maintenance costs and is not likely to be effective due to the service environment and large areas involved.

Based on existing inspection reports, Engineering assessments and a review of other ongoing penstock recoating projects, Alternative iii, to restore the interior coating, addresses the issues identified above and is expected to be the preferred alternative, but this will be confirmed when the project is initiated.

Project Impacts and Benefits:

- Extend penstock life by restoring the interior coating to protect from corrosion.
- Improve equipment reliability and safety by addressing the deteriorating condition of the penstock.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.
Additional Information: Besides the value provided by generation, the ability to move water through the Lake Buntzen 1 penstock is important for flood risk management and mitigating impacts due to spilling from Lake Buntzen Dam.	

Investment Planning ID: G003211	Project Name: Mica - Reactor 5RX3 Replacement	
Forecast Capital Cost: $42.8 million	**Forecast In-Service Date:** Fiscal 2024	**Start Date of Construction:**[1] Fiscal 2020
Development Phase: Implementation	**Filing Reference:** F20-F21 RRA: • BCOAPO IR 3.174.2 F22 RRA: • Chapter 6, page 6-28 • Appendix I - Generation, line 69 • BCUC IR 1.54.1	

Description:

The purpose of this project is to replace the two 500 kV transmission line reactor banks at the Mica Generating Facility.

Key Drivers:

- Operational Requirements
- Reliability
- Financial Loss

Issues Being Addressed:

There are two reactor banks at Mica (5RX3 and 5RX4), each comprised of three single phase reactors and a neutral. These reactor banks are used for system stability to absorb reactive power and lower line voltages when the transmission lines are lightly loaded. Without these reactors in service, the system operates without its intended redundancy, increasing reliability risks, operational constraints and limiting export opportunities.

On March 31, 2019 the 5RX3 reactor bank at Mica was damaged during an electrical event. Operating restrictions were placed on Mica until the reactor bank is returned to service. Replacement of these reactors was released as an emergency project in April 2019. In response to a separate equipment failure event on the 5RX4 reactor bank at Mica in January 2020, the replacement of the second reactor bank was advanced with a forecast in-service date of 2022. Efficiencies result from completing the work under a single project.

Discussion of Alternatives:

BC Hydro considered four alternatives:

i. **Do Nothing:** Two reactor banks at Mica to remain out of service;

ii. **Replace with Existing Spares:** Existing system spares require modifications that would take a year or more to complete;

iii. **Repair:** Severe damage on two of the single phase 5RX3 reactors included rupture of the main tank. Re-welding and repair is not viable; and

iv. **Replace with New:** Purchase of six single phase reactors, plus a spare.

Alternative iv, replace with new, was selected as the selected alternative. Alternative i is not viable because system operation would remain impaired. Alternative iii is not feasible due to severe damage on two of the single phase 5RX3 reactors including rupture of the main tank and oil loss, such that re-welding and repair of these units is not viable. Alternative ii is not feasible as it would prolong operating constraints by at least one year, and further would result in the need to re-use the remaining Mica single

[1] Start Date of Construction is the Implementation Approval Date.

phase reactors, which would leave Mica with a mix of single-phase reactors that could potentially cause overheating. Furthermore, existing reactors and spares at Mica are vintage 1979 equipment and prior to failure were rated in “Poor” condition. Thus, repair and use of system spares is not a viable option.	
Project Impacts and Benefits: • Restore Mica to normal system operation. • Reduce reliability risks. • Improve export capabilities.	
Project Implementation Phase Risk: Due to equipment damage on one of three single phase reactors, that occurred during shipment of the 5RX4 reactors to Mica, there is a risk of schedule delay to the project in-service date.	**Risk Treatment:** This risk can be mitigated by using the spare reactor at Mica, if the damaged equipment cannot be repaired to meet the project timeline.
Additional Information: N/A

<tr><td colspan="3">Description:
Mica Dam discharge facilities include both a three-gated spillway and a two-gated outlet works. The objective of this project is to upgrade these discharge facilities to provide for continued safe containment of the reservoir during an earthquake, safe discharge of water from the reservoir after such an earthquake, and sufficiently reliable operation for all other service conditions, including during periods of high inflows up to extreme floods.
Refer to Appendix K – Mica Facility Asset Plan for additional information.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Reliability
• Financial
• Reputational</td></tr>
<tr><td colspan="3">Issues Being Addressed:
• The Mica Dam is classified as an Extreme Consequence Category Dam based on the BC Dam Safety Regulations. As such, the expected seismic performance is for no uncontrolled release of the reservoir for the Maximum Design Earthquake (MDE) with an annual exceedance frequency of once in 10,000 years. The MDE has been updated since the dam’s original design and construction and demands from the current design earthquake exceeds the original design capacities. Seismic deficiencies have been identified in various spillway and outlet works structures. Moreover, the gates’ mechanical, electrical, control and power supply equipment have not been seismically qualified and cannot be relied upon to operate after an earthquake. Inability to safely operate the discharge facilities after an earthquake:
- Would preclude a drawdown of the reservoir for dam inspections, repairs, or other emergency measures; and
- Could lead to eventual overtopping of the earthfill dam, resulting in erosion and possible dam failure with significant risk to life, financial loss, environmental consequences and reputational impact.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

- The discharge gates at Mica Dam do not have sufficient reliability to ensure operability when needed during periods of high inflows and reservoir levels, such as during freshet and floods. Failure of the discharge facilities to operate during high inflow events could lead to eventual overtopping of the earthfill dam, resulting in erosion and possible dam failure. Operational reliability improvements to the gate systems in accordance with current BC Hydro principles—including mechanical, electrical, control and power supply sub-systems—are required in order that they can be relied upon to operate when needed.

Discussion of Alternatives:

The Single Viable Alternative is to upgrade the deficient components to meet the current seismic and operational reliability requirements. Given the safety and reliability issues identified and the extreme consequences of Mica Dam failure, do-nothing or long-term retention of the status quo is not acceptable. The project is in Identification phase and in the process of further developing specific scope items.

Project Impacts and Benefits:

- Assured reservoir containment up to and including extreme earthquakes and provision of safe and reliable post-earthquake discharge and drawdown capability to allow for dam inspection, repairs, and other emergency measures, as required.
- Increased operational reliability to reasonably assure discharge function and prevent dam overtopping during high inflows up to and including extreme flood events.
- Reduced potential for fatalities, financial loss and reputational impact due to an uncontrolled release of water from the reservoir.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

Mica Dam provides flow regulation, power generation and flood control under the terms of the Columbia River Treaty.

Investment Planning ID: G003207	Project Name: Mica Replace Units 1 to 4 Generator Transformers	
Forecast Capital Cost: $79.8 million	**Forecast In-Service Date:** Fiscal 2023	**Start Date of Construction:**[1] Fiscal 2018
Development Phase: Implementation	**Filing Reference:** F17-F19 RRA: • Appendix I, line 67, Appendix J, page 34 • BCUC IRs 1.70.3, 1.92.1-1.92.3, 2.249.8, 2.260.4 • BCOAPO IR 1.36.1 F20-F21 RRA: • Chapter 6, page 6-95 • Appendix H, page 14 • Appendix I - Generation, line 30; Appendix J, page 34; Appendix K, page 26 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-27 • Appendix I - Generation, line 27	

Description:

The purpose of this project is to replace 12 single-phase generating unit transformers at the Mica Generating facility with explosion-resistant transformers for safe and reliable operation.

Key Drivers:

- Safety
- Reliability

Issues Being Addressed:

The Mica Generating Station is categorized as a Key facility according to BC Hydro's Facility Asset Plans. Twelve single-phase transformers connect the Unit 1 to 4 Mica generators to the transmission network by stepping up the generator output voltage of 16 kV to transmission voltage of 500 kV. The reliability and safety risks associated with these transformers are increasing as the assets age and degrade.

The Asset Health Rating of 10 of the transformers is Poor. After nearly 40 years of service, several of the transformers are showing signs of overheating while others have indications of insulation degradation. The Mica transformers are located in an underground powerhouse, and a failure presents a safety risk for people working in the underground powerhouse in addition to the reliability risks associated a forced outage.

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives: BC Hydro considered three alternatives: i. **Do nothing:** replace transformers at failure; ii. **Refurbishment** and partial replacement; and iii. **Replace** with new single-phase explosion-resistant transformers. Alternative iii, replace, was selected as the preferred alternative because it is the only technically feasible alternative that meets the project objectives. Alternative ii would not allow for installation of explosion-resistant transformer design which were selected for Mica Units 5 and 6 Project based on eliminating the risks associated with working near live oil filled transformers in the underground facility at Mica. Alternative ii would not allow BC Hydro to take advantage of the Master Supply Agreement which specifies the explosion-resistant transformers.	
Project Impacts and Benefits: • Improve transformer reliability. • Reduce safety risk.	
Project Implementation Phase Risk: Due to the age of the old transformers, and the work taking place underground while some other units are operating and energized, there is a risk of serious worker injury or fatality in the event of a transformer explosion in the underground chamber. Due to the inability to verify all as-built conditions and design assumptions, there is a risk that as found conditions during construction differ from design and budget assumptions. This could lead to unplanned work and potential schedule and cost impacts.	**Risk Treatment:** To mitigate this risk, the project has developed a Safety Plan (conforming with BC Hydro's Contractor Safety Program) and utilized the procedures, knowledge and experience gained from other projects performed in the transformer chamber. The project has also implemented safety outages of the adjacent transformers which are not explosion resistant, while work is underway in the chamber. This risk materialized and the estimated increased cost to the project was approved by the Capital Project Committee of the Board in June 2020.
Additional Information: N/A	

Investment Planning ID: G000183	**Project Name:** Mica - U1 - U2 Turbine Overhaul	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** F20-F21 RRA: • BCUC IR 1.115.2 F22 RRA: • Chapter 6, page 6-28 • Appendix I - Generation, line 70 • BCUC IR 1.45.2	

Description:

The purpose of the project is to improve the reliability of the Unit 1 and 2 turbines at the Mica Generating Station.

Key Drivers:

- Reliability
- Financial

Issues Being Addressed:

The Unit 1 and 2 turbines are in Poor condition. These units have been in service for over 40 years without any major turbine overhaul or intervention. The main issues leading to a Poor Asset Health Rating include:

- Ongoing cavitation damage to the runner blades and wicket gates
- Evidence of rubbing between the runner crown and the seal ring in the headcover
- Poor condition of wicket gate bushing

It is expected that turbine efficiency has been reduced because of changes in runner blade profile as a result of cavitation repair. The cavitation damage to the runner blades and wicket gates is managed with interventions and monitoring. The runner clearance and wicket gate bushing condition are managed with inspections and monitoring.

Discussion of Alternatives:

BC Hydro is considering three alternatives:

i. **Do Nothing**: Continue with Preventative Maintenance program to inspect turbines and make repairs where possible without disassembling the unit;

ii. **Overhaul turbines and associated components**: Restore turbine components to “as new” condition to enable reliable operation for 25 years; and

iii. **Replace runners and overhaul turbine and associated components**: Includes Alternative ii. scope as well as replacement of the turbine runners.

Project Impacts and Benefits:

- Improve the reliability of the turbines of Units 1 and 2.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.
Additional Information: N/A	

Investment Planning ID: G003456	Project Name: Mica Upgrade 600 V Circuit Breakers	
Forecast Capital Cost: $25.7 million	**Forecast In-Service Date:** Fiscal 2022	**Start Date of Construction:**[1] Fiscal 2019
Development Phase: Implementation	**Filing Reference:** F17-F19 RRA: • Appendix I, Hydroelectric - line 40 F20-F21 RRA: • Chapter 6, page 6-95 • Appendix G, page 25 • Appendix I, Generation - line 41, Appendix K, page 26 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 • CEC IR 3.104.2 F22 RRA: • Appendix I, Generation - line 28 • BCUC IR 1.43.1	

Description:

The purpose of this project is to address safety risks with essential loads and the physical location of the diesel generators as well as reliability risk with the 600 V circuit breakers at the Mica Generating Station.

Key Drivers:

- Safety
- Reliability

Issues Being Addressed:

The Mica generating station is categorized as a Key facility according to BC Hydro's Facility Asset Plans. It is over 45 years old. The primary issues being addressed by this project are:

- The station service breakers and switchgear are original equipment, in poor condition resulting in increased frequency of failures and they introduce safety risks with high arc flash categories.
- Station loads placed on essential power are not adequate to maintain safe operation in the event of a fire in the powerhouse. For example, additional intake and exhaust fans are required to operate on essential power to ensure smoke from a fire can be cleared from the powerhouse.
- Location of the diesel generators (i.e. the back-up power for the essential bus) poses a risk of blocking the powerhouse egress route.

Discussion of Alternatives:

BC Hydro considered the following alternatives:

Circuit Breaker and Switchgear Alternatives

i. **Do Nothing:** Operate to failure, accept safety risks;

ii. **Replace Switchgear & Install New Metal Enclosures**: extends life of asset by 25 years but significant arc flash risk remains; and

iii. **Replace Switchgear & Install Arc Resistant Enclosures**: extends life of asset by 25 years and

[1] Start Date of Construction is the Implementation Approval Date.

reduces arc flash risk.

Alternative iii was selected as the preferred alternative for Circuit Breaker and Switchgear Alternatives as it addresses the safety and reliability risks of the equipment. Alternative ii was not selected as a significant arc flash risk will remain. Alternative i was not selected because it does not address the safety risks nor meet the project objectives.

Essential Bus Upgrade Alternatives

i. **Do Nothing**: maintain existing essential load configuration, accept risks of blocking egress route;

ii. Relocate existing 400 kW diesel generators and install additional 600 kW diesel generator: Addresses safety risks but introduces reliability risks; and

iii. **Install two new diesel generators in a new location:** addresses safety risks with no new reliability risks.

Alternative iii was selected as the preferred alternative for the Essential Bus Upgrade Alternatives as the most cost-effective alternative to satisfy the safety and reliability objectives of the project. Alternative ii was not selected because introduces cost and reliability risks with integration of the old diesel generator with the modern control systems. Alternative i was not selected because it does not address the safety risks nor meet the project objectives.

Project Impacts and Benefits:

- Improved reliability of the 600 V circuit breakers and switchgear
- Reduced safety risks of the 600 V circuit breakers and switchgear
- Reduced safety risks of a blocked egress route when back-up power is being provided by the diesel generators

Project Implementation Phase Risk:	**Risk Treatment:**
Due to the configuration of energized bus around the cable connections, removing the cables while the bus is energized, as was originally planned, is not recommended. This may result in the outage requirements to complete load transfers increasing from four days to 12 days and require multiple units out of service during portions of the 12 days. This may require rescheduling of the planned work to accommodate overall system impacts and may result in missing the March 27, 2022 in service date milestone.	The project team will verify the outage requirements and any system constraints to consider regarding the duration and timing of the outages. To minimize schedule impact, some outage work may be moved to evening shifts and project contingency will be used to cover any additional costs.

<tr><td colspan="3">Description:
The purpose of this project is to address safety and reliability risks associated with the Puntledge Generating Station penstock, and achieve an asset life extension through a strip and recoat intervention.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Safety
• Financial
• Environmental</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Puntledge Generating Station is classified as a Strategic facility according to BC Hydro’s Facility Asset Plans. It is located downstream of the Comox Dam and the Puntledge Diversion Dam which are rated Extreme and Very High consequence dams, respectively, based on the BC Dam Safety Regulation.
The penstock at the Puntledge Generating Station has been in-service since 1954. The long steel penstock sections are exhibiting signs of coating failure. The Asset Health Rating for the long steel sections of the penstock is Unsatisfactory.
Without recoating, the extent of corrosion damage will increase and, over time will impact the structural integrity of the steel material to the point where recoating is no longer an option and a penstock replacement is required. Continued corrosion may require the penstock to be removed from service when it is no longer safe to operate. Failure of the penstock could lead to uncontrolled release of water with significant risk to life, financial loss, and reputational damage.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

BC Hydro considered four alternatives:

i. **Do Nothing and Monitor**;

ii. **Strip and Recoat Only Exterior Surface of Steel Penstocks**;

iii. **Strip and Recoat Exterior and Interior Surfaces of Steel Penstocks**; and

iv. **Complete Replacement of Penstocks**.

Alternative iii, strip and recoat exterior and interior surfaces of steel penstocks, was selected as the preferred alternative as it addresses safety and reliability objectives, and extends the penstock life. Alternative i or Alternative ii would not deliver a significant overall penstock life extension because corrosion of the uncoated and unprotected steel penstock sections would not be achieved. Loss of steel would persist, potentially undermining the structural integrity of the penstock, which are considered high pressure vessels conveying significant volumes of water and are key water passage components used for generation. Penstock failures may cause extensive economic and infrastructure damage. Alternative iv was not selected as it would be too costly compared to Alternative iii which also addresses the project objectives.

Project Impacts and Benefits:

- Improve equipment reliability and safety.
- Extend penstock life.
- Reduce potential for fatalities, financial loss, and reputational damage due to an uncontrolled release of water from the reservoir.

Project Implementation Phase Risk:	**Risk Treatment:**
There is a risk that the conditions encountered during construction are worse than was assumed at the time the project budget was approved	This risk materialized. During the recoating of the steel penstock, it was determined that the woodstave portion of the penstock, (not included in the original project scope), requires a preservative application in some areas where the previously applied creosote coating has deteriorated and no longer provides protecton from wood rot. Doing so will extend the life of the woodstave portion of the penstock. Whether or not to add this scope to the project is currently being evaluated.

Additional Information:

The water conveyed by the approximately five km penstock is also used by Department of Fisheries and Oceans Canada and the Comox Valley Regional District. The use by Comox Valley Regional District is expected to continue until July 2021 at which time they will complete their new intake and pipeline project and start drawing water directly from Comox Lake. Given the penstock's proximity to municipalities, and Department of Fisheries and Oceans Canada's reliance on the water conveyed by the penstock, it is important that the safety and reliability of the penstock be sustained.

Investment Planning ID: G000543	Project Name: Seton - Canal Flow Control Structure Upgrade	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** New	

Description:

The purpose of this project is to improve the functionality of the five headworks operating gates for the Seton Canal by addressing existing deficiencies and operating concerns and by upgrading them to allow closure under flow.

Key Drivers:

- Safety
- Reputational
- Financial

Issues Being Addressed:

The five headworks operating gates at Seton Dam are required to isolate the power canal from Seton Lake Reservoir for periodic canal liner maintenance, during significant floods, or in the event of an emergency.

The canal intake gates are designed to be closed in no-flow conditions only. The inability of the gates to close under flow means that failure of the canal, aqueduct, penstock forebay, or penstock would likely result in uncontrolled flow through the canal until Seton Lake was drained to the level of the concrete dam approach channel. The uncontrolled release of water in this way could lead to loss of life and economic damage. In addition, several equipment defects have been identified with the gates' current operation. Some of the gate lifting equipment is unserviceable and a crane is used instead. The gates are difficult to close and significant leakage passing through them has been observed during recent closures.

Discussion of Alternatives:

BC Hydro is considering three alternatives:

i. **Do Nothing**: defer, either temporarily or permanently, the upgrade of the headworks operating gates. Adoption of this alternative may be acceptable if other emergency measures to control canal flows can be established;

ii. **Upgrade the Headworks Operating Gate System**: upgrade the existing gate system to address operability issues and to allow gate closure under flow; and

iii. **Replace the Headworks Operating Gate System**: design and install new gate system to address operability issues and to allow gate closure under flow.

Project Impacts and Benefits:

- Improve public safety by enabling the closure of the headworks operating gates under flow in the event of a dam safety emergency.
- Improve worker safety and reliability by addressing operability issues of the headworks operating gates for maintenance and regular operations.

[1] Start Date of Construction is the Implementation Approval Date.

Page 1 of 2

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.
Additional Information: N/A	

Investment Planning ID: G003026	Project Name: Seton – Upgrade Unit	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-95 • Appendix I, Generation - line 64; Appendix J, page 57 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-28 • Appendix I, Generation - line 55	

Description:

The purpose of this project is to upgrade the unit equipment to ensure safe and reliable operation at the Seton Generating Facility.

Key Drivers:

- Reliability
- Safety
- Environment
- Reputational

Issues Being Addressed:

The Seton Generating Facility is operated almost continuously except for fisheries and maintenance requirements. Both the Seton generator and turbine are original equipment (1956) and their Asset Health Rating is Poor.

Due to the age and condition of the generator and turbine there is a risk that they could fail leading to loss of generation and an extended outage. This would result in high flows down Seton River and Lower Bridge River which could cause impacts to fish and fish habitat, as well as deviations to the Bridge/Seton system operating regime. We are engaging St’át’imc Nation and regulators as part of regularly scheduled meetings to discuss flows on these two rivers, and in the event of an unplanned outage we would notify all parties to discuss how to best manage the system. Also, if water needs to be diverted through Lower Bridge River, then this could result in an increased likelihood and magnitude of spills from Terzaghi Dam to Lower Bridge River beyond the Water Use Plan Order targets for annual average flows and those same targets in settlement agreements with the St’át’imc Nation. BC Hydro is operating under a variance to our Water Use Plan order approved by the Comptroller of Water rights (February 16, 2017).

Discussion of Alternatives:

BC Hydro is considering seven alternatives:

i. **Do Nothing:** operate to failure;

ii. **Refurbish Unit with Unchanged Nameplate Rating:** It is expected that this approach could extend the unit life another 35 years;

iii. **Replace Unit with Unchanged Nameplate Rating:** It is expected that this approach would result

[1] Start Date of Construction is the Implementation Approval Date.

in a new life of 40 to 50 years; iv. **Refurbish Unit with Increased Nameplate Rating:** It is likely this approach would involve replacement of some elements of the unit and refurbishment of others, and could extend the unit life another 35 years; v. **Replace Unit with Increased Nameplate Rating:** It is expected that this approach would result in a new life of 40 to 50 years; vi. **Decommission Unit:** This alternative would see Seton being used for water passage only. The dam, canal, and intakes would be retained. The unit mechanical and electrical components would be removed or reconfigured to provide the energy dissipation needed to discharge the water safely through the powerhouse to Fraser River; and vii. **Install a Bypass with a Unit Refurbishment/Replacement:** This approach would involve refurbishing or replacing the unit as per one of the Alternatives i to v. In addition to installing a bypass past the powerhouse in a suitable location and to a suitable size to divert water from the main powerhouse during outages and/or in times of high inflows. This would allow the production of power from the bypassed water and also help to dissipate the stored energy before discharging to the Fraser River. The preferred alternative has not yet been determined.
Project Impacts and Benefits: • Improve the reliability of the Seton Generating Facility. • Improve the reliability of water conveyance capability within the Bridge River system. • Reduce the likelihood and magnitude of spills from Seton Lake Reservoir to Seton River and from Terzaghi Dam to Lower Bridge River, to minimize potential effects on fish, riparian habitat, and First Nations values. • Maintain BC Hydro's relationship with the St'at'imc Nation. • Reduce potential reputational impact due to high flow or spill events.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	To be determined as the project reaches Implementation Phase.

Additional Information: Some Generation P&C scope of work was not completed under Seton Upgrade Unit Protection & Control Project (GY0191) and the Seton Replace Governor Project (GM0075). This scope of work will be completed under this project.

Investment Planning ID: G004155	Project Name: Seven Mile - U1 - U3 Turbine Upgrade	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** F22 RRA: • Appendix E, page 13	

Description:

The purpose of this project is to improve the reliability of the Unit 1 to 3 turbines at the Seven Mile Generating Station.

Key Drivers:

- Reliability
- Financial

Issues Being Addressed:

The Unit 1 to 3 turbines are in Poor condition. These units have been in service for over 40 years without any major turbine overhaul or intervention. The main issues leading to a Poor Asset Health Rating include:

- Excessive runner crown and band seal erosion;
- Significant wear on the turbine shaft sleeve; and
- Runner cavitation requiring cavitation repairs every two years.

The efficiency of the units has also been reduced over time. The Unit 1 to 3 turbines weighted average efficiency was measured in 1984 at 91.0 per cent. This was lower than the original guaranteed weighted average efficiency of 92.7 per cent. It is expected that turbine efficiency has been further reduced since then, mainly because of changes in runner blade profile and runner seal erosion (seal clearance is larger than design).

Discussion of Alternatives:

BC Hydro is considering three alternatives:

i. **Do Nothing:** continue with cavitation weld repairs on turbine runners and routine inspections;

ii. **Overhaul turbines and associated components**: Restore/refurbish turbine components to “as new” condition to enable reliable operation for 25 years; and

iii. **Replace runners and overhaul turbine and associated components:** Includes overhaul scope (Alternative ii) as well as re-design and replacement of the runner and wicket gates to eliminate cavitation, achieve higher turbine efficiency and higher maximum capacity.

Project Impacts and Benefits:

- Improve reliability by resolving the runner seal erosion and runner cavitation issues.
- Reduce operations and maintenance costs by resolving the runner seal erosion and runner cavitation issues.
- Reduce the risk of turbine failure.

Description:

The primary purpose of this project is to provide deep reservoir drawdown capability at Strathcona Dam to mitigate dam safety risks associated with seismic events and seepage deficiencies of the dam, and to enable potential future projects to be undertaken to upgrade the dam itself if determined necessary. This capability will be provided via the selected alternative of constructing a Low Level Outlet (**LLO**) open channel on the dam's right abutment. As the LLO will include spillway functionality, the existing spillway gates will be converted to a free-crest overflow spillway that will improve the dam's ability to reliably pass high reservoir inflows.

Refer to Appendix K – Campbell River Systems Engineering Assessment for additional information.

Key Drivers:

- Safety
- Financial
- Reputational
- Environmental

Issues Being Addressed:

The Strathcona Dam is classified as an Extreme consequence category dam based on the BC Dam Safety Regulation. As such the expected seismic performance is for no uncontrolled release for the Maximum Design Earthquake with an annual exceedance frequency of once in 10,000 years. Strathcona Dam has seismic and seepage deficiencies and there is no means of enacting a deep reservoir drawdown in the event that these deficiencies manifest into damage that threatens the integrity of the

[1] Start Date of Construction is the Implementation Approval Date.

dam. Following an earthquake, there is a potential that the intake gates to the powerhouse water conduit that underlies the dam may not be able to be closed, pressurizing the conduit which may itself be damaged and lead to additional seepage through the dam. Also, there are reliability and seismic issues with the existing gated spillway that may limit its ability to operate on demand or cause it to fail following a seismic event, leading to uncontrolled release of water from the reservoir. Uncontrolled water release from the reservoir could create significant risk to life and damage to downstream residents, as water would flow downstream toward the City of Campbell River, potentially overtopping and damaging both Ladore and John Hart dams, as the Lower Campbell and John Hart reservoirs are not large enough to contain such a release. This type of event could potentially result in fatalities, financial loss and reputational damage. The provision of a new **LLO**, with a new inlet founded on a rock abutment rather than in the earth dam itself, will not only provide emergency deep drawdown of the reservoir, but will also facilitate future projects, if necessary, that would provide further safety improvements to the dam. The project scope also includes conversion of the existing gated spillway to a free-crest spillway at a higher elevation. This conversion will eliminate the need to refurbish the existing spillway gates and reinforce the existing spillway piers. Ordinary spillway functionality will be provided by sizing the LLO to allow current spillway volumes.
Discussion of Alternatives: BC Hydro considered four alternatives: i. **Construct a LLO and convert the existing spillway to a free overflow crest**; ii. **Build a seismically robust power system:** relocation of current power conduit; iii. **Rehabilitate existing dam**; and iv. **Construct a new downstream dam**. Alternative i, construct a LLO and convert the existing spillway to a free overflow crest, was selected as the preferred alternative. It provides dam safety risk reduction at the lowest cost and with the fastest delivery. The project team determined that the LLO should be the implemented first, to meet immediate dam safety needs and to enable potential future upgrades if deemed necessary to the power conduit (alternative ii) and the dam (alternative iii). Alternative iii is not feasible as a stand alone project due to the need for reservoir control during construction, but would be feasible after a new LLO is constructed. Alternative iv is not economically justified and would also require an operational LLO prior to its construction.
Project Impacts and Benefits: • Improve safety by providing a deep drawdown capability at the Strathcona Dam, so that the reservoir can be lowered and the dam unloaded in the event it suffers damage in a major earthquake or excessive seepage occurs. • Reduce potential for fatalities, financial loss and reputational impact due to an uncontrolled release of water from the reservoir in the event that the dam is damaged.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the IdentificationPhase, further developed in the Definition Phaseand finalized as the project reaches the Implementation Phase.	To be determined as the project reaches the Implementation Phase.

Additional Information: As the planning level estimate for this project is over $100 million, BC Hydro expects to submit an application to the BCUC under Section 44.2 of the Utilities Commission Act for this project. Planning is currently underway for upgrades at the downstream John Hart and Ladore facilities (John Hart Dam Seismic Upgrade Project, G000585; and Ladore Spillway Seismic Upgrade Project, G000668). Planning for these two projects is being considered in conjunction with the Strathcona Discharge Upgrade project for the following reasons:

- The projects are planned with similar and potentially overlapping construction schedules,
- The projects are relatively close geographically to one another,
- The projects have some similar scope elements that will require similar contractor expertise, and
- The projects all reside on the Campbell River and the work will need to be considered from a river system management perspective and coordinated accordingly.

Investment Planning ID: G000468	Project Name: Terzaghi - Low Level Discharge Reliability Improvement	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** F20-F21 RRA: • Appendix H, page 14	

Description:

The purpose of this project is to improve reliability and maintainability of the low-level reservoir discharge system at Terzaghi Dam so that it can be relied upon for environmental flow release, flood passage and post-earthquake operation.

Key Drivers:

- Reliability
- Environmental
- Safety

Issues Being Addressed:

The low-level outlet at Terzaghi Dam is comprised of two low-level discharge tunnels, each regulated by a downstream low-level operating gate 1 and 2 and provided with an upstream low-level maintenance gate 1 and 2. Reliable operation of the low-level operating gates is required on an ongoing basis. The low-level outlet is the primary means to provide targeted environmental flow releases downstream into the Lower Bridge River and is also required – along with the spillway – to pass the Probable Maximum Flood and for post-earthquake operation if drawdown of Carpenter Lake is required following the Maximum Design Earthquake.

The gates have failed to operate on several occasions. Subsequent troubleshooting has not been able to identify the cause. Personnel have not been able to safely access the low-level operating gates for several years as the low-level maintenance gates cannot be qualified to provide Single Device Isolation. Although a formal detailed assessment has not been conducted, the Terzaghi Dam low-level discharge system is known to have significant gaps from BC Hydro's Reliability Principles for Flood Discharge Gate Systems. In addition, post-earthquake operability of the low-level operating gates is not currently assured and is assumed to be inadequate.

Due to these design and reliability issues, there is a risk that the low-level outlet may not operate as required to regulate environmental flows into the Lower Bridge River, to pass high inflows during a flood event, or to provide reservoir drawdown capability following an earthquake.

Significant upgrades are required to improve the reliability, maintainability, and post-seismic operability of the low-level discharge system.

Discussion of Alternatives:

BC Hydro is considering two alternatives:

i. **Replace** components of the low-level discharge system: This may include a like-for-like replacement of the components at the existing location or a replacement with new equipment at a new location; and

ii. **Refurbish** components of the low-level discharge system in its existing location.

A combination of these alternatives may also be considered.

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits:	
• Improved operational reliability and maintainability of the Terzaghi Dam low-level discharge system for flood passage and for normal day-to-day environmental flow releases. • Provision of safe and reliable post-earthquake discharge and reservoir drawdown capability as required.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: N/A

<tr><td colspan="3">Description:
The purpose of the Various Sites – Reservoir Booms Replacement project is to address the poor condition and debris retention, and inadequate public safety features of existing reservoir booms at Mica, Terzaghi, Sugar Lake, Cheakamus, Stave Falls, Clowhom and W.A.C. Bennett Dams.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Risk reduction
• Operational Requirements
• Reputational</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The existing timber booms at the facilities noted above are past their intended service life, do not provide effective debris interception and retention, do not meet requirements under the Canadian Dam Association Guidelines for Public Safety, and may not have sufficient capacity to adequately protect spillways during design flow and debris conditions.
Historically, BC Hydro used booms made of timber to manage debris and to protect the public from areas of hazardous water conditions, such as near spillways and generating unit intakes. Timber booms degrade and lose freeboard (i.e., height above the waterline) over time and are prone to damage from strong winds, waves and shoreline topography.
BC Hydro developed a new steel boom after considering a variety of materials and designs and installed the first such boom at Kootenay Canal in 2018, and then at Seven Mile in 2019. The new design provides improved performance, safety features and expected asset life. This design also functions as a combined debris and public safety boom which eliminates the need for one of each at a site.
Following successful completion of those two sites, the Various Sites – Reservoir Booms Replacement project was initiated to deploy these new, more effective and longer lasting booms at other sites across the system. The project includes multiple sites to allow for efficiencies in design, procurement and construction.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
Replacement of reservoir booms was identified as a single viable alternative, based on the need for dam safety and to meet Canadian Dam Association Public Safety Guidelines. Doing nothing was not acceptable due to the condition of the existing booms, and alternative debris retention structures in reservoirs are not practical.</td></tr>
</table>

1 Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits:	
• Dam safety risks to water conveyance will be mitigated by preventing debris from impeding spillway gate operation through an enhanced design and resilience, and by replacing booms at end of life. • Public safety risks will be reduced by providing more prominent and robust barriers from areas of hazardous water conditions to boaters on the reservoir.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.

<tr><td colspan="3">Description:
The primary objective of the project is to address the dam safety risks posed by the deteriorating condition of the sluiceways and slide gates on the spillway of the W.A.C. Bennett Dam. The project will also replace the existing spillway stoplogs to allow isolation of the upstream face of the spillway and spillway gates.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Financial Loss
• Reputational</td></tr>
<tr><td colspan="3">Issues Being Addressed:
At the time the W.A.C. Bennett Dam was built the spillway, including the contribution from the sluiceways, was designed for flood inflows to the reservoir including those from the McGregor River Diversion. However, the McGregor River Diversion was not constructed, and is now prohibited under the Clean Energy Act. Without the McGregor River Diversion, the sluiceways are not needed to pass the Inflow Design Flood.
All nine slide gates have been inoperable since 1987 after issues with opening the gates and leakage after closure were experienced. Subsequent inspections revealed further deterioration of components of the slide gates.
The slide gate bonnet covers are in poor condition. Without remediation, there is a risk that one or more of the bonnet covers may fail, which would result in uncontrolled water release from the slide gate gallery to the drainage tunnels running below the earth filled dam. These drainage tunnels are not intended to handle such flows.
Leakage or failure of one or more of the slide gates would also result in uncontrolled water release to the</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

spillway chute, which may prevent inspection, repair and maintenance of the spillway chute.

Single device isolation certification of all nine slide gates is required to access the spillway chute for inspection and maintenance. Continued single device isolation certification will become more difficult and eventually will require refurbishment, replacement, or decommissioning of the slide gates.

Stoplogs are more generally required for maintenance and testing of spillway gates and other components, and the sluiceway construction planned for this project will require stoplogs to isolate the upstream face of the spillway from the reservoir. The existing stoplogs are in poor condition and do not provide adequate isolation to work behind. Moreover, recent tests have identified design deficiencies that make them prone to dislodging during installation and so unreliable for use. Therefore, the existing stoplogs cannot provide adequate isolation to complete the sluiceway construction work or future maintenance and testing of other spillway components.

Discussion of Alternatives:

BC Hydro considered three alternatives for the sluiceway:

i. **Do nothing:** the condition and leakage on the slide gates and bonnet covers would continue to be monitored. Decommissioning of the sluiceways or refurbishment (or replacement) of the slide gates and bonnet covers deferred into the future;

ii. **Decommission** nine sluiceways**.** The sluiceways will be plugged with reinforced concrete and the slide gate gallery would be partially filled with reinforced concrete, embedding the slide gate hydraulic cylinder assembly and bonnet covers; and

iii. **Rehabilitate** six sluiceways. This alternative recommissions two of the three sluiceways in each of the three spillway bays. The remaining sluiceways would be permanently decommissioned with a reinforced concrete plug upstream of the slide gate.

Alternative ii, decommissioning, was selected as the leading alternative because it addresses dam safety risks, minimizes lifecycle costs, and avoids future inspection and maintenance efforts. Alternative i was rejected because it does not address the dam safety issue of the deteriorating slide gate components. Alternative iii was rejected because of a lack of need for future sluiceway operation, constructability risks and future maintenance and testing requirements.

BC Hydro considered three alternatives for the stoplogs:

i. **Do Nothing**: defer replacement of the stoplogs to a future date. The stoplogs will not be able to be used for personnel protection of maintenance or capital works where isolation is required on the upstream face of the spillway;

ii. **Replace Stoplogs**: Replace the stoplogs with new semi-circular stoplogs with improved connection points and sealing; and

iii. **Remove Stoplogs and Replace with New Water Retention Structure**: Multiple alternative designs with either a traditional straight stoplog system similar to other facilities, or with a new structure upstream of the existing spillway headworks.

Alternative ii, replace stoplogs, was selected as the leading alternative because it will enable construction of the sluiceway seals as well as future maintenance and testing of other spillway components at the lowest lifecycle cost. Alternative i was rejected because the stoplogs are required to complete the sluiceway sealing work. Alternative iii was rejected because of cost and constructability issues associated with the major modifications necessary to create a traditional straight stoplog or the construction of a new structure upstream of the spillway.

Project Impacts and Benefits:

- Improve safety by addressing deteriorating condition of the sluiceways and slide gates.
- Reduce potential financial loss and reputational impact due to an uncontrolled release of water from the reservoir.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.
Additional Information: N/A	

Investment Planning ID: G003555	Project Name: W.A.C. Bennett Dam Seal Low Level Outlets	
Forecast Capital Cost: $53.1 million to $31.6 million	**Forecast In-Service Date:** Fiscal 2026	**Start Date of Construction:**[1] Fiscal 2023
Development Phase: Definition	**Filing Reference:** F17-F19 RRA: • Appendix I, line 24; • Appendix J, page 18, • BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1 F20-F21 RRA: • Chapter 6, page 6-89 • Appendix I, Generation - line 17, Appendix J, page 21, Appendix K, page 13 • BCUC IR 1.133.1 Confidential • BCUC IR 2.253.2, 2.253.3 • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-25	

Description:

The purpose of this project is to safely decommission the three low level outlets under the W.A.C. Bennett Dam to mitigate the hazard (uncontrolled water release from the reservoir) posed by long-term deterioration of the low-level outlets.

Key Drivers:

- Safety
- Financial Loss
- Reputational

Issues Being Addressed:

The W.A.C. Bennett Dam has been classified as an Extreme consequence dam based on the BC Dam Safety Regulation. Three Low Level Outlets (**LLOs**) are located beneath the embankment dam, in rock, in the diversion tunnels that were used to divert Peace River during dam construction. The inlets to the tunnels are located at a depth of about 160 m below the surface of the maximum normal operating level of Williston Reservoir. The LLOs were designed as temporary discharge devices for use during first filling and were not intended for use as discharge devices at normal reservoir operating levels. The LLOs are currently out-of-service and regular testing and inspections are not carried out due to worker safety concerns. The condition of these assets, almost 50-years old, is deteriorating, making them a potential hazard to the dam. An uncontrolled release of water due to component structural failures would eventually result in damage to the dam and to the potential uncontrolled release of water from the reservoir, with significant risk to life, financial loss, and reputational damage if the flow was not shut off. Such a release would be very difficult to curtail given the high head and depth of the LLOs.

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

BC Hydro considered four alternatives:

i. **Do Nothing:** maintain the status quo or deferral;

ii. **Refurbishment** of the existing LLOs for flow release as currently designed;

iii. **Re-purposing** the LLOs for reservoir evacuation capability or for installation of additional generating units; and

iv. **Decommissioning** (either permanently or with option to re-open the LLOs some time in the future).

Alternative iv was selected as the preferred alternative. Alternative i was rejected due to the age of the LLOs and their deteriorated condition which would eventually lead to a component failure and uncontrolled release of the reservoir behind an Extreme Consequence dam. Alternative ii was rejected because no future operating scenario was identified that warrants the refurbishment of the existing LLOs for flow release as currently designed. Alternative iii was rejected because, based on an engineering study, the technical feasibility of the re-purposing option is uncertain and near-term project drivers and/or benefits were not identified.

Project Impacts and Benefits:

- Reduce safety risks by decommissioning the LLOs.
- Reduce potential for fatalities, financial loss and reputational impact due to an uncontrolled release of water from Williston Reservoir.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

N/A

Investment Planning ID: G000334	Project Name: Wahleach Refurbish Generator	
Forecast Capital Cost: $51.2 million	**Forecast In-Service Date:** Fiscal 2023	**Start Date of Construction:**[1] Fiscal 2020
Development Phase: Implementation	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-95 • Appendix I, Generation - line 49, Appendix J, page 48, Appendix K, page 44 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-27 • Appendix E, page 14 • Appendix I, Generation - line 42 • Appendix Q, page 22	

Description:

The purpose of the project is to improve the reliability of the generator and extend the asset life by at least 40 years at the Wahleach (**WAH**) Generating Facility.

Key Drivers:

- Reliability
- Safety
- Reputational
- Environmental

Issues Being Addressed:

The Asset Health Rating for the WAH generator rotor and stator is Poor. Failure of the generator would result in an unplanned outage ranging from six to 24 months.

There is no water bypass at WAH Generating Facility, which means that if the generator is not operating the only means of evacuating water from the reservoir is by free spilling over the dam into Jones Creek. Large spills into Jones Creek may lead to erosion of the spillway channel and increases the risk of flooding the community of Laidlaw, with a risk to life, financial loss and reputational damage.

Discussion of Alternatives:

BC Hydro considered four alternatives:

i. **Do nothing**;

ii. **Rotor Pole Replacement:** Replace the rotor poles and retain the rotor spider and rim;

iii. **Generator Refurbishment:** Replace the stator and rotor poles and refurbish the remaining generator components; and

iv. **Generator Replacement:** Replace the entire generator.

Alternative iii, Generator Refurbishment, was selected as the preferred alternative because it is the most cost-effective solution based on a net present value analysis that will meet the project objectives and provide a generator life of at least 40 years. Alternative i was not selected given the deteriorated condition of the generator that will eventually lead to its failure and the possible safety, reputational and

[1] Start Date of Construction is the Implementation Approval Date.

environmental risks of spilling into Jones Creek. Alternative ii was not selected as it will not achieve the project benefit of extending the asset life by at least 40 years compared with Alternative iii. Alternative iv is not as cost-effective a solution as Generator Refurbishment in meeting the project objectives and achieving the project benefits.	
Project Impacts & Benefits: • Extend the generator life by at least 40 years.	
Project Implementation Phase Risk: Due to a generator outage extending longer than 100 days, there is a risk that flooding could occur into Jones Creek.	**Risk Treatment:** This risk will be treated by scheduling the unit outage to start in early February, which is a period of historically low inflows, to minimize spilling water and avoid potential flood damage downstream. Prior to the outage, the reservoir will be drawn down to a low level within the permissible operating range. Water flow passing technology will be piloted, if necessary, that will allow water to pass through the turbine pit while the generator installation continues; this will assist in managing the flood risk.
Additional Information: N/A

<tr><td colspan="3">Description:
The purpose of this project is to reduce the risk of failure of Waneta Unit 3 hydroelectric generator.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The primary issue being addressed is the condition of the stator winding and core. Inspections of Unit 3 stator have revealed a number of risks:
• Lamination migration – the steel laminations which form the generator stator core have come loose and are moving. This can result in physical damage to the stator winding or contact with the rotor which can result in an electrical fault;
• Loose wedges – the wedges which hold the stator winding in place in the stator core have come loose. This can result in physical damage to the stator winding which can result in an electrical fault;
• Core buckling – the steel laminations which form the generator stator core have come loose and can buckle. This can lead to physical or thermal damage to the stator laminations and winding which can result in an electrical fault; and
• Loss of circularity – the generator stator core can lose its circularity which can result in hotspots or vibrations which can lead to further damage or an electrical fault.
In addition, Unit 3 suffers from a number of issues which will be considered during this project;
• Runner cavitation – the runner experiences frequent cavitation resulting in extensive welding repairs;
• Runner cracking – extensive welding will lead to the build up of thermal stresses which, over time, can lead to cracking of the runner;
• Protection and Controls – the controls are original 1963 electromechanical relays. They are in Poor condition and contain asbestos wiring; and
• Governor controls – the existing Unit 3 governor is the original 1963 mechanical governor which has reached end of its design life. Parts and maintenance support are limited.</td></tr>
</table>

1 Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">

Discussion of Alternatives:

BC Hydro considered the following four alternatives:

i. **Do nothing:** Replace the stator winding, stator core at failure;

ii. **Re-wedge:** the stator winding;

iii. **Re-stack:** the stator; and

iv. **Replace:** the stator core and windings.

Alternative iv, replace the stator core and windings with a modern design, was chosen as the lead alternative as this is the only alternative that would address the root causes of the major defects reported with the stator.

In addition, the downtime required to address the stator yields the opportunity to replace other major components that are in poor condition and have reached end of life. These components include the runner, governor controls, unit transformer, wicket gates and protection and controls.

</td></tr>
<tr><td colspan="2">

Project Impacts and Benefits:

- Improved reliability of the generator.
- Reduced operating and maintenance costs of the generator.

</td></tr>
<tr><td>

Project Implementation Phase Risk:

- There is a risk of schedule delays due to COVID-19 shipping delays.
- There is also a risk of project cost increase due to commodity price increases (lumber and steel).

</td><td>

Risk Treatment:

- Logistics teams are booking transport as earlier as possible
- There is only a small portion of the scope with materials price exposure (switchgear mezzanine, temporary construction). Therefore, commodity price increase is expected to have a low impact.

</td></tr>
<tr><td colspan="2">

Additional Information:

On July 26, 2018, BC Hydro became the sole owner of Waneta. Teck Metals Ltd (**TML**) continues to act as the Operator of the facility during the 20-year lease term. In that role, Teck is required to operate, manage, and maintain Waneta in accordance with the terms of the Co-Possessors and Operating Agreement (**COPOA**), which includes capital planning and operating to a prudent owner standard, exercising the degree of care and skill of an experienced dam operator and acting in accordance with Good Utility Practice.

There are a number of projects that TML has agreed to complete as detailed in Schedule C of the COPOA, including this Unit 3 Life Extension project. As Operator at Waneta, TML will oversee the execution of the project and will provide regular updates to BC Hydro's Operating Committee representatives.

BC Hydro will retain an oversight role as part of the Waneta Operating Committee, including reviewing the annual operating plans for Waneta; however, as TML is the Operator of Waneta, processes that BC Hydro generally uses for internal asset management and planning purposes will not be applied.

• Appendix I, Transmission - line 59</td></tr>
<tr><td colspan="3">Description:
The purpose of this project is to address reliability and environmental risks associated with the poor asset health of 2L146 cable. A replaced cable will have higher capacity to serve Southern Vancouver Island load growth.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Environmental</td></tr>
<tr><td colspan="3">Issues Being Addressed:
Circuit 2L146 is a 230 kV direct buried oil-filled cable that runs 7.1 km between Horsey substation and Goward substation in Victoria. It has been in service since 1976 and has a history of leaks. The cable is in proximity to environmentally sensitive areas including fish habitat and salmon spawning grounds. Continued oil leaks could have ecological impact on such sensitive areas, and impact community-based restoration efforts targeted to improve the habitat value. In recent years, there have been at least seven leaks, including one which resulted in oil contaminating Colquitz Creek. Many of the joints were also gassing, thus requiring replacement; more replacements are expected to be required in the future.
In addition, 2L146 was identified as being at high risk for failure during an earthquake in a 2014 seismic review. Currently, the cable has an Asset Health Index score of Very Poor. Failure of this cable would mean that Goward, Horsey, or Esquimalt substations would be reliant on a single circuit and would be at risk of total station outages for six weeks to one year if a concurrent outage occurred on any one of the other circuits supplying this area (2L143, 2L144 or 2L145). This represents up to 375 MVA of load in the Victoria area at risk in the event of a concurrent outage on any of the other circuits.
Based on load forecasts for the Southern Vancouver Island region and a desire to prevent overloads on existing circuits, the existing 2L146 cable will not provide sufficient capacity to meet the local load following a single contingency event after fiscal 2030. This would result in load shedding in the Victoria area.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives: Three alternatives were evaluated: i. **Do nothing / deferral:** This option would defer the replacement of the cable for five years, which may lead to an ongoing risk of oil leaks and system risks, leading a reactive replacement; ii. **Replace:** Replace the existing cable with a new cable with the existing rating installed in a new duct bank to improve maintainability and mitigate seismic risks. Solid dielectric insulation would eliminate the use of oil and the risk of future oil leaks; and iii. **Upgrade: Same as the Replace alternative but with** a new cable capable of meeting load growth in the future. Alternative iii, Upgrade the cable, was selected as the Single Viable Alternative for the project that will meet expected future load growth. The increased risk of circuit failure under Alternative i would leave Horsey and other Victoria substations with diminished reliability for extended periods. Alternative ii does not address the overload issues expected in the future.
Project Impacts & Benefits: • Improve reliability associated with Very Poor asset health. • Reduce environmental risks associated with the 2L146 cable. • Ensure that future load growth can be met.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information: N/A

Investment Planning ID:	Project Name:	
94035	5L063 Telkwa Relocation	
Forecast Capital Cost: $66.4 million	**Forecast In-Service Date:** Fiscal 2024	**Start Date of Construction:**[1] Fiscal 2021
Development Phase: Implementation	**Filing Reference:** F17-F19 RRA: • Appendix I, line 45, • Appendix J, page 71 • BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1 F20-F21 RRA: • Chapter 6, page 6-117 • Appendix E, page 14 • Appendix I, Transmission - line 66, Appendix J, page 116 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-53 • Appendix I, Transmission - line 64	

Description:

The purpose of the project is to continue reliable transmission of electricity on 5L63 by relocating the line segment currently situated in an active landslide area.

Key Drivers:

- Safety
- Reliability

Issues Being Addressed:

Northwest British Columbia, including the communities of Prince Rupert, Terrace, Kitimat and Smithers are interconnected by a series of 500 kV transmission lines: 5L61, 5L62 and 5L63. Circuit 5L63, built in 1973 / 74 is a 500 kV radial transmission line between Telkwa substation and Skeena substation. As a radial feed, the reliability of this line is essential for this large region of the province.

The line crosses an unstable area of land, known as the “Bulbous Toe”, which has been slowly sliding for approximately 35 years and has caused a tower on the line to be displaced by 15 cm to 44 cm annually. BC Hydro has been monitoring this area, which is a large, deep slide approximately three km long and 1.5 km wide at its widest point and impacts approximately 1.4 km of the line. Over time, the tower has moved approximately eight meters placing increased stress on conductors and local structures. It is no longer possible to adjust guy wires and insulator strings to compensate for its movement resulting in flashover risk or catastrophic failure of the line. The continued movement of the tower is a safety concern for personnel who are performing maintenance on the system. There is potential for the slide to accelerate or release in a single catastrophic event involving hundreds of cubic meters of debris that would wipe out the tower and result in an extended outage.

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">Discussion of Alternatives:
BC Hydro considered four alternatives:
i. Do nothing and continue to maintain;
ii. Defer through risk mitigation;
iii. Do nothing but acquire spares and pre-plan an emergency response; and
iv. Relocate 5L63 away from landslide area.
Alternative iv, relocate 5L63 away from landslide area, was selected as the Single Viable Alternative to meet the project objectives. The other alternatives would not address the reliability risks and safety risks.</td></tr>
<tr><td colspan="2">Project Impacts and Benefits:
• Improve the reliability of 5L63 and the supply to the large region of the province that it serves.
• Address safety risks associated with the section of 5L63 in the “Bulbous Toe” landslide area.</td></tr>
<tr><td>Project Implementation Phase Risk:
Due to the unstable slopes and earth flows in the project area, there is a risk that towers on unstable soil may get displaced prior to the project in service date. This may result in a prolonged forced outage of 5L63.</td><td>Risk Treatment:
The treatment plan is to install dead end structures on either side of the Bulbous Toe landslide to prevent cascading failure of 5L63 and a longer outage should a landslide occur prior to the full relocation route being constructed.</td></tr>
<tr><td colspan="2">Additional Information:
BC Hydro is targeting completion of the project for September 2023 to accommodate customer load interconnection requirements.</td></tr>

<tr><td colspan="3">Description:
The purpose of this project is to replace the 12 kV Feeder Section 50/60 series, 230 kV and 12 kV protection and control equipment and telecommunication assets at Barnard Substation.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Safety</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Barnard substation 50/60 feeder section equipment, installed between 1950 and 1955, has reached end of life, resulting in increased reliability and safety risk. The Asset Health Index rating on the electrical equipment in the feeder section (e.g., bulk oil breakers and disconnect switches) is Very Poor. Failures may cause safety hazards and potentially long outages to impacted feeders. The design of the feeder section is obsolete and there are clearance issues associated with the equipment leading to increased safety risks. Maintenance work cannot be performed safely without significant time and expense to offload feeders.
The identified 230 kV and 12 kV protection and control and telecommunication equipment in the substation is over 50-years old and has reached end of life and needs replacement.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
BC Hydro considered two alternatives:
i. Replace Feeder Section 50/60 and replace aging protection, control and telecommunication equipment; and
ii. Do Nothing.
Alternative i, replace Feeder Section 50/60 and replace aging protection, control and telecommunication equipment, was selected as the preferred alternative. This was the Single Viable Alternative that met the project objectives of addressing the reliability risk of the end-of-life equipment and minimizing worker safety risks.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits: • Improved reliability for customers served through the Barnard Substation. • Improved worker safety.	
Project Implementation Phase Risk: Due to limited information on existing underground infrastructure, duct bank design may need to be modified during construction leading to increased cost and a potential schedule delay.	**Risk Treatment:** Perform underground surveys to verify the locations of the utilities, to the extent possible, before completing the design. Use methods such as hydro vacuuming ahead of excavation to verify locations and, if required, modify the design.
Additional Information: N/A	

Investment Planning ID: 900247	Project Name: Bridge River – T4 Transformer Replacement	
Forecast Capital Cost: $48.1 million to $27.7 million	**Forecast In-Service Date:** Fiscal 2023	**Start Date of Construction:**[1] Fiscal 2022
Development Phase: Definition	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-111 • Appendix I, Transmission - line 29, Appendix J, page 99 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-45 • Appendix I, Transmission - line 26	

Description:

The purpose of this project is to improve the reliability and environmental risks, associated with the T4 Transformers (**T4**) at Bridge River Terminal (**BRT**).

Key Drivers:

- Reliability
- Environmental

Issues Being Addressed:

At BRT, the T4 Phases A and B, as well as the spare at BRT substation are all approaching end of life. The Asset Health Index for Phases A and B are Poor. A significant failure of these phases could cause an extended reduction in the ability to transmit power from BRT.

T4 does not have oil spill containment or fire protection for any of the transformer phases, and therefore a catastrophic failure of T4 may result in an uncontrolled release of transformer oil into the environment. In the event of an unplanned outage of T4 there is a risk that generation would need to be curtailed from the Bridge River Generating Facility and Independent Power Producers connected to Upper Harrison Terminal. Curtailing generation may result in spilling water at Terzaghi Dam into Lower Bridge River that could affect fish and fish habitat.

Discussion of Alternatives:

BC Hydro considered four alternatives:

i. **Replace T4A with refurbished T4D, refurbish T4B, obtain a new phase T4D for use as a spare transformer**;

ii. **Replace T4A and T4B with new single-phase transformers, refurbish T4D for use as a spare transformer**;

iii. **Replace all three phases of T4 with a new three-phase transformer, obtain an additional new three-phase transformer as a spare**; and

iv. **Deferral of the project for a period of up to five years**.

Alternative ii "Replace T4A and T4B with new single-phase transformers, refurbish T4D for use as a spare transformer" was selected as the preferred alternative as it will address the project objectives of improving reliability and reducing the likelihood of high water levels at Terzaghi Dam during an unplanned outage. Compared to Alternative i, Alternative ii has lower constructability risk due to not refurbishing old equipment. Compared to Alternative iii, Alternative ii has lower constructability risk and less potential

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">archeological impact because it does not require deep foundations. Alternative iii also has higher transportation risk due to the size of the three-phase transformer. Alternative ii had slightly higher worker safety risk than Alternative iii; however, this risk can be mitigated with a robust worker safety plan. Environmental risks due to an unplanned outage were too great for BC Hydro to accept Alternative iv.</td></tr>
<tr><td colspan="2">Project Impacts and Benefits:
• Improved reliability of transformer T4 at BRT reduces the outage risk</td></tr>
<tr><td>Project Implementation Phase Risk:
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.</td><td>Risk Treatment:
To be determined as the project reaches Implementation Phase.</td></tr>
<tr><td colspan="2">Additional Information:

<tr><td colspan="3">Description:
The purpose of this project is to increase current-carrying capacity of the Bridge River Transmission System to address system constraints caused by increase in generation in the Bridge River area. In addition, the project will address asset health issues to improve the reliability and safety of the 2L90 circuit.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Environment
• Financial Loss
• Reputational</td></tr>
<tr><td colspan="3">Issues Being Addressed:
Generation from the Bridge River System[2] and several nearby IPPs[3] is transmitted through three regional transmission paths towards the Lower Mainland load centre. By 2022, approximately 400 MW of IPP generation is expected to be connected to the Bridge River Transmission System. While BC Hydro’s Bridge River 1 and 2 Generating Stations have been derated over the past decade, BC Hydro is now investing in these units to restore their capacity. Units 5 and 6 at the Bridge River 2 Generating Station were replaced in fiscal 2019 and fiscal 2020, respectively. Generating Units 7 and 8 at the Bridge River 2 Generating Station are being replaced in fiscal 2021 and fiscal 2022. The Bridge River 1 Project will replace Units 1 to 4 at the Bridge River 1 Generating Station. Collectively, these projects will restore the overall capacity of the Bridge River Facility to 532 MW.
During freshet and summer months when generation output is high and local load is low, the 2L90 circuit</td></tr>
</table>

1 Start Date of Construction is the Implementation Approval Date.

2 The Bridge River System consists of the La Joie Generating Station, Bridge River 1 and Bridge River 2 Generating Stations, and Seton Generating Station.

3 IPPs on these paths include: the Kwalsa projects, Upper Stave River, Northwest Stave River, Trethewy Creek, and Big Silver, all of which connect at the Upper Harrison Terminal; Rutherford Creek, Ashlu Creek, Fitzsimmons Creek, Upper Lillooet, and Boulder Creek, all of which connect along the Sea-to-Sky corridor; and Hunter Creek, which connects at Hope. Another IPP, Bremner Trio Hydro, is currently under construction and expected to connect to the Bridge River Transmission System at the Upper Harrison Terminal Station.

would become overloaded, and would cause the 2L90 circuit to exceed its thermal limits, potentially leading to overheating, thermal damage and unsafe clearances. These transmission constraints require generation curtailment in response to high ambient temperatures.

In addition, the 2L90 circuit also has asset health defects and issues that need to be addressed. Defects that are not addressed will eventually lead to line de-rating as well as electrical, structural and/or mechanical failures. This could result in unplanned outages, as well as worker and public safety risks.

Discussion of Alternatives:

BC Hydro considered three alternatives:

i. **Increase the capacity of the 2L90 Circuit including refurbishment of the 2L90 circuit**;

ii. **Increase the capacity of the T1 transformer at Rosedale (ROS) Substation** and refurbish and restore the 2L90 circuit; and

iii. **Curtail IPP generation** and refurbish and restore the 2L90 circuit.

Alternative i, increase the capacity of the 2L90 Circuit, was selected as the leading alternative because it has the lowest present value of lifecycle cost relative to the competing alternatives, and the incremental environmental and archaeological impacts are expected to be addressed through mitigation and avoidance measures developed throughout the Feasibility Design stage, informed through engagement with Indigenous communities.

Project Impacts and Benefits:

- Increase maximum capacity of the Bridge River Transmission System to meet the higher generation demands of the area.
- Reduce financial losses associated with generation curtailment.
- Maintain BC Hydro’s relationship with the St’at’imc Nation.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase	To be determined when the project reaches Implementation.

Additional Information:

In October 2020, the BCUC issued its decision on BC Hydro’s Fiscal 2020 to Fiscal 2021 Revenue Requirements Application. In Directive 29 of the Decision, it directed BC Hydro to file a joint CPCN for both the Bridge River 1 Units 1 to 4 Generator Replacement Project and the Bridge River Transmission Project. In accordance with this directive, BC Hydro will file a joint CPCN application in summer 2021.

<tr><td colspan="3">Description:
The purpose of this project is to improve the reliability and reduce the safety risks at Capilano substation.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Safety</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Capilano substation is over 60 years old and most of its major equipment is near end of life and needs immediate replacement. In particular, the 60 kV bulk-oil and 12 kV air-blast circuit breakers are obsolete and pose worker safety and reliability risks. The Asset Health Index of key equipment in the station such as the Protection and Control System, Instrument Transformers and Disconnect Switches is rated as Poor or Very Poor. In addition, the existing feeder section buildings do not meet current seismic standards and the equipment inside one of the buildings does not meet required safe electrical working clearances.
The new Capilano substation will provide 25 kV distribution voltage. The existing 12 kV substation will be decommissioned after the surrounding service area has been converted to 25 kV operation which is planned to align with the construction of the new substation.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

BC Hydro considered four alternatives:

i. **Do Nothing**;

ii. **Upgrade: upgrade the** existing Capilano substation;

iii. **Replace: replace the** Capilano substation on new property; and

iv. **Defer: defer the** project beyond fiscal 2022.

Alternative ii, upgrade the existing Capilano substation, was selected as the preferred alternative as it meets the project objectives. Alternative iii was not selected because it would be more costly and have schedule delay risks compared to Alternative ii because of the additional scope to find a new property and realign two transmission lines. Alternatives i and iv were not selected as doing nothing, or deferring, would not address the current rating of Poor or Very Poor for most of the substation equipment that is near the end of life.

Project Impacts and Benefits:

- Improved reliability for the North Vancouver area through addressing aging equipment concerns.
- Reduced worker safety risks caused by electrical working clearances and seismic issues.

Project Implementation Phase Risk:	**Risk Treatment:**
Due to possible opposition to the rebuild at Capilano substation by stakeholders, including local residents and the District of North Vancouver, as a result of a number of issues such as tree removal, perceived impacts to private property, access to local parks/trails, and the potential for increased noise and dust levels during construction, there is a risk of incurring project delays and increased costs.	This risk is treated through an enhanced stakeholder consultation and communication plan, involving project signage and regular scheduled meetings with the District of North Vancouver.

Additional Information:

N/A

Investment Planning ID: 92910	Project Name: Clayburn Substation Upgrade	
Forecast Capital Cost: $35.7 million	**Forecast In-Service Date:** Fiscal 2024	**Start Date of Construction:**[1] Fiscal 2021
Development Phase: Implementation	**Filing Reference:** F17-F19 RRA: • Appendix I, line 37 • BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1 F20-F21 RRA: • Chapter 6, page 6-104 • Appendix I, Transmission - line 14, Appendix J, page 91, Appendix K, page 46 and 51 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-40 • Appendix I, Transmission - line 13	

Description:

The purpose of this project is to upgrade the Clayburn (**CBN**) substation to reduce safety risks and increase the capacity from 180 MVA to 200 MVA, which serves the load in the Abbotsford area and enables the decommissioning of the Sumas Way (**SMW**) substation.

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

The Abbotsford area is currently supplied by the Mount Lehman (**MLE**), CBN, Gloucester, and SMW substations. At present, the total capacity of these four stations is 360 MVA. The general strategy for the area is to upgrade the MLE substation, upgrade and address safety issues at the CBN substation, and after the capacity upgrades, decommission the SMW substation.

At CBN substation, the existing 25 kV feeder sections are outdoor compact air insulated switchgear with inadequate clearances to energized equipment. These require extended outages for routine operation and maintenance. However, opportunities to take the required outages at CBN substation have been very limited due to the unacceptable impact on customers. As a result of the safety issues associated with performing work, coupled with the challenges with finding appropriate outage times, maintenance on the CBN substation feeder sections has been postponed indefinitely.

Upgrading the CBN substation to 200 MVA is required to enable decommissioning of the SMW substation. SMW has increased reliability risks due to degrading asset condition and has elevated safety risks due to the non-arc resistant metalclad design of the 25 kV feeder section.

Discussion of Alternatives:

This project was identified as a result of a 30-year study carried out for the Abbotsford area in 2013 to mitigate safety issues at SMW and CBN substations and address capacity shortage in the Abbotsford area. The area study resulted in three alternative solutions being identified and reviewed. The alternatives compared different implementation strategies to determine not only what should be done, but also the

[1] Start Date of Construction is the Implementation Approval Date.

timing.

BC Hydro considered three sets of alternatives for the Abbotsford area strategy:

i. Expand MLE in the First Phase;
Reinforce CBN in the Near Term and Expand in the Future; and
Decommission SMW in the Near Term.

ii. Expand MLE in the Future;
Reinforce CBN in the Near Term and Expand in the Future; and
Expand SMW in the First Phase and Replace Metalclad in the Near Term.

iii. Expand MLE in the Future;
Expand CBN in the Near Term; and
Decommission SMW in the Near Term.

Alternative i was accepted as the overall strategy as it was technically superior to Alternative iii, and more cost effective that Alternative ii. The MLE Substation upgrade to 150 MVA in the first phase will address the issues and meet the objectives of the overall Abbotsford area strategy. The MLE Substation upgrade is less expensive than the other alternatives, provides sufficient capacity to supply the area's needs for 6 years longer than the other alternatives, has the lowest transmission reinforcement costs and system losses, and facilitates the important migration of load from the constrained Fraser Valley 60kV systems to the more robust Fraser Valley 230kV systems.

To deliver this selected strategy three phases of upgrades and four major projects were advanced:

First Phase:

i. MLE Substation upgrade to 150 MVA;

Second Phase:

ii. CBN Substation upgrade to 200 MVA (this project);

iii. SMW Substation decommissioning; and

Third Phase:

iv. CBN Substation upgrade to 300 MVA.

The CBN Substation upgrade to 200 MVA project is the Single Viable Alternative that meets the objectives of the accepted overall strategy for the Abbotsford area.

Project Impacts & Benefits:

- Improved reliability in the Abbotsford area by increasing the capacity of CBN substation to 200 MVA.
- Improved safety at CBN substation.
- Increasing the capacity of MLE and CBN to service the Abbotsford area will facilitate the decommissioning of the SMW substation as this is the most cost-effective way to address the safety risks at this substation.

Project Implementation Phase Risk:	**Risk Treatment:**
Due to the need to work within an energized substation there is a risk of violating the limits of approach that could result in a worker injury or fatality.	To mitigate this risk, BC Hydro safe work procedures including emergency plans will be followed, including signage, training, flagging and isolation. Construction activities will be staged according to outages to ensure workers are completing tasks in de-energized areas. Safety watcher will be utilized, as required.

Additional Information:

N/A

Investment Planning ID: 900266	**Project Name:** East Vancouver - Substation Construction	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-102 • Appendix I, Transmission - line 7, Appendix J, page 79, Appendix K, page 54 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Appendix E, page 14 • BCUC IR 1.47.1 and 1.47.2 • CEC IR 1.39.2.1	

Description:

This project will build a new 230/12 kV – 25 kV, 400 MVA (ultimate capacity) station in the Eastside/Strathcona neighbourhood of Downtown Vancouver as part of the second stage of the 30-year Downtown Vancouver Electricity Supply Plan.

Key Drivers:

- Reliability

Issues Being Addressed:

The Downtown Vancouver area is comprised of the Downtown, West End, Strathcona, and Grandview-Woodland neighbourhoods. The area is supplied by a 230 kV and 69 kV transmission network and three substations:

- Cathedral Square substation (built in 1984);
- Dal Grauer substation (built in 1953); and
- Murrin substation (built in 1947).

There are number of risks and issues at the ageing Dal Grauer and Murrin substations. More than half of the assets are expected to degrade to an Asset Health of Poor or Very Poor in the next 10 to 20 years, presenting a reliability risk. Murrin substation is on seismically unstable soil. Approximately half of the 230 kV switchyard, which supplies both Murrin and Dal Grauer loads, is vulnerable to severe earthquake damage from liquefaction and settlement.

The long-term strategy for the area is to mitigate the above reliability and safety risks by replacing Murrin and Dal Grauer substations with new substations. One of these is the new East Vancouver Substation.

Discussion of Alternatives:

The ultimate capacity of the East Vancouver substation will be 400 MVA, located in the Strathcona neighbourhood of Vancouver. The project will consider different options for the initial size of the substation when it is first constructed, given that the 400 MVA capacity will not be required immediately.

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits:	
• Improve East side/Strathcona Vancouver area reliability. • Minimize worker safety risks in the area.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.

Description:

The substations on the Gulf Islands, Saltspring (**SAL**) Substation and Galiano (**GLS**) Substation, are supplied from Arnott (**ARN**) Substation on the mainland and the Vancouver Island Terminal (**VIT**) on Vancouver Island by circuit 1L18. In service since 1958, 1L18 is a hybrid circuit of overhead lines and submarine cables.

The 1L18 cables that lie in the Georgia Strait and Trincomali Channel are approaching end-of-life with inspections identifying major concerns, resulting in the cables being assigned a Poor asset health rating with a high risk of mechanical failure. Failure of these cables will compromise energy reliability, resulting in extended outages to the Gulf Islands. Repair of the aging cables after a failure would be a significant unplanned sustainment cost, and would be of limited value since the repair would be at best temporary and depending on the mode of failure the repair could be potentially not possible, forcing an emergency cable replacement project. BC Hydro is proposing to reinforce the transmission supply to the Gulf Islands to mitigate for the 1L18 cable end-of-life condition and reduce the reliability risk in the event of a 1L18 failure.

Key Drivers:

- Reliability

Issues Being Addressed:

The most recent inspections of 1L18 show severe damage to its armor at key locations in the Georgia Strait at points where tidal currents cause the cable to rub against the rocky seabed. In this state, the cables are at a high risk of mechanical failure (causing an outage, and environmental risk from oil leaks). Further, the circuit is also expected to fail if a moderate earthquake were to occur in these locations. If the cables fail, the energy supply to the Gulf Islands will be compromised and extended outages are expected as secondary services are currently insufficient.

The desired outcome of the project is to continue to supply the load in the Gulf Islands with improved levels of reliability and mitigate seismic risk to the Gulf Islands energy supply.

[1] Start Date of Construction is the Implementation Approval Date.

Page 1 of 2

Discussion of Alternatives:

BC Hydro is considering two alternatives:

i. **Tap 2L129 in the Gulf Islands:** This alternative involves constructing a tap from 2L129 into SAL substation and provides a second supply in the event 1L18 fails. This will require the upgrade of the station to 230 kV, including the installation of a new transformer and breaker. In addition, a shunt capacitor and thermal upgrades on Vancouver Island will be needed due to the increased energy flows and power factor correction in the system. This will address the immediate supply concern with the 1L18 cable condition and reliability but defer addressing the eventual replacement of the 1L18 cables to a future project that will address load growth on Vancouver Island; and

ii. **Construct Additional 138 kV overhead line from VIT to SAL:** This alternative will construct a new 138 kV overhead transmission line (about 16 km in length) using existing rights of way from VIT to SAL substation, in order to provide a second supply to SAL substation. Similar to Alternative i, this will require a new line position, and the installation of a shunt capacitor and thermal upgrades at VIT.

Project Impacts and Benefits:

- Improved energy reliability to Gulf Island communities as 1L18 approaches end-of-life.
- Mitigate the risk of 1L18 failure as there will be a secondary energy path to supply the Gulf Islands.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

Eventual replacement of the 1L18 cables will be deferred to a future project to address supply to Vancouver Island.

Investment Planning ID: 900268	Project Name: Horne Payne - Feeder Section Addition	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** New	

Description:

This project will add a new 50 MVA, 25 kV gas insulated feeder section to the existing 25 kV gas insulated feeder section building at Horne Payne substation.

Key Drivers:

- Reliability

Issues Being Addressed:

The 12 kV feeder section at Lougheed and the 12 kV, 50/60 series feeder section at Horne Payne are aging and approaching end of life presenting a reliability risk. As these assets reach end of life they are being decommissioned, and the load transferred to the existing 25 kV gas insulated feeder section building at Horne Payne. These load transfers, along with natural load growth in the area, are driving the need for additional feeder section capacity in the 25 kV switchyard at Horne Payne.

Discussion of Alternatives:

BC Hydro is considering two alternatives:

i. **Add a 25 kV gas insulated feeder section:** Add 6 feeder positions in the existing gas insulated feeder section building at Horne Payne. This alternative addresses the reliability risk associated with end-of-life equipment and the station exceeding capacity as well as the long-term plan to convert area distribution system to 25 kV; and

ii. **Do nothing:** this alternative does not address the issues identified above.

Project Impacts and Benefits:

- Improve North Burnaby area reliability.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

N/A

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: 93731	Project Name: Jordan River – Switchyard Upgrade	
Forecast Capital Cost: $43.6 million	**Forecast In-Service Date:** Fiscal 2023	**Start Date of Construction:**[1] Fiscal 2020
Development Phase: Implementation	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-111 • Appendix I, Transmission - line 31, Appendix J, page 101 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-45 • Appendix I, Transmission - line 23	

Description:

The purpose of the project is to reconfigure and replace aging equipment at the Jordan River (**JOR**) switchyard to address reliability, safety, environmental, and seismic deficiencies.

Key Drivers:

- Reliability
- Safety
- Environmental

Issues Being Addressed:

The JOR switchyard is 50 years old and the majority of its equipment is nearing end-of-life. The switchyard does not meet current safety, environmental and seismic standards. In particular, transformers Transformer 1 (**T1**) and Transformer 2 (**T2**) have numerous deficiencies, including the lack of monitoring gauges, lack of effective cooling, leaking bushings and significant oil leakage with no oil containment. T2 is being closely monitored due to elevated levels of combustible gasses which caused an outage in 2015. T1 and T2 are unique transformers with no system spare. In addition, the present layout of the switchyard is deficient as there is insufficient clearance between major equipment which increases safety and reliability risks.

Discussion of Alternatives:

BC Hydro considered five alternatives:

i. **Like for like replacement** of end of life equipment (not viable);

ii. **Transformer replacement with separate distribution** transformers (not viable);

iii. **Transformer replacement and switchyard expansion**;

iv. **Single-phase step-up transformers**; and

v. **Transformer replacement and switchyard expansion and new pad mount distribution transformers.** The two step-up transformers will be replaced, and a portion of the switchyard will be rebuilt. Distribution voltage connection would be through two new pad mounted transformers.

Alternative v, Transformer replacement and switchyard expansion and new pad mount distribution transformers, was selected as the leading alternative because it was the lowest cost viable alternative that addressed the reliability and safety risks. Alternative i was not selected because it does not meet current safety requirements and does not mitigate reliability risk of equipment and requires an

[1] Start Date of Construction is the Implementation Approval Date.

extended outage during construction. Alternative ii is not viable because there is insufficient physical space to install two new separate distribution transformers. Alternative iii and iv were not selected as both required the need to relocate 138 kV transmission lines and were more expensive without providing greater benefits compared to Alternative v.	
Project Impacts and Benefits: • Reduced environmental risk by installing oil containment for the new T1 and T2 transformers. • Improved reliability of the overall switchyard by replacement and reconfiguration of major equipment. • Reduced worker safety risk though improved access for operation and maintenance.	
Project Implementation Phase Risk: Due to the unknown soil conditions beneath existing T1 and T2, there is an increased likelihood of encountering contaminated soil which could delay the schedule and increase the cost for clean-up.	**Risk Treatment:** The treatment plan is to ensure project contingency includes additional disposal costs for contaminated soil and ensure that the schedule has sufficient float for additional excavation to remove the contaminated soil.
Additional Information: N/A	

Investment Planning ID: 93705	Project Name: Kidd1 – 60 kV Renovation, 4 kV Decommission & Control Room	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-111 • Appendix I, Transmission - line 32 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-32 • Appendix I, Transmission - line 27	

Description:

The purpose of the project is to upgrade the equipment to ensure safe and reliable operation at the Kidd1 Substation.

Key Drivers:

- Reliability
- Safety
- Environmental

Issues Being Addressed:

Originally built in 1951, the Kidd1 Substation is a transmission and 100 MVA distribution substation that supplies over 20,000 customers in the Vancouver South area. There are reliability risks with eleven of the twelve 60 kV circuit breakers, 4 kV transformers and much of the equipment in the feeder section that have an Asset Health Index rating of Poor and are nearing end-of-life. The end-of-life conditions are confirmed by repeated failure of the equipment, engineering analysis, lack of parts and support from the original equipment manufacturer, and the high cost of maintenance and repair. There are safety risks due to the probability of a catastrophic failure of the equipment.

In addition, the main control building is in very poor condition as it has a leaking roof, contains asbestos and is seismically deficient. Approximately 40 per cent of the Protection and Control relays and panels in the control building have an Asset Health Index rating of poor. Additionally, approximately 70 per cent of the Protection and Control relays are the older, mechanical type relays from the original installation, and are obsolete and no longer supported by the manufacturer.

Some equipment contains Polychlorinated Biphenyl (**PCB**) contaminated oil. Current Federal PCB Regulations require phase out of electrical equipment containing PCB levels of 50 ppm or more by 2025.

Discussion of Alternatives:

BC Hydro is considering four alternatives:

i. **Replace the 60 kV bulk oil circuit breakers with new dead tank breakers in the existing 60 kV lattice structure**;
ii. **Replace the 60 kV equipment in place and retrofit the existing 60 kV lattice structure and supporting foundations to resist seismic loads**;
iii. **Build a new compact structure 60 kV switchyard:** The new switchyard would be located in the old 4 kV switchyard which is being decommissioned. The foundation and the overlaying structures would

[1] Start Date of Construction is the Implementation Approval Date.

be designed to withstand earthquakes with the present BC Hydro standards; and iv. **Build a new low profile 60 kV switchyard:** The new switchyard to be located in the old 4 kV switchyard which is being decommissioned. The foundation and the overlaying structures would be designed to withstand the earthquakes with the present BC Hydro standards. All alternatives include replacing the 60 kV circuit breakers, decommissioning the 4 kV switchyard, and relocating the 60 kV control room onto the third floor of the Gas Insulated Switchgear building. The project has not yet completed an evaluation of the alternatives.
Project Impacts and Benefits: • Improved reliability from end-of-life equipment. • Removed safety risk from the catastrophic failure of end-of-life equipment. • Removed environmental risk from possible oil leaks from end-of-life equipment. • Removed equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	To be determined as the project reaches Implementation Phase.

Additional Information: N/A

• Appendix I, Transmission - line 33</td></tr>
</table>

Description:

The purpose of this project is to replace the Kimberly (**KBY**) substation with an expansion of the Marysville (**MVL**) substation which will improve the safety and reliability of the substation to service the load of a key account industrial customer.

Key Drivers:

- Reliability
- Safety
- Environmental

Issues Being Addressed:

The KBY substation was built on leased land in 1968 and the structural poles, relays, switches, circuit breakers and controls have an Asset Health Index rating of Poor or Very Poor and are nearing their end-of-life. There is a risk of catastrophic failure (i.e., an explosion and fire) of the equipment that poses a safety hazard to workers. Additionally, the circuit breakers contain Polychlorinated Biphenyl contaminated oil that are a worker health hazard and a risk to the environment if it leaks from the end-of-life equipment. The new switchyard will be built on property owned by BC Hydro by expanding our existing MVL substation.

Discussion of Alternatives:

BC Hydro considered three alternatives:

i. **Do Nothing**;

ii. **Rebuild in place:** replaces the equipment in place but requires lease or procurement of adjacent land from the industrial customer; and

iii. **Rebuild in a new location at Marysville:** replaces the equipment on BC Hydro owned land adjacent to our existing MVL substation. No new lines are required.

Alternative iii, rebuild in a new location at Marysville is the Single Viable Alternative that addresses all of the project objectives and is more cost-effective than Alternative ii.

Alternative i does not address the risks at the KBY substation.

Alternative ii is a higher cost option with a longer schedule and compared to Alternative iii would require land lease or purchase from the industrial customer adjacent to KBY to execute the rebuild in place, would be difficult to perform some sustainment work at KBY, and has a risk of ground contamination at the site.

Project Impacts and Benefits:

- Improved reliability with new equipment having a 50-year service life.
- Removed safety risks by decommissioning the KBY substation.
- Removed environmental risks by decommissioning old equipment that could leak Polychlorinated Biphenyl.

Project Implementation Phase Risk: Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	Risk Treatment: To be determined as the project reaches Implementation Phase.

<tr><td colspan="3">Description:
The purpose of the project is to eliminate the safety hazard to the public and workers posed by the end-of-life conductor on the Jervis inlet and Agamemnon channel crossings and improve the thermal capacity of the circuit at these locations to match the other sections of the circuits.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
1L37 was constructed in 1966/67 and runs from Malaspina to Saltery Bay, serves communities on the Sunshine Coast, and provides tie-ins for several Independent Power Producers in the area. There are two major water crossings, one over the Agamemnon Channel and a second across Jervis Inlet. The Jervis Inlet crossing spans approximately 3.1 km and is the longest overhead crossing in the BC Hydro system.
An inspection of the Jervis inlet and Agamemnon channel water crossings for the circuit was conducted in 2015. The inspection identified that both the Jervis Inlet and Agamemnon Channel crossings have become hazards due to corrosion of the conductor and are no longer feasible to safely operate regularly, and the conductor has been de-rated. The circuit is operational only in case of emergency with very limited load.
The condition of the parallel crossing of 2L48 will be addressed in a future project. As part of this project, the security of supply to the Powell River area is also being considered, including the transmission performance planning criteria for elements of the transmission system that could take longer than one year to repair. As part of the analysis, the ability to use a replacement 1L37 crossing as a backup crossing for 2L48 will be considered.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
BC Hydro is considering three alternatives:
i. Re-Conductor and Refurbish structures: Refurbish the existing structures and their foundations and install new conductor on the crossings on 1L37;
ii. Re-Conductor with new structures: Design and build new structures and foundations and install new conductor on the crossings on 1L37; and
iii. Removal of Crossing spans: Remove the conductor from the crossing spans and remove the associated structures which will return the Powell River area to service by a single radial line.
The project is currently evaluating the alternatives.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits:	
• Address the safety risk by removing the end-of-life conductor on the Jervis inlet and Agamemnon channel crossings.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	**Risk Treatment:** To be determined as the project reaches Implementation Phase.

<tr><td colspan="3">Description:
The purpose of this project is to supply sufficient reactive power compensation in the Lower Mainland transmission system to provide voltage support and control to the Lower Mainland transmission system, and to address the Fraser Valley voltage stability constraints.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The four Burrard Synchronous Condenser units are reaching end-of-life, and the Equipment Health Rating of the equipment is either Poor or Unsatisfactory. The units are expected to experience reliability issues within the short to medium term. Each of the four units is rated as -50 Mega Volt Amps reactive (MVAr) / +100 MVAr and provide capacitive and reactive power to the Lower Mainland transmission system, which allows voltage control and prevents voltage instability during peak load periods.
In addition, the 2016 transmission planning Mandatory Reliability Standard assessment of the Fraser Valley transmission system identified voltage stability constraints caused by additional reactive power losses within the 10-year planning horizon that will need to be reinforced. The voltage instability would result in voltage collapse and subsequent load loss in the Fraser Valley.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

BC Hydro is considering three alternatives:

i. **Install 230 kV Shunt Capacitor and Shunt Reactor Compensation:** A total of 750 MVAr of capacitive power compensation and a total of 200 MVAr of shunt reactive power compensation would be installed in the Lower Mainland at 230 kV;

ii. **Install 500 kV and 230 kV Shunt Capacitor and Shunt Reactor Compensation:** A total of 750 MVAr of capacitive power compensation would be installed in the Lower Mainland: 250 MVAr at 500 kV, and 500 MVAr at 230 kV. A total of 200 MVAr shunt reactive power compensation would be installed in the Lower Mainland at 230 kV; and

iii. **Restore Burrard Synchronous Condenser Capability and Install Shunt Capacitor Compensation:** Burrard Synchronous Condenser reactive power function would be restored and 500 MVAr of capacitive power compensation would be installed in the Fraser Valley at 230 kV.

The project has not yet completed an evaluation of the alternatives.

Project Impacts and Benefits:

- Maintain BC Hydro's Lower Mainland bulk transmission system reliability during heavy winter load periods under single contingency conditions.
- Reduce the likelihood of cascading outages to the rest of the Western Electricity Coordinating Council regional system.
- Secure regional Fraser Valley transmission system reliability by compensating for Volt Amp reactive (VAr) losses during heavy winter load periods under single contingency conditions.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	To be determined as the project reaches Implementation Phase.

<tr><td colspan="3">Description:
The purpose of this project is to improve the reliability, safety and environmental risks at the Mainwaring (MAN) substation.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Safety
• Environmental</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Issues Being Addressed: The MAN substation transformers T1 and T3 have been in service for 60 years, and are nearing their end-of-life, resulting in increasing reliability and safety risks. T3 has an Asset Health Index rating of Poor. T1 has an Asset Health Index rating of Satisfactory but must be regularly maintained as it is leaking oil. Both transformers have no on-load tap changers resulting in the need for 40 voltage regulators on the feeder positions. The voltage regulators also have an Asset Health Index rating of Poor. The majority of the feeder sections have an Asset Health Index rating of Poor, and are nearing their end-of-life, resulting in increasing reliability risks. The existing feeder section also has clearance issues that poses a safety risk for workers. Many of the circuit breakers and voltage regulators contain Polychlorinated Biphenyl (**PCB**) contaminated oil. Current Federal PCB Regulations require the phase out of electrical equipment containing PCB levels of 50 ppm or more by 2025.	
Discussion of Alternatives: For the power transformers T1 and T3 portion of the scope, replacing the transformers with new units was selected as the preferred alternative as this was the only alternative that met the project objectives of addressing the reliability risk of the aging equipment. For the 50/60 Series Feeder Section portion of the scope, BC Hydro considered three alternatives: i. **Refurbish** the existing 50/60 series feeder section; ii. **Replace** the existing 50/60 series feeder section with a new indoor Gas Insulated (**GIS**) feeder section; and iii. **Replace part of** the existing 50/60 series feeder section with a new GIS feeder section, refurbish the remainder. Alternate ii, Replace the existing 50/60 series feeder section with a new indoor GIS feeder section, was selected as the preferred alternative because it would eliminate the existing safety hazards and seismic risks and would include provisions to add seven more feeders to serve future growth, for a reasonable cost relative to the other viable alternatives.	
Project Impacts and Benefits: • Improve reliability of the aging equipment. • Reduce worker safety risks by extending and upgrading the substation. • Removed equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	**Risk Treatment:** To be determined as the project reaches Implementation Phase.
Additional Information: Although the project forecasts a cost to be less than $100 million (Capital Filing Guidelines application expenditure threshold for Power System projects), in Directive 3 of the BCUC's Decision on the Fiscal 2017 to Fiscal 2019 Revenue Requirements Application, the BCUC stated that the Mainwaring Substation Upgrade project could have potentially significant public interest issues and directed BC Hydro to file a CPCN.	

Investment Planning ID: 901613	Project Name: Maple Ridge - Feeder Section 60 Series Refurbishment	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** F22 RRA: • Chapter 6, page 6-45 • Appendix I, Transmission - line 34	

Description:

This project will address reliability risks associated with the end-of-life equipment of the Maple Ridge (**MRG**) substation, as well as inadequate feeder section electrical clearances and seismic risks.

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

The MRG substation is a 69/25 kV distribution station serving the City of Maple Ridge. This station supplies approximately 70 MVA of load. The MRG substation feeder section (60 Series) was originally built in the 1950s at 12 kV and later upgraded in the 1970s to 25 kV. As a result, the electrical clearance to ground is less than typical for a 25 kV feeder section and does not meet the current engineering standards. The concrete block retaining wall that supports the feeder section and the lattice-type steel structure in the feeder section were not designed to withstand a major seismic event. The electro-mechanical Protection and Control relays are obsolete and there is not adequate space in the building to carry out any Protection and Control equipment upgrades. The condition of oil circuit breakers and disconnect switches on the feeder section 60 series have reached end of life. The original equipment manufacturers have discontinued parts and technical support. One of the bulk oil circuit breakers needs to be removed due to its polychlorinated biphenyl content by 2025 to meet the federal regulation.

Discussion of Alternatives:

BC Hydro is considering two alternatives:

i. **Replace the feeder section with a GIS feeder section with control room in the same building:** This alternative will replace the feeder section, replace the end-of-life assets and remove the seismic risk of the concrete retaining wall; and

ii. **Do nothing:** this alternative does not address the issues identified above.

Project Impacts and Benefits:

- Maintain reliability in the area served by the MRG substation.
- Address safety concerns at the MRG substation.
- Address seismic concerns at the MRG substation.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

N/A

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: 92907	Project Name: Mount Lehman Substation Upgrade	
Forecast Capital Cost: $59.1 million	**Forecast In-Service Date:** Fiscal 2023	**Start Date of Construction:**[1] Fiscal 2020
Development Phase: Implementation	**Filing Reference:** F2014 Annual Report to the BCUC: • Appendix I, line 116; • Appendix J, page 61. F17-F19 RRA: • Appendix I, line 33, Appendix J, page 61, • BCUC IRs 1.70.3, 2.249.8, 2.254.1.1, 2.260.4, BCOAPO IR 1.36.1 F20-F21 RRA: • Chapter 6, page 6-104 • Appendix H, page 14 • Appendix I, Transmission - line 13, Appendix J, page 89, Appendix K, page 46 and page 51 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 • CEC IR 3.104.1 and 4.22.1 F22 RRA: • Chapter 6, page 6-34 and 6-40 • Appendix E, page 14 • Appendix I, Transmission - line 12 • Appendix Q, page 23	

Description:

The purpose of this project is to upgrade the Mount Lehman (**MLE**) substation to increase the capacity from 100 MVA to 150 MVA, which serves the load in the Abbotsford area and enables decommissioning of the Sumas Way (**SMW**) substation.

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

The Abbotsford area is currently supplied by the MLE, Clayburn (**CBN**), Gloucester, and SMW substations. At present, the total capacity of these four stations is 360 MVA. The general strategy for the area is to upgrade the MLE substation, upgrade and address safety issues at the CBN substation, and after the capacity upgrades, decommission the SMW substation.

MLE is a 230/25 kV substation and was placed in service in 2007, with a total transformation capacity of 100 MVA. Upgrading the MLE substation to 150 MVA is required to enable decommissioning of the SMW substation. SMW substation has increased reliability risks due to degrading asset condition and has elevated safety risks due to the non-arc resistant metalclad design of the 25 kV feeder section. The expansion of MLE substation will also enable safety improvements to be undertaken at CBN substation

[1] Start Date of Construction is the Implementation Approval Date.

and ensure that load in the Abbotsford area continues to be served over time.
Discussion of Alternatives: This project was identified as a result of a 30-year study carried out for the Abbotsford area in 2013 to mitigate safety issues at SMW and CBN substations and address capacity shortage in the Abbotsford area. The area study resulted in three alternative solutions being identified and reviewed. The alternative comparison was a comparison of different implementation strategies to determine not only what should be done, but also their timing. BC Hydro considered three sets of alternatives: i. Expand MLE in the First Phase' Reinforce CBN in the Near Term and Expand in the Future; and Decommission SMW in the Near Term. ii. Expand MLE in the Future; Reinforce CBN in the Near Term and Expand in the Future; and Expand SMW in the First Phase and Replace Metalclad in the Near Term. iii. Expand MLE in the Future; Expand CBN in the Near Term; and Decommission SMW in the Near Term. Alternative i was accepted as the overall strategy as it was technically superior to Alternative iii, and more cost effective that Alternative ii. The strategy includes four projects over three phases. The MLE Substation upgrade to 150 MVA in the first phase will address the issues and meet the objectives of the overall Abbotsford area strategy. The MLE Substation upgrade is less expensive than the other alternatives, provides sufficient capacity to supply the area's needs for 6 years longer than the other alternatives, has the lowest transmission reinforcement costs and system losses, and facilitates the important migration of load from the constrained Fraser Valley 60kV systems to the more robust Fraser Valley 230 kV systems. First Phase: i. MLE Substation upgrade to 150 MVA (this project); Second Phase: ii. CBN Substation upgrade to 200 MVA; iii. SMW Substation decommissioning; and Third Phase: iv. CBN Substation upgrade to 300 MVA. This project is the MLE Substation Upgrade (first phase) and is the only alternative to deliver the overall Abbotsford area strategy, as discussed in Alternative i above.
Project Impacts and Benefits: • Increase capacity in the Abbotsford area to ensure that BC Hydro can continue to reliably meet the needs of existing and future customers for at least the next 10 years. • Enable safety improvements and a capacity increase at CBN substation. • Increasing the capacity of MLE and CBN to service the Abbotsford area will facilitate the decommissioning of the SMW substation as this is the most cost-effective way to address the safety risks at this substation.

Project Implementation Phase Risk:	**Risk Treatment:**
Schedule delay risk if an outage is not available when needed for completion of construction.	There is float in the schedule and dialogue is ongoing with Fraser Valley Operations to confirm the outage date.

1 Forecast Capital Cost was $40.1 million at December 31, 2018.
2 The new expected In-Service Date is fiscal 2022 based on the scope change described in the Description section.

Project Impacts and Benefits: • Meet compliance requirements of version 5 of the CIP MRS. • Improve overall cyber security of Bulk Electric System Cyber Assets. • Mitigate risk of financial penalties for non-compliance.	
Project Implementation Phase Risk: The ongoing Transmission Stations element currently does not have any identified Zone 3 (high) Implementation Phase risks.	**Risk Treatment:** N/A
Additional Information: N/A	

Investment Planning ID: 92479	Project Name: Newell Substation Upgrade	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-111 • Appendix I, Transmission - line 35, Appendix K, page 51 and 61 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: Under $5M Project Estimate	

Description:

The purpose of this project is to improve the safety, environmental and reliability issues at Newell substation.

Key Drivers:

- Reliability
- Safety
- Environmental

Issues Being Addressed:

The Newell Substation has reliability risks with the transformer T1 and some equipment in the 50/60 series feeder section that were installed in the 1950s, have an Asset Health Index rating or Poor or Very Poor, and are nearing end-of-life. The lattice type steel structure of the feeder section was also built in the 1950s and it was not designed to withstand a major seismic event.

There are also safety risks due to insufficient electrical clearances in the feeder section. The feeder section was built for 4 kV in the 1950s and bus to finished grade electrical clearances do not meet the current engineering standards. In the feeder section, the bulk oil circuit breakers are the same type that have failed catastrophically in recent years in some other substations.

There are environmental risks due to polychlorinated biphenyls, which are below 43 ppm, in the bulk oil circuit breakers. End-of-life oil-filled equipment has high risks of oil leak due to deterioration of the seals.

Discussion of Alternatives:

BC Hydro is considering two alternatives:

i. **Replace Feeder Section 50/60 Series and Remove Transformer T1**: This involves transferring 14 existing feeders to a new Gas Insulated Switchgear feeder section, retrofitting 4 existing feeder positions and removing transformer T1 and associated protection and control equipment; and

ii. **Retrofit 50/60 Feeder Section and Remove Transformer T1**: This involves retrofitting the equipment by replacing end-of-life components of the equipment, and similar to Alternative i, removing transformer T1 and associated protection and control equipment.

The preferred alternative has not yet been determined.

Project Impacts and Benefits:

- Reduce reliability, environmental and safety risks by extending and upgrading the substation.

1 Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	To be determined as the project reaches Implementation Phase.
Additional Information: N/A	

Investment Planning ID: 901572	Project Name: North Montney Region - Electrification	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F22 RRA: • Chapter 6, page 6-36 • Appendix I: Transmission - line 4 • BCUC IRs 1.45.2, 1.43.1 • BCOAPO IRs 1.56.1	

Description:

The purpose of this project is to expand BC Hydro's transmission system into the North Montney region of northeastern B.C. to provide transmission service to industrial operations to reduce greenhouse gases emissions. The absence of transmission infrastructure in this region is a barrier to electrification of current and future industry.

Key Drivers:

- Environmental
- Reliability

Issues Being Addressed:

The North Montney Natural Gas Field, located northeast of BC Hydro's GM Shrum Generating Station, is one of the sources for natural gas for LNG Canada and other proposed liquified natural gas facilities. The upstream gas producers are developing several gas plants and an opportunity exists to have these gas plants use electric drive compressors instead of natural gas drive compressors.

A number of gas producers in the area have expressed interest in grid supply service from BC Hydro. The costs of interconnecting to BC Hydro's grid can be a significant barrier for gas producers not located close to major transmission lines. The lack of transmission infrastructure in this region is one impediment to these potential customers connecting to and taking service from BC Hydro because it is uneconomic for any single customer or group of customers to build a transmission extension to this area. A transmission expansion into this area would reduce the cost of electrifying the operations for these upstream gas producers to a point where a significant number of gas processing facilities (200-300 MW) could choose to use grid power.

A joint Memorandum of Understanding released by the federal and provincial governments on August 29, 2019 announced an opportunity to access Government of Canada funding and explore Indigenous ownership. The Memorandum of Understanding included the formation of a Canada-British Columbia Clean Power Planning Committee, with senior representation from both jurisdictions, including BC Hydro, to advance natural gas and liquified natural gas electrification, and specifically mentions the North Montney Region – Electrification project.

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">Discussion of Alternatives:
Two alternatives are being considered:
i. Construct a transmission line between GM Shrum Generating Station and a new substation in the vicinity of the Wonowon community; and
ii. Construct a transmission line between South Bank Substation and a new substation in the vicinity of the Wonowon community.
The project is currently in Conceptual Design Stage, and investigations are underway to assess the two alternatives.</td></tr>
<tr><td colspan="2">Project Impacts and Benefits:
• Contribute to the Government of B.C.'s CleanBC program goal of increasing access to clean electricity for large operations to reduce greenhouse gas emissions.
• Facilitate interconnection to provide clean electricity to planned natural gas productions.</td></tr>
<tr><td>Project Implementation Phase Risk:
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.</td><td>Risk Treatment:
To be determined as the project reaches Implementation Phase.</td></tr>
<tr><td colspan="2">Additional Information:
BC Hydro launched an expression of interest process in 2021 to assess the interest in electrification and the electrification needs of existing and planned industrial operations in the North Montney region. Based on the responses, BC Hydro is considering whether to move forward to the next stage of project development.</td></tr>
</table>

Investment Planning ID: 92759	Project Name: Patricia – Substation Upgrade	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-111 • Appendix I: Transmission - line 39, Appendix K: pages 51 and 65 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-45 • Appendix I: Transmission - line 36	

Description:

The purpose of the Patricia (**PCA**) Substation Upgrade project is to address reliability, safety and environmental risks associated with the end-of-life condition of the substation assets.

Key Drivers:

- Reliability
- Safety
- Environmental

Issues Being Addressed:

The most significant issues and risks associated with the PCA Substation include:

- Thirteen 12 kV bulk oil circuit breakers are in poor condition and contain Polychlorinated Biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline;
- The three power transformers were manufactured in the 1960s and do not have on-load tap changers, and therefore voltage regulators are required to regulate the voltage. The asset health of one of the power transformers is Poor;
- All 12 kV voltage regulators are in poor condition; and
- The 12 kV feeder section was designed to be compact in size and poses safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs.

Discussion of Alternatives:

BC Hydro considered several alternatives prior to the start of the project through the Prince George Area Study. The planning study looked at six alternatives to address capacity, asset health and reliability of the system servicing Prince George:

i. Upgrade all PCA Substation feeders to 25 kV, and then offload them to Foothills (**FHS**) and Chief Lake (**CHF**) substations until both substations reach firm capacity. Upgrade Pineview (**PVW**) substation to increase substation firm capacity;

ii. Upgrade all PCA Substation feeders to 25 kV then offload them to FHS Substation until it reaches its substation firm capacity. Then upgrade Beaverly substation to increase substation firm capacity;

iii. Upgrade all PCA feeders to 25 kV then offload them to FHS Substation. Upgrade FHS and PVW

[1] Start Date of Construction is the Implementation Approval Date.

Substations to increase substation firm capacity; iv. Decommission seven PCA Substation feeders. Upgrade 13 PCA Substation feeders to 25 kV then offload them to FHS, Chief Lake and Beaverly substations until these substations reach firm capacity; **v.** Build a new 25 kV substation adjacent to the existing PCA Substation. Upgrade PVW Substation to increase substation firm capacity; and vi. Rebuild PCA Substation at 12 kV. Alternative vi, Rebuild PCA Substation at 12 kV, was selected as the Single Viable Alternative during the Identification phase as this was the only alternative that would meet the project objectives and the regulatory deadline for PCB removal. In addition, the other alternatives would require significant capital investments that are not justified given there is no significant load growth forecast in the area and the PCA 12 kV feeder continues to perform reliably. The progression of design identified outage staging and construction complexities associated with the brownfield site. This has caused significant increases to cost and schedule. Based on these changes, the project alternatives will be re-assessed.
Project Impacts and Benefits: • Maintain reliability in the area served by PCA substation. • Address safety concerns at PCA substation. • Remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal PCB Regulation deadline. This work may move forward as a separate project as the alternatives are re-assessed.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	To be determined as the project reaches Implementation Phase.

Additional Information:
N/A

Investment Planning ID: 901821	Project Name: Peace to Kelly Lake - Stations Sustainment	
Forecast Capital Cost: $299 million to $172 million	**Forecast In-Service Date:** Fiscal 2027	**Start Date of Construction:**[1] Fiscal 2023
Development Phase: Definition	**Filing Reference:** New	

Description:

The purpose of this project is to address aging assets on the Peace Region to Kelly Lake 500 kV transmission system to improve the reliability of the system.

Key Drivers:

- Reliability

Issues Being Addressed:

The Peace to Kelly Lake 500 kV transmission system is the critical backbone infrastructure for moving power generated in the Peace Region to the province's load centre in the south. There are three 500 kV transmission lines that run from Gordon M. Shrum / Peace Canyon to Williston (**WSN**) substation and three lines that run from WSN substation to Kelly Lake substation. There are a number of assets along this corridor that have reached end-of-life that must be addressed to maintain this critical function.

The control systems for the 5CX2/3 series capacitor at Kennedy Capacitor Station (**KDY**) and 5CX3 series capacitor at McLeese Capacitor Station have reached end-of-life and their asset health is rated as Poor. There is a high risk of failure of these control systems. Failure of the control systems would reduce the transfer capability of the bulk transmission system by approximately 50 per cent. Because this equipment is obsolete, there is a lack of spares and original equipment manufacturer support. This has resulted in long outages and reduced system availability.

Shunt reactors 5RX1 at Peace Canyon Generating Station and 5RX6 at WSN substation are approaching end-of-life and their asset health is Poor. If these reactors fail, the system would experience high voltages when the 500 kV lines are under light load conditions; as a result, the lines may need to be taken out of service thus reducing the availability of the system.

The 500 kV control buildings at KDY and WSN substations are over 50 years old and have reached end-of-life and are not fit for future use. The diesel generator room is next to the control buildings, which is a safety concern and fire risk. The heating, ventilation, and air conditioning system, battery room and size of the existing control rooms are inadequate, and the control buildings contain hazardous materials such as asbestos.

Discussion of Alternatives:

The project spans many locations and asset types. The following alternatives were identified to address each of the aging assets: Control systems, 500 kV Shunt Reactors, KDY substation 500 kV Control Building and WSN substation 500 kV Control Building:

i. **Replace the aging asset**;

ii. **Repair or refurbish the aging asset**; and

iii. **Do nothing**.

For the WSN substation control building, Alternative i was selected, due to less risk with building a new control building compared to repairing the existing asset in the following areas: unforeseen costs, reliability of the system during and after construction, and worker safety during and after construction.

For the other assets Alternative i, replace the aging asset, is the only viable alternative. For the control systems, the only viable alternative is to replace the control systems because the parts required to complete the repairs and for ongoing maintenance are no longer available. For the shunt reactors, the only viable alternative is to replace the reactors because the old components are not readily available and

[1] Start Date of Construction is the Implementation Approval Date.

significant engineering and design effort would be required to make these components compatible with other new equipment being installed at WSN substation. For the KDY substation control building, the only viable alternative is to replace the control building because there are significant construction challenges and risks with refurbishing the control building. For each asset, the Do Nothing alternative was not considered a viable option as it does not address the issue of reliability due to the aging condition of these critical system assets.
Project Impacts and Benefits: • Improve reliability through reinforcement of the transmission corridor between the Peace Region and Kelly Lake substation so power from generation in the Peace Region can be moved south.

Project Implementation Phase Risk:	**Risk Treatment:**
This project is not yet in Implementation.	N/A

Additional Information: In fiscal 2020, BC Hydro cancelled the Peace to Kelly Lake Capacitors Project (**PKCP**). The PKCP contemplated both the work required to increase the transfer capability and the sustaining work. With the cancellation of PKCP, the sustaining work still needed to be completed in a timely manner to ensure the continued reliability of the existing Peace to Kelly Lake 500 kV transmission system. To leverage activities completed as part of PKCP, BC Hydro bundled the sustaining work into a new project and named it the Peace to Kelly Lake Stations Sustainment Project. A section 44.2 application will be filed with the BCUC in fall 2021.

F22 RRA (900185):
• Chapter 6, page 6-45
• Appendix I, Transmission - line 37</td></tr>
<tr><td colspan="3"></td></tr>
<tr><td colspan="3">Description of Program of Projects:
The Peace to Kelly Lake transmission line reactors are required for the operation of the 500 kV bulk transmission system from the Peace Generation system. Failure of any one of the reactors may result in unacceptable high voltage in the 500 kV system and affect the continued operation of the 500 kV system.
This Program of Projects was defined to replace aging 500 kV shunt reactors associated with the Peace Region to Kelly Lake transmission system. The majority of these reactors were installed in the late 1960s, are leaking oil and have seismically vulnerable bushings. Refurbishing to correct the issues is costly and generally has little impact on extending the life of the equipment.
The replacements will be completed via the following phased approach:
• Phase 1 - G.M. Shrum 5RX1, 5RX2. This project is in Implementation phase with an in-service date of fiscal 2022;
• Phase 2 - Kelly Lake 5RX1, 5RX3;
• Phase 3 - Williston 5RX2, 5RX3, 5RX4; and
• Phase 4 - Williston 5RX5, 5RX7.
A Program Delivery Strategy was developed during Phase 1's Identification Phase. This delivery strategy included:
• A blanket contract order for 500 kV shunt reactors; and
• A blanket construction contract which included unit pricing for shunt reactors.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Issues to be addressed:

The Peace to Kelly Lake transmission lines are the only means of delivering the power generated in the Peace Region to load centers in the southern portion of the province. These load centers include the Lower Mainland and Vancouver Island, which comprise approximately two-thirds of the BC Hydro's load. The net generation in the Peace Region, including heritage generating stations such as Gordon M. Shrum (**GMS**) and Peace Canyon (**PCN**), and independent power producers, is approximately 4,360 MW, or approximately 23 per cent of the total provincial generation capacity.

The Peace to Kelly Lake transmission line reactors have an Asset Health Rating of Poor indicating an increased likelihood of failure. Each will be replaced with a new reactor with an expected life of about 40 years. Their replacement will reduce the risk of forced outages and risk to workers within the substations.

Schedule of Program of Projects:

The program strategy was initiated to replace the reactors over an approximate 10-year period.

Risks and Mitigation Strategies:

Each project phase will:

- Identify project risks starting in Identification Phase and finalized in the Implementation Phase; and
- Identify risk mitigation strategies when the project reaches Definition phase.

To be determined</td></tr>
<tr><td>Development Phase:
Future</td><td colspan="2">Filing Reference:
F22 RRA:
• Chapter 6, page 6-48
• Appendix I, Transmission - line 48</td></tr>
</table>

Description:

This project will address reliability risks associated with the end-of-life equipment of the Port Alberni (**PAL**) substation, as well as seismic and tsunami risks.

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

PAL substation is in Port Alberni on Vancouver Island. The station provides power to Port Alberni customers and the Catalyst Paper pulp and paper mill.

The control building at PAL was built in 1956. It is a brick building past end of life, was not built to seismic standards, and is in a high risk seismic and tsunami area. Asbestos is present in various components. The control building does not meet current building code or BC Hydro design standards.

Additional assets that are at end of life include:

- Six 138 kV bulk oil circuit breakers installed in 1982;
- Four SF6 breakers installed in 1983 with the current transformers;
- Five 12 kV bulk oil circuit breakers and six 25 kV bulk oil circuit breakers; and
- Oil filled current transformers, voltage transformers and others for protection functions.

Discussion of Alternatives:

BC Hydro is considering three alternatives:

i. **Build a new station and decommission existing PAL station:** This alternative will build a new station at a new site and decommission the existing substation. This alternative would address the end of life equipment, tsunami and seismic risk;

ii. **Rebuild the station at the existing site:** This alternative will rebuild the station at the existing site and replace the end of life assets. This alternative would address the end of life equipment but retain tsunami and seismic risk; and

iii. **Do nothing:** this alternative would not address the issues identified above.

Project Impacts and Benefits:

- Maintain reliability in the area served by PAL station.
- Address seismic and tsunami concerns at PAL station.
- Address safety concerns at PAL station.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.
Additional Information: N/A	

Investment Planning ID: 901574	Project Name: Prince George to Terrace Capacitors Project	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:** To be determined
Development Phase: Identification	**Filing Reference:** F20-F21 RRA: • BCUC IRs 1.254.2.1 and 2.247.6.1 F22 RRA: • BCOAPO IR 1.56.1	

Description:

The purpose of this project is to increase capacity of the North Coast 500 kV transmission system by at least 500 MW to meet the needs of interconnection customers currently in the interconnection queue and support the provincial government's initiatives under CleanBC.

This project has secured federal funding up to a maximum of $97 million from the Green Infrastructure stream of the Investing in Canada Infrastructure Program, in recognition of the greenhouse gas reductions to be achieved.

Key Drivers:

- Operational Requirements
- Environmental

Issues Being Addressed:

There are a number of customers who are requesting interconnections in the North Coast. BC Hydro's existing north coast 500 kV transmission system transfer capacity is insufficient to supply all the customers who are currently requesting interconnections. To meet the needs of interconnection customers and their requested in-service dates, additional system capacity will be required by fall 2026.

Discussion of Alternatives:

BC Hydro considered five alternatives:

i. **Do Nothing:** This alternative would not increase the electricity supply in the north coast area and BC Hydro would fail to meet its obligation to provide service to customers who request it per the Tariff;

ii. **Deferral:** Due to the long lead time for the Project, a deferral would increase the risk that the required incremental supply of electricity would not be in place to meet the needs of customers. As a result, the customers would be less likely to electrify their load;

iii. **Construct second 500 kV transmission line** – A second new, 450 km transmission line parallel to the existing line was anticipated to be approximately $1.9 billion. Although this alternative would provide a N-1 level of reliability, the customer has indicated that a N-0 level of reliability is sufficient to meet their needs;

iv. **Local generation with dependable capacity** – Gas turbine generators are the only potential local generation with dependable capacity in the region and they do not meet the project's objective of supporting the BC Government in achieving its climate goals; and

v. **Install series compensation on the existing 500 kV line** – construct three new capacitor stations along transmission lines 5L61, 5L62 and 5L63 and install a third transformer at Skeena substation.

Alternative v, install series compensation on existing 500 kV line, was selected as the Single Viable Alternative for the following reasons: (1) it is the only alternative that meets the project objective to provide service to the interconnection customers in the required timeframe; (2) it has the lowest capital cost and lowest environmental impact; (3) it supports the BC Government's climate change objectives; and (4) is able to meet the BC Hydro Tariff obligation to serve interconnection customers.

Project Impacts and Benefits:	
BC Hydro will meet the expectations of its customers to be able to reliably serve new load. The completion of the project will serve a number of interconnection customers who are currently in the queue. The amount of CO_2 greenhouse gas avoidance will depend on the actual loads that would materialize.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: There is uncertainty with how fast customer loads will materialize. BC Hydro may choose to proceed with the project regardless of the individual customer decisions in order to provide sufficient capacity to meet the needs of customers currently in the queue and other potential customers who may request interconnections in the future.	

Investment Planning ID: 93958	**Project Name:** South Fraser Transmission Relocation Project	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Deferred	**Filing Reference:** F20-F21 RRA: • Appendix E, page 29 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 • CEC 3.104.1 F22 RRA: • Appendix Q, page 20	

Description:

The purpose of this project is to relocate certain sections of two 230 kV transmission circuits (Circuit 2L62 and Circuit 2L58) from their present location adjacent to Highway 99 and in the George Massey tunnel to accommodate the Ministry of Transportation and Infrastructure's planned replacement of the George Massey tunnel.

Key Drivers:

- Operational Requirements
- Reliability

Issues Being Addressed:

In order to accommodate Ministry of Transportation and Infrastructure's new crossing infrastructure, the existing transmission lines (2L062) needs to be relocated. These two 230 kV circuits form a critical part of BC Hydro's transmission network supplying power to customers in Richmond, Delta and the Greater Vancouver area. The type of transmission crossing (overhead or underground) will be reassessed based on the Province's August 2021 announcement that they plan to construct a new tunnel by 2030.

Discussion of Alternatives:

The project is currently on hold. BC Hydro will reassess alternatives for the relocation of 2L062 and 2L058 now that the Province has made their decision on their George Massey Tunnel replacement project.

Project Impacts and Benefits:

- Ensure continued service of reliable power to Delta and Richmond.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

This project began in 2014 when the Province initially announced its plans to replace the tunnel with a bridge and an overhead relocation of 2L062 was selected. The project was placed on hold in 2017 when the Province announced it was re-evaluating its crossing options for the tunnel replacement which could be either a new bridge or new tunnel. BC Hydro can re-evaluate alternatives for relocation of 2L062 and 2L058 now that the Province has decided on a solution for its project.

[1] Start Date of Construction is the Implementation Approval Date.

• BCOAPO IR 1.58.1</td></tr>
<tr><td colspan="3">Description:
The purpose of this project is to improve the reliability and reduce the safety risks at Sperling (SPG) substation.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Safety</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The SPG substation has a 60 series feeder section which consists of 12 kV bulk oil breakers and a lattice steel structure built for 4 kV prior to 1950. The 60 series feeder section and the bulk oil breakers in the 70/80 series feeder section have an Asset Health Index of Poor or Very Poor and are at end-of-life. One breaker in the feeder section has failed, and more breaker failures are expected in the near future. The 60 series feeder section also has insufficient Limits of Approach to protect worker safety. The existing lattice structure does not meet current seismic requirements and is at end-of-life due to aging and corrosion.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
BC Hydro considered five alternatives:
i. Do nothing and defer the work;
ii. Replace only the bulk oil breakers in the 60 series feeder section;
iii. Replace the existing 60 series feeder section, the bulk oil breaker in the 70/80 series feeder section and four end-of-life electromagnetic protection relays (non-arc resistant metalclad switchgears would be replaced with new arc-resistant switchgears);
iv. Decommission SPG substation and transfer load to other stations; and
v. Replace SPG substation with a new substation.
Alternative iii, Replace the existing 60 series feeder section, the bulk oil breaker in the 70/80 series feeder section and four end-of-life electromagnetic protection relays, was selected as the preferred alternative. The non-arc resistant metalclad switchgears will be replaced with new arc-resistant switchgears.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">Alternative i was not selected because it would not address the reliability and safety risks associated with the 60 series feeder section. Alternative ii was not selected because it would not address the issues with electrical clearances, fault level, and other aging equipment in the feeder section, such as the end of life disconnect switches, bus structure and steel lattice structures. Alternative iv was not selected because no substation in the area has sufficient feeder positions to take on the additional load. Alternative v was not selected because it would be cost prohibitive.</td></tr>
<tr><td colspan="2">Project Impacts & Benefits:
• Improved reliability of end-of-life equipment
• Improved worker safety</td></tr>
<tr><td>Project Implementation Phase Risk

Risk 1:
Due to the age of the substation, there is a risk of encountering unexpected buried cables/utilities. This could result in design changes, accidental damage to cables/utilities, forced outage, construction delays, and cost increase.

Risk 2:
Due to a complex construction and constrained work area there is a risk that construction activities cannot be completed as planned, resulting in construction delays and contractor delay claims.</td><td>Risk Treatment

Risk 1:
To mitigate this risk an underground Ground Penetrating Radar survey was completed during the Feasibility Design stage to locate underground utilities that could potentially conflict with routing of new cables. In addition, Hydro-Vac will be utilized in areas of concern during construction.

Risk 2:
To mitigate possible outage related issues, the project team has completed a staging plan with participation from Fraser Valley Operations; Field Operations, Communication, Protection and Control Technicians; Construction and Engineering. This staging plan will be included in tender documents. In addition, Solid Insulated Bus components will be utilized in congested areas.</td></tr>

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: 900019	Project Name: System Wide – Bulk Electric System Telecom Equipment Replacement (formerly Various Sites – Microwave Radio Replacement)	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F20-F21 RRA: • BCUC IR 1.133.1 Confidential F22 RRA: • Chapter 6, page 6-50 • Appendix I: Transmission - line 58	

Description:

The purpose of the project is to replace Bulk Electric System telecommunication equipment that is at the end of life throughout B.C., with the exception of Vancouver Island which is being addressed under a separate project (Vancouver Island Microwave Radio Replacement Project) that is currently in the Implementation phase.

Key Drivers:

- Reliability

Issues Being Addressed:

BC Hydro operates a province-wide telecommunication system to support the operation of BC Hydro's grid, in part by enabling Class 1 and 2 teleprotection and Remedial Action Scheme (**RAS**) services. The telecommunications system also provides Supervisory Control and Data Acquisition (**SCADA**), operational data, operational voice, asset health monitoring, remote engineering access, corporate data and security services to enable BC Hydro to manage and operate the power system.

This telecommunications system has been expanded incrementally to support the protection and control of new transmission lines, transmission and generating stations, and large customer interconnections. However, the majority of the equipment in the province was last replaced in the late 1990s/early 2000s and is at end of useful life.

The equipment is no longer sold or supported by the original manufacturer, and only limited support is still available from third-party service providers. It is increasingly challenging to find spares to repair faulty equipment. There has been an increase in outages, and despite equipment redundancy, some recent outages to network equipment have taken out both primary and secondary protection circuits. Failures of equipment at mountaintop sites are difficult to repair in a safe and timely manner, especially in the winter, and outages to telecommunications equipment can lead to the loss of SCADA, teleprotection and RAS signals. System Operating Orders direct that extended outages to teleprotection and RAS signals would require remedial actions on the power system, such as reducing generation output or the intertie capacity on various transmission lines between BC Hydro and other entities.

Discussion of Alternatives:

This project has a Single Viable Alternative. The components of the telecommunications system are at end of life and must be replaced. This alternative will replace end of life microwave radio, switching, and network equipment with new models whose manufacturers provide spare equipment and technical support. Multi-protocol label switching equipment will be added to enhance the efficient use of limited microwave radio capacity for Internet Protocol based services. This alternative would reduce the risk of failure of equipment at the end of its useful life, it would support the ability to replace or repair failed

1 Start Date of Construction is the Implementation Approval Date.

equipment with like models, and it would make more efficient use of the radio capacity we have. The alternative to obtain telecommunication services from third parties has been rejected, as BC Hydro would not be able to control the operation or repair of the third-party circuits. The use of these circuits would result in BC Hydro being unable to meet the availability and performance requirements of the SCADA, Teleprotection and RAS schemes.	
Project Impacts and Benefits: • Maintain reliability and capacity of the power system by addressing the telecommunication equipment end-of-life condition. • Reduce reliance on third-parties to provide spares and support.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: This investment was previously identified as Various Sites - Microwave Radio Replacement, but it was renamed to reflect that the scope now includes other telecom equipment, such as routers, switches, and network equipment. The individual telecom equipment components planned for replacement function together as a system. BC Hydro determined that replacing all the components together under a single project would be more efficient and have lower implementation risks. BC Hydro expects to file a section 44.2 application with the BCUC during the Definition phase of the project.

<tr><td colspan="3">Description:
The purpose of this project is to replace end-of-life microwave radio and associated equipment and extend the Multi-Protocol Label Switching network to Vancouver Island. Multi-Protocol Label Switching is a network technology that increases the efficiency of transporting Telemetry and Control, Corporate LAN, voice, and operational traffic.
In addition, the microwave system will be extended to Gold River (GLD) substation through a new off-grid Microwave Repeater on Strathcona Mountain substation and a new passive repeater John Rae Newstead substation. The project involves work at a total of 38 facilities.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
BC Hydro operates a province-wide private telecommunications system to support the operation of the Bulk Electric System. The telecom system enables high-speed line protection and control of the transmission system. The telecom equipment on Vancouver Island is the oldest in the BC Hydro system and is experiencing an increased rate of failures. The issues and risks associated with the BC Hydro Telecommunication system on Vancouver Island include:
• Equipment reliability and repair issues due to aging equipment that is no longer manufactured or supported by the manufacturer; and
• Owing to capacity constraints with the existing system, BC Hydro cannot support increasing communication needs.</td></tr>
</table>

1 Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives: BC Hydro considered two alternatives: i. **Replace** equipment that has not been supported since 2018 and extend the microwave network to GLD substation; and ii. **Do nothing:** Continue to use the existing end-of-life telecom equipment and continue performing repairs. Alternative i, replace equipment that has not been supported since 2018 and extend the microwave network to GLD substation, was selected as the preferred alternative as it will improve system reliability, ensure sufficient capacity on the Vancouver Island Power Line Carrier system, and provide increased bandwidth to GLD substation. Alternative ii was not selected because of the increased number of failures of the existing telecom equipment that has reached end of life and is no longer supported by the manufacturer.	
Project Impacts and Benefits: • Improve reliability of the microwave radio system. • Improve operating capacity of the microwave radio system. • Salvage end-of-life telecom equipment to use as spares for the rest of the province.	
Project Implementation Phase Risk: This project currently does not have any identified Zone 3 (high) Implementation Phase risks	**Risk Treatment:** N/A
Additional Information: N/A	

Investment Planning ID: 901592	Project Name: Various Sites – NERC CIP 003v7 Implementation[1]	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** Fiscal 2024	**Start Date of Construction:**[2] Fiscal 2022
Development Phase: Definition	**Filing Reference:** F22 RRA: • Chapter 6, page 6-47 • Appendix I: Transmission - line 41 • RCIG IR 1.8.6	

Description:

This project is required to install equipment and establish processes, practices, and procedures to ensure that BC Hydro is compliant with Critical Infrastructure Protection (**CIP**) CIP-003-8 Mandatory Reliability Standards (**MRS**) on all low impact Bulk Electric System (**BES**) Cyber Assets.

Key Drivers:

- Reliability
- Reputational
- Financial Loss

Issues Being Addressed:

The CIP-003-8 MRS was adopted in B.C. by BCUC Order No. R-19-20 in September 2020. BC Hydro must comply with all the CIP-003-8 MRS on a staged basis per the BCUC-adopted CIP-003-8 Implementation Plan in lead up to October 1, 2023. This project is intended to bring BC Hydro into compliance with the CIP-003-8 MRS by October 1, 2023, in the following four areas:

i. Electronic Access Controls – Monitoring systems for generation and transmission stations that contain low impact BES cyber assets connected to untrusted networks are required. Eighty-one sites require the installation of dial-up Electronic Access Controls (i.e., firewalls for cyber assets connected by telephone lines) and 53 sites require the installation of external routable connection access controls (i.e., firewalls that are commonly used in network security systems);

ii. Physical Access Controls – Measures designed to prevent unauthorized access to BES cyber assets/systems in generation and transmission stations are required. One hundred thirty-three sites require the installation of physical key management systems and 26 sites require physical access controls (i.e., card readers, cameras, alarms);

iii. Information Technology in 2021 – Deployment of additional dedicated-secure laptops for connecting to CIP cyber assets/systems; hardening of existing laptops to ensure they comply with CIP MRS; and training of personnel on the protocols and procedures for using these secure laptop computers in accordance with CIP MRS is required. The compliance date mandated by the BCUC for this work is October 1, 2021; and

iv. Information Technology in 2023 – Assessment and upgrade of enterprise systems, and update of corporate CIP policies, plans and procedures for the access and use of low impact BES cyber assets is required.

---

1 This project was initiated when the CIP-003-7 MRS was issued which represented “Version 7” of the MRS. This MRS was revised to CIP-003-8 “Version 8” by BCUC Order No. R-19-20.

2 Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:	
BC Hydro considered three alternatives: i. **Defer**; ii. **Do Nothing**; and iii. **Implement four work streams to address the four areas identified above**. Alternative iii, implement four work streams, is the selected as the preferred alternative that will bring BC Hydro into compliance with the CIP-003-8 MRS by October 2023. Alternative i was not considered viable as deferring the project increases the risk that BC Hydro would not be in compliance by the regulatory deadline. Alternative ii was not considered viable because taking no action to implement security management controls to protect bulk electric system cyber systems within generating and transmission stations would not be compliant with the CIP-003-8 MRS.	
Project Impacts and Benefits: • Meet regulatory (CIP-003-8 MRS) requirements. • Improve overall cyber security of BES Cyber Assets. • Mitigate risk of financial penalties for non-compliance	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: N/A	

Investment Planning ID:	Project Name:	
902241	Various Sites – Telecom Transport Network Resiliency Enhancement	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** New	

Description:

BC Hydro owns and operates a telecom network in order support the Bulk Electric System, providing high-availability Supervisory Control and Data Acquisition, Teleprotection and Remedial Action Scheme (**RAS**) services. The objective of this project is to build redundant network links between high-priority Bulk Electric System stations to eliminate single points of failure for certain critical telecom circuits. The elimination of single points of failure would increase the availability of the Teleprotection and RAS circuits, and it would decrease the likelihood of telecom outage events requiring power system actions. It would also simplify cutover during equipment replacement projects and reduce the capital and maintenance costs associated with designing highly-available telecom paths.

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

Although the telecom network is engineered to have high reliability, there are many single points of failure, primarily located at mountaintop locations. There remains a risk that a failure at a mountaintop site could not be repaired promptly and would lead to an extended telecom outage that would require actions on the power system such as reducing generation and reducing the capacity of intertie lines with third parties. There have been recent incidents where smoke, ice, hail and equipment failures have led to extended telecom outages at mountaintop sites. The impact to the power system resulting from failed telecom circuits is increasing due to increased generation and load on the grid, so the risk of single points of failure is higher now than previously.

A failure of telecom equipment and circuits requires the rapid dispatch of crew to repair the fault. System Operating Orders define the power system response that must be undertaken if the repair cannot be affected within a certain time limit. Typical actions include reducing output at generation stations or transfer capacity on interconnections with other entities. For the most critical circuits, the typical permitted time limit to affect a repair is four hours. For remote mountaintop repeaters, accessing and repairing faults within four hours can be difficult under ideal conditions. In the winter or under storm conditions, it may not be safe or possible to access the site before power system actions are required.

Discussion of Alternatives:

BC Hydro is considering four alternatives:

i. **Obtain dark fiber from carriers:** Build fiber optic cable entrances from substation control rooms to demarcation point on carrier poles. Connect telecom electronics to fiber optic cables. This option has OMA implication as it requires dark fiber agreement for connections between key substations;

ii. **Build redundant network:** Build new BC Hydro owned telecom facilities across the province, based either on microwave or fiber optic technologies. This option would have a significant cost and is most likely not viable;

iii. **Obtain telecommunications services from a Telecom Carrier:** Services from telecom carriers currently have technical limitations that make them incompatible with the operation of Teleprotection and RAS circuits. This alternative may not be viable due to this limitation; and

[1] Start Date of Construction is the Implementation Approval Date.

iv. **Do Nothing:** Continue to design, sustain and operate critical microwave sites as single points for failure for the telecom system. Manage the risk of failure of a site for longer than four hours.

Project Impacts and Benefits:

- Reduce the capital and maintenance costs associated with building and maintaining highly-available microwave repeaters at mountaintop locations.
- Reduce the equipment requirements and simplify the circuit cutovers for equipment replacement projects.
- Reduction of the impact to the power system of a long-term failure (>4hrs) of a microwave site.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

<tr><td colspan="3">Description:
This project will build a new 230 kV to 25 kV, 400 MVA (ultimate capacity), underground substation in the West End neighbourhood of Downtown Vancouver as part of the first stage of the 30-year Downtown Vancouver Electricity Supply Plan.
Refer to Appendix K – Downtown Vancouver Electric Supply Plan for additional information.</td></tr>
<tr><td colspan="3">Key Drivers:
Reliability</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Issues Being Addressed:

The Downtown Vancouver area is comprised of the Downtown, West End, Strathcona, and Grandview-Woodland neighborhoods. The area is supplied by a 230 kV and 69 kV transmission network and three substations:

- Cathedral Square substation (built in 1984);
- Dal Grauer substation (built in 1953); and
- Murrin substation (built in 1947).

There are a number of risks and issues at the aging Dal Grauer and Murrin substations. More than half of the assets are expected to degrade to an Asset Health Index of Poor or Very Poor in the next 10 to 20 years, presenting elevated safety and reliability risks. Murrin substation is on seismically unstable soil. Approximately half of the 230 kV switchyard, which supplies both Murrin and Dal Grauer loads, is vulnerable to severe earthquake damage from liquefaction and settlement. Physical space constraints at Dal Grauer make redevelopment of the substation in its current location a challenge.

The long-term strategy for the area is to mitigate the reliability and safety risks by replacing the Dal Grauer and Murrin substations with new substations. The first of these is the West End Substation.

Discussion of Alternatives:

The ultimate capacity of the underground substation will be 400 MVA, located in the West End neighborhood of Downtown Vancouver. The project will consider different options for the size of the substation before it begins construction, given that the 400 MVA capacity may not be required immediately.

Project Impacts and Benefits:

- Improve West End Vancouver area reliability.
- Minimize future worker safety risks in the Dal Grauer and Murrin substations.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase, further developed in the Definition Phase and finalized as the project reaches the Implementation Phase.	To be determined as the project reaches Implementation Phase.

Westbank Substation Upgrade Project:
• Reliability</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Issues Being Addressed:

The West Kelowna area is located in the Okanagan Valley on the west bank of the Okanagan Lake and has serves approximately 22,000 BC Hydro customers. The West Kelowna area is serviced by a single 138/25 kV substation (Westbank Substation) that is supplied by a single 80 km, radial 138 kV transmission line from Nicola Substation in the Nicola Valley. Westbank Substation is the second largest distribution station in the BC Hydro system supplied by a radial transmission line. Westbank Substation has no ties to any other substations and there is no local generation. Consequently, if the transmission line is removed from service the substation will lose supply and not be able to serve local customers.

West Kelowna Transmission Project

Since 1994 there have been three sustained forced outages; one in 1994 caused by lightning resulting in a six-hour outage; one in October 2007 caused by lightning resulting in a seven-hour outage; and the October 2014 pole-top fire related outage resulting in a nine-hour outage. The single outage in 2014 resulted in significant Customer Hours Lost (**CHL**) (180,000) for West Kelowna. The CHL consequence due to an outage in the area is significant and indicated that BC Hydro should address this risk. Other factors that contribute to the challenge of restoring power include the length of the existing transmission line, its location in rugged and remote terrain, and susceptibility to forest fires and landslides.

While the existing line is considered reliable, adding a new, second transmission line (or cable) will provide redundancy to the system, ensuring continued, reliable power in the event of an outage on the existing line.

Westbank Substation Upgrade Project

The peak summer load at Westbank Substation exceeds the firm summer capacity of the station. Several components of the substation are also reaching end of life. This includes one 138 kV oil circuit breaker and one 25 kV oil circuit breaker, two circuit switchers and one voltage transformer.

Discussion of Alternatives:

West Kelowna Transmission Project

Over the life of the Project, three alternatives have been explored:

i. **BC Hydro Transmission:** new transmission line connecting Westbank Substation to BC Hydro's transmission system;

ii. **BC Hydro & Fortis Transmission:** new transmission line connecting Westbank Substation to FortisBC's transmission system; and

iii. **Resiliency:** improving resiliency of the existing transmission line supplying Westbank Substation.

All of the alternatives have been evaluated on cost, reliability, environment, safety, and First Nations and stakeholder benefits / impacts through a Structured Decision-Making process. Alternative i, was selected as the leading alternative in 2016. Upon further study the cost estimate to build the new transmission line increased to more than double the original estimate. Given this cost increase it is prudent to re-evaluate the alternatives and consider any potential new alternatives available. Alternative ii is being re-evaluated.

Westbank Substation Upgrade Project

BC Hydro considered three alternatives:

i. **Upgrade Westbank Substation** to increase firm transformation capacity, replace end of life assets and add space provision to interconnect the new transmission line;

ii. **Build a new substation** to accommodate load growth in the West Kelowna area; and

iii. **Do nothing:** continue as usual, with curtailment of customer load during transformer contingency.

Alternative i, Upgrade Westbank Substation, was selected as the Single Viable Alternative that meets the objectives. Alternative, ii, Building a new substation, would be at a much greater cost, and was therefore considered an unnecessary alternative.

Project Impacts and Benefits:

West Kelowna Transmission Project:

- Improve reliability in West Kelowna by providing redundancy to the system.

Westbank Substation Upgrade Project:

- Increase firm transformation capacity to meet demand.
- Replace end of life assets on an expanded footprint.
- Space provisions for a new transmission line position and a 50 MVA feeder section.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

In Directive 3 of the BCUC's Decision on the F2017 to F2019 Revenue Requirement Application, BC Hydro was directed to file a Certificate of Public Convenience and Necessity application for both the West Kelowna Transmission Project and Westbank Substation Upgrade Project. The BCUC also found these two projects to be sufficiently linked that they could be expediently reviewed in one process. The decision provides some flexibility for BC Hydro to have the two projects reviewed in a single process or separately if necessary.

Program of Projects Name: H-Frame Elimination - Gastown		
Appendix I Reference: Distribution, page 5, line 17		
Investment Planning ID: 900391	**Project Name:** Downtown Vancouver - Underground Murrin Feeders to Eliminate H-Frames in Gastown	
Forecast Capital Cost: $26.6 million	**Forecast In-Service Date:** Fiscal 2022	**Start Date of Construction:**[1] Fiscal 2019
Development Phase: Implementation	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-129 • Appendix I, Distribution - line 25 • BCUC IRs 1.113.2.1 and 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-64 • Appendix I, Distribution - line 17	
Description of Program of Projects: The objective of this Program of Projects is to reduce the risk of public contact incidents associated with the distribution lines built on H-frame structures located in back lanes in the Gastown area of Downtown Vancouver. Approximately 37 H-frame structures will be removed by constructing new underground feeders and relocating overhead feeders and services to the new underground system. This will include the installation of new automated switchgear and street vaults, as well as underground cables to connect these units and serve customers. These projects are being delivered as a program to allow BC Hydro to quickly adjust plans and projects to optimally respond to the dynamic nature of the distribution system and to opportunities presented to reduce cost or prioritize projects as a result of ongoing development, load growth, and/or customer initiatives.		

1 Start Date of Construction is the Implementation Approval Date.

Issues to be addressed:
This Program of Projects will address safety hazards with H-frame structures in back lanes of Gastown which violate current electrical clearance codes and standards. These structures have primary conductors that do not meet current safety clearances relative to the existing buildings. The close proximity of energized conductors to fire escapes and windows in the back lanes of buildings poses a significant safety risk to the public. In many of the narrow back lanes, it is not possible to bring the H-frame system into compliance with current safety clearance codes and standards due to lack of space. Considering the high consequence of electrical contact with members of the public, the decision was made to eliminate the H-frame structures. Benefits that will be achieved through completion of this program include: • Relocating electrical equipment underground in new civil infrastructure to reduce potential public electrical contact hazard, mitigate the risk of vandalism, and improve visual aesthetics; and • Expansion of the open loop system to mitigate reliability risk to customers and improve worker safety.
Schedule of Program of Projects:
This program of projects has a planned in-service date of March 31, 2022. For individual projects, the in-service dates are: • LM-VAN-025 Primary Removal Gastown South: January 31, 2022; • LM-VAN-037 Primary Removal Gastown Middle: January 31, 2022; • LM-VAN-038 Primary Removal Gastown North: January 31, 2022; • LM-VAN-124 Secondary Removal Gastown South: March 31, 2022; • LM-VAN-125 Secondary Removal Gastown Middle: March 31, 2022; • LM-VAN-126 Secondary Removal Gastown North: March 31, 2022; and • LM-VAN-025A Automation: January 31, 2022.
Risks and Mitigation Strategies:
The timely procurement of long lead time underground equipment (vaults, submersible transformers and switchgear). Any delays in procuring equipment may delay construction schedules. This risk is being mitigated by placing early pre-orders of long lead time equipment. Identifying acceptable locations for underground vault and above ground control enclosures with the City of Vancouver and impacted stakeholders. This is a challenge due to the congested underground infrastructure in Downtown Vancouver. This risk is being mitigated through regular interactions with the City of Vancouver and impacted stakeholders during the design phase. There are challenges with negotiating upgrades to customer-owned secondary electrical infrastructure due to a lack of interest or responsiveness from some customers, or difficulty in identifying or contacting building owners (e.g., owners may reside outside B.C. or Canada or the building may be owned by a numbered company). This risk is being mitigated through BC Hydro's Community Engagement team involvement in working with the design team and Key Account Managers to help identify building owners, communicate the project objectives, identify the required building modifications and work to obtain signed new Electric Service Agreements. Other construction challenges include limited resources to perform civil work, management of vehicle and pedestrian traffic, congestion with other underground utilities, and limited working hours for construction. These risks are being mitigated by early and frequent engagement with the City of Vancouver and the local Business Improvement Association.

Program of Projects Name: H-Frame Elimination - Chinatown		
Appendix I Reference: Distribution, page 6, line 18		
Investment Planning ID: 900557	**Project Name:** H-Frame Elimination – Chinatown	
Forecast Capital Cost: $48.4 million	**Forecast In-Service Date:** Fiscal 2022	**Start Date of Construction:**[1] Fiscal 2016
Development Phase: Implementation	**Filing Reference:** F20-F21 RRA: Chapter 6, page 6-129 • Appendix I, Distribution - line 21, Appendix J, page 118 • BCUC IRs 1.113.2.1, 1.133.1 Confidential and 2.258.2 • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-64 • Appendix I, Distribution - line 18 • CEC IR 1.34.1.1	
Description of Program of Projects: The objective of this Program of Projects is to reduce the risk of public contact incidents associated with the distribution lines built on H-frame structures located in back lanes in the Chinatown area of Downtown Vancouver. Approximately 110 H-frame structures will be removed by constructing new underground feeders and relocating overhead feeders and services to the new underground system. This will include the installation of new automated switchgear and street vaults, as well as underground cables to connect these units and serve customers. These projects are being delivered as a program to allow BC Hydro to quickly adjust plans and projects to optimally respond to the dynamic nature of the distribution system and to opportunities presented to reduce cost or prioritize projects as a result of ongoing development, load growth, and/or customer initiatives.		

1 Start Date of Construction is the Implementation Approval Date.

Issues to be addressed:
This Program of Projects will address safety hazards with H-frame structures in back lanes of Chinatown which violate current electrical clearance codes and standards. These structures have primary conductors that do not meet current safety clearances relative to the existing buildings. The close proximity of energized conductors to fire escapes and windows in the back lanes of buildings poses a significant safety risk to the public. In many of the narrow back lanes, it is not possible to bring the H-frame system into compliance with current safety clearance codes and standards due to lack of space. Considering the high consequence of electrical contact with members of the public, the decision was made to eliminate the H-frame structures. Benefits that will be achieved through completion of this program include: • Relocating electrical equipment underground in new civil infrastructure to reduce potential public electrical contact hazard, mitigate the risk of vandalism, and improve visual aesthetics; and • Expansion of the open loop system to mitigate reliability risk to customers and improve worker safety.
Schedule of Program of Projects: This program of projects has a planned in-service date of March 31, 2022. For individual projects, in-service dates are: • LM-VAN-006 Primary Removal Chinatown West: April 3, 2018 (completed); • LM-VAN-007 Primary Removal Chinatown North: March 27, 2018 (completed); • LM-VAN-008 Primary Removal Chinatown East: March 20, 2020 (completed); • LM-VAN-055 Primary Removal Chinatown South: March 20, 2020 (completed); • LM-VAN-058 Secondary Removal Chinatown West: March 31, 2021; • LM-VAN-059 Secondary Removal Chinatown North: July 24, 2020 (completed); • LM-VAN-060 Secondary Removal Chinatown East: December 31, 2021; • LM-VAN-061 Secondary Removal Chinatown South: July 31, 2021; • LM-VAN-006A Automation and Fiber: February 21, 2020 (completed); and • LM-VAN-058A Dismantling: March 31, 2022.

Risks and Mitigation Strategies:
• The timely procurement of long lead time underground equipment (vaults, submersible transformers and switchgear). Any delays in procuring equipment may delay construction schedules. This risk is being mitigated by placing early pre-orders of long lead time equipment. • Identifying acceptable locations for underground vault and above ground control enclosures with the City of Vancouver and impacted stakeholders. This is a challenge due to the congested underground infrastructure in Downtown Vancouver. This risk is being mitigated through regular interactions with the City of Vancouver and impacted stakeholders during the design phase. • There are challenges with negotiating upgrades to customer-owned secondary electrical infrastructure due to a lack of interest or responsiveness from some customers, or difficulty identifying or contacting building owners (e.g., owners may reside outside B.C. or Canada or the building may be owned by a numbered company). This risk is being mitigated through BC Hydro's Community Engagement team involvement in working with the design team and Key Account Managers to help identify building owners, communicate the project objectives, identify the required building modifications and work to obtain signed new Electric Service Agreements. • Other construction challenges include limited resources to perform civil work, management of vehicle and pedestrian traffic, congestion with other underground utilities, and limited working hours for construction. These risks are being mitigated by early and frequent engagement with the City of Vancouver and the local Business Improvement Association.

Investment Planning ID: 900541	Project Name: Vancouver Island - Saltspring 25F61 Cable Extension to North Pender Island (VI-GUL-005)	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** F22 RRA: • Chapter 6, page 6-62 • Appendix I, Distribution - line 13	

Description:

The purpose of this project is to improve the reliability of the islands of Mayne, Saturna, and Pender, that are part of the Gulf Islands off the eastern coast of Vancouver Island.

These islands are supplied from two BC Hydro substations, one on Salt Spring Island and one on Galiano Island. Electricity to Mayne, Saturna and Pender islands is supplied by either of these two substations via a two-circuit intertie consisting of overhead and underwater (submarine cables) infrastructure. The two-circuit intertie serves as an electrical loop, referred to as the Gulf Island Loop, such that one circuit can provide the supply if the other fails or has a forced outage.

Key Drivers:

- Reliability

Issues Being Addressed:

This project will address reliability to the Gulf Island Loop. Due to the geographical challenges involved in serving the islands, long outages are a regular occurrence to various sections of the Gulf Island Loop. As a result, these two circuits have historically been among the worst performing circuits in the province. The reliability is expected to degrade further as the winter peak loading on the circuits has grown to a level that in the event of an outage to one circuit the other circuit does not have enough capacity to supply the load of these three islands.

Discussion of Alternatives:

The long-term plan for the Gulf Island Loop includes making improvements to address poor reliability, as well as adding capacity to the Gulf Island Loop. The new submarine cable will bring enough capacity to offload an additional 4 MW from the circuit supplying Pender Island.

BC Hydro is considering four alternatives:

i. **Adding an additional circuit** to the Gulf Island Loop to convert the loop from a two-circuit supply to a three-circuit supply. Several cable routes are possible to complete this alternative which would result in increased capacity, and improved reliability;

ii. **Extension of the existing submarine cable** from Mayne Island to Pender Island. This would provide a moderate improvement in reliability by improving the sectionalisation of the system; i.e. improve the ability to divide the loop into sections to isolate problem areas and minimize customer impacts. However, it would still be a two-circuit supply and it would not provide any additional capacity for the Gulf Island Loop system;

iii. **New Pender Island Substation.** This alternative would involve building new transmission to Pender Island and constructing a new substation. This would provide capacity and reliability improvements; however, it requires the largest capital investment and the most amount of time to implement; and

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">iv. Distribution Battery Storage Backup. This alternative uses developing technology and additional study would be needed to determine if this option would have enough storage capacity capable of providing backup for the duration of time that is typical of permanent outages on the Gulf Island Loop system.</td></tr>
<tr><td colspan="2">Project Impacts and Benefits:
• Improve reliability of the Gulf Island Loop.
• Ensure future load growth in the area can be supported.</td></tr>
<tr><td>Project Implementation Phase Risk:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.</td><td>Risk Treatment:
To be determined when the project reaches Implementation.</td></tr>
<tr><td colspan="2">Additional Information:

</table>

Investment Planning ID: 900556	Project Name: Various Sites – LED Street Light Conversion	
Forecast Capital Cost: $74.9 million	**Forecast In-Service Date:** Fiscal 2024	**Start Date of Construction:**[1] Fiscal 2018
Development Phase: Implementation	**Filing Reference:** F20-F21 RRA: • Chapter 6, page 6-131 • Appendix I, Distribution - line 26, Appendix J, page 120 • BCUC IRs 1.133.1 Confidential and 2.258.2 • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-66 • Appendix I, Distribution - line 19	

Description:

This project involves the mass conversion of approximately 90,000 mostly high-pressure sodium streetlights and approximately 370 of the mostly mercury vapor private outdoor lights to LED lights. The remaining 4,600 private outdoor lights will be removed from the system as part of this project.

Key Drivers:

- Reputational
- Environmental

Issues Being Addressed:

This Project will address the following:

- Compliance with federal Polychlorinated Biphenyl (**PCB**) Regulations;
- Mitigation of increasing support and maintenance costs;
- Improvement of customer service and experience; and
- Increased data and billing accuracy.

Discussion of Alternatives:

BC Hydro considered four alternatives:

i. **Status Quo:** reactive replacement of failed streetlights and private outdoor lights with new bulbs or fixtures. This alternative was rejected due to not meeting Federal PCB regulatory requirements;

ii. **Reactive Replacement:** Replacement of failed streetlights/private outdoor lights or streetlights/private outdoor lights containing PCBs in a concentration of 50 ppm or more with new PCB free high-pressure sodium streetlights. Remove 4,600 private outdoor lights from the system;

iii. **Reactive Upgrade:** Conversion of failed streetlights/private outdoor lights or streetlights/private outdoor lights containing PCBs in a concentration of 50 ppm or more with new LED streetlights. Remove 4,600 private outdoor lights from the system; and

iv. **Proactive Replacement**: Mass conversion of all streetlights and 370 private outdoor lights to LED streetlights. Remove 4,600 private outdoor lights from the system.

Alternative iv, was selected as the leading alternative. It addresses the four key issues identified above: it meets the regulatory requirement, has the lowest lifecycle costs, provides the best customer service and experience, and is technically superior. It also meets the environmental and safety objectives. The other

[1] Start Date of Construction is the Implementation Approval Date.

alternatives considered are less efficient and more costly, and do not necessarily meet regulatory compliance and/or improve customer experience and service.	
Project Impacts and Benefits: All street lights and private outdoor lights replaced with higher efficiency LEDs or removed from the system (private outdoor lights only) resulting in: compliance with Federal PCB Regulations; reduction in annual street light maintenance costs; and improved customer experience with improved lighting, less outages and accurate billing. The conversions to LED will result in savings of approximately 32 GWh per year.	
Project Implementation Phase Risk: • **Reputational Risk** with Customers unsatisfied with new LED rates. • **Financial Risk** with the cost of using internal Power Line Technicians capable of completing more complex work being more expensive than Contractor crews in performing this work. • **Reputational and Financial Risks** with fines due to lack of compliance with meeting Federal PCB deadline for removing all units with PCB before December 31, 2025. Some units could be missed as they may not be included in BC Hydro's databases. Add risks for completeness. • **Reputational Risk** of delay in obtaining new street light rate for LEDs.	**Risk Treatment:** • Engage customers early and consult with customers to communicate the costs and benefits of the program and to ensure adequate financial constraint of program costs. • Contractors have been deployed in all parts of the province to complete the work and internal crews are assigned higher complexity work outside of this program where available. • A mass replacement approach is being used to sweep areas to find any units not in BC Hydro databases and replace these additional units to ensure compliance. • Interim rate requested and received from BCUC to ensure that conversions can occur before a final rate.
Additional Information: N/A	

Investment Planning ID: T002016 (formerly 901654)	Project Name: Advanced Distribution Management System Replacement	
Forecast Capital Cost: $ 11 million	**Forecast In-Service Date:** Fiscal 2023	**Start Date of Construction:**[1] Fiscal 2022
Development Phase: Definition	**Filing Reference:** F22 RRA: • Appendix I, Technology - line 4	

Description:

A Distribution Management System (**DMS**) is needed to assist Real-Time Operations and field operating personnel with the monitoring and control of the electric distribution system. This project will extend BC Hydro's existing suite of systems to include an Advanced Distribution Management system (**ADMS**), replacing the existing, end-of-life DMS.

Key Drivers:

- Risk reduction
- Capability enhancement

Issues Being Addressed:

- Reliability risk from continued operation of an end-of-life DMS system. The current DMS software and hardware is now at end-of-life.
- Enable distribution management capabilities:
  - Support increased Real-Time Operations responsibilities due to growth in distribution assets;
  - Allow Real Time Operations to monitor and control the distribution system in real-time using the same systems as deployed for transmission real-time monitoring and control. In this way, operators will be able to seamlessly navigate between distribution stations views and feeder network views which will further improve safety and reliability; and
  - Enable support for Transmission and Distribution Operations functions including volt/VAR optimization, planned outage management and restoration, safety procedures management, and management of distributed energy resources.

Discussion of Alternatives:

BC Hydro evaluated the following two alternatives:

i. Extend the existing suite of management systems to include an ADMS, replacing the existing, end-of-life DMS, and

ii. Replace the existing suite of management systems with another vendor's single integrated Energy Management System (**EMS**) and ADMS.

Alternative i was chosen after it was determined that extending the existing suite of management systems was the only solution that could meet the requirement of a single integrated control system at reasonable cost and risk. This alternative will prepare BC Hydro for the future with a foundational platform that will support integration with demand response, vehicle to grid management and other "behind the meter technologies".

Alternative ii was ruled out because the cost to BC Hydro to completely replace the existing suite of management systems would be significantly higher and carry a high risk of disruption to the electric system operation and reliability.

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts & Benefits:

- Risk Reduction achieved through:
  - Further utilization of automation devices and smart meters during critical events such as major storms and disasters;
  - Simplifying safety processes and reducing manual activities, which is expected to reduce near-miss incidents; and
  - Integrating distribution and low-voltage substation management and monitoring functions to improve decision making and maintain safety standards for control centre operation
- Productivity Improvement:
  - Synchronization of EMS and DMS information in real-time;
  - Optimizing distribution system monitoring control and operation, and utilizing non-wire solutions such as distributed energy resources, demand response, energy conservation, and vehicle to grid management;
  - Improvement in planned outage management and faster restoration for unplanned outages; and
  - Improvement in service voltage management (power quality).

Project Implementation Phase Risk:	**Risk Treatment:**
This project is not yet in Implementation.	To be determined when the project reaches Implementation

Additional Information:

Start date of Implementation is expected during fiscal 2022.

Investment Planning ID: T001397	**Project Name:** Contact Centre Technology Foundation	
Forecast Capital Cost: $ 23.6 million	**Forecast In-Service Date:** Fiscal 2023	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F20-F21 RRA: • Application, pages 6-153, 6-154 • Appendix I, line 7 • Appendix L, pages 13, 24 • Exhibit B-29, page 3 • BCUC IRs 1.97.1 and 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Application, pages 6-74, 6-75 • Appendix I, line 4 • Appendix F, pages 14, 25, 26 • BCUC IR 1.50.2 • CEC IRs 1.45.1 CONF, 1.45.1 PUB, 1.45.2, 1.45.3	

Description:

The Contact Centre Technology Foundation project will address end-of-life Contact Centre Information Technology (**IT**) assets. The project will implement modern contact centre technologies to provide a stable and capable IT platform for all of BC Hydro’s contact centres.

Key Drivers:

- Risk reduction
- Capability enhancement

Issues Being Addressed:

The following issues will be addressed as part of this project:

1. Technology Obsolescence
   - BC Hydro’s current Contact Centre systems are considered by the vendor to be obsolete[2]. Although still functional, these IT systems are increasingly unstable and unable to meet growing business needs.
2. System Stability & Reliability Risk
   - Since the Contact Centre systems are considered obsolete, there is limited support from the vendor and only critical fixes are provided.
   - The existing solution does not have the capacity and flexibility to handle the increased call volumes seen during large scale power outages. For example, on a typical day the contact centre receives 500 trouble calls, this can increase to more than 50 times the volume during large scale outage events.

[1] Start Date of Construction is the Implementation Approval Date.

[2] Approximately $10.7 million was invested from 2015-2017 for Contact Centre system upgrades ($9.2 million capital and $1.6 million IOMA), of which $6.5 million was to maintain vendor support without adding new capabilities.

- BC Hydro's small regional centers have also experienced system reliability issues impacting the ability for customers to contact Customer Connections and the availability of call centre management tools.

3. Complex Operations Management
   - Modern call centre systems are single-vendor, fully-integrated platforms which reduce the complexity for sustainment and enhancements.
   - The current multi-vendor system leads to accountability issues and has resulted in a complex support model where confusion and miscommunication occurs.
4. Limited Capabilities for Agents & Customers
   - Existing Contact Centre functionality and integration capability limit agent's ability to better understand and address customer needs.
   - Limited functionality and reporting capabilities with the current Contact Centre platform.
   - Lack of information exchange among Contact Centres as a result of dispersed technology architecture limits agent's access to caller information across departments.

Discussion of Alternatives:

BC Hydro considered three alternatives:

i. Maintain the current technology solution;

ii. Pursue upgrades using solutions provided by vendors that already have systems deployed in BC Hydro’s environment; and

iii. Replace the current solutions and technology through competitive sourcing.

Alternative iii, Replacement, was chosen because it addresses all the identified issues at the lowest total cost of ownership. Alternative i would require costly infrastructure upgrades to extend life expectancy and maintain system reliability, but would not address issues 3 and 4. Alternative ii would involve implementation of a vendor product without review of competing products from other vendors, would likely not fully address issues 3 and 4, and would likely cost more than Alternative i.

Project Impacts and Benefits:

- Technology obsolescence risk will be mitigated through the implementation of a modern vendor-supported platform.
- Improved system stability and reliability with modern contact centre technology which allows for performance scalability during peak outage events.
- Streamlined operations management and sustainment of the contact centre technology platform.
- Improved functionality and capabilities for the contact centre, including investment options for enhanced self service capabilities that reduce operating costs.

Project Implementation Phase Risk:	Risk Treatment:
This project is not yet in Implementation.	To be determined when the project reaches Implementation.

Additional Information:

BC Hydro expects to file an application under section 44.2 of the *Utilities Commission Act* for this project.

Investment Planning ID: T002549	Project Name: Distribution Design Modernization	
Forecast Capital Cost: $23 million	**Forecast In-Service Date:** Fiscal 2025	**Start Date of Construction:**[1] Fiscal 2023
Development Phase: Planning	**Filing Reference:** New	

Description:

Modernize the distribution design processes through improved software tools for estimation, design, and work order creation. The project will migrate and enhance existing work management capabilities from Passport to SAP, implement new graphical design software and enhance the electrical connection request processes.

Key Drivers:

- Risk reduction
- Increased operational efficiency

Issues Being Addressed:

BC Hydro plans for the following issues to be addressed:

- Distribution Design and Customer Connections work relies on a suite of custom Information technology (**IT**) applications and the Passport Enterprise Resource Planning (**ERP**) platform, considered to be obsolete. This represents an increasing cybersecurity and reliability risk. The technology is functionally limited, imposes a high administrative burden on BC Hydro, and can no longer be cost-effectively improved. Continued use of Passport ERP prolongs and extends unnecessary complexity to BC Hydro's IT landscape; and
- Distribution Design workforce productivity is hampered by separate IT solutions for tabular, graphical and CAD based Design.

Discussion of Alternatives

BC Hydro has identified the following two potential alternatives for evaluation in the Identification phase:

i. Migration from Passport to SAP while keeping DAD as the graphical design tool; and
ii. Migration from Passport to SAP with implementation of modern graphical design tool.

Project Impacts and Benefits:

The following potential benefits may be identified and evaluated in the Identification phase:

- Reduced reliability and cybersecurity risk through eliminated reliance on unsupported software;
- Operating cost savings through improved design and drafting productivity, improved optimization of materials and labour, and improved efficiencies in processing electrical connection requests; and
- Capital cost savings through improved asset sizing and use of materials in designs and by reducing the likelihood of overbuilding distribution equipment.

Project Implementation Phase Risk:	Risk Treatment:
This project is not yet in Implementation.	To be determined when the project reaches Implementation.

Additional Information:

The project's most recent, revised capital cost estimate is $48 million. BC Hydro expects to file an application under section 44.2 of the *Utilities Commission Act* for this project.

1 Start Date of Construction is the Implementation Approval Date.

Investment Planning ID:	Project Name:	
T002036	Energy Management System Upgrade	
Forecast Capital Cost: $ 12.4 million	**Forecast In-Service Date:** Fiscal 2023	**Start Date of Construction:**[1] Fiscal 2021
Development Phase: Definition	**Filing Reference:** F20-F21 RRA: • Exhibit B-29, page 2 F22 RRA: • Application, pages 6-74 • Appendix I, line 7 • BCUC IR 1.50.2	

Description:

The Energy Management System (**EMS**) is a critical engineering system used by Transmission and Distribution System Operations to operate the bulk electric system in the province of B.C. and comply with Mandatory Reliability Standards (**MRS**). The system provides real-time monitoring and control of the power system and is the primary tool for control room operators in the Lower Mainland and the Interior. This project will upgrade BC Hydro's existing EMS software to a newer version, and will also replace the existing, end-of-life EMS technical infrastructure.

Key Drivers:

- Operational Requirements
- Risk reduction

Issues Being Addressed:

In order to maintain EMS reliability and security, and manage risk to the bulk electric system, the EMS software must be upgraded, and EMS technical infrastructure replaced in a timely manner.

BC Hydro generally maintains the EMS software at the latest version and replaces the technical infrastructure approximately every five years. The last major EMS software upgrade and hardware replacement was completed in 2017.

Discussion of Alternatives:

BC Hydro considered five alternatives:

i. **Full Upgrade** of EMS - includes upgrade of both software and hardware infrastructure;

ii. **Status Quo** – continue to use current software and hardware infrastructure with no plans for replacement;

iii. **Defer** – defer the start of the project;

iv. **Upgrade software only** – upgrade the EMS application without upgrading the underlying hardware technology to reduce project costs; and

v. **Upgrade hardware only** – upgrade the EMS hardware only and do not upgrade the application software to reduce project costs.

BC Hydro selected Alternative i, Full Upgrade. Alternatives ii and iii did not address the issues. Alternative iv is not viable due to the incompatibility between the legacy hardware and the new software. The same applies for Alternative v as the legacy software and the newer hardware are incompatible. Upgraded software requires a current hardware format to comply with software specifications.

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits: • The EMS availability is maintained, and BC Hydro operational requirements are met. • MRS compliance is supported for real-time operations and personnel training, long-term transmission system planning, protection system maintenance programs and critical infrastructure protection. The upgrade will reduce the risk of the following: • Increased cost of technology system repairs due to unplanned technology failures; and • Increased cost to Operations due to failures caused by unplanned technology that impacts the ability to manage the bulk electrical systems.	
Project Implementation Phase Risk: This project is not yet in Implementation.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: The project's most recent, revised capital cost estimate is $26.9 million. BC Hydro expects to file an application under section 44.2 of the *Utilities Commission Act* for this project.	

Investment Planning ID: T002718	Project Name: Enterprise MRS Compliance Management System	
Forecast Capital Cost: $ 2.9 million	**Forecast In-Service Date:** Fiscal 2024	**Start Date of Construction:**[1] Fiscal 2023
Development Phase: Future	**Filing Reference:** New	

Description:

Establish a standard governance and compliance oversight process and expand and improve the existing Compliance Management System software solution to support BC Hydro's continued compliance with Mandatory Reliability Standards (**MRS**). The existing software solution will be enhanced to include 102 adopted MRS within approximately 511 MRS requirements across Operations and Planning (**O&P**) and Critical Infrastructure Protection (**CIP**).

Key Drivers:

- Reliability
- Risk reduction

Issues Being Addressed:

Currently, BC Hydro does not have a standard and uniform compliance process or supporting solution for MRS that encompasses both O&P and CIP standards. The current compliance management system is limited to a selection of CIP standards and requirements. Having a consistent and standard MRS compliance process and a solution that supports this process ensures BC Hydro continues to comply with MRS, reducing reliability, reputation, and financial risks.

The Enterprise MRS Compliance Management System project has been identified as a key enabler for the processes and internal controls referenced within BC Hydro's Internal Compliance Program (**ICP**) to strengthen our compliance objectives. The project will leverage a central compliance system as BC Hydro's single platform for managing compliance workflows.

Discussion of Alternatives:

BC Hydro will identify and evaluate the alternatives in the Identification phase.

Project Impacts and Benefits:

The following potential benefits may be identified for evaluation in the Identification phase:

- Improved MRS compliance by establishing standardized governance, management and control across standards with the objective to increase effectiveness and efficiency of MRS compliance activities;
- Identification and documentation of risks, controls and processes associated with MRS based on Industry best practices and implementation of relevant subset of controls within the compliance management system;
- Improved reporting, dashboarding and competency management and standardization of reports for enterprise-wide use;
- Enhanced asset inventory, configuration, workflow and reporting and monitoring capabilities; and
- Improved and automated evidence collection, self certification and Reliability Standards Audit Worksheet (**RSAW**) generation process with user friendly and easy to use documents packaging capability for data requests.
- Built in security and controls based on roles and responsibilities.

[1] Start Date of Construction is the Implementation Approval Date.

The project will reduce the risk of the following: • Financial penalties brought about by MRS non-compliance. • Electricity reliability impacts to B.C. customers and interconnected utilities.	
Project Implementation Phase Risk: This project is not yet in Implementation.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: A study was conducted from March to May 2021 to assess BC Hydro's existing software's capabilities to support the vision of having a single MRS compliance management system. The results of the study were used as an input to this project and the current, revised estimates indicate a capital cost range of $10 million to $12 million.	

Program of Projects Name: Corporation Telephony Replacement		
Appendix I Reference: Corporate Telephony Replacement		
Investment Planning ID: T002202 T002669	**Project Name:** Corporate Telephony Replacement Project Corporate Telephony Replacement Work Program F23-F25	
Forecast Capital Cost: $6.6 million	**Forecast In-Service Date(s):** Fiscal 2023, 2024, 2025	**Start Date of Construction:**[1] Fiscal 2022
Development Phase: Project in Identification Work Programs in Planning	**Filing Reference:** New	
Description of Program of Projects: Corporate Telephony Replacement is a program of projects to replace the end-of-life corporate telephony system with a fully supported system featuring improved, modern capabilities. The initial project will replace the core telephony system and set the standard for the replacement of telephony at corporate and field offices as well as refresh three sites with the new telephony system. The Corporate Telephony Replacement Work Program F23-F25 will continue the replacement of the current telephony at additional sites. Additional capital expenditure may be required in the fiscal 2026 to fiscal 2028 period to complete replacements of equipment at remaining sites and/or to initiate asset refresh.		
Issues to be addressed: • Obsolete, unreliable and unsupported telephony technologies and infrastructure (licenses, hardware and software). • Limited ability to support new employees and sites. • Complex infrastructure with components from multiple vendors combined together. • Unable to provide modern unified communication capabilities such as integration with Microsoft desktop and collaboration tools. • Unable to provide self-serve capabilities including deskphone password reset and employee onboard/offboard automation.		
Schedule of Program of Projects: • Corporate Telephony Replacement Project (T002202) in service fiscal 2023 • Corporate Telephony Replacement Work Program (T002669) in service fiscal 2023 to fiscal 2025		
Risks and Mitigation Strategies: N/A		
Additional Information: N/A

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID:	Project Name:	
T001379	SAP S/4HANA Upgrade	
Forecast Capital Cost: $ 22.5 million	**Forecast In-Service Date:** Fiscal 2027	**Start Date of Construction:**[1] To be determined
Development Phase: Planning	**Filing Reference:** F20-F21 RRA: • Application, pages 6-153 • Appendix I - Technology, line 9 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • BCUC IR 1.50.2	

Description:

Upgrade and migrate BC Hydro's primary Enterprise Resource Planning (**ERP**) system and solutions from our current SAP product version to SAP S/4HANA[2] in alignment with SAP's product roadmap and BC Hydro's Technology ERP roadmap. This is to ensure the long-term availability of SAP product support and innovation to avoid IT obsolescence and associated business risks.

Key Drivers:

- Reliability
- Risk reduction

Issues Being Addressed:

Operating an unsupported version of our primary ERP system represents an unacceptable reliability and cybersecurity risk. Mainstream vendor support for BC Hydro's SAP version ends in 2027.

Discussion of Alternatives:

BC Hydro uses SAP software to enable key business functions, including Finance, Human Resources, Customer Care & Billing, Environmental / Health / Safety Management, Project & Portfolio Management, Supply Chain, Enterprise Asset Management and Work Management.

BC Hydro is committed to a single ERP system strategy with regular product updates to avoid product obsolescence and appropriately balance asset performance, cost and risk. The importance of the SAP software, the need for continuity of vendor support, and the expected three-year project duration make it imperative for BC Hydro to start the project by fiscal 2025.

Project Impacts and Benefits:

The project will avoid ERP system obsolescence through the long-term continuity of access to SAP's products, support and innovation. Benefits will be identified and assessed during the Identification phase.

Project Implementation Phase Risk:	Risk Treatment:
This project is not yet in Implementation.	To be determined prior to Implementation phase.

Additional Information:

BC Hydro expects to file an application under section 44.2 of the *Utilities Commission Act* for this project.

1 Start Date of Construction is the Implementation Approval Date.
2 S/4HANA is SAP's current generation of its core ERP application.

Investment Planning ID: T002122	**Project Name:** Stations Work Management	
Forecast Capital Cost: $ 22 million	**Forecast In-Service Date:** Fiscal 2023	**Start Date of Construction:**[1] To be determined
Development Phase: Planning	**Filing Reference:** New	

Description:

Mitigate work management issues and risks in Stations Field Operations by addressing IT obsolescence. Stations work records will be migrated out of Passport and into SAP, and an enterprise grade work planning and scheduling tool will be implemented to replace the existing spreadsheet solution. These changes will facilitate the decommissioning of Passport, improve maintenance productivity and streamline work processes.

Key Drivers:

- Risk reduction
- Increased operational efficiency

Issues Being Addressed:

A range of Stations work management issues are being caused, worsened, or prolonged by the obsolescence of the current work management core system, Passport, and the spreadsheet-based planning and scheduling solution.

Discussion of Alternatives:

BC Hydro will identify and assess alternatives during the Identification phase

Project Impacts and Benefits:

Benefits will be identified during the Identification phase.

Project Implementation Phase Risk:	**Risk Treatment:**
To be assessed prior to Implementation phase.	To be determined prior to Implementation phase.

Additional Information:

BC Hydro expects to file an application under section 44.2 of the *Utilities Commission Act* for this project.

1 Start Date of Construction is the Implementation Approval Date.

Investment Planning ID:	Project Name:	
P201703	Chilliwack Field Building Redevelopment

Development Phase: Definition	**Filing Reference:** F17-F19 RRA: • Appendix I, line 15, Appendix J, pages 84-85 • BCUC IRs 1.70.3, 1.116.1, 1.116.2, 1.116.3, 1.116.4, 1.116.5, 2.249.8, 2.260.4, 2.270.1, BCOAPO IRs 1.36.1, 2.77.1 F20-F21 RRA: • Chapter 6, pages 6-162 • Appendix I - Properties, line 4, Appendix J, page 123 • BCUC IR 1.133.1 Confidential • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-80 • Appendix I - Properties, line 2	

Description:

This project involves the redevelopment of a district field building located in Chilliwack.

BC Hydro operations are based out of two locations in Chilliwack, one of which is located within the Atchelitz substation property at 6155 Lickman Road and the other which is a leased property within a multi-tenanted facility, consisting of approximately 12,000 ft^2 of office and warehouse space at 44550 South Sumas Road. The Atchelitz facility is owned by BC Hydro and was built approximately 40 years ago, and comprises about 5,500 ft^2 of office space. A total of approximately 35 staff are based at these two sites.

There is a long-term need for a suitable field office to provide operational and post-disaster recovery and emergency support to meet the needs of the almost 100,000 residents served in Chilliwack and the surrounding areas of Atchelitz, Cultus Lake, Sardis, Promontory Heights, Vedder, Yarrow, and Greendale. This includes appropriate outage response, planning and execution of the electric system to support local/regional development, and maintenance and upgrades to infrastructure to ensure ongoing system reliability in the region. In order to “keep the lights on”, the facilities must remain operational to support 24/7 emergency response in the worst weather conditions and in the event of a natural disaster.

Key Drivers:

- Operational Requirements
- Safety
- Reliability

Issues Being Addressed:

The existing facilities have been prioritized for redevelopment due to the following: lack of adequate space for current and projected business operations; the inability to expand either the Chilliwack facility (it is a leased building) and the Atchelitz location (close proximity to a substation); and the condition and associated seismic concerns of the existing buildings. The key issues are:

1 Start Date of Construction is the Implementation Approval Date.

- The facilities have inadequate space for existing staff and materials, requiring some staff to work out of the Abbotsford facility, approximately 35 km away, and requiring the Abbotsford office to store a large volume of materials, including poles and transformers, for the Chilliwack/Atchelitz operations. This can delay response time, especially in the winter or during emergencies;
- The facilities are inadequate for working, maneuvering and loading line trucks. The location of the Atchelitz office on the same site as a substation prevents office expansion and puts a strain on the safe and efficient use of yard space. It is also difficult to safely move and load line vehicles in the multi-tenanted Chilliwack office complex;
- Both facilities are located in a high seismic region and do not meet requirements for a facility that is expected to be fully functional in a post-disaster situation;
- The facilities have inadequate fire suppression and sprinklers, contain hazardous materials, lack an emergency generator, and require the replacement of the Atchelitz end of life roof; and
- The facilities have inadequate office space to support the current and future demands.

Discussion of Alternatives:

The six alternatives being considered include:

i. **Do nothing:** continue with existing facilities;
ii. **Lease** additional space adjacent to the existing Chilliwack facility;
iii. **Renovate and expand** the existing Atchelitz facility, or build new, and maintain the leased Chilliwack facility;
iv. **Construct** a new facility at a BC Hydro owned location;
v. **Acquire** a new site and construct a new facility; and
vi. **Lease** a larger facility, long-term.

Alternative iv, Construct a new facility at a BC Hydro owned location, has been selected as the preferred alternative as it meets the current and future needs for servicing the Chilliwack Region. In the previous Appendix J for this project in the Fiscal 2020 to Fiscal 2021 Revenue Requirements Application, Alternative v was the recommended alternative but we were unable to acquire a suitable property. As a result, an owned property has been revisited and a design developed for a modified facility to work within the constraints of the site.

Alternative i was not selected as it did not address safety issues and space constraints. Alternative ii was not selected as there was no space available that met the specific requirements for office, warehouse, yard and parking. Alternative iii was not selected as the site was too small for the required operations. Alternative vi was not selected as there was no available leased land that met the operational requirements.

Project Impacts and Benefits:

- Project will result in a new facility that meets current and anticipated functional and operational needs.
- The new facility will meet all current building codes including post-disaster standards.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks will be identified starting in the Identification Phase and finalized in the Implementation Phase	To be determined when the project reaches implementation

</table>

Description:

This project involves the redevelopment of the Material Classification Facility in Surrey. The Material Classification Facility is located at 12345 88th Avenue in Surrey, B.C. on the BC Hydro Surrey campus. The facility comprises the Transformer Shop and Hazardous Waste Operations including salvage and disposal operations and occupies an area of 19,800 sq.ft. of building area and 8.6 acres of yard space. The buildings were constructed throughout the 1970's and 1980's as business needs required. Approximately 27 employees work out of this facility.

The facility receives recovered electrical equipment and hazardous wastes from BC Hydro's operations from across the entire province, making it critical in supporting other business units' waste needs. The products are received, drained of any oils, sorted, stored, and packaged or re-packaged prior to being transported offsite for recycling, treatment, or disposal at authorized hazardous waste management facilities.

Key Drivers:

- Environmental
- Operational Requirements
- Safety

Issues Being Addressed:

The Material Classification Facility has been identified as a priority for redevelopment due to environmental regulation requirements, zoning non-compliance, operational challenges, building conditions, and code compliance.

The key issues are that the facilities:

- Do not meet the Ministry of Environment's protection measures that prevent the release of contaminants of concern and prevent pollution;
- Contravene existing zoning regulations from the City of Surrey;
- Do not provide sufficient enclosed areas to sort and store materials;

[1] Start Date of Construction is the Implementation Approval Date.

- Cannot support current business requirements of oil storage and Paper Insulated Lead Covered cable sampling;
- Do not meet current building code standards, including meeting less than 50 per cent of the BC Building Code minimum requirements for normal buildings being able to withstand a seismic event; and
- Have numerous building components (building envelope, mechanical and electrical systems) at the end of their useful life and needing replacement.

Discussion of Alternatives:

BC Hydro evaluated the following five alternatives:

i. **Do nothing:** continue with existing facilities;

ii. **Apply for rezoning and, if approved, renovate** and expand the existing facilities to meet current building code, safety and program requirements;

iii. **Apply for rezoning and, if approved, construct** a new facility on the existing site and demolish the existing building;

iv. **Construct** a new facility at a new location on Surrey campus; and

v. **Acquire** a new site off the Surrey campus and construct a new facility.

Alternative iv, Construct a new facility at a new location on Surrey campus, was selected as the recommended alternative as it is the most cost effective alternative as it utilizes property BC Hydro owns, reduces maintenance costs for aged facilities, and meets the environmental, operational and zoning requirements. Alternative i was not selected due to non-compliance with Ministry of Environment guidelines for storage and contaminated materials as well as zoning non-compliance. Alternatives ii and iii were not selected as applications for re-zoning are lengthy and approval is not guaranteed. Alternative v was not selected as the project team was unable to find a suitable site with the appropriate zoning and size.

Project Impacts and Benefits:

- New facility that is compliant with Ministry of Environment's Hazardous Waste Regulations
- New facility being compliant with City of Surrey zoning regulations.
- New facility that meets operational needs and current building codes including seismic withstand.

Project Implementation Phase Risk:	**Risk Treatment:**
Impact to schedule due to delays in procurement for major equipment.	Expected equipment lead times and shop drawing approval times have been factored into the project schedule. In addition, target delivery dates have been included in the tender documents.
Potential for unforeseen cost increases during construction.	A construction contingency has been applied for unforeseen items, such as increasing commodity costs during construction. Early procurement of high value, high risk work packages to reduce the risk of price escalations.

Additional Information:

N/A

Investment Planning ID: P201901	**Project Name:** Kamloops Field Building Redevelopment	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** F20-F21 RRA: • Chapter 6, pages 6-162 • Appendix I - Properties, line 6, Appendix J, page 127 • BCOAPO IR 1.62.1 PUBLIC Attachment 1 F22 RRA: • Chapter 6, page 6-80 • Appendix I - Properties, line 4	

Description:

This project involves the redevelopment of the large district field office located in Kamloops.

The Kamloops District Office is located at 1155 McGill Road in Kamloops and was constructed in 1981. The District Office is approximately 34,000 ft2 in size and serves BC Hydro customers in Kamloops and the surrounding areas. The facility currently accommodates approximately 130 staff.

There is a long-term need for a suitable field office to provide operational and post disaster recovery and emergency support, and to meet the needs of more than 100,000 customers in the surrounding area that spans east to Chase, west to Savona, north to Barierre, and south to Lac Le Jeune. This support includes outage response, planning and execution of the electric system to support local/regional development, and maintenance and upgrades to infrastructure to ensure ongoing system reliability in the region. In order to “keep the lights on”, the facilities must remain operational to support 24/7 emergency response in the worst weather conditions and in the event of a natural disaster.

Key Drivers:

- Operational Requirements
- Safety

Issues Being Addressed:

The existing facility has been prioritized for redevelopment due to a lack of adequate space for current and projected business operations, requirement for seismic and safety upgrades, and to address building condition, and code compliance. The key issues are that the facility:

- Does not meet current functional and operational needs, or future growth. The facility does not provide sufficient space to accommodate all current staff, does not provide adequate truck bays for truck storage or for Fleet’s current needs, and does not provide sufficient yard space for vehicles and materials;
- Is almost 40 years old, and does not meet current building code standards, including meeting less than 50 per cent of the BC Building Code minimum requirements for a post disaster resistance building;
- Has inadequate fire protection and accessibility, including non-conforming fire separation between the garage and offices; and
- Has numerous building components (mechanical, electrical, HVAC, interiors) requiring replacement.

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives: BC Hydro is considering four alternatives: **i.** **Do nothing** and continue to budget for major maintenance and replacements**;** **ii.** **Renovate and expand** the existing facility; **iii.** **Construct** a new facility on the existing site, and iv. **Build** a new facility on a new purchased or leased site.	
Project Impacts and Benefits: To be determined when project reaches Definition phase	
Project Implementation Phase Risk: Risks will be identified starting in the Identification Phase and finalized in the Implementation Phase	**Risk Treatment:** To be determined when the project reaches implementation
Additional Information: N/A	

Investment Planning ID: P201902	Project Name: North Vancouver Field Building Redevelopment	
Forecast Capital Cost: $43.0 million	**Forecast In-Service Date:** Fiscal 2026	**Start Date of Construction:**[1] Fiscal 2023
Development Phase: Definition	**Filing Reference:** F22 RRA: • Chapter 6, page 6-80 • Appendix I - Properties, line 6	

Description:

This project involves the redevelopment of a district field office located in North Vancouver. The existing North Vancouver District Office facility is located at 630 Brooksbank Avenue. The existing facility is a two-storey steel frame building that was constructed in 1985. The main building has a total area of 26,000 sq.ft. Indoor accommodations are categorized as administrative, industrial, and base building components. The facility currently accommodates 67 staff.

There is a long-term need for a suitable field office to provide operational and post disaster recovery and emergency support and to meet the needs of approximately 182,000 customers within North Vancouver, West Vancouver, Lions Bay and Bowen Island. This support includes outage response, planning and execution of the electric system to support local/regional development, and maintenance and upgrades to infrastructure to ensure ongoing system reliability in the region. The facility must remain operational to support 24/7 emergency response in the worst weather conditions and in the event of a natural disaster. Additionally, in the event of an emergency where the Lions Gate and Iron Workers bridges are compromised, BC Hydro's disaster response plan will be compromised for the North Shore operational area and the greater Sea to Sky corridor, unless this North Vancouver District Office is fully operational.

Key Drivers:

- Operational Requirements
- Safety

Issues Being Addressed:

The existing facilities have been prioritized for redevelopment due to the following issues:

- Lack of adequate space for current and projected business operations
- Need for additional truck bays, and right-sizing of existing truck bays;
- Lack of storage space, and workshop space;
- Non-compliance with the current Building Code; and
- Emergency response and system restoration for the North Shore operational area and the greater Sea to Sky corridor.

Discussion of Alternatives:

The following four alternatives were considered in the Identification phase.

i. **Status Quo:** Continue to maintain and repair the existing facility and plan for increased maintenance costs;

ii. **Renovate and Expand** the existing facility

iii. **Construct** a new facility on the existing site; and

iv. **Construct** a new facility on a new site.

Alternative iii, Construct a new building on existing site, was selected as the preferred alternative as it addresses the safety concerns associated with the current facility, ensures operational business

[1] Start Date of Construction is the Implementation Approval Date.

continuity in the event of an emergency and addresses operational deficiencies. Utilizing our existing property prevents a challenging search for low cost land in the area. Alternative i was not selected due to lack of seismic resistance that could negatively impact business continuity, safety and space constraints for operations. Alternative ii was not selected as renovating the existing facility, adding an expansion and parking would not fit on the two acre site. Alternative iv was not selected as there was no viable industrial property available in close proximity to the customer base and thoroughfares.
Project Impacts and Benefits: • Facility that meets current and anticipated functional and operational needs • Facility that meets all current Building Code standards including safety and post-disaster withstand.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation

Additional Information: N/A

Investment Planning ID:	Project Name:	
P202202	Campbell River II Field Building Redevelopment	
Forecast Capital Cost: $43.0 million	**Forecast In-Service Date:** Fiscal 2026	**Start Date of Construction:**[1] Fiscal 2023
Development Phase: Definition	**Filing Reference:** New	

Description:

This project involves the redevelopment of a district field office facility in Campbell River.

The existing Ironwood facility is a leased property located at 1280/1400 Ironwood Street, within the Ironwood Mall in Campbell River. The current single-story lease is comprised of 9,000 sq. ft. of office space, 10,000 sq. ft. of storage space, yard, and parking.

The existing John Hart Administration building, located at 10 John Hart Road, was constructed in 1991. It is a two-story pre-engineered building with a wood framed entry administration space. The overall floor area is 8,000 sq. ft. The two facilities currently accommodate approximately 100 staff combined, who provide service to six Generation stations and associated dams, canals, and spillways, as well as provide service to 23 substations.

The purpose of the Campbell River Phase II project is to provide a new and permanent office location for the 100 staff currently located at the Ironwood Facility and the John Hart Administration building and consolidate all operations in the Campbell River area on one location at the existing Campbell River I office facility, which is located on land leased under a long term agreement with a local First Nation.

Key Drivers:

- Operational Requirements
- Safety
- Reliability

Issues Being Addressed:

The existing BC Hydro facilities at Ironwood and John Hart are not meeting the current operational needs of the business. The key issues are that the facilities:

- Do not meet operational needs as the office is located in a retail space, there is insufficient yard space and minimal parking for trucks;
- Do not meet current Building Code, including seismic withstand requirements; and
- Are geographically separated with staff in three facilities within the Campbell River area.

Discussion of Alternatives:

BC Hydro evaluated the following four alternatives:

i. **Do nothing:** Continue to maintain and repair the existing facilities at Ironwood and John Hart facilities, and plan for increased maintenance and asset replacement costs moving forward;

ii. **Expansion on existing Campbell River I site:** new build and parking on the existing BC Hydro leased field office site;

iii. **Expansion on existing Campbell River I site and adjacent site:** lease adjacent site and construct new building, parking and operations yard; and

iv. **Renovate and expand John Hart Facility:** Renovate and expand the existing John Hart Admin facility.

1 Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">Alternative iii, Expansion on existing Campbell River site and adjacent site, was selected as the recommended alternative as it will avoid long-term lease costs and utilize space originally built in the Campbell River I office facility for future staff. In addition, it will achieve the primary goal to consolidate the three facilities and create an effective solution for staff and operations. Alternative i was not selected as it did not address building code compliance and seismic issues and there was inadequate space for operations. Alternative ii was not selected as the site was not large enough to accommodate the space requirements of the three facilities. Alternative iv was not selected as it was an unsuitable location on a flood plain and could not accommodate the primary goal of consolidating three facilities in one location.</td></tr>
<tr><td colspan="2">Project Impacts and Benefits:
• Project will result in a new facility that meets current and anticipated functional and operational needs.
• The new facility will meet all current building codes including post-disaster standards.</td></tr>
<tr><td>Project Implementation Phase Risk:
Risks will be identified starting in the Identification Phase and finalized in the Implementation Phase</td><td>Risk Treatment:
To be determined when the project reaches implementation</td></tr>
<tr><td colspan="2">Additional Information:
N/A</td></tr>
</table>

Investment Planning ID: P202101	Project Name: Duncan Field Building Redevelopment	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Future	**Filing Reference:** F22 RRA: • Chapter 6, page 6-80 • Appendix I - Properties, line 5	

Description:

This project involves the redevelopment of a district field office facility in Duncan. The Duncan Field Office facility is located at 6494 Norcross Road, Duncan, on Vancouver Island. Originally constructed in mid-1970s as a car dealership, the building and grounds were converted into a BC Hydro district office in 1980. The current office and warehouse facility occupy approximately 9,000 sq. ft. on a two-acre site, and has 20 staff based at this location.

There is a long-term need for a suitable field office to provide operational and post disaster recovery and emergency support and to meet the needs of approximately 80,000 customers within the Cowichan Valley Regional District. This support includes outage response, planning and execution of the electric system to support local/regional development, and maintenance and upgrades to infrastructure to ensure ongoing system reliability in the region. The facility must remain operational to support 24/7 emergency response in the worst weather conditions and in the event of a natural disaster.

Key Drivers:

- Operational Requirements
- Safety
- Reliability

Issues Being Addressed:

The existing facility has been prioritized for re-development due to the following issues:

- The facility meets less than 50 per cent seismic resistance capacity per current Building Code and is located in the highest seismic vulnerability region in Canada;
- Numerous Building Code non-compliance issues including inadequate fire safety and accessibility;
- A highly constrained yard – inadequate size, insufficient line-truck turning radius, steep slopes, resulting in unsafe yard and traffic flow conditions;
- Many of the original building components are in poor condition and now at or near end-of-life
- The truck bays are too small to service the larger line trucks; and
- Current building size is too small for users' needs and cannot be reconfigured to meet operational requirements.

Discussion of Alternatives:

BC Hydro is considering four alternatives:

i. **Do nothing:** continue to maintain and replace components at high cost;

ii. **Renovate and expand the existing facility**;

iii. **Construct a new facility on the existing site**; and

iv. **Construct a new facility on a new site**.

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits:	
To be determined when project reaches Definition phase.	
Project Implementation Phase Risk:	**Risk Treatment:**
Risks will be identified starting in the Identification Phase and finalized in the Implementation Phase	To be determined when the project reaches implementation
Additional Information:	
$5 million has been included in the fiscal 2023 of the F22-F31 Capital Plan for land purchase as the existing site is too small for redevelopment.	

Investment Planning ID:	Project Name:	
P202202	Cranbrook Field Building Redevelopment	
Forecast Capital Cost: To be determined	**Forecast In-Service Date:** To be determined	**Start Date of Construction:**[1] To be determined
Development Phase: Identification	**Filing Reference:** New	

Description:

This project involves the redevelopment of a district field office facility in Cranbrook. The Cranbrook Field Office is located at 629 Industrial Road No. 2. It was originally constructed in 1972. The 25,000 sq. ft main building includes offices, workshops, truck storage, and warehouses. A total of 61 employees are based at the facility.

Key Drivers:

- Operational Requirements
- Safety
- Reliability

Issues Being Addressed:

There is a long-term need for a suitable field office to provide operational and post disaster recovery and emergency support to meet the needs of approximately 40,000 customers in the East Kootenay Region including the City of Cranbrook and City of Kimberley. This includes appropriate outage response, planning and execution of the electric system to support local/regional development, and maintenance and upgrades to infrastructure to ensure ongoing system reliability in the region. The Cranbrook Field Office is a critical service provider of operations and maintenance of the power grid system and must remain operational to support 24/7/365 emergency response in all weather and natural disaster conditions to “keep the lights on” and support residential, commercial and industrial customers.

The existing facility has been prioritized for redevelopment due to a lack of adequate space for current and projected business operations, requirements for seismic and safety upgrades, and to address building condition and code compliance. The key issues are that:

- The facility is in a high seismic region and does not meet requirements to be fully functional in a post-disaster situation;
- The roof does not meet the current snow load requirements and snow removal is required to provide safety and business continuity;
- The roof does not meet the current snow load requirements, which presents a safety issue to the occupants inside the building and a risk to business continuity;
- There is a lack of adequate fire suppression and sprinklers;
- Space constraints associated with the building, truck storage and yard, which need to be addressed to ensure safety and efficiency of operations, and business continuity; and
- The building contains identified encapsulated hazardous material that can pose a safety risk to occupants if disturbed.

---

</table>

Description:

Site C will be a third dam and hydroelectric generating station on the Peace River approximately 7 kilometres southwest of Fort St. John. It will be capable of producing approximately 5,100 gigawatt-hours of electricity annually and 1,100 megawatts of capacity.

Project components include:

- Access roads and a temporary construction access bridge across the river at the dam site;
- A worker accommodation camp at the dam site;
- Upgrades to roads and realignment of segments of Highway 29;
- Two new 500 kV transmission lines connecting Site C to the existing Peace Canyon Substation, along an existing right-of-way;
- Shoreline protection at Hudson's Hope;
- An 800-metre roller-compacted concrete buttress to improve foundation stability and seismic protection;
- An earthfill dam, approximately 1,050 metres long and 60 metres high above the riverbed;
- A generating station with six 183 MW generating units, and spillways; and
- An 83-kilometre-long reservoir that would be, on average, two to three times the width of the current river.

As announced in February 2021 and approved in June 2021, the cost of the Site C project has been revised and is $16 billion, with a one year delay to 2025 for the project in-service date. This updated budget includes capital costs, charges subject to regulatory deferral and certain operating expenditures.

Key Drivers:

- Generation Growth

Issues Being Addressed:

As the third project on one river system, Site C will gain significant efficiencies by taking advantage of water already stored in the Williston Reservoir. This means that Site C will generate approximately 35 per cent of the energy produced at W.A.C. Bennett Dam, with only 5 per cent of the reservoir area.

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

Site C has been compared to alternatives in multiple BC Hydro and BCUC processes.

The decision to proceed with Site C was based on the 2013 IRP, which showed that Site C would provide substantial benefits compared to alternative portfolios of clean resources which could include wind, solar, or energy efficiency measures.

A comparison of Site C to alternatives was also done in the 2017 BCUC Inquiry, once again reviewing Site C compared to a range of clean alternative resources. This analysis showed that over 70 years, completing Site C is significantly less expensive than an Alternative Clean Portfolio.

Project Impacts and Benefits:

Project Benefits

Site C is part of the existing and committed resources under BC Hydro's Draft 2021 Integrated Resource Plan. In addition to providing energy, capacity, and flexibility, the Site C Project is providing key benefits for B.C. including regional economic development, job creation, and benefits for communities and Indigenous groups.

Project Attributes

- Site C will provide 1,100 megawatts of capacity, and produce about 5,100 gigawatt hours of electricity each year – enough energy to power the equivalent of about 450,000 homes per year in B.C.
- It will be a source of clean and renewable electricity for more than 100 years.
- Site C will have among the lowest GHG emissions, per gigawatt hour, compared to other resource options.
- As the third project on the Peace River, Site C will rely on the existing Williston Reservoir for water storage. This means Site C will generate approximately 35 per cent of the energy produced at the W.A.C. Bennett Dam, with only 5 per cent of the reservoir area.
- Site C will employ approximately 4,500 workers and create approximately 19,000 person-years of direct employment during construction.
- Construction provides significant opportunities for businesses of all sizes.
- Provides employment, training and contracting opportunities for Indigenous communities
- Once in operation, Site C will result in $2 million in revenue from grants-in-lieu and school taxes.
- Site C will be a source of affordable power to meet B.C.'s future electricity needs.

Environmental Assessment Process

The Site C Project received environmental approval from the federal and provincial governments in October 2014. The approval of the project followed a cooperative federal-provincial environmental assessment process by the Canadian Environmental Assessment Agency (**CEA Agency**) and the British Columbia Environmental Assessment Office (**BCEAO**). The process started in August 2011 and took approximately three years to complete.

The environmental assessment process for Site C was thorough and independent and included multiple opportunities for timely and meaningful participation by the public, Indigenous groups, all levels of government, and other interested stakeholders.

As part of the environmental assessment, BC Hydro undertook multi-year studies to identify and assess potential project effects and proposed comprehensive mitigation measures. All of this information was documented in more than 29,000 pages in the Site C Environmental Impact Statement (EIS) and associated documentation. The extensive review process included two months of public hearings in several regional and Indigenous communities under an independent Joint Review Panel.

Community Benefits and Mitigation Measures

To date, BC Hydro has reached a regional legacy benefits agreement with the Peace River Regional District and community agreements with:

- District of Chetwynd;
- District of Taylor;
- City of Fort St. John; and
- District of Hudson's Hope.

Among the benefits to local communities from the Site C Project are a regional legacy benefits agreement, infrastructure improvements, recreation and tourism opportunities, and affordable housing.

Additional Information:

Risk Description	Impact and Response Plan Summary
Risk that COVID-19 event impacts continuation of construction activities at site or in Vancouver.	**Impact:** BC Hydro and contractors do not have access to the required labour for daily construction and project management activities. BC Hydro and contractor costs increase to respond to COVID-19 and schedule delay impacts; camp capacity reduction and/or shutdown due to COVID-19 outbreaks. **Response:** Minimize non-essential travel to site. Screen workers before they travel to site and at site before entry; implement camp mitigation measures (additional cleaning, closed cafeteria self serve stations, establish isolation wings); put in place BC Hydro and contractor worker protection exposure protocols and plans.
Risk that the Project cannot attract and retain sufficient skilled workers.	**Impact:** Contractors may not be able to adequately source, supply, attract, and retain sufficient project labour due to workforce demographics, increased competition for labour from other major projects, the requirement for specialized workers, and the effects of COVID-19. This may result in potential impacts to schedule, safety, productivity and cost. **Response:** Contractors provide labour sourcing and supply plans, provide advance notice of foreign workers, and participate in local job fairs. BC Hydro encourages and facilitates capacity building initiatives and monitors employee turnover rates and labour conditions on other projects.
Risk that increased interest rates and changes in expenditure timing increases borrowing costs.	**Impact:** Rising interest rates and changes in expenditure timing result in an increase to the Project's interest costs above the amount budgeted. **Response:** Implement interest rate hedging program for future debt placements to reduce the potential impact of rising interest rates. Monitor changes to expenditure timing.
Risk of contractor claims.	**Impact:** Increased construction management and contract management effort required to respond and investigate claims; settlement of claims may result in increased costs. **Response:** Ensure sufficient commercial management resources in place, proactively resolve claims as received, and ensure commercial management procedures are in place.
Risk of a safety incident resulting in a fatality or disabling injury.	**Impact:** Serious worker injury or fatality; project delays and associated costs. **Response:** Continue with BC Hydro and contractor safety steering committee to address shared safety issues and opportunities; BC Hydro and contractors have implemented safety cultural leadership training; increase BC Hydro executive involvement and engagement with site safety leadership; regularly hold on site safety conferences; continue to include safety in BC Hydro and contractor on boarding orientations; and continue to promote a strong safety culture.

Risk Description	Impact and Response Plan Summary
Risk of earthfill dam construction delays due to instrumentation installations.	**Impact:** Earthfill dam construction is delayed awaiting the installation of instruments; Instruments are non-functional and/or damaged. **Response:** Close oversight of the main civil works contractor's current effort to self perform work; main civil works contractor refining/training personnel and drilling techniques/equipment; communicating to main civil works contractor the importance of instrumentation and scheduling to mitigate delays.
Risk of a slope failure on transmission right-of-way above the Site C substation.	**Impact:** Slope failure on the transmission line right-of-way above the substation. Costs to repair transmission lines and substation. **Response:** Conduct geotechnical investigations, install additional instrumentation, and implement agreed upon slope failure mitigation measures prepare by an independent engineering firm.
Risk of erosion of the outlet riprap material.	**Impact:** Cost of remediation; schedule delay and potential generation flow restriction on G.M. Shrum and Peace Canyon generation stations. **Response:** Complete both temporary and permanent solutions to prevent erosion. Monitor outlet area for any signs of erosion.
Risk of procurement uncertainty for the right bank foundation enhancement work.	**Impact:** Existing contractors' scope of work and schedule impacted by potential new right bank foundation enhancement contractor interfaces. **Response:** Rely on change schedule terms of existing contracts to proceed with change orders for the right bank foundation enhancement work scope, and if agreement can't be reached, proceed with an open procurement process.
Risk of lack of access to intake deck impacts transmission lines from generating station to substation.	**Impact:** Delays to transmission lines in-service date and turbine-generator unit 1 in-service date **Response**: Work with interface management and construction management to update the schedule to ensure the transmission lines are available when required. Develop plan to complete the work and resolve any potential lack of access to the intake deck.

Appendix K

Capital Project Strategies, Plans and Studies

Table of Contents

1 Introduction

BC Hydro's strategies, plans and studies are developed to seek potential solutions to upgrade the Power System and related infrastructure and do not in themselves create a financial commitment. These strategies, plans and studies investigate and/or recommend broader regional, system, or business solutions or policies, supporting the need or justification for a future project or solution. This appendix includes summaries of Power System strategies, plans or studies that are linked to specific projects included in Appendix I.[1,2]

This appendix is organized as follows:

- Section 2 provides an overview of the current state of BC Hydro's Power System;
- Section 3 explains BC Hydro's strategic planning process and the types of documents that are included in this appendix; and
- Attachment 1 provides summaries of 62 Power System strategies, plans and studies.

2 BC Hydro's Power System

2.1 Overall System

As described in Chapter 6, BC Hydro's generation, transmission and distribution systems form the Power System, generating electricity and delivering it to our customers throughout B.C.

[1] A Technology Strategy and Five-Year Plan is included as Appendix O. Specific strategies are not developed for the Properties, Fleet or Business Support/Other asset categories.

[2] Where applicable, the strategy, plan or study linked to a specific project has been identified in column Y of Appendix I.

Through BC Hydro’s capital investments over the last decade, reliability has been maintained, system capacity has been increased, the effective life of numerous critical assets in the system has improved and many of the most critical Dam Safety risks have been mitigated. BC Hydro continues to provide reliable, affordable, clean electricity throughout B.C. as a result of our asset management and capital investment strategies. As shown in Chapter 6, section 6.3.1, BC Hydro’s customer reliability, as measured by two industry-standard metrics, System Average Interruption Duration Index (**SAIDI**) and System Average Interruption Frequency Index (**SAIFI**), has performed consistently and BC Hydro’s Customer Satisfaction Index indicates that customers continue to be satisfied with the level of reliability they are receiving.

Over time, the condition and performance of existing assets degrade, regulatory and safety requirements change, and new assets are required to address load growth and connect new customers. Together, these factors create new issues, risks and opportunities to be addressed through continued maintenance and capital investment.

The following sections provide an overview of the current state of BC Hydro’s Power System, with remaining issues, risks and opportunities highlighted. More detailed descriptions of the risks, issues and opportunities are discussed through the summaries of strategies, plans or studies in Attachment 1 of this appendix.

2.2 The Generation System

BC Hydro’s generation assets include 83 generating units at 30 hydroelectric generating facilities as well as 85 dams located at generating stations and at additional locations to provide water storage and water diversion functions. Generation assets also include four gas-fired units at BC Hydro’s two thermal generating facilities and four synchronous condenser units at a dedicated synchronous condenser facility. The generating facilities are categorized as “Key”, "Strategic" or "Available" according to the significance of the facility to BC Hydro's system. BC Hydro has adopted life cycle asset management practices as its approach to managing generating assets. The objective is to maximize the economic return on physical assets over their life by achieving desired performance outcomes, while effectively managing the risks inherent in owning, managing and operating a large asset base.

2.2.1 Key Facilities

BC Hydro's seven "Key" generating facilities represent the largest hydroelectric facilities on the BC Hydro system and produce approximately 90 per cent of BC Hydro's average annual energy supply. In the past decade, BC Hydro completed the installation of Unit 5 at Revelstoke generating station and Units 5 and 6 at Mica generating station which have added approximately 1500 MW of capacity to the Power System. In addition, BC Hydro completed sustaining investments to address end of life condition and reliability risks associated with critical equipment. These investments have included turbine overhauls, generator upgrades and replacement of transformers, governors and exciters. Looking ahead, the Bridge River facility contains approximately 30 per cent of all Key facility equipment currently rated as Poor and Very Poor. Capital projects underway will restore the condition of major assets at the facility and improve the aggregate condition at Key facilities.

BC Hydro will continue to focus on preserving reliability at the Key facilities, by directing investments towards mitigating the risks associated with major equipment currently rated as Poor and Very Poor. Under this strategy, investments will be initiated within 10-years to restore Poor and Very Poor equipment to Good or Fair condition in order to support meeting our Service Plan reliability targets and aligning with our objective of having the reliability of our Key facilities at or slightly above the average of similar facilities, as reported by the Canadian Electricity Association.

2.2.2 Strategic Facilities

BC Hydro’s 18 “Strategic” facilities represent all generating stations on Vancouver Island, all stations located on cascading river systems, all thermal generation stations, and generating stations required to provide voltage support to the transmission network. These facilities produce approximately 9 per cent of BC Hydro’s average annual energy and provide significant additional value to BC Hydro due to their geographic location and system support services.

In recent years, there have been considerable investments in Strategic facilities such as the redevelopment of the Ruskin and John Hart facilities which went into service in fiscal 2018 and fiscal 2019, respectively. BC Hydro is also restoring the health of generators such as those at Cheakamus, Seton and Wahleach as well as Strathcona Unit 1 and Ash River on Vancouver Island.

Looking out over the next 10 years, equipment in Poor or Very Poor condition at Strategic facilities will either be refurbished or replaced, will have work underway to be refurbished or replaced, or will have a long-term plan developed to mitigate the risk of equipment failure. Discrete investments are being made at Strategic facilities (including thermal generating facilities) to address the highest risks. However, some smaller strategic facilities (e.g., Alouette and Clowhom) may experience extended forced outages or be forced out of service prior to reinvestment. Alouette is the smallest Strategic facility (9 MW) and is currently out of service. The expected outcome of this strategy is that, in aggregate, the reliability of Strategic facilities will be comparable to similar facilities, as reported by the Canadian Electricity Association.

2.2.3 Available Facilities

BC Hydro’s seven “Available” facilities represent those not included in the other categories and produce less than one per cent of BC Hydro’s average annual energy. Two of these facilities are out of service (Elko and Spillimacheen) and one is partially out of service (Shuswap). Many of the assets at two other facilities (Falls River and Walter Hardman) are in Poor and Very Poor condition. Based on the current plan, the five facilities above will receive minimal capital investment and will be taken out of service when they are no longer able to safely generate electricity. BC Hydro will perform regular maintenance and inspection on these assets to keep them safe and inform investment and operating decisions. Options to refurbish, redevelop or decommission Available facilities that have been taken out of service will be developed as required. There is a high likelihood that a number of these facilities will experience long outages or be forced out of service over the next ten years. BC Hydro expects to continue to provide reliable electricity service to customers with these five facilities out of service.

2.2.4 Dam Safety

BC Hydro operates 85 dams at 41 different sites. Safe operation of a dam considers more than just the physical structure that retains water within the reservoir; it also considers:

- The structures and devices that control and convey water over, through or around the dam leading up to or around the generating station, e.g., spillways, tunnels, penstocks, and gates and valves;
- The natural structures, slopes and barriers that support the dam and surround the reservoir; and
- The supporting infrastructure and instrumentation required to monitor and maintain these various constructed and natural features.

In managing its dams, BC Hydro monitors, maintains and, as necessary and practicable, upgrades all of these structures and devices, natural features and supporting infrastructure. BC Hydro’s dams are diverse in character. They range in size from a few very small dams that are upstream of no or only a few persons, to some of the largest dams in the world that are upstream of several thousands of persons. These dams are classified by the potential consequences of their failure in accordance with the BC Dam Safety Regulation. Of BC Hydro's 41 regulated dam sites:

- 20 are classified as being of Extreme consequence;
- Seven are classified as being of Very High Consequence;
- Three are classified as being of High Consequence;
- 10 are classified as being of Significant Consequence; and
- One is classified as being of Low Consequence.

BC Hydro's dams vary in age from just over 10 years old to over 100 years old, with most being between 40 and 75 years old. The dams are situated in a demanding environment, frequently being stressed by extremes in temperature and high inflows. This leads to continuing and expected deterioration of the structures, in particular the spillways, requiring ongoing maintenance and occasional capital investments to extend their service lives.

The age of the dam also contributes to a state where some equipment is at its end of life or where design approaches in use at the time of its construction are no longer considered to be adequate. This is particularly true when it comes to the operational reliability of spillway gates and other flow control equipment, which presents a risk of malfunction that could lead to gates or valves failing to open when needed to route flood inflows or mis-operation that could cause sudden changes in downstream flows, and endanger the public. BC Hydro actively manages this risk through its continuing program to upgrade and rehabilitate its spillway gates systems.

BC Hydro's dams are located in a part of the world that is subject to natural hazards such as earthquakes and landslides. In response, BC Hydro has developed an industry-leading model to calculate seismic hazards at its dam sites and inform the needs and criteria for seismic upgrades. BC Hydro also maintains a program to monitor the slopes along its reservoirs, which includes instrumentation and drainage infrastructure in some slopes of key interest. Investments are regularly required to replace or remediate this instrumentation and drainage as it ages and loses effectiveness.

BC Hydro has made significant investments in safety upgrades to its dams since 2005, including:

- Approximately $400 million on upgrades to spillway gates systems at various dams, including Hugh Keenleyside and W.A.C. Bennett Dams;
- Over $200 million in upgrades to Ruskin Dam to address seismic and seepage deficiencies, to increase its flood discharge capacity and to replace its spillway gates systems;
- $120 million to replace the deteriorated rip rap on the upstream face of W.A.C. Bennett Dam;
- $65 million to rebuild Coquitlam Dam; and
- $55 million to perform upgrades to the spillway structure at W.A.C. Bennett Dam and stabilize the rock slope above it.

These investments were prioritized to address the biggest identified risks related to BC Hydro's dams. Many other, smaller-scale investments in upgrades to the dams and their infrastructure, such as monitoring instrumentation, have also been made in recent years.

Overall, BC Hydro aims to improve or at least maintain the current level of risk across its entire fleet of dams, which we believe is well within the limits of what is considered to be tolerable. Our strategy considers the availability of the necessary expert engineering services (both internal and external) and experienced construction services, as well as our capacity to oversee this work. Our planned level of investment in dam upgrades is primarily driven by our ability to execute these upgrades effectively. On this basis, required investments in upgrades to BC Hydro's dams have been prioritized over the coming decade and beyond. In the coming years, major investments in BC Hydro's dams will target the biggest current contributors to risk and will be made in the following areas:

- Major upgrades to improve seismic resistance, reservoir discharge capability and spillway gate reliability at the three main dams in the Campbell River system, namely John Hart Dam, Ladore Dam and Strathcona Dam;
- Major upgrades to reduce seepage and improve the seismic resistance of the La Joie Dam and intake tower;
- Upgrades to Cheakamus Dam to improve seismic resistance and reduce the potential for internal erosion;
- Continued upgrades to W.A.C. Bennett Dam to decommission disused and deteriorating low level outlets and sluice gates—eliminating two potential weaknesses in the dam's water barrier—and the dam's network of monitoring instrumentation; and
- Improvements in the seismic resistance and operating reliability of the spillways and gates at Mica Dam and Revelstoke Dam.

Another area of focus will be the upgrade of the instrumentation at Downie slide and Little Chief slide to allow continued and improved monitoring of the landslides and to inform possible stability improvement works in the future. Smaller investments will also be made to improve or replace dam infrastructure such as reservoir booms and miscellaneous instrumentation.

2.3 The Transmission and Distribution System

The overarching strategy for the Transmission and Distribution system is to maximize the long-term value of the system while minimizing the total life cycle costs of assets and ensuring safety and maintaining reliability. The strategy is accomplished by finding the optimal balance between performance, cost, risk, security, regulatory requirements, and environmental and social aspects.

2.3.1 Transmission System

BC Hydro's bulk transmission system includes the 500 kV transmission system, parts of the 345 kV, 287 kV and 230 kV systems, the transmission connections to Vancouver Island, and interconnections with other utilities through transmission interties. These lines connect the large remote generating stations in the Peace River and Columbia River areas with the major load centres of the Lower Mainland and Vancouver Island, which together represent over 70 per cent of the BC Hydro load.

Four regional transmission systems transfer energy within four specific geographic areas of the province: the Lower Mainland, Vancouver Island, Northern and Southern Interior regions. The regional systems generally consist of 230 kV, 138 kV, and 60 kV transmission networks that connect local generation and deliver power to distribution utilities or transmission customers located within the region.

Long-term planning related to bulk and regional transmission needs are typically associated with moving energy over long distances. Long-term planning considers a wide range of supply-side and demand-side options, resulting in an integrated system plan. BC Hydro conducts assessments to evaluate the transfer capability of the system and to ensure the system meets the Mandatory Reliability Standards for transmission system planning performance. Investments are identified that are necessary to fund transmission system capacity additions.

2.3.1.1 Lower Mainland and Vancouver Island

In the last decade BC Hydro has made significant investments to increase the capacity of the bulk transmission system including the Interior to Lower Mainland and Vancouver Island Transmission Reinforcement projects. These investments have enhanced BC Hydro's ability to continue to serve the electricity needs of our customers in the highest density areas of the province.

With the completion of the Interior to Lower Mainland transmission line, installation of Mica Units 5 and 6 and the third transformer at the Meridian substation, the natural gas fired, peak generation capability from the Burrard Generating Station is no longer required to meet critical loads in the Lower Mainland. Accordingly, Burrard is instead being operated to provide voltage support for the transmission system in the Lower Mainland, using its capability to operate in synchronous condense mode. The four Burrard Synchronous Condenser units are now reaching end of life and are expected to experience reliability issues within the short to medium term. The near-term focus of capital investment in the Lower Mainland transmission system will be to maintain BC Hydro's Lower Mainland bulk transmission system reliability during heavy winter load periods under single contingency conditions.

Ensuring the reliability of service in the region also requires addressing reliability risks associated with the end of life condition of 230 kV high voltage cables in the short term. These include the cable between Horsey substation and Goward substation in Victoria, a partial replacement of the 230 kV cable between Barnard substation and Como Lake substation, as well as addressing the reliability of transmission supply to the Gulf Islands.

BC Hydro has recently been addressing an emergent issue on the 500 kV submarine cables to Vancouver Island. This is discussed further in Chapter 6, section 6.4.2.2.

2.3.1.2 Northern Region

BC Hydro is investing in the Northern transmission system to address load and system growth requirements driven primarily by the development in the Oil and Gas sector in the Peace and North Coast regions. Recent investments include the 230 kV Peace Region Electric Supply project and interconnecting major industrial customer loads in this region.

Due to the continued economic activities expected in the Liquefied Natural Gas and Oil and Gas sectors, there are potentially significant additional upgrades to the transmission system in the North Coast and Peace region that may be required in the short to medium term which are not included in BC Hydro's Capital Plan. BC Hydro will work with customers in the area to define the need and scope of future projects. Projects will proceed once there is a formal commitment from potential customers. Expanding the capacity of the electricity supply in this region of the province will enable BC Hydro to supply reliable power to our industrial customers and help reduce greenhouse gas emissions by enabling customers to use clean electricity rather than fossil fuels to power their operations.

BC Hydro will also be investing to improve customer reliability in the region through investments such as the 5L63 Telkwa Relocation project, which will relocate a segment of the radial line that serves customers on the north coast and is currently situated in an active landslide area.

2.3.1.3 Southern Interior Region

BC Hydro is continuing to invest in the transmission system in the Southern Interior region of the province to provide reliable service to our customers. BC Hydro is continuing to evaluate alternatives for adding redundant supply to West Kelowna. BC Hydro is also moving forward with its strategy to ensure adequate transmission to meet the needs of the Bridge River regional system. Elsewhere in the region, BC Hydro is not expecting any major investments to serve load growth in the medium to long term as there is sufficient capacity to meet the load forecast.

2.3.2 The Regional Substation and Distribution System

BC Hydro has four regional systems (the Lower Mainland; the Northern Interior; the Southern Interior; and Vancouver Island) which connect the transmission system to the local distribution systems. The substation and distribution network are made up of over 300 stations and 68,000 kilometres of distribution circuits in order to serve customers throughout the province.

In the past decade, BC Hydro has built 28 new substations within these regions, including 12 distribution substations enabling BC Hydro to supply more than 900 MVA additional load at distribution voltages. Projects have included Fleetwood substation in Surrey, Big Bend substation in South Burnaby, the West Kamloops substation in Kamloops and the upgrade expansion of Horne Payne substation. In addition to the increased capacity, these new substations have improved the operational flexibility of the system. In some cases, the addition of new substations has facilitated the load transfer from other substations that were reaching end of life or ultimate capacity. This approach helps BC Hydro minimize the total cost of capital investment and maintenance over the life cycle of the substations.

We have also completed the Smart Metering and Infrastructure Program, which included the installation of 1.9 million smart meters in homes and businesses across the province. This provides an advanced telecommunications infrastructure to support electricity system management and customer applications, and information technology to support customer billing, load forecasting and outage management systems.

Our investments in the regional systems mean that BC Hydro’s capacity to reliably serve the forecast load growth in many areas of the province has been enhanced.

Load growth in certain areas of the province, particularly the Fraser Valley, will require continued investment in new substation and distribution infrastructure to reliably supply customers.

BC Hydro will continue to mitigate end-of-life, safety and environmental risks by investing in new substations, such as the new West End Substation in downtown Vancouver. This new substation will enable the load transfer from Dal Grauer and Murrin substations, which have reached end of life, and have many risks including safety and seismic. For other existing stations, a component-by-component asset replacement strategy may be implemented, such as at Horsey substation, to replace assets as needed. One of the key considerations in determining the timing and strategy of investments is the requirement to replace equipment with polychlorinated biphenyl levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline.

3 BC Hydro's Strategies, Plans and Studies

As part of its planning practices, BC Hydro identifies investments required on the Power System by evaluating the issues, risks and opportunities related to Power System assets. Long term planning information is captured in planning documents such as strategies, plans and studies.

At times the terms strategy, plan and study may be used interchangeably to refer to a document that is used to support long-term asset investment planning. Strategies generally cover the asset management approach for an entire population of an asset class. Plans are most often used for a specific facility, such as a substation or generating facility, incorporating the results of any relevant asset-based strategies. Studies are generally a technical analysis undertaken when the system needs extend beyond a facility and may incorporate the needs of multiple facilities and asset classes.

For the Power System, documents such as these help BC Hydro to assess system needs and develop solutions based on a region or area, river system, a facility or group of facilities, and asset classes. These planning documents provide context with respect to the rationale for investments that are either underway or planned to start in the future. In some instances, changing underlying factors, such as adjustments to load growth forecasts, resource or financial constraints, deterioration in asset condition as well as new information or corporate priorities can lead to a change in the original scope of projects or solutions proposed in these planning documents. This means that while the planning documents capture the essence of the approach, the plans and investments proposed may change in response to new information. These changes will be reflected in the planning documents during the next update of the strategy, plan or study. The process through which Power System strategies, plans and studies are developed is explained in detail as part of the bottom-up planning process descriptions included in Appendix N.

The summaries within this appendix belong to one of the following categories:

- **Strategies**: Asset class focused, considering the condition and performance of each asset with the goal of optimizing its value over the life cycle of the asset. Examples include:
  - **Transmission and Distribution Asset Strategies:** BC Hydro has documented Asset Strategies for most of its Transmission and Distribution key asset classes. These Asset Strategies provide a program approach to the management of each asset class across the entire system, and over the entire asset lifecycle.

- **Plans**: Generally related to a facility, documenting the proposed investments for each facility considering the facility's role, performance expectations, risks, issues and growth opportunities. Examples include:
  - **Generation Facility Asset Plans:** Generation facility asset plans outline the proposed long-term investment strategy at a specific time. Facility Asset Plans are key inputs to the planning process and may be informed by asset strategies. The investment strategies that are proposed for discrete facility asset plans are reviewed by management and prioritized to provide the most appropriate suite of investments across the system given resource and financial constraints, outage planning, and other considerations; and
  - **Transmission and Distribution Substation Facility Asset Plans:** These plans are developed when a substation requires major investments to address end-of-life and other sustaining needs and may be informed by asset strategies. The longer-term capacity needed at the substation is also integrated into the Facility Asset Plan.
- **Studies**: Focused on a specific area or system, integrating multiple needs within a similar timeframe, so that they can proceed through the planning process in an integrated approach. Examples include:
  - **Transmission and Distribution Area Studies:** These area studies are typically prepared, or updated, when capacity additions are required in an area, which may include optimizing system reinforcements for transmission, substation, and distribution systems in the specific area. Other known needs in the area, including addressing or aligning sustainment needs at the area's substations, are integrated into the Area Studies; and
  - **Dam Safety System Studies:** These studies are initiated to identify options that would permit the optimal risk management and investment strategy for the system using a Systems Engineering approach. A Systems Engineering

approach provides a framework to manage complexities within the constraints of the river system to ensure technical coordination across a broad range of disciplines.

Not all projects in the Capital Plan may be related to an underlying strategy, plan or study (for example where emergency work is being completed and any required studies are going to be completed as part of the scope of the actual project) and some investments may have multiple references. Where applicable, the most relevant strategies, plans, or studies for the investments listed in Appendix I have been identified in column Y. A summary of the identified strategies, plans and studies are provided in this appendix. These documents can cover a period of up to 30 years or longer in some cases. Within each of the summaries in this appendix, the following principles were applied for identifying investments within the Short, Medium and Long-Term time frames:

- **Short-Term:** Investments with expenditures within the fiscal 2023 to fiscal 2025 test period are defined in the Short-Term Solution;
- **Medium-Term:** Investments with expenditures anticipated to start within the next 10 years, but after the fiscal 2023 to fiscal 2025 test period are outlined in the Medium-Term Solution; and
- **Long-Term:** Investments with potential expenditures beyond the next 10 years are summarized in the Long-Term Solution.

BC Hydro Fiscal 2023 to Fiscal 2025

Name of Capital Strategy, Plan or Study: Bridge River System Study
Summary of Issue: The Bridge River Generation System is a cascade of three hydroelectric projects located in the Squamish Lillooet Regional District. It includes Downton, Carpenter and Seton Lakes which are upstream of the La Joie, Terzaghi and Seton dams, respectively. It also includes the La Joie, Bridge 1 and 2 and Seton Generating Stations. Many of BC Hydro's assets in the Bridge River Generation System were constructed in the 1950s and 1960's and are in the late stages of their life cycle. Decisions are needed to be made about refurbishment, replacement, decommissioning or reconfiguration of existing BC Hydro facilities. In 2011, BC Hydro initiated a study to evaluate the best long-term configuration for the Bridge River Generation System. The objective of the Bridge River System Study was to establish a river system investment strategy that addressed risk, issues and opportunities at a system and facility level, providing BC Hydro with the required guidance for asset decisions and for prioritizing the Bridge River Generation System investments against those to be made across BC Hydro's fleet. The System Study included scoping level assessment of the capital costs, energy benefits, and risk reduction achieved by alternatives. The System Study also included qualitative consideration of potential environmental and social impacts associated with system alternatives but did not include a detailed examination of these complex interactions. The System Study defined the following Key Capability Requirements for the Bridge River Generation System, which were considered in developing and comparing several alternative integrated river system concepts: • Generate power from the Bridge River Generation System; • Maintain reservoir levels within acceptable bounds under operational based loading and plant fault conditions; • Maintain downstream river flow within acceptable bounds under operational based loading conditions; • Be supported by the First Nations; • Maintain hydraulic control during floods; and • Maintain hydraulic control post-earthquake.
Summary of Solution: The Bridge River System Study (completed in 2014) concluded that, from the perspective of both maximizing energy benefits and minimizing risks associated with the dams, the preferred future configuration is substantially the same as currently exists. Upgrades were proposed, however, so that the Bridge River Generation System could better satisfy the Key Capability Requirements. The System Study prioritized and recommended sequencing of the capital projects by comparing the risk reduction cost effectiveness for the leading concepts. The System Study also identified remaining information gaps that would further inform sequencing and scope of investment decisions. As recommended, BC Hydro subsequently conducted a seismic performance assessment at Terzaghi Dam which established that, with some upgrades to the dam and appurtenances, the dam would be capable of meeting current seismic standards. As a result, BC Hydro is advancing more moderate dam safety projects at Terzaghi Dam rather than replacing the Terzaghi Dam, as had been originally proposed in the base case of the System Study. BC Hydro also decided not to relocate the Bridge River 1 Generating Station. Analysis of the risk reduction by cost had the relocation of the generating station ranked last out of all dominant risks. When coupled with the length of time it would take to relocate the generating station and the risk of stranding assets and the inability to manage flows, BC Hydro decided to proceed with a component by component replacement program at the Bridge River 1 Generating Station. A preferred strategy for sequencing of the risk reductions was refined during development of the capital plan and the Facility Asset Plans for La Joie, Bridge River, and Seton.

Short-Term:

A number of projects dealing with the highest priority dam safety issues and risks are already underway. Investments planned for the short term are as follows:

- La Joie Dam – upgrade the dam and intake tower to address seismic risks. The project is currently in the Identification phase to evaluate and select the leading alternative;
- Bridge River 1 and 2 Generating Stations – address risks of aging penstocks by recoating penstock surfaces and refurbishing the penstock concrete foundations;
- Terzaghi Dam – construct a downstream infill berm to improve seismic performance of the embankment dam;
- Terzaghi Dam – upgrade the low-level outlet and equipment to improve the long-term operational reliability and maintainability of the low-level discharge system;
- Seton Generating Station – replace the aging generating unit to address generator and runner failure risks and install hydraulic bypass system to maintain flow rates during unit outages;
- Seton Dam – upgrade and replace the five headworks gates that are required to isolate the power canal from Seton Lake Reservoir such that they can operate and be closed under a range of water flow conditions; and
- Seton Canal – refurbish the canal's concrete slabs and the joints between them along the four-kilometer-long canal lining.

Medium-Term:

- Terzaghi Dam – upgrade earthfill dam upstream cut-off to manage risks of sinkholes.
- Bridge River 1 and 2 Generating Stations – seismically upgrade the intake towers that pass water from Carpenter Reservoir to the generating stations.
- Seton Canal – seismically upgrade the aqueduct structure that carries flows from the canal over Cayoosh Creek.
- Seton Dam – improve the seismic withstand of the left bank dyke, including treatment for potential foundation liquefaction, and prevention of erosion during normal and flood conditions.
- Bridge River 1 Generating Station – replace the penstock inlet valves with valves that are capable of closing under a full rupture event.

Long-Term:

- Seton Dam – upgrade the Seton Dam to improve the seismic withstand capacity.

Name of Capital Strategy, Plan or Study: Campbell River Systems Engineering Assessment
Summary of Issue: The Campbell River hydroelectric system on Vancouver Island consists of three reservoirs and dams (Strathcona, Ladore and John Hart) which are close-coupled and in series on the Campbell River. All three facilities are categorized as Extreme Consequence per the BC Dam Safety Regulation. The Campbell River system is an important water resource that makes a major contribution to power generation on Vancouver Island, supports valuable fish habitats and spawning grounds, and provides a wide range of community and recreational services in the area. The objective of the Campbell River Systems Engineering Assessment (completed in 2012) was to identify the preferred risk management strategy for the Campbell River system in view of the potential for future redevelopment. Previous investigations into dam safety deficiencies in the Campbell River system identified that: • John Hart Dam and Strathcona Dam have wide-ranging seismic deficiencies. At Strathcona Dam these deficiencies are compounded by the seismically deficient powerhouse and generation water passage that runs beneath the dam; • The spillway gates system at Ladore Dam has insufficient resistance to seismic loads; and • The spillway gates systems at all three dams have operational reliability deficiencies. Owing to their common period of original design and construction, the seismic deficiencies at these dams make all of them vulnerable to failure in an earthquake of intensity expected to occur, on average, once every 500 to 1000 years. Given that these are all Extreme consequence dams, current expectations – as outlined in the Canadian Dam Association’s Dam Safety Guidelines – are that they should be able to withstand an earthquake of intensity expected to occur once every 10,000 years. In 2009, knowing that significant reliability and dam safety investments on this system were going to be required, BC Hydro initiated a top-down systems engineering assessment that investigated the full range of options for the development of the river system in order to identify how investments should be prioritized to deliver safe and sustainable long-term management of the river system assets. The range of configurations was bounded at one end by full or partial decommissioning and at the other end by a complete re-configuration and redevelopment of the entire system. Conceptual solutions included the following considerations: • Least total risk (to people, property and the environment) configuration; • Maximum peak demand availability; and • Maximum total energy output per year. The Campbell River Systems Engineering Assessment concluded that the river system should not be substantially reconfigured and confirmed that redevelopment of the generating capability at John Hart would be appropriate. It further concluded that improvements in seismic withstand and operational reliability of the flood discharge systems at all three main dams are required and, finally, that protection against flooding is best achieved through adequate storage upstream of Strathcona Dam.
Summary of Solution: The Campbell River Systems Engineering Assessment prioritized and recommended sequencing of the capital projects by reviewing the relative costs of the projects versus the anticipated risk reductions. A preferred strategy for sequencing of the risk reductions was refined during development of the capital plan and the Facility Asset Plans for Strathcona, Ladore and John Hart. The strategy considers technical resource availability along with our understanding of the precedent project timelines and numerous site and project timing and schedule requirements. One of the projects considered within this strategy, the John Hart Generating Station Replacement, is now in service.

Short-Term:

A number of projects dealing with the highest priority dam safety issues and risks are already underway. These projects will address the inadequate seismic withstand of various components of John Hart and Ladore Dams and establish a deep drawdown capability at Strathcona Dam for post-earthquake response. These projects will also address reliability deficiencies in the three dams' spillway gates systems. They are:

- John Hart - Dam Seismic Upgrade;
- Ladore - Spillway Seismic Upgrade; and
- Strathcona - Upgrade Discharge.

Medium and Long-Term:

In the medium term, projects to address the inadequate seismic withstand of the Strathcona generating station water passage under the dam and of the dam itself will be evaluated and advanced based on the assessed need. These projects may include decommissioning and redeveloping the existing generating station—including the water passage—and upgrading the dam. The Strathcona – Upgrade Discharge project must be completed before implementation of the following can commence:

- Strathcona - Dam Improvements – New Powerhouse; and
- Strathcona - Dam Improvements – Embankment Dam.

Name of Capital Strategy, Plan or Study:

Generation Asset Management Strategy – Penstock Recoating

Summary of Issue:

There are 67 penstocks supplying 79 units at BC Hydro's hydroelectric generating stations. Penstocks are high-value assets that convey water from reservoirs and headponds to turbines of generating units. All but one of the penstocks are entirely steel or have steel sections. Generally, the exterior and interior surfaces of the steel penstocks are coated to protect the underlying material from abrasion, corrosion, and ultimately material loss and a reduction in structural strength.

Over time, the coatings wear, degrade and fail, leading to corrosion of the underlying penstock material. Recoating of the penstock ensures that its life can be preserved. However, if the window of opportunity to recoat the penstock is missed, the underlying material will continue to corrode over time, and eventually, the penstock can no longer be used to safely convey water to the generating facility.

If the corrosion is too severe, it may not be possible to recoat the penstock, resulting in a number of issues and risks:

- Financial – A much more expensive penstock replacement and significantly longer generating unit outage would be required;
- Reliability – The asset can no longer safely convey water to the turbine forcing the generator to be taken out of service; and
- Safety and Environmental – Severe corrosion and metal loss can result in sudden failure and large uncontrolled releases of water. BC Hydro mitigates this risk by monitoring the condition of its penstocks over time and would proactively remove an asset from service if degradation became too severe.

Currently, 12 steel penstocks are between 50 and 60 years old, and 25 are more than 60 years old (of which three are no longer in service). Age is one factor but operating environment and water pressure, the quality of the coating and design factors have a larger effect on the asset health. Presently, 34 of these steel penstocks have been assessed as Poor or Unsatisfactory, primarily due to issues with the coatings, indicating there is an increased likelihood of loss of structural strength if not addressed in a timely manner.

Summary of Solution:

BC Hydro has undertaken a number of activities to better understand the condition of the penstocks and coatings. Work was undertaken to assess the health of all of BC Hydro's penstocks to establish a baseline of condition and risks. An enhanced penstock asset health methodology was developed to assess both the condition of the penstocks and the coatings. The information has been used to identify the poorest condition penstock coatings and to estimate the window of time remaining to recoat the penstocks before a replacement of the asset would be required.

As a result of this work, a number of capital projects have been identified to remediate the risks associated with the higher risk penstocks with a focus on penstock coatings. The planned scope and timing of these investments has considered factors such as:

- The need to recoat both the exterior and interior, or whether one surface is a higher priority;
- The need to recoat an entire penstock or whether only localized coating refurbishment would be sufficient;
- The opportunity to co-ordinate the investment with similar duration unit outages; and
- The operating pressure of the penstock, with higher pressure penstocks generally given higher priority for recoating.

Given the coating condition of a large number of penstocks, consideration was given to a project delivery strategy that minimizes costs, reduces quality risks and more efficiently delivers the recoating projects.

Short-Term:

The condition of assets is reviewed on a regular basis considering such factors as recurring test results, visual inspections, and detailed engineering assessments. This information is used to assess the condition of each penstock to help prepare a consolidated list across the fleet to identify the most appropriate time to address the risks while best coordinating other planned generating unit outages. Below is a list of those penstocks with higher priority requiring investment in the short-term and with capital improvement projects ongoing:

- Ash River steel penstock (external recoating);
- Bridge River 1 penstocks 1 to 4 (internal and external recoating);
- Bridge River 2 penstock 2 (internal recoating);
- Cheakamus penstocks 1 and 2 (internal and external recoating);
- Jordan River penstock (external recoating);
- Lake Buntzen 1 penstock (external recoating);
- Puntledge steel penstock (internal and external recoating of high criticality areas); and
- Wahleach penstock (internal and external recoating).

Medium-Term:

There are a number of penstock coating refurbishment projects that will need to be initiated in the medium term. The strategy and prioritization will be adjusted over time to respond to new information becoming available from penstock condition assessments. Currently, the following locations have been identified as higher risk:

- Puntledge steel penstock (remaining internal and external recoating);
- Kootenay Canal penstocks 1 to 4 (internal recoating);
- Lake Buntzen 1 penstock (internal recoating);
- Peace Canyon penstocks 1 to 4 (external recoating);
- Walter Hardman penstock (exterior recoating);
- Mica Creek penstocks 1 to 6 (targeted recoating);
- La Joie south penstock (internal recoating);
- Seton penstock (internal recoating); and
- GM Shrum penstocks 1 to 10 (internal recoating).

Long-Term:

Over the next 10 years, a number of penstock coatings will continue to degrade. Remediation of the risks associated with these assets will be required in the long-term, applying similar assessment and prioritization techniques to those outlined above.

Name of Capital Strategy, Plan or Study:

Alouette Facility Asset Plan

Summary of Issue:

The single unit, 9 MW Alouette facility is located in the Fraser Valley and was commissioned in 1928. It forms part of the Stave River system, with Stave Falls and Ruskin facilities located downstream. It consists of the Alouette Lake Reservoir, Alouette Dam, Power Tunnel from Alouette Reservoir to Stave Lake Reservoir, and Alouette Generating Station. Alouette is a Strategic[1] facility for asset management purposes and Alouette Dam is an Extreme consequence dam per the BC Dam Safety Regulation. The original dam was replaced in 1983 when the current earthfill dam was constructed immediately downstream of the original dam. Alouette Generating Station has been out of service since 2010, due to condition and reliability issues with the majority of the generating equipment; however, the water conveyance components of the facility remain an important mechanism for conveying water to the Stave Falls and Ruskin facilities.

Although Alouette Generating Station is currently out of service, investments are being made to ensure public and worker safety, water conveyance, dam safety, and environmental risks are mitigated. BC Hydro has invested over $10 million over the past 10 years. These investments include safety upgrades, and operating gate and trashrack replacements. The most significant remaining issues and risks associated with the Alouette facility include:

Dam Safety:

- Potential damage to the dam’s spillway in a major earthquake expected to occur once every 1,000 to 2,500 years that would render it unsafe for spills or drawdowns after the earthquake;
- Potential failure of the dam’s right abutment foundation in a major earthquake expected to occur once every 2,500 years, which would lead to the eventual failure of the concrete weir structures that regulate flow over the spillway;
- Expected failure of the power tunnel’s headworks and surge tower structures and ancillary equipment in an earthquake expected to occur once every 100 to 200 years, which could block the post earthquake discharge of water from Alouette Reservoir to Stave Lake Reservoir; and
- Potential rupture in a major earthquake of the seismically deficient low level outlet conduit (having unquantifiable withstand) that runs under the dam and provides environmental flows into the Alouette River downstream of the dam, which introduces the risk of internal erosion damage to the dam.

Summary of Solution:

The Alouette Facility Asset Plan presents short and long term investment strategies to mitigate risks related to dam safety, water conveyance, and the environment. In the short term, investments at Alouette will focus on addressing deficiencies related to post earthquake discharge of the reservoir and associated risks posed to the dam by ensuring post earthquake operability of the power tunnel leading from Alouette Lake Reservoir to Stave Lake Reservoir, and by upgrading or replacing the water conduit used to pass environmental flows past the dam and down the Alouette River. The medium to longer term focus will be to preserve the operational capability and infrastructure and, when appropriate, restore generation.

Short & Medium-Term:

Dam Safety:

- Headworks and surge tower seismic stability improvement; and
- Environmental flow discharge upgrade.

1 Refer to Appendix N for information on generating facility classifications.

Long-Term:

Generating Equipment:

- Powerhouse redevelopment.

The following are retained risks that are intended to be managed by completion of the Headworks and Surge Tower Seismic Stability Improvement project that is presently underway. These include:

- Seismic deficiency of the dam’s right abutment foundation and spillway weir; and
- Seismic deficiency of the dam’s spillway.

On completion, this project will provide post earthquake reservoir discharge into Stave Lake Reservoir via the power tunnel, thereby protecting these potentially damaged dam and spillway assets. Prior to the project’s completion, Alouette Lake Reservoir will be operated in a manner that provides sufficient time to provide emergency response following a major earthquake.

Name of Capital Strategy, Plan or Study:
Ash River Facility Asset Plan

Summary of Issue:

The single unit, 28 MW Ash River facility is located on Vancouver Island and was commissioned in 1959. It consists of Elsie Lake Reservoir, Elsie Main Dam, four Saddle Dams, Elsie Spillway Dam, and Ash River Generating Station. Ash River is classified as a Strategic[1] facility for asset management purposes and the dams are classified per BC Dam Safety Regulation as follows:

- Elsie Main Dam – Extreme consequence;
- Saddle Dam 1 – Extreme consequence;
- Saddle Dam 2 – Very High consequence;
- Saddle Dam 3 – Significant consequence;
- Saddle Dam 4 – Significant consequence; and
- Elsie Spillway Dam – High consequence.

Investments totaling over $5 million have been made to address safety and reliability concerns at the facility over the past 10 years. Completed capital investments have included upgrading the fire protection system, extending the life of the pressure regulating valve, improving security at Elsie Dam and upgrading the powerhouse crane.

The most significant remaining issues and risks associated with the Ash River facility include:

- Generating Equipment:
  - Asset Health Rating of Very Poor condition of the generator, elevating the reliability risks associated with the single unit and increasing the likelihood that the facility may experience an extended forced outage; and
  - Obsolete and deteriorating protection and controls and metering systems pose a reliability risk and could result in misoperation, equipment damage, and forced outages.
- Dam Safety:
  - The coatings on the steel penstock have failed which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to recoat the assets before a much more extensive replacement / refurbishment is required; and
  - The ongoing deterioration and accelerated decay of the woodstave penstock is reducing its ability to continue to safely convey water which may prematurely impact ongoing generation from the facility.

Summary of Solution:

The Ash River Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality.

In the short term, activities to address the risks with the steel penstock, generator, communication system, and protection and control and metering systems will be undertaken in order to address reliability and power supply risks. In the medium-term, risks with the woodstave penstock will be mitigated. In the longer-term, work on other major unit components will be undertaken in order to mitigate reliability risks.

[1] Refer to Appendix N for information on generating facility classifications.

Short-Term:

- Generating Equipment:
  - Generator upgrade; and
  - Protection and control and metering systems upgrade.
- Dam Safety:
  - Steel penstock recoat.
- Telecommunications:
  - Communication system upgrade.

Long-Term:

- Generating Equipment:
  - Turbine overhaul; and
  - Governor replacement.
- Dam Safety:
  - Woodstave penstock replacement.

Name of Capital Strategy, Plan or Study: Bridge River Facility Asset Plan

Summary of Issue:
The eight-unit, 500 MW Bridge River facility is located approximately 60 km west of Lillooet and forms part of the Bridge River system with the La Joie facility and the Seton facility located upstream and downstream, respectively. The facility consists of:
• Carpenter Lake Reservoir;
• Terzaghi Dam, which was completed in 1960;
• The four-unit, 200 MW Bridge River 1 (**BR1**) Generating Station, which was commissioned in 1954; and
• The four-unit, 300 MW Bridge River 2 (**BR2**) Generating Station, which was commissioned in 1960.
The Bridge River facility is classified as a Key[1] facility for asset management purposes and Terzaghi Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation.
BC Hydro has made a number of investments in the Bridge River facility over the past 10 years, totaling over $293 million. Investments in the generating equipment have included: BR1 Transformer replacements, BR1 Switchgear Replacement, BR1 Penstock Leak Detection, BR1 Powerhouse Piping Replacement, BR2 Unit 7 and Unit 8 Circuit Breaker replacement, BR2 Penstock Inlet Valve Hydraulic Control Upgrade, and Unit Replacement for Units 5-8. Other key investments have included: the Bridge River Town Site redevelopment and reliability upgrades of the Terzaghi Dam Spillway Gates.
The overriding concern in the Bridge River System is that of water management and operating in accordance with the water licenses that have been issued to BC Hydro. The system is heavily constrained by limits on allowable flows past Terzaghi Dam into the lower Bridge River. At present, the generating capacities of all four units at BR2 have been de-rated due to degrading equipment condition, reducing the flow of water that can be routed through that generating station and hindering BC Hydro's ability to prevent excessive flows in the lower Bridge River. This is compounded by the fact that Downton Reservoir behind La Joie Dam at the upstream end of the system has been drawn down to manage dam safety risks at that facility, removing a portion of the system's available storage buffer and flexibility. Restoring reliable generation to historic levels, at both the BR1 and BR2 generating stations, will enable more effective water management throughout the system, and mitigate reliability risks associated with lost generation.
The most significant remaining issues and risks associated with the Bridge River facility include:
• Generating Equipment:
  - BR1 generators are in Very Poor condition per the Asset Health Ratings, elevating the reliability and water management risks associated with the generating units and increasing the likelihood that the facility may experience an extended forced outage;
  - Obsolescence of the BR1 exciters, elevating the risk of forced outages; and
  - BR1 governors are in Poor condition per the Asset Health Ratings, elevating the risk of forced outages; and
• Dam Safety:
  - Failed coatings on the steel penstocks which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstocks. A finite window of opportunity exists to recoat the assets before a much more extensive replacement or refurbishment is required;
  - Deficiencies in the seismic withstand and operational reliability of the low level outlet gates at Terzaghi Dam, which could result in their failure to open as needed in a flood event or following an earthquake, for which the risk is managed in part by regular testing and maintenance of the gate system;

[1] Refer to Appendix N for information on generating facility classifications.

- Inadequate seepage monitoring at Terzaghi Dam to detect progression of internal erosion and piping within the foundation. Internal erosion has the potential to lead to failure at Terzaghi Dam as a result of seepage through the cut-off wall bedrock. The leakage through the cut-off has resulted in periodic sinkhole repairs;
- Deficiencies in the seismic withstand of the two intake towers on Carpenter Lake Reservoir, which would likely be damaged in an earthquake somewhat smaller than that expected to occur once every 500 years, limiting or disrupting their ability to direct water to the BR1 and BR2 powerhouses for generation and managing the reservoir level;
- Stability of the BR1 penstock slope and powerhouse foundation, especially during an earthquake, comprising a risk that slope, or powerhouse movement could cause a penstock rupture. Slope stability is a retained risk that is managed at the powerhouse with wells and sensors to control and monitor groundwater pressures, and a leak/rupture detection system on the BR1 penstocks; and
- Rock fall hazard in the Terzaghi Dam spillway chute that prevents safe entry to the spillway without significant preparatory work such as rock scaling and installation of protective structures. Lack of safe access to the spillway chute impedes the inspection, maintenance and assurance of safe condition of the spillway.

Summary of Solution:

The Bridge River Facility Asset Plan presents a strategy to replace assets on a component by component basis considering factors such as condition, rate of deterioration, the operating environment and criticality.

Investments requiring outages have been consolidated to reduce the impact on water management in the system. In the short term, the focus will be on higher priority investments required for water management and safe and reliable generation. The medium to longer-term activities will focus on the stability of the two intake towers and the replacement of major valves.

Short-Term:

- Generating Equipment:
  - BR1 generating station Unit 1-4 generators, exciters and governors replacement.
- Dam Safety:
  - BR2 interior penstock recoating;
  - BR1 interior and exterior penstock recoating;
  - BR1 slope stability improvement;
  - BR1 penstock concrete foundation refurbishment;
  - Terzaghi Dam spillway chute safe access improvements;
  - Terzaghi Dam low level outlet reliability improvements;
  - Terzaghi Dam instrumentation upgrades;
  - Terzaghi Dam downstream infill berm construction; and
  - BR1 Mitigate Surge Spill Hazard.

Medium-Term:

- Dam Safety:
  - Terzaghi Dam upstream cut-off upgrade; and
  - BR1 and BR2 intake seismic stability improvements.

Long-Term:

- Generating Equipment:
  - BR1 and BR2 major valve replacements.

Name of Capital Strategy, Plan or Study: Burrard Synchronous Condensers Station Facility Asset Plan
Summary of Issue: Burrard Thermal was a natural gas fired generating station with six 150 MW thermal generating units that were first put into operation in 1962. Since 2016, the Burrard facility has only operated as a synchronous condenser station. As a synchronous condenser station, Burrard is a major reactive power source in the Lower Mainland and is used to regulate system voltage under various system operating conditions. BC Hydro has invested over $33 million in this station and the previous operating regime as a thermal generating facility. Recent investments have been focused on sustaining reliable operations as a synchronous condenser station. The facility is over 55 years old and approaching end of life which poses system reliability, environmental, and safety risks. The most significant issues and risks associated with the Burrard Synchronous Condenser Station (**BSY**) are associated with aging infrastructure and equipment: • The synchronous condensers at BSY are at or approaching end of life. The potential failure of BSY is a transmission system reliability risk, given the reactive power capacity that BSY provides to the transmission system.
Summary of Solution: The BSY Facility Asset Plan presents an interim strategy to continue operations, maintenance, and sustaining capital to ensure reliable operation through to October 2025. In the short term, projects are staged to prioritize reliability, safety, and environmental risks. The medium to long-term strategy will be dependent on the outcome of the Burrard Synchronous Condensers Replacement Study and advancement of the Lower Mainland – Capacitive and Reactive Power Reinforcement Project. **Short-Term:** • Modify for post-generation operations: - Transmission system stability three unit reliability sustainment; - Synchronous condense control systems reliability sustainment; - Units 1 to 3 unit protection reliability sustainment; - Saltwater ducting reliability monitoring and sustainment; and - Fire protection system replacement. • Turbine hall roof upgrades. • Buntzen pumphouse maintenance. **Medium-Term to Long Term:** • Refer to the Burrard Synchronous Condensers Replacement Study Appendix K for medium to long-term considerations.

Page 1 of 1

Name of Capital Strategy, Plan or Study:

Cheakamus Facility Asset Plan

Summary of Issue:

The two-unit, 158 MW Cheakamus facility is located near Squamish and was commissioned in 1957. It consists of Daisy Lake Reservoir, Cheakamus Dam and Cheakamus Generating Station. Cheakamus is classified as a Strategic[1] facility for asset management purposes and Cheakamus Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation.

BC Hydro has made substantial progress restoring the health of this generating facility over the past 10 years through a number of investments totaling over $104 million. Investments in the generating equipment have included the turbine runner upgrades, generator replacements, powerhouse crane refurbishment, sump controls upgrade, and an improvement of the plant's fire protection and security. Investments in dam safety have included spillway gate reliability improvements.

The most significant remaining issues and risks associated with the Cheakamus facility include:

- Generating Equipment:
  - The Asset Health rating is Very Poor for the Unit 1 and Unit 2 turbine inlet valves which increases the operational risks associated with the generating units.
- Dam Safety:
  - Failed interior and exterior coatings on Unit 1 and Unit 2 penstocks, which will lead to corrosion and metal loss of the underlying material thereby reducing the life of the penstock;
  - Seepage and potential internal erosion of the dam at high reservoir levels which is currently mitigated by maintaining a reduced maximum reservoir elevation;
  - Insufficient resistance to seismic loads that may lead to failure of the dam, spillway, spillway gates and/or penstock pedestals in a major earthquake occurring, on average, about once every 1,000 years or more;
  - Residual deficiencies in the reliability of the upgraded spillway gates system, notably the lack of "black start" capability of the system's uninterruptible power supply that would restore electrical power to the gates in the event of a local blackout. The risk of the gates failing to operate as required in such events is currently mitigated by maintaining and testing back-up diesel generators on site; and
  - Potential for a landslide at the Barrier and 4th Lobe slopes to impact the dam and downstream channel.

Summary of Solution:

The Cheakamus Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. In the short-term, the focus will be on higher priority investments required for safe and reliable generation that are sequenced to minimize outages. The medium to longer-term activities will focus on the dam and spillway facilities.

Short-Term:

- Generating Equipment:
  - Units 1 and 2 turbine inlet valves replacement.
- Dam Safety:
  - Units 1 and 2 penstocks recoat (interior and exterior); and
  - Concrete dam instrumentation upgrade.

[1] Refer to Appendix N for information on generating facility classifications.

Medium and Long-Term: • Dam Safety: - Spillway seismic upgrade; - Earthfill dam seepage and seismic upgrade; - Addition of penstock rupture detection system; - Penstock pedestals and slope improvement; and - Spillway gates reliability improvement. The retained risk associated with a landslide at the Barrier and 4th Lobe slopes is managed by ongoing inspection and monitoring of the slopes.

Name of Capital Strategy, Plan or Study: Cutler Hammer Exciter Risk Mitigation Review
Summary of Issue: BC Hydro conducted a fleet-wide review on Cutler Hammer excitation systems in 2014 following several exciter failures. The review identified 26 Cutler Hammer exciters in service in 11 facilities with most of the assets being put into service in the early 2000s. As part of the review, BC Hydro engaged Basler (now the owner of Cutler Hammer) to evaluate the exciter protection and control systems at G. M. Shrum and propose a method to modify the existing units to achieve faster energy dissipation after a fault to reduce the risk of catastrophic failure. The review identified a number of limitations with the exciter protection and control and remedial actions to reduce the risk of a fault resulting in an explosive failure that would pose a risk to staff. The most significant issues and risks associated with the existing Cutler Hammer excitation systems include: • Cutler Hammer exciters are not capable of discharging the supply to the generators fast enough during a fault which could result in a prolonged fault duration and significant equipment damage; and • The existing protection relays are non-redundant and do not provide adequate protection for certain failure scenarios.
Summary of Solution: BC Hydro initiated a fleet-wide program to upgrade the existing Cutler Hammer protection and control systems to address the safety risk. The new protection and control systems will reduce the duration and intensity of a fault, therefore reducing the severity of the fault and subsequent damage to the exciter and safety risk to personnel. The focus of the phase one capital investment released in fiscal 2021 is to address the immediate safety risk associated with failure of a Cutler Hammer exciter at the G.M. Shrum and Seven Mile Generating stations, which were ranked the highest priority across the BC Hydro fleet. A phase two capital project is proposed for release in fiscal 2026 to address risks with the remaining Cutler Hammer exciters within the fleet. **Short-Term:** • Cutler Hammer excitation systems upgrade at G.M. Shrum and Seven Mile facilities to address the highest safety and reliability risks across the fleet. **Medium-Term:** • Cutler Hammer excitation systems upgrade at the remaining generation stations with these assets including: Aberfeldie, Cheakamus, Lake Buntzen 1, Ladore, Strathcona, Puntledge, Wahleach, Seton and Ash River. **Long-Term:** • None.

Page 1 of 1

Name of Capital Strategy, Plan or Study:
Fort Nelson Facility Asset Plan

Summary of Issue:

The two unit 73 MW Fort Nelson facility is located 22 km from the community of Fort Nelson and was constructed in 1999 as a simple-cycle 47 MW plant and upgraded in 2012 to the current 73 MW output combined-cycle plant. Fort Nelson is not connected to the BC Hydro grid and is connected to the Alberta electric system via a transmission line. The facility is a combined-cycle power plant that uses both a gas and a steam turbine together to produce more electricity from the same fuel than a traditional simple-cycle plant as it was prior to upgrade. The Unit 1 Generator (**G1**) is run by a gas turbine. The G1 once-through-steam-generator uses the waste heat from the gas turbine to generate steam which in turn drives the Unit 2 Generator (**G2**) turbine.

The Fort Nelson facility can run in three operating modes:

i. Simple Cycle – run the G1 gas turbine only for faster start-up and ramping.
ii. Combined Cycle – run the G1 gas turbine and G2 steam turbine together for higher output and better efficiency without using extra fuel.
iii. Combined Cycle with Duct Firing – burn extra fuel using the duct burner to maximize G2’s output but at a lesser overall efficiency.

G1 can run alone without having G2 online (simple cycle operation). However, G2 can only run if G1 is online (combined cycle operation).

Over the past 10 years, over $70 million of the total $103 million in investments made at the facility have been to upgrade the simple-cycle facility to a combined cycle facility. The remaining investments have gone towards facility upgrades and targeted investments to sustain the reliable operation of the facility.

The most significant remaining issues and risks associated with the Fort Nelson facility include:

- Generating Equipment:
  - The G2 steam turbine is approaching the recommended overhaul interval which increases the reliability risk and could result in an extended forced outage resulting in a loss of generation and inability to service customers appropriately; and
  - The G1 gas turbine anti-icing system is constrained by mechanical and process control limitations which prevent optimal performance and dispatch flexibility of the system.

Summary of Solution:

The Fort Nelson Facility Asset Plan presents a strategy that initially focuses on addressing the highest priority items. Given that significant facility upgrades have occurred in the past 10 years, targeted sustainment activities are the priority at the Fort Nelson facility. In the short term, activities will address the identified risks and issues associated with the G2 turbine and addressing performance limitations with the anti-icing system. In the long-term, targeted upgrades associated with the generating assets in accordance with equipment supplier guidelines will be required to ensure optimal asset performance.

Short-Term:

- Generating Equipment:
  - Turbine (G2) refurbishment; and
  - Turbine (G1) anti-icing system upgrade.

Medium and Long-Term:

- Sustaining investments as required based on operating profile.

Name of Capital Strategy, Plan or Study:

G.M. Shrum Facility Asset Plan

Summary of Issue:

The 10-unit, 2,917 MW G.M. Shrum facility is located 23 km upstream of Peace Canyon Dam and approximately 160 km from the Alberta border. It was commissioned in stages from 1968 through 1980. It is comprised of the Williston Reservoir, W.A.C. Bennett Dam and the G.M. Shrum Generating Station. G.M. Shrum is classified as a Key[1] facility for asset management purposes and W.A.C. Bennett Dam is classified as an Extreme consequence dam per the B.C Dam Safety Regulation.

BC Hydro has made substantial progress in maintaining and improving the health of this generating facility over the past ten years through investments totaling about $580 million. Investments in the generating equipment have included replacement/refurbishment of many of the original key components, including units 1 to 5 turbine upgrade, units 1 to 4 stator replacement, increased capacity of units 6 to 8, three of four phases of transformer replacements, and station service replacement. Significant investments in dam safety have included: stabilization of the rock slope above the dam’s spillway, resurfacing and other upgrades to the concrete lining of the spillway chute, upgrades to the rip rap on the upstream face of the dam, and upgrades to the dam’s core including rehabilitation of instrumentation wells.

The most significant remaining issues and risks associated with the G.M. Shrum facility include:

- Generating Equipment:
  - Asset Health Rating of Poor condition of eight of the 30-unit transformers, combined with emerging deficiencies on some of the unit transformers, poses an operational reliability risk; and
  - Asset Health Rating of Poor condition of the unit 5 and unit 6 generators, elevating the reliability risks associated with the units and increasing the likelihood of an extended forced outage.
- Dam Safety:
  - Deficiencies in the operational reliability of the spillway gates that could result in their failure to operate as needed during high inflows, the risk of which is currently managed by regular testing and maintenance of the gates system;
  - Unknown but presumably deteriorating condition of now-disused low-level outlets situated within the construction-period diversion tunnels, failure of which would lead to uncontrolled release of Williston Reservoir;
  - Deteriorating, non-functioning and disused sluice gates below the spillway gates, failure of which would lead to uncontrolled release of Williston Reservoir;
  - Continued erosion of the rock face above the spillway approach channel which is beginning to undermine the storage location of the spillway’s maintenance stoplogs, the risk of which is managed by ongoing surveillance of the slope and progression of erosion;
  - Presumed seismic deficiency of the spillway’s structures and electrical and mechanical equipment (presently the subject of a Dam Safety Investigation);
  - Failed coatings of the intake operating gates and intake maintenance gates, which could lead to corrosion and metal loss of the underlying material, thereby reducing the life of the gates;
  - Deficiencies in the hydraulic systems of the intake operating gates that could result in operational reliability risks; and
  - Degrading condition of various coatings in the water passages, including penstocks, scroll case, and coupling chamber, which could lead to corrosion and metal loss of the underlying material, thereby reducing the life of the assets.

[1] Refer to Appendix N for information on generating facility classifications.

Summary of Solution:

The G.M. Shrum Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality. In the short-term, projects are staged to prioritize investments in key generating equipment and high-risk dam safety components. In the medium to long-term, projects are staged to address the next highest risks in the generating equipment, including upgrade of units 9 and 10, and improve reliability and seismic performance of the flood discharge system.

Short-Term:

- Generating Equipment:
  - Unit 5 and Unit 6 generator refurbishment;
  - Unit 9 and Unit 10 circuit breaker replacement;
  - Unit 3A, 3B, and 10A transformer replacement; and
  - Unit 2, 5, 6, 7, and 8 Pauwels transformer life extension.
- Dam Safety:
  - Spillway gate reliability upgrade;
  - Sealing of the low-level outlets;
  - Recommissioning or sealing the spillway sluice gates;
  - Intake operating gate and intake maintenance gate refurbishment; and
  - Intake operating gate hydraulic upgrade.

Medium-Term:

- Generating Equipment:
  - Unit 9 and Unit 10 turbine overhaul; and
  - Unit 9 generator refurbishment.
- Dam Safety:
  - Spillway seismic upgrade;
  - Spillway approach channel upgrade; and
  - Water passage refurbishment.

Long-Term:

- Generating Equipment:
  - Unit 7 and Unit 8 generator refurbishment.
- Dam Safety:
  - Spillway gate electrical and mechanical improvements.

Name of Capital Strategy, Plan or Study:

Hugh Keenleyside Facility Asset Plan

Summary of Issue:

The Hugh Keenleyside facility is located on the Columbia River, about 8 km upstream of Castlegar. Hugh Keenleyside Dam was commissioned in 1968 under the terms of the Columbia River Treaty to provide storage for flood control and to maximize hydro generation in both the United States and Canada. The major components of the Hugh Keenleyside facility include the Arrow Lakes Reservoir, Hugh Keenleyside Dam comprising an earthfill dam and a concrete gravity dam with spillway and low-level outlets, and a Navigation Lock to provide a passage for commercial and recreational marine traffic through the dam. The Hugh Keenleyside facility does not have a generating station, but a power canal on the left abutment diverts water from the Arrow Lakes Reservoir to the Arrow Lakes Generating Station owned by Columbia Power and the Columbia Basin Trust. Hugh Keenleyside Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation.

BC Hydro has made substantial progress restoring the health of this facility over the past 10 years through investments totaling over $100 million, including an upgrade of the navigation lock controls, a major spillway gate reliability upgrade, replacement of the debris boom, dam instrumentation improvements, and a facility security system upgrade.

The most significant remaining Dam Safety risks associated with the Hugh Keenleyside facility include:

- Spillway and low-level outlet concrete erosion which, if not addressed, could impact the operation of the facility and the maintenance and inspection of the gates. There is also a risk that the eroded zones could grow in size during high water discharges, resulting in an extended outage of the spillway. These risks are currently managed by having implemented modified discharge operating procedures to slow the damage and by periodic underwater inspections;
- Degrading condition of the foundation drains and instrumentation, where non-functioning drains would reduce the stability of the dam. This risk is managed by continuous monitoring of the uplift pressures under the dam and the condition of the instruments;
- Potential post-earthquake deformation of the concrete spillway piers, which would render the low-level outlet gates inoperable and limit the post-earthquake reservoir discharge capability;
- Moderately deficient seismic withstand of the earthfill dam relative to its Extreme consequence classification, estimated to be equivalent to an earthquake expected to occur once every 8,000 years.
- Degrading condition of the coatings on the navigation lock gates, which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the asset;
- Deterioration of the service water piping;
- Degradation of main deck gantry crane, which is required to perform maintenance on the spillway and low-level outlets; and
- Degradation of spillway and low-level outlet stoplogs condition, which are required for isolation and to perform maintenance on the spillway and low-level outlets.

Summary of Solution:

The Hugh Keenleyside Facility Asset Plan presents a strategy to mitigate risks related to safe storage and reliable passage of water under normal and unusual (e.g., flood and earthquake) conditions. The short-term investments include upgrading the concrete discharge structures to ensure continued safe and reliable water discharge, upgrading the main deck gantry crane, and preserving the critical navigation lock infrastructure. The medium-term investments focus on addressing the seismic withstand deficiencies of the concrete dam (i.e., deformation of the spillway piers), upgrading the instrumentation and monitoring of water pressures under the dam, enhancing the operability of the select components of the discharge system and addressing the seismic withstand deficiencies of the earthfill dam.

Short-Term:

- Spillway and low-level outlet concrete upgrade;
- Service water piping replacement;
- Navigation lock gates recoating; and
- Main deck gantry crane upgrade.

Medium and Long-Term:

- Concrete dam seismic stability upgrade;
- Dam foundation drains and instrumentation replacement;
- Spillway and low-level outlet stoplogs upgrade; and
- Earthfill dam seismic stability upgrade.

Name of Capital Strategy, Plan or Study: John Hart Facility Asset Plan
Summary of Issue: The three-unit, 135 MW John Hart facility is located on Vancouver Island and was originally constructed in 1947. John Hart forms part of the Campbell River system, with Ladore and Strathcona facilities located upstream. The facility includes the John Hart Reservoir, John Hart Dam, and the John Hart New Generating Station. The original John Hart Generating Station was developed in 1947 and permanently ceased operation when the John Hart New Generating Station was placed into service in 2018. John Hart is classified as a Strategic[1] generating facility for asset management purposes and the John Hart Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation. The John Hart facility has received a significant level of investment in the last 10 years, with over $1 billion of investments made to construct a new power intake, power tunnel, underground generating station, and environmental flow bypass, as well as provide interim upgrades for the most pressing dam safety issues. Prior to making this investment, in 2009 BC Hydro initiated the Campbell River Systems Engineering Assessment and investigated the full range of options for the development of the river system in order to identify how investment should be prioritized to deliver safe and sustainable long-term management of the river system assets. The most significant remaining issues and risks at the John Hart facility include: • Dam Safety: - Susceptibility of the dam to fail in an earthquake expected to occur, on average, once every 500 years; - Deficiencies in the operational reliability and seismic withstand of the spillway gates system, for which the risk is currently managed by regular testing and maintenance of the system; - Potential for flow imbalance due to interruption of generation at John Hart while generation continues at Ladore Generating Station upstream, for which the risk has been partially addressed by improvements implemented within the generating station redevelopment with the residual risk being managed through controls to automatically shut down generation at Ladore in the event of a shutdown at John Hart; and - Unreliable water level gauges downstream of John Hart Dam.
Summary of Solution: Following the recent redevelopment of the generating station, this facility's investment strategy exclusively targets the existing Dam Safety risks identified above. Capital upgrade projects are currently underway or scheduled to commence in the short term to address these risks. **Short-Term:** • Dam Safety: - Upgrades to the John Hart Dam to address seismic, flow imbalance and spillway gate reliability issues; and - Upgrades to the Campbell River water level monitoring system.

[1] Refer to Appendix N for information on generating facility classifications

Name of Capital Strategy, Plan or Study: Jordan River Facility Asset Plan
Summary of Issue: The single unit, 167 MW Jordan River facility is located on the southern part of Vancouver Island, approximately 40 km west of Sooke at the end of a radial transmission line. The facility was redeveloped in 1971. It consists of: • Bear Creek Reservoir; • Jordan Diversion Reservoir; • Elliot Headpond; • Bear Creek Dam; • Jordan Diversion Dam; • Elliot Dam; and • Jordan River Generating Station. Jordan River is classified as a Strategic[1] Facility for asset management purposes and the dams are classified per BC Dam Safety Regulation as follows: • Elliott Dam - Very High consequence; • Jordan Diversion Dam - Very High consequence; and • Bear Creek Dam - Low consequence. In the past 10 years, Jordan River has benefited from a number of capital investments totaling approximately $25 million. Recent equipment investments have included fire protection system upgrades and recoating a significant section of the penstock. Other recent investments have included the acquisition of properties downstream of Jordan River. These acquisitions are part of the effort to reduce public exposure in downstream areas that could be in inundated in the event of a major earthquake. The most significant remaining issues and risks associated with the Jordan River facility include: • Generating Equipment: - Governor and pressure reducing valve obsolescence leading to system reliability and maintainability issues; - Mitigating reliability risks related to the 13 kV circuit breaker system; and - Deteriorating condition of the powerhouse fire protection system which could lead to localized damage of the piping and a subsequent failure to operate normally when required. • Dam Safety: - The coatings on a number of sections of the penstock have failed which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to recoat the assets before a much more extensive replacement or refurbishment is required; - Susceptibility of the Low consequence Bear Creek Dam to failure in a small to moderate earthquake; - Obstruction of the Bear Creek Spillway that can cause outflows to back up against the downstream “toe” of the dam and cause potential damage; and - Susceptibility of Jordan Diversion Dam and Elliott Dam to failure in an earthquake expected to occur, on average, approximately once in every 500 years, for which the risk is currently being managed as described above.

[1] Refer to Appendix N for information on generating facility classifications

Summary of Solution:

The Jordan River Facility Asset Plan proposes a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality.

In the short-term, activities to address the risks with the governor, 13 kV circuit breaker system and fire protection system. In the medium to long term, activities will be started to address Bear Creek Dam and spillway pending the recommendations from a forthcoming strategic review of these assets. In the longer term, investments in the aging generating equipment as well as refurbishment of the Jordan Diversion Dam low level outlets may be required.

Short-Term:

- Generating Equipment:
  - Upgrade of the governor and pressure reducing valve system;
  - Upgrades to the 13 kV circuit breaker system; and
  - Upgrades to the powerhouse fire protection system.
- Dam Safety:
  - Penstock recoating.

Medium-Term:

- Dam Safety:
  - Potential upgrades to the Bear Creek spillway.

Long-Term:

- Generating Equipment:
  - Turbine overhaul;
  - Generator overhaul; and
  - Exciter upgrade.
- Dam Safety:
  - Jordan Diversion Dam low level outlets refurbishment; and
  - Potential seismic upgrade at Bear Creek Dam.

Name of Capital Strategy, Plan or Study:

Kootenay Canal Facility Asset Plan

Summary of Issue:

The four-unit, 580 MW Kootenay Canal facility is located on the Kootenay River approximately 20 kilometres upstream of its confluence with the Columbia River near the city of Castlegar. The facility was commissioned in 1975 and consists of Kootenay Canal, which diverts water from the Kootenay River into a concrete lined forebay, Kootenay Canal Dam and Kootenay Canal Generating Station. Kootenay Canal is classified as a Key[1] facility for asset management purposes and Kootenay Canal Dam is classified as a Very High consequence dam per the BC Dam Safety Regulation.

BC Hydro has made effective progress restoring the health of several components of this generating facility over the past 10 years through investments totaling over $36 million. Investments in the facility equipment have included upgrades to the intake gantry and the powerhouse cranes and replacement of the station service transformer. Dam safety investments have included the installation of a membrane liner within the forebay to seal off leakage through joints between the concrete slabs, instrumentation improvement in the Power Intake concrete blocks and in the slopes located south and west of the main dam structure above the penstocks. The most significant remaining issues and risks associated with the Kootenay Canal facility include:

- Generating Equipment:
  - All four generators and protection and control equipment have an Asset Health Rating of Poor which could impact the reliability of the generating equipment and result in loss of generation; and
  - Deficiencies in the existing fire protection system that have increased the risk of system failure due to accelerated corrosion and potential rupture of the piping.
- Dam Safety:
  - Failing and leaking joints between the canal's concrete slabs—upstream of the remediated forebay—that could eventually allow seepage to undermine the slabs. This risk is currently managed by regular visual inspections of the canal's concrete liner and embankments and by measurements of seepage through collection weirs; and
  - Failed coatings on the penstocks and intake operating gates that will lead to corrosion and metal loss and reduce the life of the penstocks and the gates.

Summary of Solution:

The Kootenay Canal Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality.

In the short term, investments to address the risks associated with the protection and control equipment as well as the generators will be undertaken. In the medium to long term, investments are proposed to address risks with anticipated degradation of major equipment, auxiliary equipment and water passage infrastructure.

Short-Term:

- Generating Equipment:
  - Unit 1 to 4 unit protection upgrade;
  - Fire detection and alarm system replacement;
  - Unit 1 to 4 generators refurbishment; and
  - Unit 1 to 4 controls modernization.

[1] Refer to Appendix N for information on generating facility classifications

- Dam Safety:
  - Canal concrete liner slab joints upgrade; and
  - Unit 1 to 4 intake operating gate refurbishment.

Medium & Long-Term:

- Generating Equipment:
  - Fire protection piping replacement;
  - Unit 1 to 2 transformer replacement;
  - Unit 1 to 4 turbine overhaul;
  - Tailrace gantry crane upgrade;
  - AC station service upgrade; and
  - Unit 1 to 4 cooling water piping replacement.
- Dam Safety:
  - Unit 1 to 4 penstocks recoat;
  - Headworks structure upgrade; and
  - Penstock Pedestals Upgrade.

Name of Capital Strategy, Plan or Study: La Joie Facility Asset Plan
Summary of Issue: The single unit, 22 MW La Joie Facility is located near the village of Goldbridge approximately 100 km west of Lillooet. It consists of: • Downton Reservoir; • La Joie Dam; and • La Joie Generating station. La Joie is a Strategic[1] facility for asset management purposes and La Joie Dam is classified as an Extreme Consequence dam per the BC Dam Safety Regulation. Investments in the past 10 years have been relatively modest at $15.2 million, mostly to address reliability concerns with the discharge facilities (gates, valves and conduits). In 2014, BC Hydro lowered the Downton maximum normal reservoir operating level from an elevation of 749.8 million to an elevation of 734.0 million to mitigate the risk of a dam failure in the event of a seismic event, and to minimize the impacts downstream. This is a temporary measure until the dam's deficiencies can be mitigated through a planned project to upgrade the dam. The most significant remaining issues and risks associated with the La Joie facility include: Generating Equipment: • The generating unit protection and controls system is original, obsolete and difficult to maintain. Unreliable protection could lead to extended outages or damage to equipment if it fails to operate; • The governor per the Asset Health Rating is in poor condition primarily due to age, decreasing reliability and a lack of spare parts. There is a risk that the governor could fail, which would lead to a long forced outage and a loss of generation. The La Joie governor is unique in that it also controls the Pressure Regulating Valve (**PRV**) and a governor failure may make the PRV inoperable. Either the generating unit or the PRV need to be operable to manage the Downton Reservoir and keep it below the lower maximum operating level imposed as an interim risk mitigation measure until the La Joie Dam deficiencies are addressed; • The PRV is a butterfly style valve that was installed in 1956. It has suffered from severe cavitation and fatigue damage. Due to the deteriorated condition of the PRV, there is a risk it may fail which would lead to a long, forced outage, a loss of generation and limit our ability to manage the Downton Reservoir; • The generator is original and per the Asset Health Rating is in poor condition. Due to its age, it has an increasing risk of a failure that would result in a loss of generation; • The turbine per the Asset Health Rating is in poor condition. Due to age and wear on the turbine components, there is a risk the runner will fail, which could lead to a long, forced outage resulting in lost generation; and • The exciter is original and per the Asset Health Rating is in poor condition. Due to age, there is a risk it could fail which would lead to a medium-length forced outage and a loss off generation. Dam Safety: • La Joie Dam is constructed of uncompacted rockfill with a shotcrete face. The shotcrete face cracks as the underlying rockfill settles over time, requiring regular maintenance to manage seepage under normal operating conditions. During an earthquake, the dam could move and settle, creating larger cracks in the shotcrete face and leading to leakage through the dam. Excessive leakage through the dam could wash out the toe material resulting in dam failure and an uncontrolled release of the reservoir. If insufficient storage is available in the downstream Carpenter Reservoir, a failure of La Joie dam could result in overtopping of the Terzaghi earth filled dam and a cascading dam failure that would have severe impacts to communities downstream on the Bridge and Fraser Rivers;

[1] Refer to Appendix N for information on generating facility classifications

- Due to the design and deteriorated condition of the intake tower, a major earthquake expected to occur once every 1,000 years could cause the intake tower to collapse, blocking the intakes and preventing the passage of water through the powerhouse or hollow cone valves to the Middle Bridge River; and
- The south conduit passes water to the generating unit and PRV. It is in very poor condition per the Asset Health Rating due to coating failure, design limitations, and the presence of active corrosion. If left unmitigated there is a risk of structural failure of the conduit. This would lead to it being taken out of service resulting in a long, forced outage, a loss of generation and a reduced ability to manage the Downton Reservoir level.

Summary of Solution:

The La Joie Facility Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment and criticality. In the short term, the focus will be on higher priority investments that are required for dam safety and water management issues as well as issues with controls and protection. In the medium-term, focus will shift to major components on the generating equipment.

Short-Term:

Dam Safety:

- Upgrades to La Joie Dam and intake tower.

Generating Equipment:

- Unit protection and control upgrades; and
- Governor and PRV replacement.

Medium and Long-Term:

- Generator, turbine, governor replacement; and
- Turbine inlet valve replacement.

Name of Capital Strategy, Plan or Study: Ladore Facility Asset Plan
Summary of Issue: The two-unit, 47 MW Ladore facility is located on Vancouver Island and was commissioned in 1958. It was built as part of the Campbell River development and forms part of the Campbell River system with the Strathcona facility and John Hart facility located upstream and downstream, respectively. The facility consists of the Lower Campbell Lake Reservoir, the Ladore Dam, the Loveland Bay Saddle Dam, the Big Slide and McIvor Bay Natural Barriers and the Ladore Generating Station. The facility is classified as a Strategic[1] Facility for asset management purposes and the dams are classified per the BC Dam Safety Regulation as follows: • Ladore Dam - Extreme consequence; • Loveland Bay Saddle Dam - Significant consequence; and • Big Slide Saddle Dam - Significant consequence. In 2009 BC Hydro initiated the Campbell River Systems Engineering Assessment and investigated the full range of options for the development of the river system in order to identify how investment should be prioritized to deliver safe and sustainable long-term management of the river system assets. In the last 10 years, a number of capital investments totaling $29 million have been made at the Ladore facility. Recent investments have included the replacement of the intake gates, upgrade of the oil containment and replacement of the powerhouse and tailrace cranes. The most significant remaining issues and risks at the Ladore facility include: • Generating Equipment: - The protection and controls equipment is over 55 years old, with deteriorated electro-mechanical relays with no failure detection system which pose a risk of misoperation leading to increased equipment damage and extended outage; and - Asset Health Rating of Poor condition of the Unit 1 and Unit 2 generators, transformers and turbines increase the reliability risks of both generating units and could result in an extended forced outage. • Dam Safety: - Inadequate seismic withstand of the spillway gates and hoist structures which could result in a loss of control of the reservoir following a major earthquake expected to occur, on average, once every 1200 years; - Unreliable operability of the Low-Level Outlet that has not been in operation for over 40 years due to concerns over debris jamming the Hollow Cone Valve; and - Deficiencies in the operational reliability of the spillway gates that could result in their failure to open as needed in a flood event.
Summary of Solution: The Ladore Facility Asset Plan presents a component-by-component investment strategy to address the identified risks and overall condition of the facility while considering factors such as condition, rate of deterioration, the operating environment, and criticality. In the short term, activities to address the risks with the spillway gates, communication system, protection and control systems, and the transformers and generators will be started to mitigate reliability and power supply risks. In the medium to longer term, activities to address risks associated with the turbine and governor will be undertaken.

[1] Refer to Appendix N for information on generating facility classifications

Short-Term:

- Generating Equipment:
  - Address protection and control issues; and
  - Procurement of a spare transformer.
- Dam Safety:
  - Seismic and reliability upgrades of Ladore Dam spillway gate systems; and
  - Decommissioning or restoration of the Low-Level Outlet and Hollow Cone Valve.
- Telecommunications:
  - Communication system upgrade.

Medium-Term:

- Generating Equipment:
  - Generator upgrade;
  - Turbine overhaul; and
  - Governor replacement.

Name of Capital Strategy, Plan or Study: Coquitlam Buntzen System Facility Asset Plan
Summary of Issue: The single unit, 60 MW Lake Buntzen facility is located in Metro Vancouver and was commissioned in 1951. It is part of the Coquitlam-Buntzen system, which consists of Coquitlam Reservoir and Dam, Coquitlam diversion tunnel, Buntzen Lake Reservoir and Dam, and Lake Buntzen 1 and 2 Generating Stations. Lake Buntzen is classified as a Strategic[1] facility for asset management purposes. Coquitlam Dam is an Extreme consequence dam and Lake Buntzen Dam is a Significant consequence dam per the BC Dam Safety Regulation. The original Lake Buntzen 1 Generating Station first went into service in 1903. In 1951 the original generating units were replaced with a single 60 MW unit that continues to operate today. The three unit Lake Buntzen 2 Generating Station was built in 1913, and permanently ceased operation 2013. The original Coquitlam Dam, constructed in 1905, was replaced by a second dam in 1914. This second dam was found to be severely deficient under earthquake loading, and a new embankment dam was constructed on the downstream toe of the second dam in 2008. The second dam remains in place, but is not relied upon to retain the reservoir. BC Hydro improved the health of the Coquitlam-Buntzen system through a number of investments in the last 10 years totaling over $31 million. Investments in generating equipment have included a turbine upgrade and powerhouse crane upgrade. Dam safety investments have included the construction of a new Coquitlam Dam, upgrades to the Coquitlam Dam low level outlet gates, and an upgrade to the Lake Buntzen spillway. The most significant remaining issues and risks associated with the Coquitlam-Buntzen system include: Generating Equipment: • Asset Health Rating of Poor for the Lake Buntzen 1 generator, which elevates the reliability risks associated with the single generating unit and increases the likelihood that the facility may experience an extended forced outage. Dam Safety: • Poor condition of the Coquitlam tunnel gates, a failure of which would result in the loss of control of water conveyance from Coquitlam Reservoir to Buntzen Lake Reservoir; • Failed interior and exterior coatings on the Lake Buntzen 1 penstock which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to recoat the asset before a much more extensive refurbishment or replacement is required; • Potential failure of the Coquitlam tunnel's inlet and outlet portals during an earthquake expected to occur, on average, once every 100 to 200 years; • Potential failure of the Coquitlam Low Level Outlet structure in an earthquake expected to occur, on average, once every 3,500 to 5,000 years; and • Insufficient capacity of the Lake Buntzen 1 spillway that increases the risk of overtopping Buntzen Dam and flooding Lake Buntzen 1 Generating Station, a risk that BC Hydro is currently accepting but managing through increased surveillance when reservoir elevations are high.

[1] Refer to Appendix N for information on generating facility classifications

Summary of Solution:

The Coquitlam-Buntzen Facility Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as asset condition, rate of deterioration, the operating environment, and criticality.

In the short-term, the focus will be on risks associated with the ability to transfer water between Coquitlam Reservoir and Lake Buntzen Reservoir, as well as reliability of the Lake Buntzen 1 penstock and generating unit. In the medium to longer-term, investments will continue to address the risks associated with the Coquitlam tunnel inlet portal seismic withstand as well as addressing the flood discharge capability of Lake Buntzen Dam.

Short-Term:

Generating Equipment

- Lake Buntzen 1 generator replacement.

Dam Safety:

- Coquitlam tunnel gates refurbishment;
- Lake Buntzen 1 exterior penstock recoat; and
- Lake Buntzen 1 interior penstock recoat.

Medium and Long-Term:

Dam Safety:

- Coquitlam tunnel inlet portal seismic upgrade; and
- Lake Buntzen Dam flood discharge capability improvement.

The risks associated with the low seismic withstand of the Coquitlam Tunnel outlet portal, and the Coquitlam Dam Low Level Outlet structure are monitored and will be retained as the consequences are expected to be low.

Name of Capital Strategy, Plan or Study: Mica Facility Asset Plan
Summary of Issue: The six unit, 2780 MW Mica facility is located on the Columbia River north of the town of Revelstoke. It was constructed under the terms of the Columbia River Treaty. The dam was completed in 1973, two generating units were installed and commissioned in 1976, two more in 1977 and the final two in 2015. The facility includes Kinbasket Lake Reservoir, Mica Dam and Mica Generating Station. Mica is classified as a Key[1] facility for asset management purposes and Mica Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation. Approximately $842 million has been invested at Mica over the past ten years, $626 million of which was to upgrade the gas insulated switchgear system and commission the fifth and sixth generating units. Investments in the generating equipment have also included a Unit 1 transformer replacement and battery and charger replacement. Dam Safety investments within this period included installation of new instrumentation and rehabilitation/sealing of construction era instrumentation (vertical movement gauges) to improve Mica Dam instrumentation and safety. The most significant remaining issues and risks associated with the Mica facility include: • Generating Equipment; - Asset Health Rating of Poor of the original unit transformers, line reactors and Unit 1 and 2 turbines increases the reliability risk and may result in forced outages; - Obsolescence of the original Unit 1 to 4 circuit breakers, exciter controls and governor controls increases the reliability risk and may lead to forced outages; - Deteriorated condition of the Heating, Ventilation and Air Conditioning systems increases the safety risk in the underground powerhouse as these systems are relied upon to move air through the facility in emergency situations; and - Deteriorated condition of the Unit 1 and 2 cooling water piping increases the risk of piping failure resulting in damage to the facility or equipment. • Dam Safety: - Inadequate seismic withstand of the flood discharge systems (spillway and outlet works) which could result in a loss of control of the reservoir following a major earthquake expected to occur, on average, once every 2000 to 3000 years; - Deficiencies in the operational reliability of the spillway gates that could result in their failure to open as needed in a flood event, the risk of which is currently managed by regular testing and maintenance of the existing systems; - Deterioration of the water passage protective coatings will lead to corrosion and metal loss of the underlying material thereby reducing the life of the penstock; and - Potential failure of the nearby Dutchman’s Ridge and Little Chief Slide into Kinbasket Reservoir under unusual loads (e.g., earthquake or extreme precipitation), which could lead to overtopping of the dam. This risk is managed through a sustained program of slope surveillance and monitoring.

1 Refer to Appendix N for information on generating facility classifications

Summary of Solution:

With the completion of Units 5 and 6 in 2015, Mica is continuing a period of planned refurbishment of the original four units that were installed and commissioned in the 1970s. The Facility Asset Plan proposes a component-by-component replacement strategy to sustain operation at the Mica Facility by mitigating the risk of failure of individual assets on an as-needed basis (e.g., condition, rate of deterioration, operating environment, and criticality).

Investments in the short-term will focus on the highest priority safety and reliability risks in the powerhouse that can be mitigated without an extended outage and on addressing high consequence risks associated with current spillway and outlet works deficiencies.

Work in the medium to long-term will be undertaken with continued focus on equipment that is in poor condition but requires longer duration outages, as well as works to maintain or improve the stability of Dutchman's Ridge and Little Chief Slide.

Short-Term:

- Generating Equipment:
  - Unit 1 to 4 unit transformer replacements;
  - Unit 1 to 4 exciter controls, governor controls and unit protection replacement;
  - Reactor replacement;
  - Heating, Ventilation and Air Conditioning system upgrades; and
  - 600 V switchgear and essential electrical bus upgrades.
- Dam Safety:
  - Flood discharge facilities seismic and reliability upgrades;
  - Refurbish intake gantry crane;
  - Little Chief slope inclinometer installation;
  - Units 1-4 intake gate hydraulic power unit and controls replacement; and
  - Water passage coatings restoration.

Medium-Term:

- Generating Equipment
  - Unit 1 and 2 turbine overhauls;
  - Unit 1-4 circuit breaker and iso-phase bus replacement; and
  - Unit 1 and 2 cooling water piping replacement.
- Dam Safety:
  - Dutchman's Ridge and Little Chief Slide: slope stability improvements or measures to mitigate impacts of failure.

Long-Term:

- Generating Equipment
  - Unit 3 and 4 turbine overhauls; and
  - Unit 3 and 4 cooling water piping replacement.

Name of Capital Strategy, Plan or Study: Peace Canyon Facility Asset Plan
Summary of Issue: The four-unit, 700 MW Peace Canyon facility is located 6 km upstream of Hudson's Hope and 23 km downstream of the G.M. Shrum Generating Station on the Peace River. It was placed into service in 1980 and is comprised of the Dinosaur Lake Reservoir, the Peace Canyon Dam, and the Peace Canyon Generating Station. Peace Canyon is classified as a Key[1] generating facility for asset management purposes and Peace Canyon Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation. BC Hydro has actively maintained the health of this important generating facility over the past 10 years though a number of investments totaling over $20 million. Investments in the generating equipment include replacement of the generator stators and turbine overhauls. The most significant remaining issues and risks associated with the Peace Canyon facility include: • Generating Equipment: - Failed coatings of the scroll case which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the scroll case. A finite window of opportunity exists to re-coat the asset before a much more extensive refurbishment or replacement would be required; - Increased risk of water leakages from deteriorated condition of the high and low pressure piping systems that may cause damage to critical and sensitive equipment; and - Asset Health Rating of Poor condition of Unit 1 to 4 Exciters. • Dam Safety: - Deficiencies in the operational reliability of the spillway gates that could result in their failure to open as needed in a flood event, the risk of which is currently managed by regular gate testing and maintenance as required; - Continuing erosion of rock at the rim of the plunge pool downstream of the spillway structure that could eventually progress upstream to the toe of the spillway and threaten that structure's stability, currently managed by the performance of underwater inspections following spills; - Potential failure of the dam in a major earthquake expected to occur, on average, once every 4,200 years; - Diminishing efficiency of the dam's foundation drainage systems that could eventually result in insufficient stability of the dam structure, which is currently managed by continuous monitoring of uplift pressures and drain cleaning as required; and - Failed coatings of the penstock which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to re-coat the asset before a much more extensive refurbishment or replacement would be required.

1 Refer to Appendix N for information on generating facility classifications

Summary of Solution:

The Peace Canyon Facility Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. Capital upgrade projects are carefully planned in coordination with G.M. Shrum as operations at G.M. Shrum can be restricted when Peace Canyon units are out of service. In the short-term, projects are staged to prioritize reliability investments in key generating equipment. In the medium to long term, projects are staged to restore water passage coatings, improve the reliability of the flood discharge system and improve the seismic withstand of the Peace Canyon Dam.

Short-Term:

- Generating Equipment:
  - Unit 1 to 4 Exciter Replacement; and
  - High and Low Pressure Piping Replacement.
- Dam Safety:
  - Pressure cleaning of the dam's foundation drains.

Medium-Term:

- Generating Equipment:
  - Scroll case Recoating.
- Dam Safety:
  - Spillway gates control upgrade;
  - Peace Canyon Dam seismic upgrade;
  - Dam foundation drain rehabilitation; and
  - Penstock Recoating

Long-Term:

- Dam Safety:
  - Spillway gates electrical and mechanical upgrades.

The risk that the spillway plunge pool may continue to erode during major spill events is currently being managed by monitoring the progression of the eroded area. Capital investment is not planned at this time; however, future work may be required to ensure that the spillway structure does not become undermined.

Name of Capital Strategy, Plan or Study:
Puntledge Facility Asset Plan

Summary of Issue:

The single unit, 24 MW Puntledge facility is located near the City of Courtenay on Vancouver Island. The facility is comprised of the Comox Lake Reservoir, Comox Dam, Puntledge Dam and the Puntledge Generating Station. Both dams were constructed in 1912 and the generating station was constructed in 1955. Puntledge is classified as a Strategic[1] Facility for asset management purposes. The dams are classified as follows per the BC Dam Safety Regulation:

- Comox Dam - Extreme consequence; and
- Puntledge Dam - Very High consequence.

Over the past 10 years, BC Hydro has undertaken capital investments totaling over $38 million at Puntledge in order to mitigate known public safety risks associated with the water level gauges, public warning system, and flow control system and to address penstock reliability issues.

The most significant remaining issues and risks associated with the Puntledge facility include:

- Generating Equipment:
  - The intake operating gates and pressure release valves are subject to a number of issues which can impact their reliable operation resulting in an elevated public safety risk due to unexpected changes in downstream water releases;
  - Asset Health Rating of Poor condition of the generator which increases the reliability risk and increases the likelihood that the facility may experience an extended forced outage; and
  - The coating of the steel penstock has failed along the majority of its length leading to corrosion and metal loss of the underlying material thereby reducing the life of the penstock. A finite window of opportunity exists to recoat the asset before a much more extensive rehabilitation or replacement is required.
- Dam Safety:
  - The spillway operating gates at Comox Dam have deficiencies in reliability that could render them inoperative when needed during high inflows and could lead to overtopping of the dam and abutments, the risk of which is currently managed by regular testing and maintenance of the existing systems;
  - The Comox and Puntledge Dams have seismic deficiencies that, in the event of an earthquake expected to occur, on average, once every 1000 years, could lead to their failure and consequent downstream impacts;
  - The right abutment of Comox Dam is susceptible to erosion during low probability flood conditions which could result in a breach and uncontrolled release of Comox Lake Reservoir;
  - The ongoing deterioration and accelerated decay of the woodstave penstock increases the risk that the asset will no longer be able to safely convey water; and
  - Potential overtopping of Comox Dam in the event of the extreme design flood expected to occur, on average, once every 1000 years.

Summary of Solution:

The Puntledge Facility Asset Plan proposes a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality.

[1] Refer to Appendix N for information on generating facility classifications

In the short-term, activities to address the issues with the steel penstock and flow control and water level monitoring systems will be undertaken as these have been identified as being higher priority public safety risks. In the medium term, activities will be started to address the condition of the generating unit and the seismic withstand of the Puntledge Dam in order to mitigate reliability and dam safety risks, respectively. In the longer term, seismic withstand of the Comox Dam will be addressed along with the condition of the woodstave penstock.

Short-Term:

- Generating Equipment:
  - Steel penstock recoating.
- Dam Safety:
  - Flow control improvements; and
  - Upgrades to the water level monitoring and public safety warning systems.

Medium-Term:

- Generating Equipment:
  - Generator refurbishment; and
  - Turbine refurbishment.
- Dam Safety:
  - Puntledge Dam structure seismic upgrade.

Long-Term:

- Dam Safety:
  - Woodstave penstock replacement; and
  - Comox Dam seismic upgrades.

At this time, no investment is proposed to address the overtopping risk of Comox Dam structure due to measures within ongoing and planned projects to mitigate the downstream safety risk.

Name of Capital Strategy, Plan or Study: Revelstoke Facility Asset Plan
Summary of Issue: The five-unit, 2,368 MW Revelstoke facility was built in 1984 and is located on the main stem of the Columbia River near the town of Revelstoke. The facility includes the Revelstoke Reservoir, the Revelstoke Dam, and the Revelstoke Generating Station. The first four generating units went into service in 1984, the fifth unit went into service in 2011, and there is space for a sixth unit. Revelstoke is classified as a Key[1] facility for asset management purposes and Revelstoke Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation. BC Hydro has made substantial progress in maintaining the health and increasing the capacity of this generating facility over the past 10 years through several investments totaling over $70 million. Investments in the generating equipment have included the installation of generating Unit 5, upgrades to instrumentation monitoring at Downie Slide, 731 Block Stability Improvement, rehabilitation/sealing of embankment dam construction era instrumentation (vertical movement gauges), replacing 600 V switchgear equipment, replacing unit protection equipment and upgrades to the powerhouse crane. The most significant remaining issues and risks associated with the Revelstoke facility include: • Generating Equipment; - Asset Health Rating of Poor of the Unit 2 to 4 generators increases the reliability risk and may result in long unit outages; - Configuration and expected deterioration of the iso-phase bus increases the reliability risk associated with unit outages; - Obsolescence of the Unit 1 to 4 exciter and governor controls increases the reliability risk and may result in unit outages; and, - Asset Health Rating of Poor of seven of the 12 Unit 1 to 4 transformers increases the reliability risk and may result in long unit outages. • Dam Safety: - The potential for Downie Slide, a slow-moving land mass on the Revelstoke Reservoir, to slide into and block the Columbia River, which is managed under the terms of the water license by maintaining an extensive network of drainage throughout the extent of the slide and by continuously monitoring the slide's movements and pore water pressures; - Potential failure of portions of the rock slope at the dam's left abutment that could impact the penstocks and powerhouse or damage the rock anchors that stabilize larger masses of rock on the slope, which is currently managed by monitoring and surveillance; - Inadequate reliability and seismic withstand of the flood discharge (spillway) system that may impact our ability to manage water in a controlled manner during high inflow events or in the aftermath of an earthquake, for which the risk is currently managed by regular gate testing and maintenance; and - Damaged and unreliable instrumentation in the concrete blocks, and insufficient instrumentation to monitor uplift pressures that may impact our ability to collect reliable uplift information that is needed to ensure that the concrete blocks have adequate safety factors against sliding and overturning.
Summary of Solution: The Revelstoke Facility Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. Implementing the investment strategy at Revelstoke facility is at the early stages which include refurbishing the original equipment and infrastructure. Adding the sixth generating unit is contingent upon long-term system capacity requirements.

[1] Refer to Appendix N for information on generating facility classifications

In the short-term, projects are staged to prioritize investments required for safe and reliable generation and to leverage facility growth potential to support meeting system capacity needs. Timing of the addition of the sixth unit and coordination with other Revelstoke projects creates risk due to limited physical space in the powerhouse constraining the ability to carry out several major projects at once. Investments to monitor and manage risks related to landslides are ongoing and proposed to continue through the medium term.

Short-Term:

- Generating Equipment:
  - Unit 1 to 4 generator stator replacements;
  - Refurbish intake and tailrace gantry cranes;
  - Databus system replacement.
  - Unit 1 to 4 transformer replacements;
  - Perimeter security upgrades; and
  - Addition of the sixth generating unit (continuation subject to outcome of 2021 Integrated Resource Plan).
- Dam Safety:
  - Flood discharge (spillway) system reliability improvements;
  - Left Bank slope stability improvements to reduce the risk of rockfall and protect the rock anchors in the slope from damage (ongoing project);
  - Downie Slide instrumentation replacements to ensure continued monitoring of water pressures and deformations in the slope in accordance with the dam's water license (ongoing project); and
  - Installation of new piezometers in the concrete blocks to ensure that Revelstoke Dam will have an adequate number of piezometers that effectively and reliably monitor the uplift pressures under the concrete dam (ongoing project).

Medium-Term:

- Generating Equipment:
  - Addition of the third section of gas insulated switchgear bus; and
  - Unit 1 to 4 exciter and governor controls replacement.
- Dam Safety:
  - Remediation of the slope drainage system at Downie Slide in the timeframe when its effectiveness is expected to diminish, in accordance with the dam's water license.

Long-Term:

- Generating Equipment:
  - Unit 1 to 4 turbine overhauls; and
  - Unit 1 to 4 circuit breaker replacement.
- Dam Safety:
  - Unit 1 to 4 water passage coating restoration.

Name of Capital Strategy, Plan or Study:
Seton Facility Asset Plan

Summary of Issue:

The single unit, 44 MW Seton facility is located near Lillooet and was commissioned in 1956. It consists of:

- Seton Lake;
- Seton Dam;
- Left Bank Dyke;
- Cayoosh Diversion Tunnel;
- Seton Canal; and
- Seton Generating Station.

Seton is classified as a Strategic[1] facility for asset management purposes and Seton Dam is classified as a High consequence dam per the BC Dam Safety Regulation.

BC Hydro has made a number of investments over the past 10 years totaling more than $23 million. The most significant investments have included the refurbishment of the power canal lining and upgrades to the spillway gates, replacement of the Governor and Unit Protection.

The most significant remaining issue and risks associate with Seton facility include:

- Generating Equipment:
  - The generator is rated as Poor based on the Asset Health Rating. Due to the condition the generator it will likely experience an increasing risk of a failure that could result in a loss of generation and high flows in the Seton River; and
  - The turbines are in Poor condition per the Asset Health Rating. The turbines have experienced additional wear, cracking, and excessive leakage through the wicket gates which increases reliability risk and may result in an increased number of forced outages.
- Dam Safety:
  - The coating on the penstock has failed which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to re-coat the asset before a much more extensive rehabilitation or replacement is required;
  - Cracks and leaks in the concrete lined canal could lead to a failure of the lining and breach of the canal, the risk of which is being managed by regular inspections and repairs to slow deterioration of the canal lining’s overall condition;
  - Inability to close the headworks gates and shut off flow in the event of a canal failure, resulting in an uncontrolled release of water from Seton Lake, with current risk management as per the preceding item; and
  - Uncertainty and expected deficiency of the seismic resistance of various civil assets (headworks operating gates, forebay, dam, left dyke, aqueduct, canal) which could lead to an uncontrolled release of Seton Lake. These structures are estimated to be capable of withstanding an earthquake expected to occur once every 1500 to 5000 years, depending on the asset.

[1] Refer to Appendix N for information on generating facility classifications

Summary of Solution:

The Seton Facility Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The ability to take outages at the facility can be limited given the important role that the unit plays with respect to water conveyance. The timing of investments that require unit outages have been coordinated to minimize the impact on water management.

In the short-term, the focus will be on higher priority investments that are required for water management as well as safe and reliable generation. Investments are sequenced to minimize the number and duration of outages required. The medium to longer-term activities will focus on the canal and headworks gates and seismic issues.

Short-Term:

- Generating Equipment:
  - Turbine overhaul; and
  - Generator replacement.
- Dam Safety:
  - Penstock coating replacement;
  - Headworks gates upgrades; and
  - Canal refurbishment.

Medium-Term:

- Dam Safety:
  - Canal and aqueduct seismic upgrades; and
  - Left Bank Dyke seismic upgrades.

Long-Term:

- Dam Safety:
  - Dam seismic upgrades.

An investigation is planned to assess and obtain a better understanding of the seismic performance of various civil assets at the facility relative to the criteria for a High consequence dam.

Name of Capital Strategy, Plan or Study: Seven Mile Facility Asset Plan
Summary of Issue: The four-unit, 814 MW Seven Mile facility is located on the Pend d'Oreille River in southern British Columbia, upstream of Waneta Dam and downstream of Boundary Dam which is owned by Seattle City Light. The facility includes the Seven Mile Reservoir, the Seven Mile Dam, and the Seven Mile Generating Station. The first unit at Seven Mile Generating Station went into service in 1979, with two additional units installed in 1980 and the fourth unit installed in 2003. Seven Mile is classified as a Key[1] facility for asset management purposes and Seven Mile Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation. BC Hydro has invested over $36 million in this facility over the past ten years. Investments in the generating equipment have included the excitation system replacement, Units 1 to 3 stator re-wedging, Units 1 to 4 partial discharge monitoring and Units 1 to 3 protection upgrades. Dam safety investments have included reservoir slopes instrumentation upgrades and general dam safety improvements. The most significant remaining issues and risks associated with the Seven Mile facility include: • Generating Equipment: - Poor Asset Health Rating of some of the generating equipment including unit controls, exciter transformers and unit transformers could impact the reliability of the generating equipment and result in loss of generation; - Unit 1 to 3 turbines are 37 to 38 years old and have never undergone a major intervention. The latest engineering inspection identified excessive band seal erosion and runner cavitation on these units. Furthermore, due to lack of wicket gate friction devices on these turbines, there is a risk of an undetected shear pin failure event which would result in damage to the wicket gates and unit outages; - Poor Asset Health Rating of the powerhouse, tailrace gantry and intake gantry cranes that could impact the reliability of the cranes and their lifting capabilities; - Poor Asset Health Rating of the cooling water piping that has increased the risk of piping failure; and - Deficiencies in the existing fire alarm and fire protection systems that have increased the risk of system failure due to accelerated corrosion and potential rupture of the piping. • Dam safety: - Deficiencies in the reliability of the flood discharge (spillway) facilities that could lead to a failure of the system to operate on demand during high inflows (a flood or spurious release from Boundary Dam upstream) and result in significant damages to the dam and powerhouse, the risk for which is currently managed through regular gate testing and maintenance; - Deteriorating performance of the dam's drainage system that is continually monitored but, if not remediated, would eventually compromise the dam's stability; and - Failed coatings on the intake operating gates will lead to corrosion and metal loss and reduce the life of the gates.

[1] Refer to Appendix N for information on generating facility classifications.

Summary of Solution:

The Seven Mile Facility Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality.

In the short-term, the focus will be on higher priority investments required for safe and reliable generation that are sequenced to minimize outages. Medium term activities include those related to maintaining reliable operation of the flood discharge systems. In the long term, activities will continue to focus on investments required to address safety risks and reliability risks for equipment in poor condition.

Short-Term:

- Generating Equipment:
    - Unit 1 to 4 exciter transformer replacement;
    - Powerhouse crane upgrade;
    - Unit 1 to 3 turbine upgrade;
    - Fire alarm system replacement;
    - Unit 1 to 4 controls replacement; and
    - Unit 1 transformer replacement.
- Dam Safety:
    - Flood discharge systems reliability improvements

Medium & Long-Term:

- Generating Equipment:
    - Unit 1 to 3 cooling water piping replacement;
    - Unit 2 to 3 transformers replacement;
    - Fire protection piping replacement;
    - Unit 1 to 3 generators replacement; and
    - Intake gantry crane upgrade.
- Dam Safety:
    - Foundation drains replacement; and
    - Intake operating gate refurbishment.

Name of Capital Strategy, Plan or Study: Shuswap Facility Asset Plan
Summary of Issue: The two-unit Shuswap Falls powerhouse is located on the Shuswap River approximately 35 km east of Vernon. It consists of: • Shuswap Falls Generating Station (Unit 1 - 3 MW, Unit 2 - 3.5 MW); • Wilsey Dam; • Sugar Lake Dam; and • Sugar Lake Reservoir. The Sugar Lake Reservoir is operated on an annual fill and release cycle, with the majority of inflows resulting from spring snowmelt and seasonal storm events. The downstream Shuswap generating facility operates as a run-of-river facility passing the Sugar Lake Dam discharges and local inflows. The Shuswap facility is classified as an Available[1] energy facility for asset management purposes and represents less than 0.1 per cent of BC Hydro's total hydroelectric generation capability. Plant output supplies a portion of the local area load, but the facility is not designed to run without system frequency support provided by the 138 kV lines that tie into the Lumby substation. The Shuswap Generating Station has been in service for over 90 years, is near end of life and provides limited system benefit (e.g., dependable capacity, voltage support, local load support). Unit 1 has been out of service since 2013. There are concerns around the structural condition of Wilsey Dam, and ongoing commitments to evaluate capital solutions to provide fish passage upstream of Wilsey Dam. Over the next 10 years, the total cost to refurbish the Shuswap facility is expected to exceed $50 million, including $28 million to refurbish Wilsey Dam, $11 million to construct a fish channel, and upwards of $20 million to renew the generating assets. The most significant remaining issues and risks associated with the Shuswap facility include: Generating Equipment: • Unit 1 was taken out of service and there a no current plans to reinvest in the unit; and • Unit 2 generating equipment ranges from poor to good condition, with major equipment like the governor and exciter being in the best condition and the generator being in the worst condition. Dam Safety: • Sugar Lake Dam has potential seepage issues at the right and left abutment. The abutment is the structure that joins the dam to natural ground. The left abutment is a sand and gravel embankment with two concrete cut-off walls founded, at least in part, on bedrock, and designed to impede the flow of water. The right abutment is an embankment on till with a concrete cut-off wall and a cut-off trench filled with soil. Internal erosion of the Sugar Lake Dam abutments is suspected. Erosion that is left unabated could result in abutment failure which would result in an uncontrolled release from the reservoir; • Wilsey Dam is considered to be in poor to unsatisfactory condition based on the most recent semi-annual inspection of the dam. The strength of the concrete is potentially less than originally designed, and there is extensive cracking and seepage through joints in the main arch dam. Sections of the plug dam are suffering from significant concrete spalling, thereby reducing the mass weight of the plug. The loss of concrete in the plug dam is at the point of undermining the post-tensioning anchor heads. Failure of the dam would result in significant environmental impacts due to the uncontrolled release of sediment into the river, and the facility's proximity to a Department of Fisheries and Oceans Canada fish hatchery two kilometres downstream. There is also potential for loss of worker life in the downstream area in the event of dam failure; and

1 Refer to Appendix N for information on generating facility classifications.

- For the past 12 years, the Wilsey Dam Fish Passage Committee has been working through BC Hydro's Fish Passage Decision Framework in an effort to evaluate opportunities for salmon reintroduction upstream of Wilsey Dam. In addition to re-establishing upstream fish habitat, fish passage represents an opportunity to improve the relationship with local First Nations and gain support with the regional district and local interest groups who have been working on this process for over 12 years. Delay in demonstrating progress is a reputational risk that may harm relationships and cause a loss of trust with First Nations and regional interest groups.

Summary of Solution:

Based on preliminary financial analysis and considering the strategic significance of this facility within a growing portfolio of fleet wide risks, the leading alternative for Wilsey Dam and Generating Station is to decommission the facility. The key components of adopting this long-term strategy are:

- Decommissioning of the powerhouse and all generating equipment;
- Provision of fish passage via decommissioning of Wilsey Dam and site restoration to natural state; and
- Sustained investment in Sugar Lake Dam to ensure continued safe operation.

This strategy is considered to provide the best value approach for BC Hydro and ratepayers and will provide lasting social and community benefits.

Short-Term:

- None.

Medium and Long-Term:

- Sugar Lake abutment upgrades.

Name of Capital Strategy, Plan or Study: Strathcona Facility Asset Plan
Summary of Issue: The two-unit 64 MW Strathcona facility is located on Vancouver Island and was constructed in 1958 (Unit 1) and 1968 (Unit 2). Strathcona forms part of the Campbell River system, with Ladore and John Hart facilities located downstream. The facility includes the Upper Campbell Reservoir, the Strathcona Dam, Crest Creek Diversion Dike, and the Strathcona Generating Station. Strathcona is classified as a Strategic[1] Facility for asset management purposes. Per the BC Dam Safety Regulation: • Strathcona Dam is rated as an Extreme consequence dam; and • Crest Creek Diversion Dike is rated as a Significant consequence dam. In 2009 BC Hydro initiated the Campbell River Systems Engineering Assessment and investigated the full range of options for the development of the river system in order to identify how investment should be prioritized to deliver safe and sustainable long-term management of the river system assets. Remediation of seismic concerns may mean that the generating facility cannot continue to operate in its current location. This still requires extensive investigation; however, the level of investment in the generating equipment has been limited, while the overall strategy is clarified. Over the past 10 years, $20 million of the total $30 million in investments made at the facility have been to implement intake tower seismic upgrades with the remaining investments going towards the intake gates, one of the generators and turbine inlet valves. The most significant remaining issues and risks associated with the Strathcona facility include: • Generating Equipment: - Asset Health Rating of Very Poor condition of the Unit 1 generator increases the reliability risk and could result in an extended forced outage resulting in a loss of generation and inability to maintain necessary water conveyance past the facility. • Dam Safety: - Expected poor post-seismic performance of the embankment dam after an earthquake occurring, on average, about once every 500 years; - Insufficient seismic withstand of the intake tower and the water conduit and penstock that pass under the dam to the powerhouse, raising concerns for their failure in an earthquake occurring, on average, about once every 500 to 1,000 years, resulting in seepage through the dam fills and potential dam failure; - Deficiencies in the operational reliability of the spillway gates that could result in their failure to open as needed in a flood event; - Insufficient seismic withstand of the spillway gates and hoist structures that, in an earthquake occurring, on average, about once every 1,000 years, could fail and result in a loss of containment and/or control of the reservoir; and - Inability to draw down the reservoir to a sufficiently low elevation following a major earthquake, as required by the expectedly poor post-seismic performance of the dam (described above).
Summary of Solution: The Strathcona Facility Asset Plan presents a strategy that initially focuses on addressing the highest priority water conveyance and dam safety items. The strategy to be taken for upgrades to the dam and ancillary flow control structures is described within the Campbell River Systems Engineering Assessment which is referenced above and has its own summary within Appendix K. Limited investments in the existing generating equipment will be considered on a component-by-component basis (i.e., undertake discrete investments, as needed), considering factors such as condition, rate of deterioration, the operating environment and criticality.

[1] Refer to Appendix N for information on generating facility classifications.

In the short-term, activities will address the identified risks and issues associated with the communication system, reservoir discharge capability, and generating units, in order to address immediate high priority dam safety and reliability risks, respectively. In the medium term, the focus will remain on water conveyance and addressing the seismic withstand risks associated with the dam. It is possible that the solution required to remediate the seismic issues associated with the dam may result in an inability to continue generation within the existing powerhouse. If this is the case, in the long term, opportunities to redevelop the generating station will be investigated.

Short-Term:

- Generating Equipment:
  - Generator (G1) refurbishment.
- Dam Safety:
  - Upgrade of the reservoir discharge facilities to provide sufficient operational reliability, required seismic withstand, post-earthquake drawdown capability, and capability to provide compensatory flows in the event of lost or discontinued generation.
- Telecommunications:
  - Communication system upgrade.

Medium-Term:

- Dam Safety:
  - Embankment dam seismic upgrades; and
  - Possible decommissioning of the intake tower, water conduit and penstock under the dam and concomitant decommissioning of the generating station or reducing the generating station to a non-operational station.

Long-Term:

- Generating Equipment:
  - Potential redevelopment of the Strathcona generating station.

Name of Capital Strategy, Plan or Study:

Wahleach Facility Asset Plan

Summary of Issue:

The single unit, 61 MW Wahleach facility is located in the Lower Mainland and was commissioned in 1952. It consists of the Jones Lake Reservoir, Wahleach Dam, Boulder Creek Diversion Dyke, Jones Lake Intake structure, and a water conveyance tunnel and penstock leading to the Wahleach Generating Station. Wahleach is classified as a Strategic[1] facility for asset management purposes and Wahleach Dam is classified as a Very High consequence dam per the BC Dam Safety Regulation.

BC Hydro has maintained the health of the Wahleach facility through a number of investments in the past 10 years totaling over $66 million. Investments have been focused on generating equipment, which included penstock inlet valve, governor, exciter, protection and control, transformer, switchgear, and cooling water replacements, and a fire protection system upgrade.

The most significant remaining issues and risks associated with the Wahleach facility include:

Generating Equipment:

- Asset Health Rating of Poor for the generator, which elevates the reliability risks associated with the single unit and increases the likelihood that the facility may experience an extended forced outage; and
- The coatings on the penstock and tunnel steel liner have failed which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to recoat the assets before a much more extensive refurbishment or replacement is required.

Dam Safety:

- Potential defects in the seepage control sheet piles at Wahleach Dam that could lead to erosion of dam or foundation materials and risk of dam failure. This risk is being managed by monitoring seepage through instrumentation and weekly inspections, and a response plan is in place in the event that any sign of significant seepage through the dam is observed;
- Potential failure of the intake gates at Jones Lake during a major earthquake occurring, on average, about once every 4,800 years, which would prevent the closure of the water passage and cessation of flows to what would likely be a damaged generating station and could result in the inundation of adjacent utility and transportation corridors;
- Dewatering of the tunnel has the potential to destabilize the unlined vertical shaft and can result in significant rock fall from the shaft. This risk is being managed by procedures and equipment protections which reduce the frequency and rate of dewatering; and
- Potential slope failure at Four Brothers Mountain that could result in the loss of the Wahleach facility and impact adjacent utility and transportation corridors.

Summary of Solution:

The Wahleach Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. In the short-term, the focus will be on higher priority investments required for safe and reliable generation that are sequenced to minimize outages, as well as improving seismic withstand of water retention structures and control devices. The medium to longer term investments will focus on controlling seepage to ensure dam stability and addressing rockfall issues that can occur when the tunnel vertical shaft is dewatered.

[1] Refer to Appendix N for information on generating facility classifications.

Short-Term:

Generating Equipment:

- Generator refurbishment; and
- Penstock and tunnel liner coatings replacement.

Dam Safety:

- Intake Tower and gates seismic upgrade

Medium and Long Term:

Dam Safety:

- Dam foundation seepage control upgrade; and
- Possible unlined tunnel vertical shaft protection from rock fall.

The potential for a slope failure at Four Brothers Mountain is a retained risk, with no practicable means available to reduce or eliminate it. BC Hydro has implemented an ongoing surveillance program to identify changes in the slope's behaviour and to provide warning of impending instability.

Name of Capital Strategy, Plan or Study:

Whatshan Facility Asset Plan

Summary of Issue:

The Whatshan facility consists of the Whatshan Generating Station and the Whatshan Lake Reservoir impounded by the Whatshan Dam and a saddle dam. An intake structure on the east shore of the reservoir conveys water to the generating station via a 3.6 km partially lined tunnel/penstock. The single unit, 55 MW Whatshan generating station is located about 130 km east of Vernon on the west shore of the Lower Arrow Lake Reservoir near Needles, B.C. The facility was originally developed in 1951 and rebuilt in 1953 following a rock and mudslide which destroyed the original powerhouse. The second powerhouse was replaced by the existing powerhouse in 1972. The current powerhouse was placed at an elevation 12 m higher than the earlier ones due to the raising of Arrow Lakes after the completion of the Hugh Keenleyside Dam in 1968.

BC Hydro has invested approximately $12 million at Whatshan over the past 10 years, $6 million of which was to provide burial protection to a former Oatscott Reserve burial site and $3 million to replace the unit transformer.

The most significant remaining issues and risks associated with the Whatshan facility include:

- Generating Equipment:
  - Asset Health Rating of Poor of the original governor increases the reliability risk and may result in forced outages; and
  - Asset Health Rating of Fair of the original exciter system and lack of spare part availability and original equipment manufacturer support increases the reliability risk and may result in forced outages;
- Dam Safety:
  - There is uncertainty regarding the adequacy of seepage control provisions in the left abutment embankment and under the main dam. A dam safety investigation project is planned to investigate the potential piping/internal erosion risks at Whatshan Dam and to identify the seepage control measures required to address the potential dam safety concerns; and
  - Excessive leakage from the tunnel increases the risk of further deterioration of the tunnel liner, high water pressure in the rock slope and possible slope failure. Failure of the rock slope could damage the switchyard and powerhouse. This risk is currently being managed through seepage monitoring and inspections of the slope and the tunnel.

Summary of Solution:

The proposed strategy for the Whatshan facility is to make modest life extension and equipment replacement investments in order to continue to maintain and operate the facility over the long-term. A component-by-component strategy to maintain generation and water passage is proposed to upgrade/refurbish existing equipment at end-of-life over the next 20 years.

Over the short-term, the focus is on the highest priority safety and reliability risks in the powerhouse, such as replacing the governor system and restoring the coating on the turbine inlet valve. Work in the medium term will be undertaken to address the seepage issue under the main dam and to upgrade the tunnel lining. In the long-term, the exciter system will be replaced due to end of life and potential reliability risk and forced outage risk.

Short-Term:

Generating Equipment:

- Unit 1 governor replacement; and
- Turbine inlet valve coating restoration.

Medium-Term:

Dam Safety:

- Seepage control mitigation to eliminate seepage and potential erosion under the main dam; and
- Tunnel lining upgrade to reduce seepage which could lead to slope instability above the powerhouse.

Long-Term:

Generating Equipment:

- Unit 1 exciter replacement.

Name of Capital Strategy, Plan or Study:
Abbotsford Area Study

Summary of Issue:

The Abbotsford area is supplied by a 230 kV and 60 kV transmission system and the following four substations:

- Mount Lehman has a capacity of 100 MVA and was built in 2007;
- Gloucester has a capacity of 25 MVA and was built in 2002;
- Clayburn has a capacity of 180 MVA, and was built in 1984; and
- Sumas Way has a capacity of 55 MVA and was built in 1977.

The four substations supply the entire load in the study area which extends from about 248 St in Langley to Sumas Prairie east of the City of Abbotsford, and from the Fraser River to the Canada/U.S. border. The Abbotsford area has approximately 60,000 customers and a peak load of 333 MVA in fiscal 2020. The present area firm capacity is 360 MVA. In the last 10 years, the area load has grown by approximately 1.3 per cent each year. In fiscal 2020, the actual demand was approximately 333 MVA.

The City of Abbotsford, the largest municipality in this area, has a population of over 130,000. It is the largest municipality in the Fraser Valley Regional District and the fifth largest municipality in British Columbia.

BC Hydro has made investments in this area in the last 20 years totaling over $65 million. The latest investments have included the construction of two substations: Mount Lehman substation and Gloucester substation, together with the decommissioning of the old Abbotsford substation.

The most significant issues and risks remaining in the Abbotsford area include:

- Clayburn substation has feeder sections that were designed to be compact in size and at present are safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs; however, workers are unable to work on the equipment safely and efficiently without taking extended customer outages. As a result, some maintenance work at the substation cannot be completed; and
- At the Sumas Way substation, all of the equipment in the 25 kV switchyard is in poor condition. The metalclad feeder sections have arc flash hazards. Due to this safety concern, workers are restricted from entering the feeder section buildings while the equipment is energized.

Summary of Solution:

The strategy for this area is to mitigate the above reliability and safety risks while continuing to provide a reliable supply to the customers. BC Hydro has developed alternatives that upgrade the area supply in coordination with the need to retire equipment in poor condition, and to address existing safety risks at Clayburn and Sumas Way substations. The coordination will avoid stranded investments in asset replacement projects to sustain the existing system. The solution alternatives consider a number of factors, including:

- The present capacity and future load growth in the area;
- The health of the assets at area substations, and their expected degradation overtime;
- Opportunities to utilize capacity at neighboring substations;
- The timing of future projects at area substations combined with the need to retain adequate overall area capacity; and
- The need to develop the sequencing of projects in a way that minimizes/ avoids stranded investments.

Short and Medium-Term:

- Expand Mount Lehman capacity from 100 MVA to 150 MVA;
- Address the safety risks associated with Clayburn by decommissioning the unsafe feeder section with a new feeder section meeting all the present safety standards and retrofitting the other feeder section; and
- The completion of the above will allow offload Clayburn load to Mount Lehman and offload Sumas Way load to Clayburn and decommission Sumas Way. Upon completion, there will be a significant improvement in the overall equipment condition and reliability, the safety risks will be mitigated, and the area will have sufficient capacity to accommodate future load growth in the area.

Long-Term:

In the longer term, it is expected that a component replacement strategy will be implemented at the various substations to address risks with discrete assets as these degrade over time. In addition, growth in the area will continue to be monitored, to determine whether additional capacity is required.

Name of Capital Strategy, Plan or Study:

Analog 4W Inventory Study

Summary of Issue:

BC Hydro is using Analog Private Lines (**APL**) provided by TELUS for Teleprotection, Supervisory Control And Data Acquisition, telemetry, alarms and mobile radio backhaul. BC Hydro uses 175 analog lines for a total annual recurring cost of approximately $1,700,000.

TELUS has announced its intent to end this service by 2022 because of the system's age and the unavailability of spare parts with which to maintain the system. This discontinuation would require BC Hydro to migrate to alternative technologies. BC Hydro must migrate the circuits to new services prior to the discontinuation of the APL service.

Although TELUS has indicated it is willing to be flexible with its planned discontinuation date to accommodate BC Hydro's complex migration, there is a risk that failed APL circuit would not be repairable, which would lead to an extended outage to the service. Depending on the nature of the failed circuit, there could be safety or operational consequences.

Transmission Voltage Customers and Independent Power Producers also use APL services to support their interconnections with BC Hydro.

Summary of Solution:

A number of potential alternatives to APL were identified in this study, including cellular, satellite, private radio systems, and digital leased services from a carrier. The study recommends migrating the circuits off the APL services onto one of the alternatives.

Short-Term:

- Initiate a project to migrate the circuits from APL onto alternative services; and
- Work with Interconnections to identify Transmission Voltage Customers and Independent Power Producers using APL service, and initiate cutover projects with the third-parties.

Medium-Term:

- Complete migration project.

Long-Term:

No long-term capital investments are identified in this study. The alternative solution will be maintained under the Telecom maintenance work plan and may be at higher cost than current APL services.

Page 1 of 1

Name of Capital Strategy, Plan or Study: Asset Management Strategy - Protection and Control (P&C)
Summary of Issue: P&C Systems provide critical support to the primary circuit elements of the BC Hydro Transmission System by preserving the integrity and life of this equipment, maintaining overall system reliability, ensuring worker and public safety and enabling the gathering and storing or operational data. Historically, the majority of P&C equipment was comprised of older electro-mechanical type protective relay devices and later solid state type protection and control devices. While these legacy technologies are still prevalent on our system for protecting power system assets, when possible, they are replaced by modern micro-processor based equipment. This modern equipment provides additional functionality and data availability to improve operational visibility and control and improved protection capabilities. The use of micro-processor based equipment also enables the implementation of a number of advanced applications to improve the reliability and performance of the power delivery system (i.e., Volt-Var Optimization). Criticality of P&C asset failures varies depending on the type and location of the protected equipment and the type and location of the P&C asset. Impacts of P&C asset failures can be critical and can result in significant system or customer outages, and possible public and worker safety risk. The most significant issues and risks associated with the P&C assets include: • Lack of Original Equipment Manufacturer support for most legacy P&C equipment due to advanced age; • Risks of complete failure associated with poor health condition of older P&C equipment; • Increased corrective work and cost for emergency repair / replacement; • Constantly evolving and expanding compliance requirements impact operating budgets that have remained fixed; • Proportionally increasing risk of noncompliance with the expanding compliance requirements; • Specialized skill set requirements for staff; • Inaccuracies and inadequate availability of inventory data limits effective planning capabilities; • Existing control buildings often lack the required space to accommodate modern solutions that apply standards for increased capacity and added redundancy; and • Cyber Security, Compliance, and System Risk Management
Summary of Solution: Projects are planned for the sustainment of the P&C system assets by considering asset condition, function and their criticality for meeting power system reliability and safety requirements. To address the above issues and risk the following staging of investments is planned: **Short-Term:** Address the most critical elements of the P&C system: • Replace the Remote Terminal Units (**RTU**) at the following stations: Kennedy, Savona, Harewood, Sakunka, and Taylor; • Replace the Digital Fault Recorders (**DFR**) at the following stations: Malaspina, Dunsmuir, Clayburn, Nelway and Natal; • Replace Control Systems at GM Shrum and Williston susbstations and the Capacitor Bank Control System at American Creek substation; • Ensure compliance with Mandatory Reliability Standards, including CIP version 7; and • Continue work on pilot project initiated at Kent substation to apply and test new architecture for the protection and control modernization program, which is expected to improve the delivery of future P&C projects and could change the current relay sourcing strategy.

Medium-Term:

Replacement of end-of-life P&C assets will continue with a focus on the highest risk assets including remaining legacy models of protection relays, RTUs, and DFRs.

- Replace DFRs at the Seven Mile, Glenannan, Minette, Telkwa and Vaseux Lake substations;
- Replace RTUs at Maple Ridge, Foot Hills, Rainbow and Horseshoe Bay;
- Evaluate Kent Protection and Control Modernization project to initiate a program of projects to modernize small and medium sized distribution substations; and
- Projects may also be developed to comply with new Mandatory Reliability Standards.

Long-Term:

In the long-term, the P&C systems will need to continue be replaced and modernized to align with industry advances that bring additional safety, reliability and operational cost benefits, and to address asset health and end of life. The redundancy designed into the system is expected to also allow for the replacement of primary and secondary systems as they fail to maximize asset life with no impact on system reliability.

Name of Capital Strategy, Plan or Study:

Asset Management Strategy – Lines – Section 2.1.4 – Conductors

Summary of Issue:

BC Hydro has approximately 19,300 circuit-km of overhead transmission conductors. The average age of conductors on the transmission system is 45 years. The objective of the conductor strategy is to achieve a life of 80 years for transmission circuits while operating at design load capacity.

Overall, conductor condition is determined by regular inspections and failure analysis. Systematic sampling is also used for analytical condition assessments, by removing short segments of conductor for laboratory testing. When defects are identified, capital projects are initiated considering an integrated approach, and factoring in the nature of the defect, site conditions, overall condition of the line and system needs.

BC Hydro's overhead transmission line conductors can be classified in two main types: aluminum conductor steel-reinforced (**ACSR**), which is the industry standard and comprises the majority of installed conductors; and copper, which is obsolete for use as conductor, in poor condition, and is being replaced with ACSR. There are some situations where other types of conductor are used on the BC Hydro transmission system: for example, all-aluminum conductor, all-steel conductor, and aluminum conductor - carbon fibre core due to specific technical requirements such as loading or long span crossings.

Since fiscal 2010, approximately 150 km of copper conductor has been replaced, including recent projects for circuits 60L02, 60L03, 60L18, and 60L19. However, approximately 300 circuit km of copper conductor remain in the BC Hydro Transmission system. Based on existing data, the majority of transmission ACSR conductor is in good or satisfactory condition and there are no major capital improvements expected in the short-term.

The risks and issues associated with overhead conductors include:

- Condition – Degradation can occur from age and stresses such as wind, ice, lightning, thermal loading, corrosion, mechanical damage and air pollution;
- Safety & Reliability – Failures due to degradation can create public and worker hazards and result in forced outages with long restoration times; and
- Capacity – Degradation of the conductor can lead to de-rating of the circuit.

Summary of Solution:

To address the above issues and risks, the following staging of investments is recommended:

Short-Term:

- Continue to maintain and prioritize conductor replacements and upratings based on condition;
- Manage operation overload limits to avoid conductor damage;
- Continue with the copper conductor replacements planned for circuits 60L004, 60L011, and 60L054 on the south side of Burrard Inlet around Burnaby Mountain;
- Continue the conductor sampling program for ACSR conductor; and
- Address the end-of-life conductor issues at Jervis Inlet Crossing.

Medium and Long-Term:

- Continue the Copper Conductor Replacement Program; and
- Continue the ACSR conductor sampling program, and explore other inspection methods, to identify scope for future overhead conductor replacement capital program.

Name of Capital Strategy, Plan or Study:

Asset Management Strategy – Stations – Section 2.2.1 - Buildings

Summary of Issue:

BC Hydro has over 400 building in substations with buildings as old as 70 years in varying condition and of varying criticality. There are several types of building inside a substation. Types of buildings include:

- Control buildings;
- Gas insulated switchgear buildings;
- Indoor substation buildings;
- Storage buildings;
- Offices, workshops, and crew headquarters; and
- Standby diesel buildings, air compressor buildings, and others.

These assets provide all-weather protection and security for:

- Switchboard panels;
- Batteries and chargers;
- Protection & control and telecom equipment;
- Gas insulated switchgear equipment;
- Metal clad switchgear;
- Tools and spare parts, etc.; and
- Employee work areas.

The general issues and risks associated with buildings include:

- Reliability: Provide a secure environment that protects critical electronic, electrical or mechanical equipment from damage by rodents and the elements;
- Safety: Provide workers with a safe working environment and workspace for substation operation and maintenance work, including hazardous materials such as asbestos; and
- Regulatory: Maintain Mandatory Reliability Standards compliance, both by housing key assets and by providing physical security.

Summary of Solution:

The strategic replacement of control buildings approaching end of life is ongoing. The building needs are integrated with other substation upgrade projects such as protection and control modernization or replacement, and major substation expansion or renovation. New building designs include a plan to accommodate for future equipment expansions needs of the substation as well as meeting current engineering and regulatory standards.

The condition of assets is reviewed on a regular basis through recurring visual inspections, and, where required, detailed engineering assessments. The information on asset condition is used to assess the risk of failure of buildings and is used to prepare a consolidated list across the fleet to identify the timing to address the risks.

Short and Medium-Term:

- Port Alberni – Control Building replacement to address reliability and seismic risks;
- Prevost – Control Building replacement to address reliability and safety risks;
- Cathedral Square HVAC – Address reliability and safety risks of a failure of the HVAC system; and
- Williston – Control Building replacement to address reliability and safety risks.

Long-Term:

Approximately 22 per cent of buildings are over 40 years of age. Over the next 10 years, it is likely that a portion of these will degrade to poor or very poor condition. Remediation of the risks associated with these degrading assets will be required in the long-term.

Name of Capital Strategy, Plan or Study:

Asset Management Strategy – Section 2.2.2 – Circuit Breakers

Summary of Issue:

There are 3,968 circuit breakers operating at voltages from 2.4 kV to 500 kV in BC Hydro's substations. A circuit breaker fulfills two roles: first, it acts as an automatically operated switch to protect an electric circuit from damage caused by high currents; second, circuit breakers are used to disconnect or connect different components of the electric system. Circuit breakers contain high pressure air, oil, vacuum or sulphur hexafluoride (**SF6**).

The general issues and risks associated with the failure of circuit breakers include:

Reliability:

- Elevated reliability risk if the circuit breaker does not operate as intended causing damage to other equipment in the circuit; and
- Elevated reliability risk due to the sudden release of energy or fire impacting adjacent equipment.

Environment:

- Elevated risk of oil spills and polychlorinated biphenyl (**PCB**) contamination in the population of 470 oil filled circuit breakers; and
- Elevated environmental and safety risk associated with SF6 leakage from the population of 1,800 SF6 filled circuit breakers.

Reputation

- 134 circuit breakers contain PCB levels at or above 50 ppm which are required to be replaced by the December 31, 2025 Federal PCB Regulation deadline.

Safety:

- Elevated safety risk due to the sudden release of energy or fire; and
- Elevated safety risk when a circuit remains energized due to the improper opening of a circuit breaker.

Over the last 10 years, BC Hydro has installed over 1,712 new circuit breakers with two-thirds being installed in the distribution substations and the balance on the transmission system.

In the total population, 768 circuit breakers are currently over 40 years old, and approximately 638 (approximately 16 per cent) of the circuit breakers have an assessed Asset Health Rating of Poor or Very Poor, indicating that there is an increased likelihood of failure.

Summary of Solution:

BC Hydro has developed a long-term replacement strategy for circuit breakers to address the large number of aging circuit breakers and their associated risks. Historically the majority of work has been focused on replacing circuit breakers on the 500 kV, 360 kV and 230 kV system. More recently, the focus has shifted towards the lower voltage circuit breakers operating at 138 kV, 69 kV and lower.

To address the issues and risks identified above, a number of approaches are being taken, including:

- The replacement of circuit breakers will be included in the scope of work in discrete capital projects. These projects will often address multiple issues at a substation, of which the circuit breakers are one element;
- Circuit breaker replacement programs will focus on remediating the risks associated with the highest priority circuit breakers;
- A SF6 release mitigation strategy will continue to explore and implement non-SF6 circuit breaker alternatives where feasible;
- A spares strategy will continue to be implemented to ensure that adequate spare breakers and parts are available to minimize the impact of failures; and
- Consideration has been given to opportunities to decommission assets where replacement is not necessary.

Short-Term:

Asset condition is reviewed on a regular basis considering factors such as recurring test results, visual inspections, and detailed engineering assessments. This information is used to assess the risks related to each circuit breaker and to update a consolidated list with the intended timing of replacement investments.

Replacement projects that will occur in the short term are described in the table below.

Upon completion of the work outlined in the table below, all 134 remaining circuit breakers containing PCBs at or above 50 ppm will have been replaced or removed from service by the December 31, 2025 Federal deadline. The internal target is March 31, 2024.

	Circuit breaker will be addressed as part of a larger project	**Projects where the circuit breaker is the primary driver**
Replacement projects that are underway and will be completed in the short-term	N/A	• Atchelitz (8 x 25 kV) • Beaverley (3 x 69 kV) • Bridge River #1 (1 x 12kV) • Brocklehurst (10 x 25kV) • Carquille (3 x 69 kV) • Chevron Canada (4 x 69 kV) • Clayton Falls (2 x 25 kV) • Colwood (3 x 25 kV) • Dunsmuir (3 x 138 kV) • Esquimalt (6 x 12 kV) • Gibsons Landing (6 x 25 kV) • Houston (3 x 25 kV) • Illecillewaet (7 x 25 kV) • Kalum (3 x 25 kV) • Maple Ridge (1 x 25 kV) • New Westminster (5 x 12 kV) • Port Alberni (5 x 12 kV) • Port Alberni (6 x 25 kV) • Rainbow (4 x 25 kV) • Rupert (6 x 69 kV) • Saltspring (2 x 25 kV) • Salmon Arm (4 x 69 kV) • Salmon Valley (2 x 138 kV) • Sechelt (3 x 25 kV) • Shellburn (4 x 69 kV) • Sidney (5 x 25 kV) • Skeena (1 x 69 kV) • Squamish (6 x 25 kV) • Seton (3 x 69 kV) • Tachick (2 x 69 kV) • Westbank (1 x 69 kV) • Westbank (3 x 25 kV) • Williams Lake (5 x 25 kV)

	Circuit breaker will be addressed as part of a larger project	Projects where the circuit breaker is the primary driver
Replacement projects that will start and will be completed in the short -term	N/A	• Grief Point (1 x 12 kV) • Harewood (11 x 25 kV) • Hundred Mile House (2 x 69 kV) • Joseph Creek (2 x 69 kV) • Kootenay Canal (1 x 69 kV) • Lajoie (1 x 69 kV) • Minette (6 x 25 kV) • Salmon Arm (5 x 25 kV) • Soda Creek (1 x 69 kV)
Replacement projects that are underway and will continue into the medium term	• Barnard (18 x 12 kV) • Capilano (1 x 69 kV and 13 x 12 kV) • Kimberley (3 x 69 kV) • Kidd No. 1 (11 x 69 kV and 15 x 4 kV) • Mainwaring (18 x 12 kV) • Natal (2 x 138 kV and 8 x 69 kV) • Newell (20 x 12 kV) • Sperling (18 x 12 kV)	N/A
Replacement projects that will start in the short term, and continue into the medium term	• George Dickie (2 x 69 kV and 17 x 4 kV) • Glenmore (3 x 69 kV and 11 x 4 kV) • Horne Payne (14 x 12 kV) Norgate (4 x 69 kV and 15 x 12 kV) • Spillimacheen (2 x 69 kV and 1 x 12 kV)	• Vernon Terminal (2 x 69 kV)

Medium and Long-Term:

Considering the age and condition of the overall population of almost 4,000 assets, it is anticipated that a continued level of investment will be required. Replacement of the 12 kV, 25 kV, 69 kV and 138 kV circuit breakers will continue through the annual circuit breaker replacement programs. In addition, a number of discrete capital projects will address risks with the higher voltage circuit breakers, as part of their broader scope of work.

The goal is to manage the highest reliability, environmental and safety risks associated with circuit breakers. Approximately 20 per cent of the population is over 40 years old and will require remediation in the medium to long term as the assets move through their lifecycle. To pace these investments over time, approximately 100 units will need to be replaced on an annual basis, considering the design life of 35 to 40 years for circuit breakers. Factors such as age, condition and criticality will continue to be used for identifying the high priority units for replacement.

Name of Capital Strategy, Plan or Study: Asset Management Strategy – Lines – Section 2.1.5 – Underground and Submarine Cables
Summary of Issue: The major objective of the strategy is to achieve a life of 55 years for transmission cable systems, which is 15 years longer than the life stated by cable manufacturers, by targeted upgrades and refurbishments. BC Hydro has approximately 350 km of transmission cables, of which 196 km are submarine with the remainder being underground in mostly the Greater Victoria and Metro Vancouver areas. Cables are used to transfer electricity where it would be difficult or impractical to install overhead transmission lines, such as across large bodies of water or through cities where tall buildings or high density make it impossible. A cable system is comprised of a cable, duct banks, manholes, and ancillary equipment (such as pressurization and monitoring systems). There are two broad categories of cables: self-contained fluid-filled which uses paper and oil for insulation, and cross-linked polyethylene, which instead uses a form of plastic and is oil-free. The main issues and risks associated with transmission cables include: • Capacity - Historic growth can result in the need to operate existing cables closer to their maximum electrical rating which can result in higher temperatures and reduced life spans; • Security - Terminal structures where the cables connect to overhead lines are vulnerable to vandalism, particularly by copper thieves; • Reliability - Cables are essential for service for reliable transfer of electricity. Failed cables leading to forced outages may cause localized load shedding and impact system reliability significantly. Repairs take a long time and leave the system in a vulnerable state; and • Environmental - Fluid-filled cables can leak oil which can result in adverse environmental impacts. The risk of leaks increases with age as the cable’s outer metallic layer (which acts to contain the oil) fatigues. Recent projects have included installing temperature monitoring systems on the 230 kV cables in Vancouver to ensure the transmission cables are not overloaded and to gauge overall health. Installation of pressure monitoring systems to provide early warning of any leaks has also been completed. Additional spare cables have been purchased to reduce response times if cables are damaged.
Summary of Solution: To address the above issues and risks, the following staging of investments is recommended: **Short-Term:** • Continue with maintenance and inspection programs; • Replace the cable (2L146) between the Goward and Horsey substations; • Gulf Islands - Transmission Reinforcement Project; and • Refurbish pumping equipment to maintain and extend service life of fluid-filled cable systems. **Medium-Term:** • Expand use of temperature monitoring systems to measure cable temperature and adopt dynamic rating systems to allow for higher power transfers (by running closer to thermal limits) and defer cable replacements that may be required by growth needs. **Long-Term:** • Consider the replacement of the 138 kV submarine cable that supplies the Gulf Islands and Vancouver Island; and • Continue practice of installing solid-dielectric insulated cables to eventually phase out use of oil-filled transmission cables to mitigate potential environmental risk.

Name of Capital Strategy, Plan or Study:
Asset Management Strategy – Section 2.2.8: Oil Spill Containment

Summary of Issue:

Oil spill containment is an engineered asset, typically consisting of oil/water separators, tanks or pits, built in conjunction with oil containing equipment such as transformers, reactors or voltage regulators. In the event the oil is released accidently from equipment, oil spill containment is used to collect the oil and prevent contamination of the surrounding environment.

The general issues and risks associated with failure to contain an oil spill include:

- Environmental:
  - Contamination of land and water resources, and plant and animal species which can have long recovery times.
- Financial:
  - Costs associated with cleaning up areas affected by oil spills; and
  - Fines may be issued in the event of environmental damage.
- Reputational:
  - Spills that threaten the environmental quality of water, land or air must be reported to the regulatory agencies and may damage BC Hydro's reputation with government and the public.

BC Hydro has over 1,000 pieces of oil-filled substation equipment that individually contain more than 4,000 litres of oil.

Significant progress has been made to remediate these risks and over 400 oil-containing pieces of equipment have new or upgraded oil containment. However, approximately 600 oil-containing pieces of equipment still do not have adequate oil spill containment.

Summary of Solution:

A risk assessment has been completed at each of the substations containing oil-containing equipment. Factors considered in the risk assessment included the quantity of oil on site, and proximity to aquatic resources, wildlife, species at risk, habitats, parkland, and First Nations land. The risk assessment also considered the water use in the area and the likelihood of a spill.

To address the issues and risks identified above, two approaches are used:

- Capital projects which install large oil containing equipment will also have oil containment installed; and
- An oil containment projects, which prioritizes upgrades of legacy substations that do not meet the current standard, will address risks that are not otherwise addressed through a capital project.

Short-Term:

Activities that will be initiated in the short term are described in the table below.

	Oil spill containment that will be addressed as part of a larger project	**Projects where oil spill containment is the primary driver**
Containment activities that will be completed in the short term	N/A	• Atchelitz • Meridian
Containment activities that are underway, and will continue into the medium term	• Bridge River 1 • Bridge River Terminal • Capilano • Hundred Mile House • Jordan River • Natal • Newell	• Nelway • Soda Creek

	Oil spill containment that will be addressed as part of a larger project	Projects where oil spill containment is the primary driver
Containment activities that will start in the short term, and continue into the medium term	• Kelly Lake • Norgate • Patricia • Rosedale • Spillamacheen • Williston	• Valleyview • Ashton Creek

Medium-Term:

The investments outlined above address the most pressing risks associated with oil spill containment. The following substations are expected to have work initiated in the medium-term:

- Red Bluff;
- Rupert;
- Cathedral Square;
- Minette;
- Gold River;
- Cranbrook; and
- Harewood.

In the short- and medium-term this approach will reduce the risks associated with oil containment of another 10 per cent of equipment. This is an addition to the 40 per cent that already have adequate oil spill containment.

Long-Term:

In the long-term, work will continue to improve oil spill containment at a rate similar to the short- and medium-term and will be risk assessed and prioritized as outlined above.

Name of Capital Strategy, Plan or Study: Asset Management Strategy – Section 2.2.9: Series Capacitors

Summary of Issue:
BC Hydro has 15 series capacitors in nine separate substations, the majority of which are 500 kV units. They are expensive substation assets with long lead times to acquire and replace. The majority of series capacitors were original installations built from 1980s to 2010s. Series capacitors are used to increase the transmission system transfer capability, improve voltage stability, and optimize power flow between parallel circuits.
The general issues and risks associated with the failure of series capacitors include:
• Reliability:
  - Reduced transfer capability and increased network risks associated with the transmission system; and
• Safety & Financial:
  - The increased likelihood of a failure or fire poses a safety risk to workers and may cause damage to surrounding assets.
Over the last 20 years, BC Hydro has refurbished 4 series capacitors at three substations (MLS, CHP, CRK). BC Hydro has also developed and implemented a spares strategy and has purchased strategic spare parts to minimize impacts of a failure.
Approximately 8 series capacitors are between 10 and 40 years old. Of the 15 series capacitors, two have been assessed as being in Poor Asset Health Rating, indicating that they have an increased likelihood of failure.

Summary of Solution: To address the issues and risks identified above, two general approaches are identified: • Capital projects have been identified to remediate the risks associated with series capacitors with the highest risk of failure. New or refurbished units will be installed; and • A spares strategy will continue to ensure that critical spares are available to minimize the impact of series capacitor failures. **Short and Medium-Term:** Condition of assets is reviewed on a regular basis considering such factors as recurring test results, visual inspections, and, where required, detailed engineering assessments. This information is used to assess the likelihood of failure of each series capacitor. This risk-based approach is used to identify the appropriate timing to replace capacitors and components thereof. The series capacitors with a highest priority for refurbishment or replacement are: • KDY 5CX1, 5CX2, 5CX3; • MLS 5CX3; and • AMC 5CX1, 5CX2. **Long-Term:** The series capacitor fleet may contain a number of units with an Asset Health Rating of poor and very poor after the completion of the short-term and medium-term investments. The risks associated with the health of these assets will need to be addressed in the long term, following similar assessment and prioritization techniques to those outlined above.

Page 1 of 1

Name of Capital Strategy, Plan or Study:

Asset Management Strategy – Section 2.2.10: Shunt Reactors

Summary of Issue:

BC Hydro has 142 shunt reactors in its substations, the majority of which are 500 kV units. Shunt reactors are oil filled and similar in construction to transformers. They are expensive substation assets with long lead times to acquire and replace. The majority of shunt reactors were installed from the 1960s to 1980s when most of the 500 kV transmission lines were built. Shunt reactors have two main purposes: firstly, they are used to help control the voltage on the transmission system under certain operating conditions and, secondly, they are used to protect the transmission cables from potential damage due to over voltages.

The general issues and risks associated with the failure of shunt reactors include:

- Reliability:
  - Reduced transfer capability and increased network risks associated with the transmission system; and
  - Elevated transmission system voltages which can damage the transmission cables.
- Environmental:
  - Elevated risk of oil spills, particularly in locations with less robust spill containment and more sensitive environments.
- Safety & Financial:
  - The increased likelihood of a fire poses a safety risk to workers and may cause damage to surrounding assets.

Over the last 20 years, BC Hydro has replaced nine shunt reactors at eight substations. BC Hydro has also developed and implemented a spares strategy and has purchased four reactors for 230 kV and 500 kV spares to minimize impacts of a failure. The total value of the investment in spares was over $5 million.

Approximately 67 shunt reactors are between 40 and 50 years old and seven are more than 50 years old. Of the 142 shunt reactors, 58 (40 per cent) have been assessed as being in Poor or Very Poor Asset Health Rating, indicating that they have an increased likelihood of failure.

Summary of Solution:

To address the issues and risks identified above, two general approaches are identified:

- Capital projects have been identified to remediate the risks associated with shunt reactors with the highest risk of failure. New units will be installed with oil spill containment; and
- A spares strategy will continue to ensure that critical spares are available to minimize the impact of shunt reactor failures.

Short & Medium-Term:

Condition of assets is reviewed on a regular basis considering such factors as recurring test results, visual inspections, and, where required, detailed engineering assessments. This information is used to assess the likelihood of failure of each reactor and to prepare a consolidated list across the system. The risk-based list is used to identify the appropriate timing to replace individual reactors. The reactors with the highest priority for replacement are:

- G.M. Shrum substation 500 kV line reactors (six in total);
- Williston substation (sixteen reactors); and
- Kelly Lake substation (six reactors).

Long-Term:

The reactor fleet will contain a number of units with an Asset Health Rating of poor and very poor after the completion of the short-term and medium-term investments. The risks associated with the failing health of these assets will need to be addressed in the long term, following similar assessment and prioritization techniques to those outlined above.

Name of Capital Strategy, Plan or Study:

Asset Management Strategy – Section 2.2.15: Synchronous Condensers

Summary of Issue:

There are eight synchronous condensers on the BC Hydro system all of which are over 40-years old. Four are located at Burrard Synchronous Condenser Station, three are at Vancouver Island Terminal and one is at Kelly Lake substation. They are expensive assets with long lead times to acquire and replace. Synchronous condensers are rotating machines that are similar to generators. Each machine has a number of supporting systems, including a gas handling system, an excitation system, and a protection and control system. These assets are used to provide system voltage control and contribute to the system stability.

This strategy focuses on the four synchronous condensers at Vancouver Island Terminal and Kelly Lake substation as the future use of synchronous condensers at Burrard Synchronous Condenser Station is presently under review.

The main issues and risks with the synchronous condensers are:

- Safety - There are fire risks associated with leaks in the hydrogen gas handling systems; and
- Reliability - The excitation and the protection and control systems are aging, with increased likelihood of failure. There are obsolescence issues and spare parts can be challenging to source given that manufacturer support is limited. These issues can result in long downtimes if a unit is forced out of service.

Over the last 10 years, BC Hydro completed refurbishment of the windings and internal components of each of the four machines. BC Hydro also developed and implemented a spares strategy and made additional investments in spare parts to minimize outage time in the event of failures. To help with troubleshooting, BC Hydro increased the use of on-board diagnostics and implemented a knowledge transfer process to enhance its repair capability in the field. The total value of these investments was over $26 million.

As a result of this work, the overall condition of the assets at Vancouver Island Terminal and Kelly Lake substation has improved. However, reliability and safety risks remain with specific supporting systems, such as gas handling, excitation and protection and control.

Summary of Solution:

To address these issues and risks, the following approaches will be taken:

- Capital projects will upgrade the gas handling, excitation, and the protection and control subsystems of each unit;
- A spares strategy will ensure that critical parts are available to facilitate breakdown repairs and shorter outages; and
- Increased use of on-board diagnostics to shorten outages.

Short-Term:

Investments will begin in the short-term with projects for each of the four synchronous condensers to focus on addressing the remaining risks in the support systems, namely the gas handling system, excitation system, and the protection and control system.

Medium and Long-Term:

Given that the assets at Vancouver Island Terminal and Kelly Lake substation are over 40-years old, a level of ongoing work will be required as the assets progress through their lifecycle and risks associated with falling health of these assets will need to be addressed. The unit located at Kelly Lake substation is expected to be replaced with a new reactor by 2025.

Name of Capital Strategy, Plan or Study:

Asset Management Strategy – Section 2.2.16: Power Transformers

Summary of Issue:

There are 672 power transformers with a voltage class of 60 kV or greater at BC Hydro substations. Transformers are one of the most critical and expensive assets in a substation and have long lead times to acquire and replace. Transformers fulfill multiple roles in the power system. Firstly, power transformers are used to increase the voltage to a level that can be transmitted over long distances via the transmission network. Secondly, in the transmission network, transformers are used to connect systems that are operated at different voltages. Finally, transformers are used to reduce transmission voltages to a lower level that can be distributed to customers.

The general issues and risks associated with a failure of a power transformer include:

- Reliability:
  - Elevated risk of customer outages at single transformer distribution substations, and a loss of redundancy at multi transformer distribution substations; and
  - Reduced transfer capability and increased network risks associated with the transmission system.
- Environment:
  - Elevated risk of oil spills, particularly in older transformers with less robust oil spill containment.
- Safety & Financial:
  - The increased likelihood of a fire poses a safety risk to workers and may cause damage to surrounding assets.

Over the last 10 years, BC Hydro has installed 62 transformers at 44 substations. BC Hydro has also developed and implemented a spares strategy and has purchased 10 new spare transformers of different ratings to minimize impacts in the event of a failure. The total value of these investments was over $330 million.

Approximately 147 transformers are between 50 and 60-years old and 71 are more than 60-years old. Approximately 69 (10 per cent) of the total power transformers have been assessed as having Poor or Very Poor Asset Health Rating, indicating that there is an increased likelihood of failure.

Summary of Solution:

The following approaches have been taken to address the issues and risks identified above:

- The identification of capital projects to remediate the risks associated with some of the transformers;
- The development of a spares strategy that will continue to be implemented, as necessary, to ensure that critical spares are available to minimize the impacts of a transformer failure; and
- The decommissioning of assets where replacement is no longer necessary.

Transformer assets may be addressed as part of larger integrated projects within a station or region of the system or as part of standalone project.

Short-Term:

The condition of assets are reviewed on a regular basis considering such factors as recurring test results, visual inspections, and, where required, detailed engineering assessments. This information is used to assess the likelihood of failure of each transformer to help prepare a consolidated list across the fleet to identify the timing to address the risks.

Activities that will occur in the short term are described in the table below. Note that many of the investments initiated in the short term will continue to have capital expenditures and will go into service in the medium term.

	Transformers that will be addressed as part of a larger project	Projects where the transformer is the primary driver
Activities that will be completed in the short-term	N/A	N/A
Activities that are underway, and will continue into the medium-term	• Capilano (60/12 kV) • Kidd 1 (60/4 kV) • Mainwaring (230/12 kV) • Mount Lehman (230/25 kV) • Natal (138/60 kV) • Newell (230/12 kV) • Skookumchuk (60/12 kV) • Woss (138/12 kV) • Canal Flats (60/12 kV) • Diana Lake (60/12 kV)	• Bridge River 1 (60/238 kV) • Bridge River Terminal (345/230 kV) • Hundred Mile House (60/238 kV) • Jordan River (13/25/138 kV) • Rosedale (345/230 kV)
Activities that will start in the short-term, and continue into the medium-term	• Norgate (60/12 kV) • Patricia (60/12 kV) • Balfour (60/12 kV); • Coquitlam (60/12 kV); • Glenmore (60/4 kV); • Loughheed (60/12 kV); • Quesnel (60/12 kV); • Richmond (60/12 kV); • Scott Road (60/12 kV); • Sumas Way (60/25 kV); • Surrey (60/12 kV)	N/A

Medium-Term:

The investments outlined above address the most pressing risks associated with the transformers. Additional transformers may need to be addressed by future projects in the medium-term. The strategy and prioritization of risk reductions will be continually monitored over time as other transformers degrade and the risk assessments are updated.

Long-Term:

There are approximately 147 transformers between 40 to 50-years of age. Over the next 10 years, it is likely that a portion of these will degrade to Poor or Very Poor Asset Health Rating. Remediation of the risks associated with these degrading assets will be required in the long-term, applying similar assessment and prioritization techniques to those outlined above.

Name of Capital Strategy, Plan or Study: Asset Management Strategy – Telecom Transport
Summary of Issue: BC Hydro's Telecommunications system enables the safe, reliable and efficient operation of the Bulk Electric System by providing highly-available telecom services in support of Teleprotection, Supervisory Control and Data Acquisition, Remedial Action Scheme, operational voice, mobile radio and corporate network functions. The system is made up of many elements, including fiber optics, microwave radios, powerline carrier equipment, satellite terminals, multiplexors, routers and switches. Ancillary equipment such as buildings, towers, antennas, batteries, chargers and backup power generators are also included. The general issues and risks associated with the failure of telecommunication equipment include: • Reliability: - Visibility and control of remote substations would be lost by the control centres; - High-speed line protection would be lost, reducing the transfer capacity of the affected lines by 40 to 60 per cent to ensure stability; and - Remedial Action Scheme schemes would be lost, leading to interconnecting entities reducing or cutting off the interconnection until the services are restored. • Safety: - The loss of operational voice and mobile radio services reduces the ability of the control centre to coordinate safety-critical work with field crews; and - Field crews are dispatched to effect a timely repair of the failed equipment. Much of this equipment is located on the tops of mountains. It can be unsafe to access these sites during winter storm conditions. The two most significant issues with Telecom Transport equipment are asset age, and the large number of single points of failure at mountaintop microwave repeaters. Both of these issues pose a risk to the reliability of the Telecommunications system. The focus of the Telecom Transport strategy is on the maintenance of the assets. The Telecom Resiliency Strategy focuses on addressing the risks of single points of failure. Much of the existing system was originally installed in the late 1990s and early 2000s and has reached end of life. Vendors no longer offer technical support or replacement parts. Currently, the Vancouver Island Microwave replacement project is replacing end of life telecom equipment in the Vancouver Island area. In addition to the above risks, the demand for telecommunications services, especially at remote stations, is growing quickly. It is difficult to meet this demand over a constrained microwave radio link, especially when no commercial services are available to supplement the BC Hydro network. Moreover, fewer telecom equipment vendors are offering for sale equipment that fully supports Time Division Multiplexing circuits, but many legacy protection and control devices require this functionality. Equipment replacement must consider both the legacy needs of the connected devices, as well as the future needs of new packet-based communications.
Summary of Solution: The overall strategy is to address the two most significant risks of equipment age and the presence of single-points of failure. Asset condition is reviewed on a regular basis, and the timing of the planned projects are adjusted relative to asset condition and system risk. **Short-Term:** • Complete the Vancouver Island Microwave radio replacement project; • Initiate a provincial telecom equipment replacement project to replace the oldest radios and network equipment. This project will also extend the use of packet technology to enable the efficient use of constrained network links, and to enable a transition to future packet-based communications system; and

Page 1 of 2

- Continue sustainment of mobile radio systems and ancillary equipment such as towers, batteries and chargers, and diesel generators.

Medium-Term:

- Initiate equipment replacement projects for radios and network equipment installed in the late 2000s to 2010s. Continue network migration to packet-based transport systems;
- Initiate powerline carrier replacement project;
- Initiate private cellular network project to replace end-of-life WiMAX and TETRA radio systems; and
- Continue sustainment of mobile radio systems and ancillary equipment such as towers, batteries and chargers, and diesel generators.

Long-Term:

- Initiate equipment replacement projects for radios and network equipment installed in the 2020s. Complete network migration to packet-based transport systems; and
- Continue sustainment of mobile radio systems ancillary equipment such as towers, batteries and chargers, and diesel generators.

Name of Capital Strategy, Plan or Study: Barnard Asset Plan
Summary of Issue: The 191 MVA Barnard substation is a transmission and distribution substation serving North Burnaby and portions of West Coquitlam and Port Moody. First commissioned in 1954, the substation consists of: • Three switchyards: 230 kV, 69 kV, and 12 kV; • Two power transformers; and • Three feeder sections. Barnard is an important substation given its dual role as both a transmission station and a distribution station. The station serves over 40,995 customers and has the seventh largest peak load (133 MVA) in the Lower Mainland Metro region. Barnard provides one of the two transmission supplies to Lougheed substation and to six transmission voltage customer substations including Simon Fraser University. Since being commissioned in 1954, BC Hydro has expanded the substation over time and made investments in the past 20 years totaling over $30 million. Recent investments have included the addition of a new feeder section in 2008 and the replacement of all the circuit breakers in the 69 kV switchyard in 2020. There is an ongoing project to replace the 50/ 60 series feeder sections. The most significant remaining issues and risks associated with Barnard substation include: • One of the older feeder sections was designed to be compact in size and poses safety risks for workers due to limited clearance between energized equipment and ground. The risk is currently partially mitigated through physical barriers and warning signs. This risk will be addressed by the ongoing 50/ 60 series feeder section replacement project; • There are elevated reliability risks associated with the above-mentioned older feeder section due to the poor condition of 67 per cent of the 18 circuit breakers and 96 per cent of the 56 disconnect switches. The oil-filled circuit breakers in this feeder section also contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline. This risk will be is addressed by the ongoing 50/ 60 series feeder section replacement project; and • There are elevated reliability risks associated with the 230 kV switchyard, due to obsolescence issues with the original mechanical protection and control relays.
Summary of Solution: The Barnard Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the feeder sections of compact size will be addressed concurrently with equipment replacement projects. In the short and medium term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out PCBs by the end of 2025. The longer-term activities are anticipated to focus on the remaining feeder sections and the transformers. **Short and Medium-Term:** • Address the safety and reliability risks associated with the older feeder section that has high risk by replacing it with a new indoor feeder section; • Address the reliability risks associated with protection and control equipment for the other older feeder section and the 230 kV switchyard by replacing the associated protection and control panels; and • Remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline.
Long-Term: • The equipment at the Barnard substation will continue to degrade over time, and a level of investment is anticipated in the longer term to preserve the reliability of the substation and address emerging risks. Expected investments are required to address the risks associated with the transformers.

Name of Capital Strategy, Plan or Study:
BC Hydro Transmission System Seismic Vulnerability Analysis
Summary of Issue: BC Hydro has significant exposure to major earthquakes that present a risk to the reliability of the transmission system including at our substations, overhead structures, and underground and submarine cables. In 2014 BC Hydro commissioned a study of the seismic vulnerability of the transmission system to better understand this risk. BC Hydro engaged specialist consultants to evaluate the key transmission assets in and around the Metro Vancouver and Victoria load centers including the substations, major overhead, underground and submarine lines, and their resiliency to transfer power to the B.C. load centres. The analysis reported that BC Hydro has been diligent in managing and mitigating the exposure to seismic risk over the past 30 years, with our performance matching or exceeding that of many other high voltage transmission system operators along the west coast of the United States. Over the past 30 years, BC Hydro has actively reduced seismic vulnerabilities to the transmission system, by a combination of construction of new submarine and buried cables; equipment replacement in high voltage yards; selective upgrades of seismically-weak control buildings; seismic upgrade of many 230 kV potheads; and selective upgrade of towers at major river crossings. Most of these upgrade efforts have been concentrated in the Lower Mainland and Vancouver Island, where the seismic hazard is highest. The analysis also identified some key vulnerabilities to BC Hydro including our buried and submarine high voltage cables, power transformer bushings, cable slack, potheads, tsunami inundation, and transmission towers subject to liquefaction or landslides. A prioritized list of system upgrades was identified to further reinforce the transmission system.
Summary of Solution: To continue addressing the known issues and risks, the following staging of investments is recommended: **Short-Term:** • Address very high priority seismic vulnerabilities including upgrading of bushings and potheads and seismic reinforcement of key infrastructure; and • Maintain robust spare strategy and response planning. **Medium and Long-Term:** • Execute the recommended capital investments in order of priority over the long-term; • Reinforce critical overhead crossings vulnerable to liquefaction including 2L003/2L49; • Monitor and reinforce critical lines vulnerable to seismic generated landslide activity including 5L42, 5L29, 5L30, 5L31, 5L32; • Seismic upgrades and reinforcement of substation yards and apparatus including ground improvement in liquefaction zones; and • Upgrades and replacements of vulnerable buried and submarine cables.

Name of Capital Strategy, Plan or Study: Bridge River Transmission System Upgrade – Network Integrated Transmission Service Study
Summary of Issue: Generation from the Bridge River System[1] and several nearby Independent Power Producers (**IPP**) is transmitted through three regional paths towards the Lower Mainland load center. By 2022, approximately 400 MW of IPP generation is expected to be connected to the Bridge River Transmission System. While BC Hydro's Bridge River 1 and 2 Generating Stations have been de-rated over the past decade, BC Hydro is now investing in these units to restore their capacity. Units 5 and 6 at the Bridge River 2 Generating Station were replaced in fiscal 2019 and fiscal 2020, respectively. Generating Units 7 and 8 at the Bridge River 2 Generating Station are being replaced in fiscal 2021 and fiscal 2022. The Bridge River 1 Project will replace Units 1 to 4 at the Bridge River 1 Generating Station. Collectively, these projects will restore the overall capacity of the Bridge River Facility to 532 MW. In 2017, BC Hydro conducted a transmission study to assess the impact of increased IPP generation and the restoration of generation capacity at the Bridge River Facility to the Bridge River Transmission System. The system study shows that by 2030, during the summer months, when generation output is high and local load is low, the amount of electric current flowing through the 2L90 circuit will reach up to 838 A (338 MVA), or over 160 per cent of its thermal rating of 510 A (203 MVA).
Summary of Solution: The strategy is to provide adequate transmission capacity to eliminate system constraints and avoid the need for generation curtailment during summer months. In all alternatives the refurbishment of 2L90 is included, as a significant number of wood structures on that circuit are in poor condition and require replacement, and there are other associated defects that require repair. **Short and Medium-Term:** Alternatives that are being considered to deliver on this strategy include: • Uprating the 230 kV transmission line (2L90) between Bridge River Terminal and Kelly Lake substation; • Upgrading Rosedale transformer and sustaining circuit 2L90; and • Curtailing local generation and sustaining circuit 2L90.

1 The Bridge River System consists of the La Joie Generating Station, Bridge River 1 and Bridge River 2 Generating Stations, and Seton Generating Station.

Name of Capital Strategy, Plan or Study:
Burrard Synchronous Condenser Replacement Study
Summary of Issue: The Burrard Synchronous Condenser Station (**BSY**) is the former Burrard Generation Station, and in past years four of the original six generating units were converted to run as synchronous condensers, each providing nominally -50/+100 MVar of reactive power to the Lower Mainland regional transmission system, and also providing support for the Interior-to-Lower Mainland power transfer. This Capital Plan addresses two issues: • Issue 1: End-of-Life BSY Asset Condition - The Burrard synchronous condensers are nearing end of life and the reactive power capacity that the units provide to the transmission system needs to be retained or replaced. • Issue 2: Fraser Valley Regional Reactive Power Support - Based on recent Transmission Planning performance assessments, the Fraser Valley regional transmission system is expected to experience voltage regulation and voltage stability constraints within next five to 10 years due to load growth. In order to meet the performance criteria required under the current Mandatory Reliability Standards, additional reactive power support is required in the Fraser Valley regional system.
Summary of Solution: The strategy is to retain or replace the capacitive and reactive power functions of Burrard synchronous condensers in the short- and medium-term using the minimum capital investment that can meet the timeline of the synchronous condenser end of life issues and Fraser Valley regional transmission system's voltage constraint problem. The two needs are addressed in one project to optimize the reactive power planning in Lower Mainland and further save the system investment and operation cost by reducing total reactive power requirement and deferring the system investment in Fraser Valley regional transmission system. The long-term strategy is to develop a plan to meet long term domestic load supply and firm transmission service requirement for the Fraser Valley regional transmission system and the Interior-to-Lower Mainland bulk transmission system. **Short and Medium-Term:** A capital plan project was initiated to retain or replace the Burrard capacitive and reactive power functions, with a projected in-service date of October 2025. The Leading Alternative comprises of installing equipment at the following substations: • Ingledow: 2 x 230 kV, 125 MVAr capacitor banks, • Meridian: 2 x 230 kV, 132 MVAr shunt reactors, • Fleetwood: 2 x 230 kV, 125 MVAr capacitor banks, • Meridian: 1 x 230 kV, 125 MVAr capacitor banks, and • Clayburn: 1 x 230 kV, 125 MVAr capacitor banks. **Long-Term:** BC Hydro will develop a long-term strategy for the Fraser Valley regional transmission system and the Interior-to-Lower Mainland bulk transmission systems once a long-term load forecast, generation resource plan and BC Hydro's 2021 Integrated Resource Plan are completed.

Page 1 of 1

Name of Capital Strategy, Plan or Study:

Downtown Vancouver Electric Supply Plan

Summary of Issue:

The Downtown Vancouver study area is comprised of the Downtown, West End, Strathcona, and Grandview-Woodland neighborhoods. The area is supplied by a 230 kV and 69 kV transmission network and three substations:

- Cathedral Square substation which has a capacity of 302 MVA was built in 1984;
- Dal Grauer substation which has a capacity of 195 MVA was built in 1953; and
- Murrin substation which has a capacity of 200 MVA was built in 1947.

The study area contains the largest commercial centre in Vancouver and has the highest load density in B.C. The area has approximately 100,000 customers and had a peak load of 409 MVA in fiscal 2020. The present area firm capacity is 697 MVA.

BC Hydro has made investments in this area in the past 20 years totaling over $300 million. Recent investments include the addition of a transformer and a feeder section at Cathedral Square substation in 2009 and the construction of a new 230 kV transmission cable circuit from Mount Pleasant substation to Cathedral Square substation in 2014.

The most significant issues and risks remaining in the Downtown Vancouver area include:

- There are elevated reliability risks at Dal Grauer and Murrin substations where more than half of the substation assets are expected to be in an assessed Asset Health Rating of Poor or Very Poor condition within the next 10 to 20 years;
- Seven of the 11 transmission cable circuits supplying the three stations are expected to be in an assessed Asset Health Rating of Poor or Very Poor condition within 20 years;
- More than half of the distribution cables at Dal Grauer and Murrin substations are expected to be in Poor or Very Poor condition within 20 years;
- The 12 kV equipment at Dal Grauer and Murrin substations exposes workers to safety risks due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs;
- The indoor circuit breakers and exposed bus at Dal Grauer and Murrin substations expose workers to safety risks from potential arc flashes in the event of insulation failures; and
- Murrin substation is on seismically unstable soil. Approximately half of the 230 kV switchyard, which supplies both Murrin and Dal Grauer substation loads, is vulnerable to severe earthquake damage from liquefaction and settlement. All loads being served from Dal Grauer and Murrin substations may experience a prolonged outage after a seismic event.

Summary of Solution:

The long-term strategy for the area is to mitigate the above reliability and safety risks by replacing Murrin and Dal Grauer substations with new substations. The addition of the new substations will be timed to precede the need to retire major existing equipment as the assets approach their end of life. This means that new capabilities will need to be created, while older assets are still in service, in anticipation of the declining condition of a large population of assets. The sequencing of activities will need to be carefully planned and staged over the long-term, to minimize or avoid stranded investments in assets that may not be required in the long-term.

The Downtown Vancouver Electricity Supply Plan examined four alternatives, each of which considered:

- The need to reduce seismic risk exposure;
- The health of each substation’s assets, and their expected degradation over time;
- The present area capacity and future load growth;
- Opportunities to transfer load to neighboring substations outside the study area;
- Opportunities to permanently decommission substations;

- The feasible timing of required work and the need to maintain sufficient area capacity;
- The costs of the different solutions;
- Performance and reliability requirements in the downtown area;
- Local stakeholder support; and
- Environmental impacts.

In light of the sizeable and complex issues noted above, the criticality of load in the downtown area, and the lead time required to build new substations in the Downtown Vancouver Area, it was particularly important to consider a long-term planning horizon.

For the Downtown Vancouver Area the following strategy is being implemented:

Short and Medium-Term:

- West End Substation:
  - Build a new underground 230/25 kV substation in the West End neighbourhood. This substation will have an ultimate capacity of 400 MVA; and
  - Build new 230 kV cable circuits to connect the new substation to the existing system.
- East Vancouver Substation:
  - Build a new indoor 230/25 kV, substation in the Strathcona neighbourhood. This substation will also have an ultimate capacity of 400 MVA.

Both new substations above represent important infrastructure in critical locations that are anticipated to be in place for more than 50 years. The ultimate 800 MVA capacity of the two substations will not be installed immediately, but provides flexibility for growth over time, as the need for the load materializes.

Long-Term:

The activities outlined above have a relatively long lead time, and will enable a number of activities in the long-term:

- Offload the Dal Grauer substation to the West End substation;
- Offload the Murrin substation to the East Vancouver substation;
- Decommission the Dal Grauer and Murrin substations, as well as the 69 kV circuits;
- Replace the 230 kV cables that are in poor condition as required; and
- Add new 230 kV transmission circuits as required to meet future load growth.

Name of Capital Strategy, Plan or Study: Fraser Valley Reinforcement Study
Summary of Issue: The Telecom Transport asset strategy identifies single points of failure at mountaintop telecom repeaters as a key system resiliency risk. The Fraser Valley Reinforcement study identifies Sumas Mountain (**SMS**) microwave repeater as a telecom site with a particularly significant impact in the event of a failure. A failure of the telecom system at the SMS microwave repeater would result in the loss of operational communications to: • One 500 kV substation in the U.S. (Custer); • One BC Hydro 500 kV substation (Clayburn); • Two 360 kV substations (Rosedale; Upper Harrison Terminal); • Three 230 kV substations (Atchelitz; McLellan; Mount Lehman); and • Three generating stations (Wahleach; Ruskin; Stave Falls New). Of these, only McLellan substation has an alternative communications path via fiber to another site on the communication network. The SMS microwave repeater is also a component of the microwave ring connecting the Lower Mainland and the South Interior. The loss of this site would reduce the communications capacity and reliability of the network supporting teleprotection, remedial action scheme and supervisory control and data acquisition services for the bulk electric system. In December 2019, a failure of telecom equipment at the SMS microwave repeater led to a four-hour outage to teleprotection and remedial action scheme circuits. Fortunately, impacts to the power system were avoided due to the rapid restoration of the failed equipment. Additional single points of failure related to mountaintop repeaters at other locations in the province will be addressed by projects resulting from the Telecom Resiliency Strategy.
Summary of Solution: The study identifies alternatives to provide diverse network paths to maintain communications in the event of a telecom system failure at the SMS microwave repeater. These alternatives include the building of new microwave repeaters and links, the building of fiber optic cables between the affected stations, the obtaining of dark fiber leases from carriers, or some combination of the above. **Short-Term:** • Reinforce the telecom system in the Fraser Valley to mitigate the risks of a failure at SMS microwave repeater. **Medium-Term:** • Complete the Fraser Valley Reinforcement project. **Long-Term:** Certain electronic components of the telecom system in the Fraser Valley have been identified as being end of life and will be replaced under another investment.

Page 1 of 1

Name of Capital Strategy, Plan or Study:

Integrated Planning Report for Capilano and Lynn Valley Substations and Distribution Area / Norgate Asset Plan

Summary of Issue:

North Vancouver is comprised of two municipalities, the City of North Vancouver and the District of North Vancouver. The area is bounded by the Capilano River to the west, the North Shore mountains to the north, Burrard Inlet to the south and Indian Arm to the east. There are approximately 64,000 customers in this area. The total load in 2020 was 206 MVA.

The City and District of North Vancouver and surrounding areas are supplied by five main substations, which together have a winter capacity of 331 MVA:

- North Vancouver has a capacity of 67 MVA and was built in 1950s;
- Lynn Valley has a capacity of 100 MVA and was built in the 1980s;
- Norgate has a capacity of 53 MVA and was built in the 1960s;
- Capilano has a capacity of 56 MVA and was built in the 1950s; and
- John Lawson has a capacity of 55 MVA and was built in the 1950s.

Over the past 10 years BC Hydro has undertaken investments to maintain and upgrade three of these substations, including the addition of a new feeder section at Lynn Valley in 2013, a complete 12 kV rebuild of the North Vancouver substation in 2012, and cable upgrades, additional feeder positions and circuit breaker replacements at John Lawson substation between 2009 and 2016. At Capilano and Norgate substations, most of the assets are at end of life and there are safety and other issues which need resolution.

The Capilano substation serves over 12,000 customers, and consists of:

- A 60-12 kV switchyard;
- Two power transformers; and
- One feeder section.

The most significant issues and risk at the Capilano substation include:

- A significant portion of the equipment has a poor Asset Health Rating, including both of the 60 kV circuit breakers, 85 per cent of the 27 protection and control assets, 88 per cent of the 56 disconnect switches, and 50 per cent of the 42 the instrument transformers; and
- The existing feeder section building does not meet current seismic standards. The feeder section has limited clearance between energized equipment and ground. The risk is currently partially mitigated through physical barriers and warning signs. The building also sustained a major water leak in 2019.

The Norgate substation serves over 4500 customers and consists of:

- A 60 -12 kV switchyard;
- Three power transformers; and
- One feeder section.

The most significant remaining issues and risks at Norgate substation include:

- All three power transformers are in poor condition and subject to oil leaks;
- Seven circuit breakers and three voltage transformers contain Polychlorinated Biphenyl (**PCB**) at levels at or above 50 ppm which will be replaced by the December 31, 2025 Federal PCB Regulation deadline;
- The majority of the remaining substation assets have a Poor Asset Health Rating including: 42 per cent of the 17 circuit breakers, 64 per cent of the 11 reactors, 94 per cent of the 31 protection and control assets, and 87 per cent of the 52 disconnect switches; and
- The feeder section has worker safety issues related to limited clearance between energized equipment and ground. The risk is currently partially mitigated through physical barriers and warning signs which create access restrictions during maintenance and operations.

Summary of Solution:

Performing work at these substations is complex. Space is often limited, meaning that workers have to work in close proximity to the energized equipment when the major construction needs to be done to replace/add the equipment. To continue to supply the load to the customers during construction, the new equipment and infrastructure has to be added before it is possible to take existing equipment out of service since there is a limited capacity to transfer the load to neighboring stations. Creating space within the substations would sometimes be challenging or require expansion of the substation footprint.

The strategy for the area is intended to sequence work in such a way that the issues and risks outlined above are mitigated, while continuing to provide reliable supply to customers. The development of a strategy for the area will consider a number of factors, including:

- The current capacity and projected growth of the area;
- The condition of the assets at different area substations, and their expected degradation over time;
- The sequencing and timing of required sustainment work at area substations combined with the need to manage overall area capacity;
- Minimize/avoid stranded investment in the area substations by optimizing the planning and the staging of work; and
- Opportunities to utilize capacity at neighboring substations.

Short and Medium-Term:

- A project is underway to rebuild Capilano substation with a capacity of 100 MVA.
  - A new substation will be built within the footprint of the existing substation fence;
  - The load from the existing 56 MVA substation will be transferred to the new substation; and
  - The existing 56 MVA substation will be decommissioned.
- A project will start in the short-term to decommission Norgate substation.
  - Cascading transfer of load from Norgate substation to North Vancouver substation and from North Vancouver to Lynn Valley substation; and
  - Decommission all equipment from Norgate substation.

When all the above investments are completed there will be significant improvements in the overall equipment condition and reliability of the area supply. The safety and seismic risks will be mitigated, and PCBs will have been removed ahead of the end of 2025 Federal PCB Regulation deadline. The area will have the necessary capacity to accommodate the future growth in the area.

Long-Term:

In the longer term, it is anticipated that a component-by-component replacement strategy will be undertaken at the different substations to address risks with discrete assets as they degrade over time.

Name of Capital Strategy, Plan or Study: Kidd 1 Asset Plan
Summary of Issue: Kidd 1 substation is a transmission and 100 MVA distribution substation that serves Vancouver South. First commissioned in 1951, the substation consists of: • One 69 kV switchyard which has nine transmission line terminal positions and four transformer positions; • Four power transformers; • One 4 kV feeder sections and two 12 kV feeder section; • One control building; and • One 230 kV cable terminal. Kidd 1 is an important substation given its dual role as both a transmission substation and a distribution substation. The station serves over 20,000 customers and has the fifteenth largest peak load (69 MVA) in the Lower Mainland Metro region. Kidd 1 substation provides the primary transmission source for George Dickie and Big Bend substations. Kidd 1 substation also supplies six transmission voltage customers and the distribution is adjoined by Sperling substation providing some flexibility to transfer load between the two substations. Since commissioning in 1951, BC Hydro has expanded the Kidd 1 substation over time and made investments in the past 20 years totaling over $35 million. Recent investments have included the replacement of two transformers and addition of a feeder section in 2014. The most significant remaining issues and risks associated with Kidd 1 substation include: • One power transformer has an assessed Asset Health Rating of Very Poor and has significant leaks; • There are elevated reliability risks associated with the 69 kV switchyard, due to an assessed Asset Health Rating of Poor of 92 per cent of the 12 circuit breakers and 95 per cent of the 37 disconnect switches. The oil-filled circuit breakers also contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which need to be replaced by the December 31, 2025 Federal PCB Regulation deadline. The 69 kV bus structure was not designed or built to the latest seismic standards. A study indicates that the structure is likely to collapse in an earthquake would occur, on average, 1 in 475 years; • There are elevated reliability and safety risks associated with the control building due to leaking, cracking, severe deterioration, overcrowding, asbestos and seismic deficiency of the control building. Approximately 40 per cent of the Protection & Control relays and panels in the control building have an assessed Asset Health Rating of Poor and approximately 70 per cent are mechanical type from the original installation and are obsolete; and • The 4 kV feeder section at Kidd 1 is obsolete and no longer provides any benefit for the system. All of the 4 kV load has been converted to 12 kV. The equipment associated with the 4 kV feeder section has an assessed Asset Health Rating of Poor and has reached end of life.
Summary of Solution: The Kidd 1 Substation Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the compact sections of the substation will be addressed concurrently with the equipment replacement projects or by the decommissioning of the equipment. In the short- and medium-term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out PCBs by the end of 2025.

Short and Medium-Term:

- Decommission the 4 kV feeder section, two 4 kV power transformers and control building;
- Replace the 60 kV circuit breakers and protection and control system; and
- Remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal PCB Regulation deadline.

Long-Term:

The equipment at the Kidd 1 substation will continue to degrade over time, and a level of investment is anticipated in the longer term to preserve the reliability of the substation and address emerging risks. Expected investments are required to address those risks associated with the remaining outdoor feeder section and the 69 kV switchyard that are not resolved in the short or medium term.

Name of Capital Strategy, Plan or Study:

Mainwaring Asset Plan

Summary of Issue:

The 211 MVA Mainwaring substation is a transmission and distribution substation serving Vancouver South. First commissioned in 1957, the substation consists of:

- Two switchyards: 230 kV and 12 kV;
- Three power transformers; and
- Two feeder sections.

Mainwaring is an important substation given its dual role as both a transmission station and a distribution station. The substation serves over 65,000 customers and has the fourth largest peak load (177 MVA) in the Lower Mainland Metro region. Mainwaring substation provides one of the two transmission supplies to Camosun substation. There is also flexibility to transfer the distribution load between the adjoining Newell and Mount Pleasant substations.

Since commissioning in 1957, BC Hydro has expanded the Mainwaring substation over time and made investments in the past 20 years totaling $25 million. Recent investments have included the replacement of a transformer in 2006 and replacement of the 230 kV circuit breakers in 2007 and 2011.

The most significant remaining issues and risks associated with Mainwaring substation include:

- One of the power transformers has an assessed Asset Health Rating of Poor and is gassing. One other transformer has significant oil leaks. It does not have on-load tap changer; therefore, voltage regulators in the feeder sections are required to regulate the voltage;
- Both feeder sections were designed to be compact in size and pose safety risks for workers due to limited clearance between energized equipment and ground. The risk is currently partially mitigated through physical barriers and warning signs;
- There are elevated reliability risks associated with the 12 kV switchyard, due to Asset Health Rating of Poor of 35 per cent of the 51 circuit breakers, 87 per cent of the 38 voltage regulators, 56 per cent of the 41 current limiting reactors and 80 per cent of the 153 disconnects; and
- One circuit breaker in the 12 kV switchyard and the bushings on two of the transformers also contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will need to be replaced by the December 31, 2025 Federal PCB Regulation deadline.

Summary of Solution:

The Mainwaring Substation Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the compact sections of the substation will be addressed concurrently with equipment replacement projects. In the short and medium term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out PCBs by the end of 2025. The longer-term activities are anticipated to focus on the remaining equipment and the control building.

Short and Medium-Term:

- Address reliability risk associated with two of the power transformers;
- Address the safety and reliability risks associated with the two feeder sections; and
- remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal PCB Regulation deadline.

Long-Term:

The equipment at the Mainwaring substation will continue to degrade over time and investment is anticipated in the longer term to preserve the reliability of the substation and address emerging risks, including those associated with the control building.

Name of Capital Strategy, Plan or Study:
Natal Asset Plan

Summary of Issue:

Natal substation is a transmission substation located in the Southern Interior region, near Sparwood, that consists of:

- Two switchyards: 230 kV and 60-138 kV; and
- Four power transformers and one voltage regulator

The 60-138 kV switchyard was commissioned in 1968 and the 230 kV switchyard was commissioned in 1972. Natal substation is an important transmission substation given its role both as a bulk transmission substation and a source of supply for industrial customers. The station serves 10 industrial customers. Natal substation is also a point of intertie with the Alberta transmission system.

BC Hydro has made investments in the past 20 years totaling over $5 million. Recent investments have included replacement of 60 kV surge arrestors, 138 kV circuit breakers and 230 kV circuit breakers.

The most significant remaining issues and risks associated with Natal substation include:

- There are elevated reliability risks due to the Asset Health Rating of Poor of two of the four power transformers, one voltage regulator, 35 per cent of the 14 circuit breakers, 49 per cent of the 44 instrument transformers, as well as a significant proportion of the protection and control systems supporting the 60-138 kV switchyard;
- Three of the 60 kV circuit breakers contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which need to be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline; and
- The 60 kV structure is wood pole and timber type, while the 138 kV structure is mixed wood and steel; they were designed and built to electrical clearance at the time and pose safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs.

Summary of Solution:

The Natal Substation Asset Plan presents a strategy to replace the 60-138 kV switchyard. The safety issues associated with the substation will be addressed concurrently with the equipment replacement projects or by the decommissioning of the equipment. In the short term, the focus will be on higher priority investments required for safe and reliable transmission of energy and to meet the requirements to phase out PCBs by the end of 2025. The medium to long-term activities are anticipated to focus on sustain activities of the remaining equipment.

Short Medium-Term:

- Address the reliability, environment and safety risks of the 60 kV and 138 kV equipment. The scope of this work will include the replacement of the power transformers, voltage regulator, circuit breakers, instrument transformers, bus structure, protection and control systems and control building in the switchyard.

Long-Term:

- The equipment at the Natal substation will continue to degrade over time, and investment is anticipated in the longer term to preserve the reliability of the substation and address emerging risks. Investments will be required to address the risks associated with the 230 kV switchyard as it approaches poor asset health.

Name of Capital Strategy, Plan or Study:
Newell Asset Plan

Summary of Issue:

The Newell substation is a transmission and 234 MVA distribution substation that serves South Burnaby. First commissioned in 1955, the substation consists of:

- One 230-60 kV switchyard;
- Five power transformers;
- Four 12 kV feeder sections; and
- One control building.

Newell is an important substation given its dual role as both a transmission station and a distribution station. The station serves over 50,000 customers and has the third largest peak load (186 MVA) in the Lower Mainland Metro region. There is flexibility to transfer the distribution load between the adjoining Big Bend and Mainwaring substations.

Since commissioning in 1955, BC Hydro has expanded the substation over time and made investments in the past 20 years totaling over $25 million. Recent investments have included addition of a new feeder section in 2003 and replacement of the 230 kV circuit breakers in 2011.

The most significant remaining issues and risks associated with Newell substation include:

- One power transformer (**T1**) has an Asset Health Rating of Poor, has significant oil leaks and contains polychlorinated biphenyl levels at 25 ppm; and
- One of the feeder sections was built in the 1950s (50/60 Series). The feeder section is compact in size and poses safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs. Of the feeder section, 16 of 18 circuit breakers, 17 of 18 voltage regulators, 16 of 18 current limiting reactors and 46 of 54 disconnect switches have an Asset Health Rating of Poor or Very Poor.

Summary of Solution:

The Newell Substation Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the compact sections of the substation will be addressed concurrently with equipment replacement projects. In the short-term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out polychlorinated biphenyls by the end of 2025. The medium to longer-term activities are anticipated to focus on the remaining feeder sections, substation security and the control building.

Short and Medium-Term

- Address reliability and safety risks associated with the power transformer and feeder section. The recommended alternative is to remove the power transformer T1 and replace feeder section 50/60 Series.

Long-Term:

- The equipment at the Newell substation will continue to degrade over time and investment is anticipated in the longer term to preserve the reliability of the substation and address emerging risks. Expected investments are required to address the risks associated with the two remaining feeder sections, enhance the security of the substation, and address risks associated with the degrading control building.

Name of Capital Strategy, Plan or Study: North Burnaby Area Study
Summary of Issue: The North Burnaby study area is comprised of a 230 kV and 69 kV transmission network and the following three substations: • Horne Payne substation which has a capacity of 340 MVA was built in 1910; • Lougheed substation which has a capacity of 55 MVA was built in 1957; and • Barnard substation which has a capacity of 188 MVA was built in 1950. The area has approximately 95,000 customers and had a peak load of 343 MVA in fiscal 2020. The present area firm capacity is 583 MVA. Recent investments include the construction of a new 230 kV to 25 kV switchyard at Horne Payne substation in 2019 and the refurbishment of the 69 kV switchyard at Barnard substation in 2019. The most significant issues and risks remaining in the North Burnaby area include: • There are elevated reliability risks at Horne Payne, Lougheed, and Barnard substations where 15 per cent of the substation assets have an Asset Health Rating of Poor or Very Poor and an additional 57 per cent are expected to be in an Asset Health Rating of Poor or Very Poor within the next 10 to 20 years; and • Some of the 12 kV equipment at the Horne Payne, Lougheed and Barnard substations exposes workers to safety risk due to limited clearance between energized equipment and ground. The risk is currently partially mitigated through physical barriers and warning sings.
Summary of Solution: The North Burnaby Area Study presents a strategy to mitigate the reliability and safety risks in the short-term by adding a new 25 kV switchyard at Horne Payne (completed in 2019) and using this supply to offload and decommission higher risk feeder sections. In the long term, assets would be replaced on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The study examined two alternatives in detail, each of which considered: • The health of each substation’s assets, and their expected degradation over time; • The present area capacity and future load growth; • Opportunities to transfer load to neighboring substations outside the study area; • Opportunities to permanently decommission substations; • The feasible timing of required work and the need to maintain sufficient area capacity; • The costs of the different solutions; • Performance and reliability requirements of the area; • Local stakeholder support; and • Environmental impacts. **Short-Term:** • Address the safety and reliability risks associated with the feeder section at Barnard substation that has high risk by replacing it with a new indoor feeder section; • Address the safety and reliability risks associated with Lougheed substation by voltage converting and transferring the load to Horne Payne substation and decommissioning Lougheed substation; • Address the safety and reliability risks associated with the feeder section at Horne Payne substation that has higher risk by voltage converting and transferring the load to the newly constructed 25 kV switchyard at Horne Payne substation and decommissioning the feeder section; and

- Remove equipment with polychlorinated biphenyl (**PCB**) levels at or above 50 ppm by the December 31, 2025 Federal PCB Regulation deadline.

Medium-Term:

- Add a new half feeder section in the Horne Payne 25 kV switchyard to facilitate further voltage conversions and offloading of higher risk feeder sections at Horne Payne substation.

Long-Term:

- In the longer term, it is anticipated that a component-by-component replacement strategy will be undertaken at the different substations to address risks with discrete assets as they degrade over time.

Name of Capital Strategy, Plan or Study:

Oldfield Asset Plan

Summary of Issue:

Oldfield substation is a 66 MVA distribution station located in the northeast corner of Yellowhead Highway 16 and 11th Ave East in Prince Rupert. First commissioned in 1967, the substation consists of:

- One 60 kV switchyard;
- Four power transformers;
- One 12 kV feeder section and one 25 kV feeder section; and
- One control building.

The station is the main source of electricity for 7357 customers in the Prince Rupert area.

Since commissioning in 1967 with 12 kV capacity, BC Hydro added 25 kV capacity to the substation in 1982. The 25 kV transformer capacity is sufficient to supply all the current load at 12 kV and 25 kV, so the 12 kV load could be converted to 25 kV.

The most significant remaining issues and risks associated with Oldfield substation include:

- There are elevated reliability risks associated with the 12 kV feeder section due to the Asset Health Rating of Poor of all the eight circuit breakers, all of the 6 voltage regulators, two 69-12 kV power transformers, lack of a transfer bus in the 25 kV feeder section and obsolete protection and control relays; and
- Five circuit breakers and three voltage regulators in the feeder section contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline.

Summary of Solution:

The Oldfield Substation Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the compact sections of the substation will be addressed concurrently with equipment replacement projects. In the short term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out PCBs by the end of 2025. The medium to longer term activities are anticipated to focus on the remaining power transformers, substation security and the control building.

Short-Term:

- Two new 25 kV feeders will be constructed. The 12 kV load will be converted and transferred to the new 25 kV feeders;
- The 12 kV feeder section and the associated protection & control relays will be decommissioned;
- Two 69-12 kV power transformers, the associated disconnect switches and protection & control relays will be decommissioned; and
- The equipment containing PCBs at levels at or above 50 ppm will be removed by the December 31, 2025 Federal PCB Regulation deadline.

Medium-Term:

- Three 25 kV vacuum circuit breakers, trench covers, and switchyard gravel are planned to be replaced by fiscal 2027 when they are expected to reach end of life.

Long-Term:

- The equipment at the Oldfield substation will continue to degrade over time, and investment is anticipated in the longer term to preserve the reliability of the substation and address emerging risks. Investments will be required to address the risks associated with the two remaining power transformers, to enhance the security of the substation and address risks associated with the degrading control building.

Name of Capital Strategy, Plan or Study: Patricia Asset Plan
Summary of Issue: The 87 MVA Patricia substation is a distribution substation that serves Prince George. First commissioned in 1964, the substation consists of: • Two switchyards: 60 kV and 12 kV; • Three power transformers; and • One feeder section. Patricia substation is the only distribution station supplying load to the downtown area of Prince George. The station serves over 14,000 customers making it the second largest substation by customer count in the Northern Interior region. The Patricia substation load cannot be served from the surrounding substations due to different distribution voltages (12 kV vs 25 kV). Since being commissioned in 1964, BC Hydro has expanded the Patricia substation over time and made limited investments in the past 20 years totaling over $2 million. Investments have included replacements of circuit breakers and surge arresters in the 12 kV and 60 kV switchyards. The most significant remaining issues and risks associated with Patricia substation include: • The three power transformers were manufactured in the 1960s and do not have on-load tap changers, therefore voltage regulators are required to regulate the voltage. One of the power transformers has an Asset Health Rating of Poor; • All 12 kV voltage regulators have an Asset Health Rating of Poor; • The 12 kV feeder section was designed to be compact in size and poses safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs; and • Thirteen 12 kV bulk oil circuit breakers have an Asset Health Rating of Poor and contain PCB levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline.
Summary of Solution: The Patricia Substation Asset Plan presents a strategy to address asset risks on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the compact section of the substation will be addressed concurrently with equipment replacement projects. In the short-term, the focus will be on higher priority investments required for safe and reliable distribution of energy and to meet the requirements to phase out PCBs by the end of 2025. The medium to longer-term activities are anticipated to focus on the remaining feeder section issues and the control building. **Short and Medium-Term:** • Address the environment risks of the 12 kV bulk oil circuit breakers containing PCBs; and • Address the reliability and safety risks of the equipment. The leading alternative is to replace the existing transformers with new transformers that have on-load tap changers, enabling the removal of the voltage regulators in the feeder section and mitigate the electrical clearance issues. **Long-Term:** • The equipment at the Patricia substation will continue to degrade over time, and investment is anticipated in the longer-term to preserve the reliability of the substation and address emerging risks. Investments will be required to address the risks associated with the two substation service transformers, and also address risks associated with the degrading control building.

Name of Capital Strategy, Plan or Study:
Sperling Asset Plan

Summary of Issue:

The 214 MVA Sperling substation is a transmission and distribution substation that serves Vancouver West. First commissioned in the 1940s, the substation consists of:

- Three switchyards: 230 kV, 69 kV and 12 kV;
- Two power transformers; and
- Four feeder sections.

Sperling is an important substation given its dual role as both a transmission station and a distribution station. The station serves approximately 60,000 customers and has the fifth largest peak load (171 MVA) in the Lower Mainland Metro region. There is also flexibility to transfer the distribution load between the adjoining Camosun, Mount Pleasant and Kidd 1 substations. The Sperling 69 kV switchyard is in the process of being decommissioned to alleviate the elevated reliability risk due to the poor condition of the disconnect switches and control panels, etc.

Since commissioning in the 1940s, BC Hydro has expanded the Sperling substation over time and made investments in the past 20 years totaling over $30 million. Recent investments have included the addition of a new indoor feeder section in 2009 and the replacement of the circuit breakers in an older indoor feeder section in 2012.

The most significant remaining issues and risks associated with Sperling substation include:

- The two outdoor feeder sections were designed to be compact in size and pose safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs;
- There are elevated reliability risks associated with one of the outdoor feeder sections and transformer circuit breakers due to the Poor Asset Health Rating of 90 per cent of the 10 circuit breakers, and 93 per cent of the 56 disconnect switches. The oil-filled circuit breakers in these feeder sections also contain Polychlorinated Biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline; and
- All eight indoor transformer circuit breakers pose safety risks for workers due to the potential for arc flash hazards in the event of failures.

Summary of Solution:

The Sperling Substation Asset Plan presents a strategy to replace assets on a component-by-component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the two feeder sections of compact size will be addressed concurrently with other equipment replacement projects. In the short and medium-term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out PCBs by the end of 2025.

Short and Medium-Term:

- Address the safety and reliability risks associated with one of the outdoor feeder sections and the bus breakers by replacing them with a new indoor feeder section in a new building;
- Remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal PCB Regulation deadline; and
- Complete addressing the reliability risk associated with the 69 kV switchyard by decommissioning the switchyard and control building at Sperling. The transfer of the UBC load to the adjoining Camosun substation was completed in 2020.

Long-Term:

The equipment at the Sperling substation will continue to degrade over time, and investment is anticipated in the longer term to preserve the reliability of the substation and address emerging risks. Expected investments are required to address the risks associated with the remaining outdoor feeder section and transformers that were installed in the 1970s.

Name of Capital Strategy, Plan or Study:

Telecom Resiliency Strategy

Summary of Issue:

The Telecom Transport asset strategy identifies single points of failure at mountaintop telecom repeaters as a key system resiliency risk. The Telecom Resiliency Strategy further defines risks and sets forth the strategy to address these risks.

The telecom network is built in parallel to the 500 kV bulk electric system using mostly microwave radio links. This system provides Teleprotection, Remedial Action Scheme and Supervisory Control and Data Acquisition services in support of the bulk system. The telecom network must meet Western Electricity Coordinating Council availability and redundancy requirements for BC Hydro to safely and reliably operate of the power system and to remain interconnected with neighbouring entities.This results in a maximum permissible outage duration of four hours to key telecom circuits before actions must be taken on the power system to reduce transmission line or interconnection capacity.

On long radial circuits, BC Hydro uses frequency diversity radios and equipment redundancy to meet the Western Electricity Coordinating Council redundancy requirements. However, single points of failure still exist in this arrangement, and there are many failure modes:

- Line of sight obstructions (icing, smoke, atmospheric conditions);
- Power interruptions (fuses, diesel generator problems, distribution power outages); and
- Infrastructure problems (antenna and waveguide breaks, tower or building issues).

It is difficult or impossible to resolve the above failures within the four-hour limit. In addition, even for simple failures, mountaintop sites can be difficult to access in a safe and timely manner to effect repairs, especially during winter storm conditions. As a result, mountaintop sites are presently engineered for very high reliability, with many redundant systems, requiring high capital and maintenance costs. Even with the high level of investment, the single points of failure are not eliminated.

The issues identified in this strategy were also studied specificially in the Fraser Valley Telecom Reinfocement study as pertaining to risks at the Sumas Mountain Microwave Repeater.

Summary of Solution:

Two independent networks, operating in parallel and having no common single points of failure, provide a higher level of availability than a single network with multiple single points of failure. Having two networks with a maximum four-day restoration time would provide equivalent performance of a single network with a four-hour restoration time. This study recommends building such a parallel network for key portions of the system.

Adding a second network in parallel would also enable the reduction of investment in capital and maintenance costs to the existing network, as the existing network would then have lower effective performance requirements. In addition, capital replacements of telecommunications network equipment would be simplified, as the old equipment would not need to be maintained in service while the cutovers are effected. This would reduce the cost and complexity of equipment replacement projects.

This study identified key areas of the telecom network that would most benefit from having a second network added in parallel, including the Peace to Kelly Lake, Prince George to Terrace, and Kelly Lake to Vernon networks. Alternatives to provide parallel paths could consist of building new microwave repeaters, building new fiber optic cables, or obtaining dark fiber leases from carriers.

Short-Term:

- Initiate a resiliency project that would build a parallel network for key segments of the system in advance of the planned major telecom equipment replacement project. This investment would enable cost and complexity savings for the equipment replacement project.
  - Confirm the priority of the network areas to receive parallel links;
  - Select a leading alternative; and

- Build the leading alternative. Coordinate the construction schedule so it is completed in advance of the equipment replacement project in order to maximize the benefits to the other project.
- Initiate a resiliency project for Sumas Mountain.

Medium-Term:

- Complete the resiliency project;
- Study the performance of the sections of the system having parallel, diverse networks;
- Optimize the capital and maintenance plans to reflect the lower level of performance required due to the presence of parallel network links; and
- Plan future network resiliency projects.

Long-Term:

- Execute further network resiliency projects;
- Optimize the capital and maintenance plans to reflect the lower level of performance required due to the presence of parallel networks; and
- Plan future network resiliency projects.

Name of Capital Strategy, Plan or Study:
Transmission Load Interconnection Studies for North Montney Region Electrification
Summary of Issue: The North Montney natural gas field has numerous gas producers for well drillings and gas extractions northeast of BC Hydro's G.M. Shrum Generating Station. Presently, BC Hydro does not have transmission facilities in this region and is not able to provide electricity supply to the natural gas producers. Recently, natural gas producers have expressed their strong interest in powering their facilities from BC Hydro's grid to reduce greenhouse gas emissions. Because this region is far from BC Hydro's existing electric grid, a major transmission system extension to North Montney region is required to accommodate transmission voltage customer load interconnections, which would be uneconomical for any single natural gas producer to undertake. BC Hydro initiated a North Montney Region Electrification project. The government funding support and First Nations' involvements would make the transmission extension project economically viable to interconnect multiple natural gas producers. This transmission extension would contribute to the Government of B.C.'s CleanBC goal of increasing access to clean electricity for large operations.
Summary of Solution: BC Hydro plans to construct a new 230 kV transmission circuit from the main grid to a new 230/138 kV substation in the vicinity of Wonowon community, which could potentially be the North Montney load centre, with an expected in-service date in 2027. **Short and Medium-Term:** BC Hydro launched an expression of interest process to learn the interest of gas producers to electrify their facilities. More technical and economic analysis will be performed to optimize the solution. The transmission extension project is currently in Conceptual Design Stage, and investigations are underway to assess the two alternatives: • Construct a 230 kV transmission line between G.M. Shrum Generating Station and the new 230/138 kV substation; and • Construct a 230 kV transmission line between South Bank substation and the new 230/138 kV substation.

Page 1 of 1

Name of Capital Strategy, Plan or Study: West Kelowna Area Study
Summary of Issue: The 138/25kV Westbank (**WBK**) Substation supplies the West Kelowna area and is connected only to Nicola Substation by a single 80 km long radial 138 kV transmission line. Westbank Substation has no ties to any other substations and there is no local generation to serve the load in the area. Consequently, if the radial transmission line is out of service, the 22,000 customers in the West Kelowna area will experience an outage. In the past, the geographic area of the transmission line has been subjected to wildfires. In addition, there is a need to increase the station capacity at Westbank Substation. The substation has three 138 kV/25 kV transformers with a summer firm capacity of 80 MVA (assumes the loss of a transformer). Firm capacity was exceeded by 15 per cent in fiscal 2019 by the summer load demand. Also, some equipment that has been in-service since the early 1970s, is nearing end-of-life and needs replacement.
Summary of Solution BC Hydro is evaluating alternatives to address the above issues with an integrated approach. **Short- and Medium-Term:** • The West Kelowna Transmission Project (**WKTP**) will mitigate the natural hazard risks to the West Kelowna transmission system by providing redundancy to the system; and • Westbank Substation Upgrade Project will increase firm transformation capacity, replace end-of-life assets at WBK and interconnect the new transmission line.

Name of Capital Strategy, Plan or Study:

Wood Pole Substation Strategy

Summary of Issue:

There are 48 substations that have been classified as Wood Pole substations for asset management and planning purposes. Collectively, all of these substations serve approximately 75,000 customers. Their common characteristics generally include:

- Individually, these are small distribution stations, the majority of which have a load of less than 15 MVA and serve less than 3,000 customers;
- Usually located in remote rural locations, often at the end of a radial line;
- A wooden structure is used to mount electrical equipment such as disconnect switches;
- A single power transformer;
- A small number of feeder positions (usually less than four);
- No control room; and
- Mobile transformers are required in the event of a failure.

The general issues and risks associated with Wood Pole substations include:

- Reliability:
  - The poor condition of the wooden structures represents an elevated reliability risk. The wooden cross members in the structure can fail, physically contacting nearby equipment, and causing customer outages; and
  - The Poor Asset Health Rating of equipment such as transformers, disconnect switches and voltage regulators represents an elevated reliability risk. Limited redundancy in these substations means that a failure of any one component has a high likelihood of causing a total outage of the station.
- Safety:
  - The degrading condition of the wooden structure represents a safety hazard to workers inside the substation; and
  - The compact size poses safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs.
- Environmental:
  - Much of the oil filled equipment in wood pole substations contains Polychlorinated Biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline.

Over the last 20 years, BC Hydro has invested approximately $60 million in addressing the most pressing risks at 12 of the 48 Wood Pole substations. Work at another three Wood Pole substations is also currently underway. BC Hydro has also invested in mobile transformers to act as emergency replacements in the event of failures at the Wood Pole substations.

Approximately 68 per cent of the 48 Wood Pole substations are over 50-years old, with 50 per cent over 60-years old. Approximately 45 per cent of equipment within the Wood Pole substations has been assessed as having an Asset Health Rating of Poor or Very Poor, indicating that there is an increased likelihood of failure.

Summary of Solution:

Wood Pole substation investments are prioritized considering factors such as the age and condition of the wood poles, the condition of equipment within the substation, as well as the criticality of the substation. To address the above issues and risks, the following staging of investments is recommended:

- Firstly, capital projects have been identified to remediate the risks associated with the Wood Pole substations. The scope of these projects will be tailored to suit the specific Wood Pole substation, and the risks, ranging from the replacement of targeted assets to a redevelopment of the substation;

- Secondly, a contingency strategy, utilizing mobile transformers, will continue to be implemented, as necessary, to ensure mobile transformers are available to minimize the impacts of equipment failure; and
- Finally, consideration has been given to find opportunities to decommission stations where replacement can be avoided by finding other economical solutions.

Short and Medium-Term:

The condition of assets is reviewed on a regular basis considering such factors as recurring test results, visual inspections, and, where required, detailed engineering assessments. This information is used to assess the risk of failure at each Wood Pole substation to help prepare a consolidated list across the fleet and identify the potential timing to address the risks. Below is a list of those substations with a higher priority:

- Clinton - Substation Wood Pole Replacement;
- Chase - Substation Wood Pole Replacement;
- Joseph Creek Substation Upgrade;
- Sandspit Substation Replacement;
- Lumby #2 - Substation Wood Pole Replacement;
- Diana Lake - Substation Wood Pole Replacement;
- Canal Flats - Substation Wood Pole Replacement;
- Skookumchuck - Substation Wood Pole Replacement;
- Woss - Substation Wood Pole Replacement; and
- Telegraph Creek - Substation Replacement.

Long-Term:

The investments outlined above will address the highest priority risks. However, considering that some Wood Pole substations were constructed in the 1970s and 1980s, additional work is anticipated in the long term. The strategy and prioritization will continually be monitored over time.

Name of Capital Strategy, Plan or Study:

Asset Management Strategy - Section 3.1.8: Street Lighting

Summary of Issue:

BC Hydro owns and maintains approximately 90,000 street lights mounted on BC Hydro or Joint Use (co-owned with TELUS) poles, and 4,970 leased private outdoor lighting units installed on customer or BC Hydro owned poles located on private property. Most BC Hydro street lights are high pressure sodium technology while most private outdoor lights are mercury vapour technology.

BC Hydro provides street lighting and private outdoor lighting service to various customers to:

- Support night-time safety for the general public and for private properties; and
- Contribute to reliability by reducing outages due to vehicular accidents through improved visibility.

The main issues and risks associated with street lighting and private outdoor lights include:

- Approximately 20 per cent of BC Hydro's lights may contain Polychlorinated Biphenyls (**PCB**), which must be removed from the system by December 31, 2025 in accordance with Federal PCB Regulations;
- Municipalities are increasingly interested in implementing various cost and energy-saving initiatives such as Light Emitting Diode (**LED**) technology lights;
- The private outdoor light rate schedule was closed in 1975 and assets including lights and poles are at or near end of life. Investing in replacing these assets without upfront cost paid by customers puts BC Hydro at financial risk of not recovering these costs from these closed rate schedule lights; and
- High pressure sodium and mercury vapour lamps fail every five to seven years on average resulting in outages that need repairs in a timely manner. Meeting the street lighting outage response target of 10 working days is challenging in certain smaller districts of the province due to lack of dedicated resources.

Summary of Solution:

BC Hydro is currently implementing a LED Street Light Conversion project that will replace all 90,000 street lights to LED and remove approximately 4,600 private outdoor lights off of the system. The remaining 370 private outdoor lights will be converted to LED and transitioned to the street light rate schedule. The project began installing LED street lights starting in December 2020.

LED street lights offer an approximate 20-year life span with no lamps or other consumables to be replaced during this period.

A Street Light Rate Application was submitted to the BCUC in November 2020 to amend the existing street light rates to include LEDs and rescind private outdoor light service.

Short-Term:

With 54,000 units planned to be addressed in fiscal 2021 and fiscal 2022, fiscal 2023 through fiscal 2025 will see approximately 36,000 street lights and 370 private outdoor lights converted to LED and 4,600 private outdoor lights removed. Beyond fiscal 2025, the program will transition to sustainment to address units that fail in-service.

Medium and Long-Term:

Sustainment will continue for approximately 20 years after installation.

Asset Health - Generation

Table of Contents

1 Introduction

BC Hydro assesses the asset health of its Generation, Transmission and Distribution assets to inform the life-cycle management of the assets, including supporting the need for capital investments. BC Hydro uses two different asset health methodologies each of which provide a systematic, objective, repeatable, and transparent assessment of asset health.

BC Hydro uses a methodology called Equipment Health Rating to evaluate the health of Generation assets. For reporting purposes, results are presented using a common Asset Health Rating for Generation, Transmission and Distribution assets on a scale of Good, Fair, Poor and Very Poor.

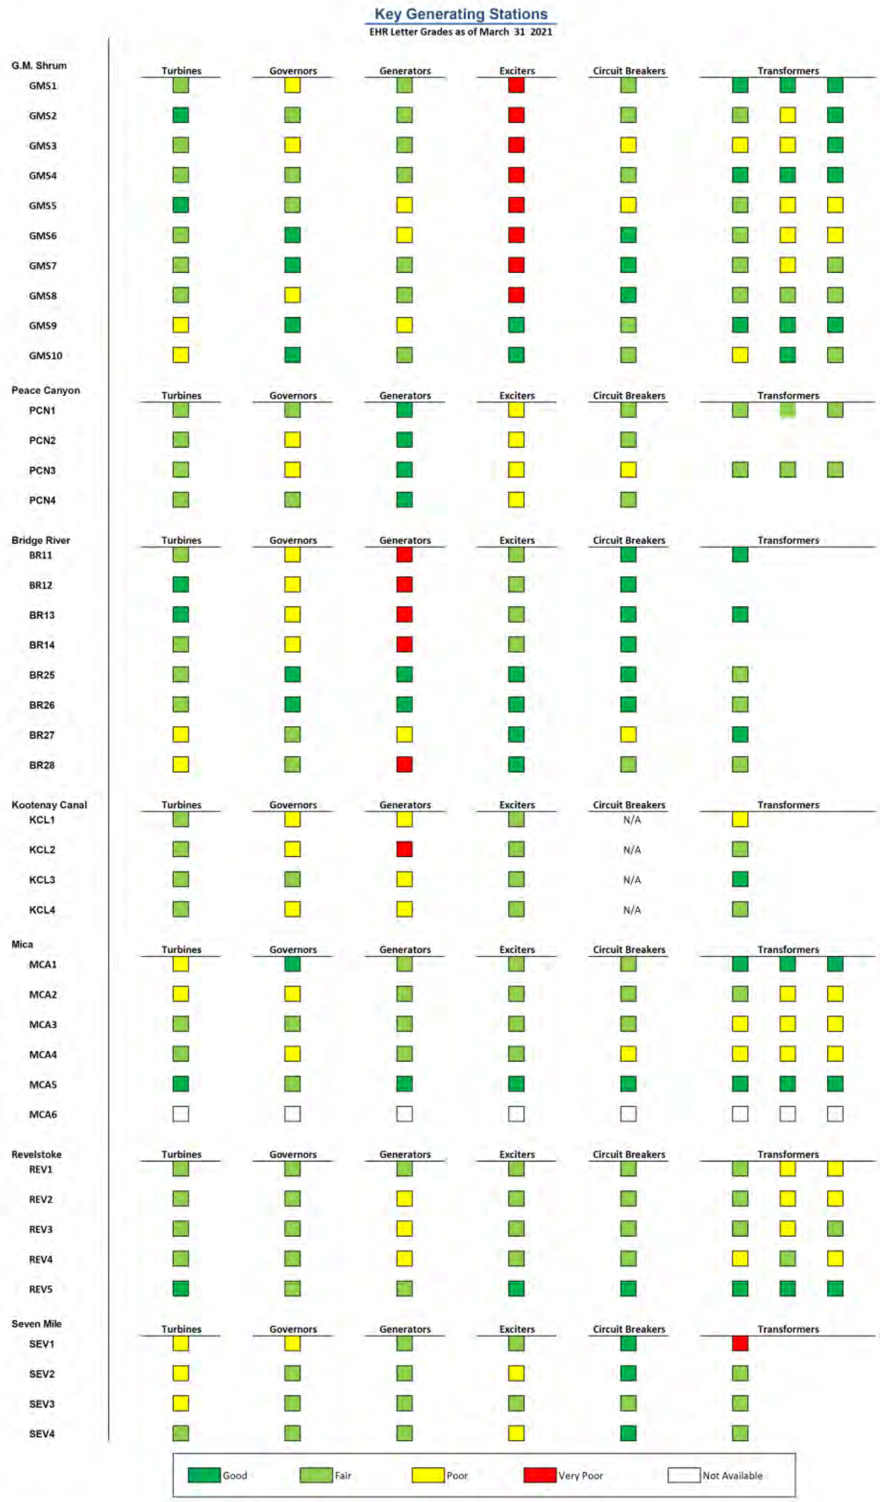
2 Generation Equipment Health Ratings

BC Hydro periodically evaluates the condition of its major generation assets (turbines, generators, governors, exciters, transformers, and circuit breakers) based on the latest available maintenance test and inspection data. Health assessments are based primarily on asset condition, but also consider safety and environmental issues, reliability, design deficiencies, asset age and industry expected life and availability of spare parts and technical expertise.

Each health assessment results in a rating of Good, Fair, Poor, or Very Poor:

	Description
Good	As new condition, with no noticeable deterioration or defects
Fair	Normal deterioration of the asset with one or more minor defects; function is not affected
Poor	Serious deterioration of the asset or serious defects
Very Poor	Extensive serious deterioration of the asset or asset function is affected

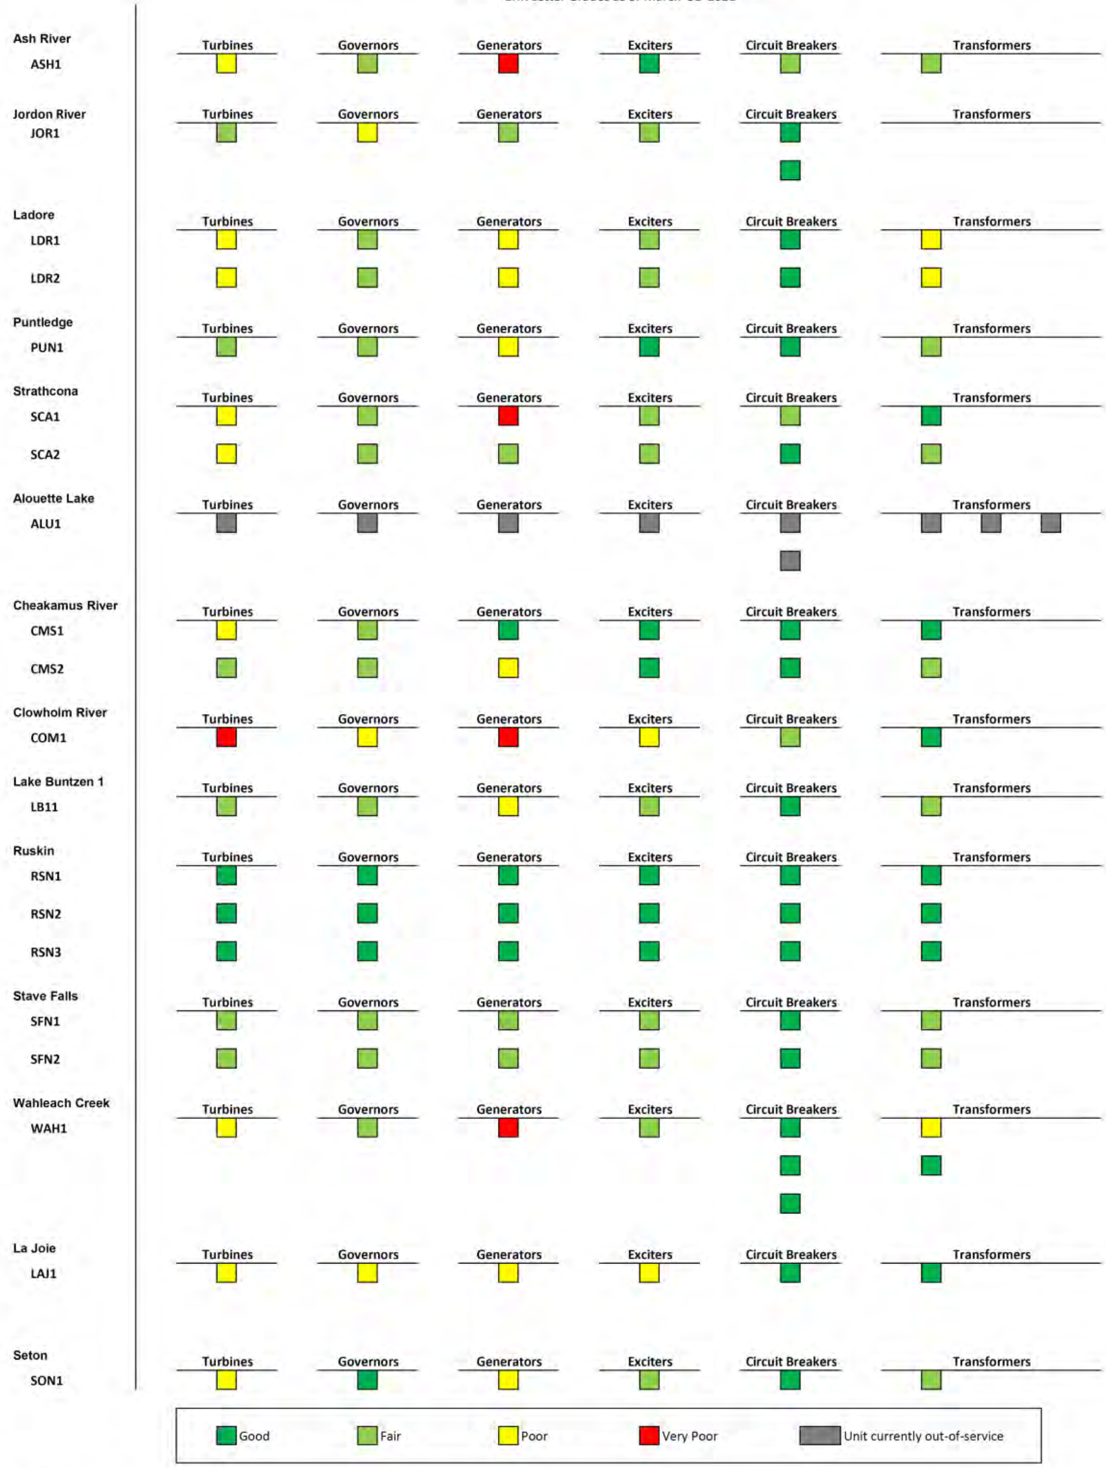
Asset Health Ratings for Generation assets as of March 2021 are provided below.



Note: Condition assessments for the newly constructed Mica (MCA) generating station Unit 6 assets are underway will be completed in 2021. Waneta (WAN) generating station is leased to Teck Metals Limited until 2038 and Teck is responsible for the management of the assets and therefore BC Hydro's Asset Health Ratings do not apply at this time.

Strategic Generating Stations

EHR Letter Grades as of March 31 2021



Note: The assets related to the three new units at the John Hart New (JHN) generating station are not currently included in BC Hydro's Asset Health Rating system. The assets are maintained by InPower BC under the terms of an operating agreement out to 2033.

Asset Health – Transmission and Distribution

Table of Contents

List of Tables

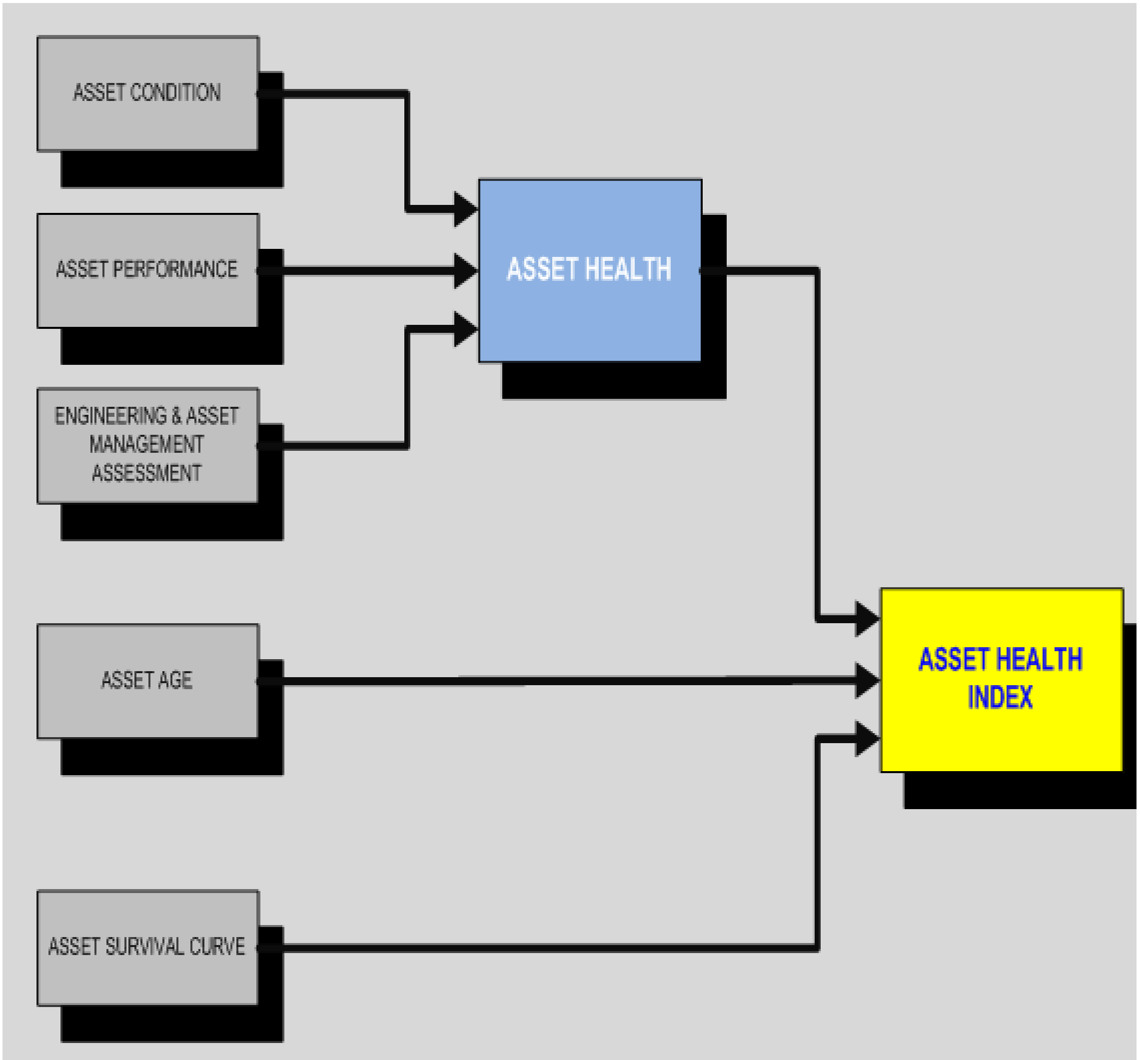
1 Introduction

BC Hydro assesses the asset health of its Generation, Transmission and Distribution assets to inform the life-cycle management of the assets, including supporting the need for capital investments. BC Hydro uses two asset health methodologies, each of which provide a systematic, objective, repeatable, and transparent assessment of asset health:

BC Hydro uses a methodology called Asset Health Index to evaluate the health of Transmission and Distribution assets. For reporting purposes, results are presented using a common Asset Health Rating for Generation, Transmission and Distribution assets on a scale of Good, Fair, Poor and Very Poor.

2 Transmission and Distribution Asset Health

The Asset Health Index is derived from maintenance and asset management data. The methodology is illustrated below.



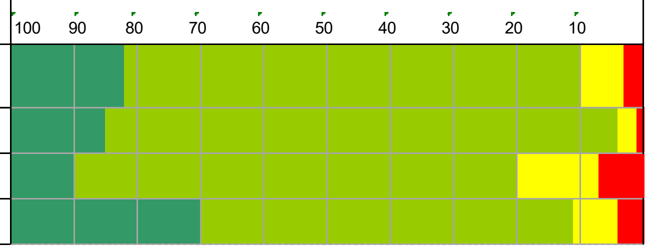
1 Asset Health Ratings and possible investment needs are:

	Description
Good	As new condition, with no noticeable deterioration or defects
Fair	Normal deterioration of the asset with one or more minor defects; function is not affected
Poor	Serious deterioration of the asset or serious defects
Very Poor	Extensive serious deterioration of the asset or asset function is affected

Asset Health Rating can be grouped and analysed by asset class and/or criticality. Below are Asset Health Rating charts for Transmission and Distribution asset classes as of March 2021.

Table M-1 Asset Health Rating Summary

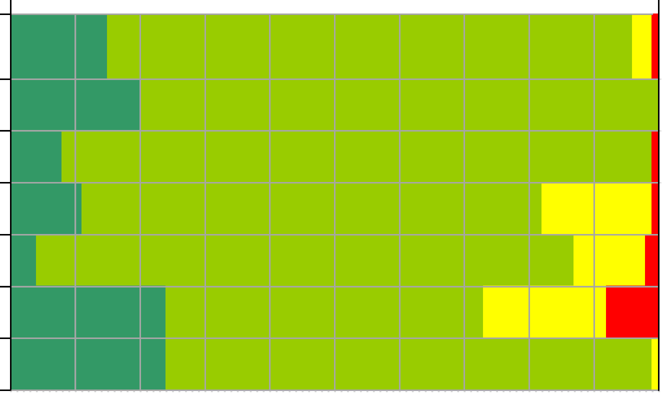
T&D Assets	Number of Assets	% of Asset Replacement Value
T&D Assets - 39 Asset Classes	4,173,150	
Transmission - 6 Asset Classes	124,586	
Substation - 20 Asset Classes	58,074	
Distribution - 13 Asset Classes	3,990,490	



Good Fair Poor Very Poor

Table M-2 Asset Health Rating for Transmission Line Assets

All Transmission Assets	Number of Assets	% of Asset Replacement Value
All Transmission Assets	124,585	
1 - Metal Support Structures	26,432	
2 - Conductor Systems (km)	19,726	
3 - Wood Pole Structures	77,499	
4 - Underground Cables (km)	346	
5 - Line Disconnect Switches	263	
6 - Others	319	



Good Fair Poor Very Poor

Table M-3 Asset Health Rating for Substation Assets

All Substation Assets	Number of Assets	% of Asset Replacement Value
All Substation Assets	58,074	
1 - Transformers	1,480	
2 - Gas Insulated Switchgear	540	
3 - Circuit Breakers	4,002	
4 - Reactors	1,983	
5 - Protection & Control Relay Systems	15,385	
6 - Shunt Capacitors	434	
7 - Disconnect Switches	14,439	
8 - Instrument Transformers	8,593	
9 - Series Capacitors	14

Capital Planning and Delivery Processes

Table of Contents

List of Figures

List of Tables

1 BC Hydro's Capital Investment Planning Process

This section describes BC Hydro's enterprise wide capital planning process for capital investments and how this process is applied to create the Capital Plan which forms the basis for the capital-related evidence contained in this application.

BC Hydro has planning and governance processes in place across the organization so that the capital investments required to sustain, expand and operate its assets appropriately balance affordability and system performance.

This section is organized around the following points:

- Section 1.1 discusses how BC Hydro's Enterprise Capital Planning Process facilitates the use of a common approach to planning, prioritizing and governing investments across the company.
- Section 1.2 discusses how BC Hydro's Executive Team sets the strategic direction and priorities for the annual capital planning process.
- Section 1.3 explains how the bottom up planning process is used for each of the asset categories.
- Section 1.4 discusses how BC Hydro uses a collaborative approach to review the capital portfolios across the enterprise and to develop the Capital Plan.
- Section 1.5 explains that BC Hydro has robust processes for the governance, oversight and ongoing management of the Capital Plan.

In 2017, BC Hydro established an Enterprise Capital Planning Working Group. The purpose of the Enterprise Capital Planning Working Group is to apply a common approach to planning, prioritizing and governing investments across the company. The Enterprise Capital Planning Working Group has representatives from the major portfolios included in BC Hydro's capital planning process which are: Integrated Planning, Properties, Technology, Finance and Fleet Services.

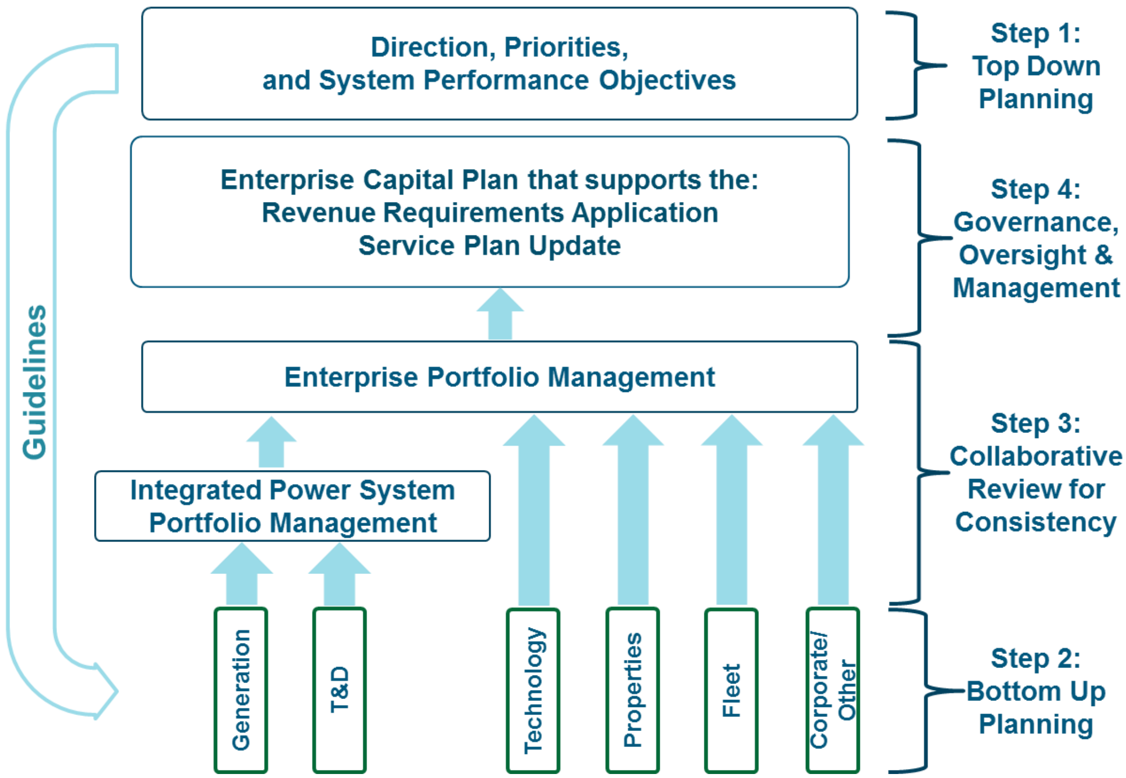
BC Hydro must be flexible and responsive to the investment needs of the system. The Enterprise Capital Planning Working Group manages the annual capital planning process so that the Capital Plan is updated and prioritized to respond to the latest information on the system risks and needs.

1.1 The Capital Planning Process and Deliverables are Clearly Articulated

The enterprise wide capital planning process that is overseen by the Enterprise Capital Planning Working Group is clearly defined and the deliverables are well understood by the relevant areas of the business.

Figure N-1 below provides a simplified depiction of our capital planning process and identifies major outcomes and deliverables of the process. Each step of the process is described in the following sections.

Figure N-1 Annual Enterprise Capital Planning Process



1.2 Step 1- Top Down Planning

A key element of the annual enterprise capital planning process is the direction provided by the Executive Team on long-term capital investment levels. In providing this direction the Executive Team considers BC Hydro's capital investment needs while balancing affordability, system performance and the need to manage the risks of our assets.

1.3 Step 2 – Bottom Up Planning

Once the long-term capital investment levels have been established, preliminary financial targets are developed for each of the asset categories considering the factors discussed in Step 1, as well as the historical composition of the capital plan.

These preliminary financial targets are an input into the bottom-up planning process, as shown in Figure N-1 above.

Within the common Enterprise Capital Planning process, each asset category uses a bottom-up planning process that is tailored to the characteristics of the portfolio, considering:

- The function, criticality, volume and complexity of the different assets;
- The magnitude of the risks, issues and opportunities;
- The size, scope, complexity and costs of the capital investments; and
- The internal stakeholders that should be involved in the process.

The processes used for the asset categories are scaled as required. For example, the largest and most complex portfolios such as Generation or Transmission and Distribution, which collectively comprise the Power System, generally require more complex and detailed planning processes, and involve a broader discussion with internal stakeholders across BC Hydro.

1.4 Step 3 – Collaborative Review for Consistency

Once bottom up planning has concluded, capital planning information is consolidated for:

- Collaborative peer reviews at the enterprise level;
- Validation of alignment with BC Hydro’s strategic direction and priorities; and
- Identification of any potential areas for improvement in the process for the next annual capital planning cycle.

Peer reviews are conducted by the Enterprise Capital Planning Working Group, before the enterprise capital plan is submitted to BC Hydro’s Executive Team and Board of Directors. Generally, these reviews focus on three main areas:

- An overall summary of each asset category portfolio;
- The quality of information used to develop the Capital Plan; and
- The risk profile of the consolidated Capital Plan.

The risk profile of the Capital Plan is based on BC Hydro's enterprise-wide framework for capital prioritization. This framework describes the assessment and prioritization process related to proposed capital investments. Investments are assessed based on the primary driver of the proposed investment, as follows:

- Investments that primarily mitigate risk are scored for prioritization using a methodology that is aligned with the BC Hydro Corporate Risk Matrix; and
- Investments that primarily create value are scored for prioritization using a net value per dollar invested metric. The value prioritization is mainly used for Technology capital expenditures expected to enhance business capability.

Through BC Hydro's enterprise-wide framework for capital prioritization, capital investments are classified into one of three categories:

- Mandatory investments driven by legal and regulatory requirements;
- Committed investments not to be postponed. This category includes projects that were prioritized in previous capital plans and are now economically unreasonable to cancel; and
- Investments to be prioritized. This category includes projects that could be re-prioritized without significant costs.[1]

[1] Risk scores are included on appendix I for to be prioritized investments.

1.5 Step 4 - Oversight and Review

The final step in BC Hydro's annual enterprise capital planning process is the review and approval of the Capital Plan by the Executive Team and Board of Directors, which occurs as part of the annual budget and five-year forecast approval process. This review is conducted to assess whether the plan meets overall business objectives and provides a consistent and appropriate management of risks across all asset categories.

Once the Capital Plan is approved by the Executive Team, it is monitored, on an ongoing basis, by the Capital Delivery Management Committee. The committee focuses on the early years of the Capital Plan so that actual and forecast capital expenditures remain aligned with the original Capital Plan. This management is done at a portfolio level so that, if required, adjustments can be made to re-direct the capital budget, as new information becomes available. To make these decisions, the committee considers financial impacts, the enterprise risk profile, and labour resource availability.

Decisions to reallocate the budget within the Capital Plan are governed through an ex-plan governance process, which considers the size of the ex-plan request. Requests less than $3 million are reviewed at the Enterprise Capital Planning Working Group level, while requests greater than $3 million are reviewed and approved at the Capital Delivery Management Committee level. Reallocations may result in the approval of new projects to address emerging issues, the advancement of future investments based on new information or the increase of funding to existing programs, in response to identified needs.

2 Power System Assets Planning & Delivery Processes

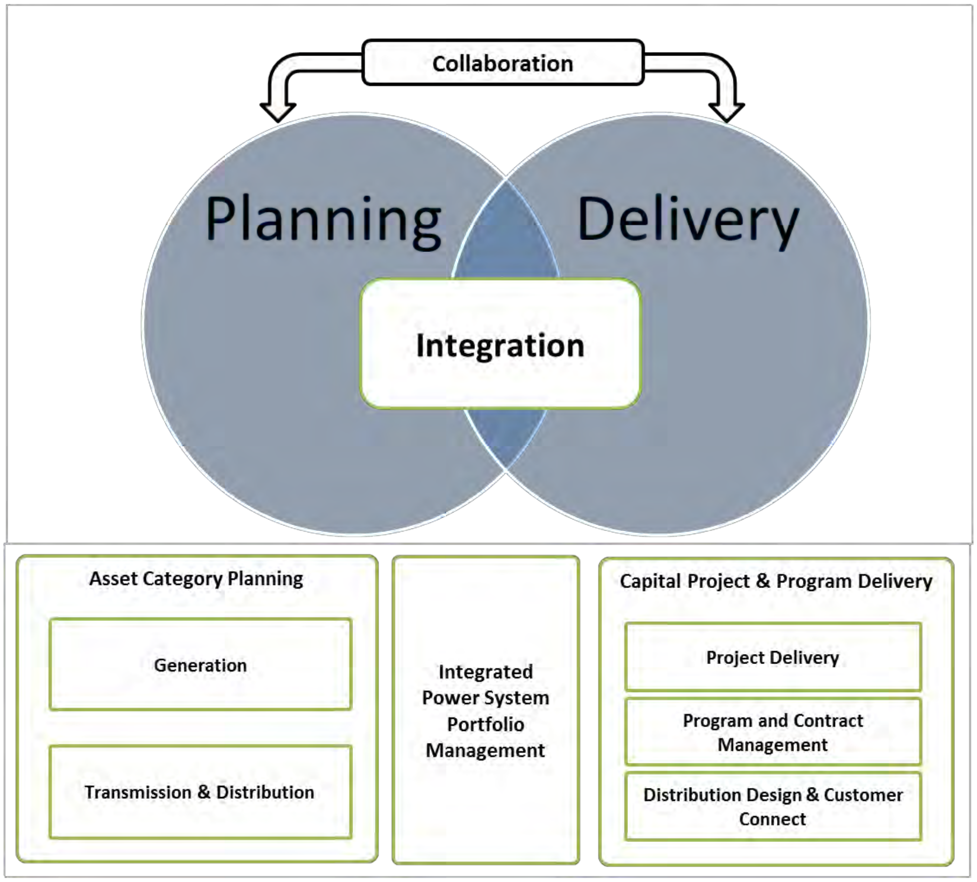
The Power System includes BC Hydro's Generation, Transmission and Distribution assets.

Over time, the condition and performance of existing assets degrade, regulatory and safety requirements change, and new assets are required to address load growth and connect new customers. Together, these factors create issues, risks and opportunities to be addressed through capital investment.

The planning and delivery processes for the Power System are integrated, requiring a high degree of collaboration across the organization.

Figure N-2 below represents a high-level depiction of the interaction between functional groups responsible for asset management and planning, and portfolio delivery when planning and delivering capital investments for the Power System.

Figure N-2 Integrated Power System Planning and Delivery



Planning processes are in place to understand the issues, risks and opportunities associated with the assets and to identify the recommended capital investments.

- Sections 2.1 to 2.4 provide further information on the Power System assets, the bottom-up planning processes for each asset category and the integrated portfolio planning process for the Power System; and
- Sections 2.5 to 2.6 provide an overview of the collaboration and integration between planning and delivery through the annual capital planning process, the work planning process and the release of projects and programs to the Key business Units (**KBUs**) responsible for delivery.

Delivery processes are in place to deliver projects and programs on time and on budget, and within scope. Investments associated with the Power System are delivered by three different KBUs: Project Delivery, Program and Contract Management and Distribution Design and Customer Connect.

- Sections 2.7 to 2.9 explain the project delivery practices used to deliver those investments;
- Section 2.10 describes the financial approval policies and procedures applicable to all capital investments; and
- Section 2.11 describes our portfolio risk adjustment.

2.1 Generation Assets Capital Investments

Capital investments in generation assets include asset sustainment, dam safety and growth investments.

2.1.1 BC Hydro Prudently Manages Generation Assets Over Their Lifecyle

BC Hydro's generation assets are aging, and a number of generation assets are now at end of life. BC Hydro's generation assets include 83 generating units at 30 hydroelectric generating facilities as well as 85 dams located at generating stations and at additional locations to provide water storage and water diversion functions. Generation assets also include three gas-fired units at BC Hydro's two thermal generating stations and four synchronous condenser units at a dedicated synchronous condenser station. BC Hydro also has 17 diesel generating stations and one hydroelectric generating station in areas not connected to the integrated electric system.

Construction of most of BC Hydro's large capacity generating facilities occurred in the 1960s, 1970s and 1980s, while the majority of BC Hydro's medium capacity facilities were constructed in the 1950s. Asset Health assessments indicate that a number of generation assets are now at end of life. An overview of generation asset health is provided in Appendix L.

BC Hydro manages its generation assets over their lifecycle by:

- Maintaining the assets so that they perform safely and reliably throughout their operating lives;
- Investing in the assets to extend their operating lives, enhance capability, manage risk, and increase efficiency and cost-effectiveness; and
- Managing public and worker safety risks associated with facilities, especially around reservoirs and dams.

Planning processes are in place to support these objectives and to align the portfolio of investments to effectively manage risk and customer needs within financial and labour resource constraints.

With the exception of the Site C Clean Energy Project, which is a growth project, the majority of capital investments in the Generation portfolio are driven by the need to address issues and risks associated with existing facilities. These investments are categorized as Generation Asset Sustainment and Dam Safety investments. The following sections describe BC Hydro’s Generation Asset Sustainment and Dam Safety portfolios in more detail and then explain BC Hydro’s bottom-up planning process for generation assets.

2.1.2 Generation Asset Sustainment Addresses the Highest Risks

Generation sustainment capital investments mitigate or resolve the highest risks identified with BC Hydro’s generation assets. The risk assessment considers how important generation facilities are to the overall system, as well as the asset condition.

BC Hydro's generation facilities are categorized as "Key", "Strategic" or "Available", according to the significance of the facility to BC Hydro's system. An investment strategy is in place for each category which reflects the significance of the category of facility to the power system. Table N-1 below provides a list of BC Hydro's generation facilities by category.

Table N-1 BC Hydro's Generating Facilities by Category

Facility Abb'n	Facilities	Facility Category	Year of Initial Operation	Current Age (Years) 2021	Current Maximum Capacity (MW)	Number of Units
BRR	Bridge River 1 & 2 (Originally developed 1934)	Key (Hydro)	1948	73	495	8
GMS	GM Shrum	Key (Hydro)	1968	53	2916	10
KCL	Kootenay Canal	Key (Hydro)	1975	46	582	4

Note 1	On July 26, 2018, BC Hydro became the sole owner of Waneta. Teck Metals Ltd ("TML") continues to act as the Operator of the facility during the 20 year lease term, and is required to operate, manage, and maintain Waneta in accordance with the terms of the Co-Possessors and Operating Agreement ("COPOA").					
Note 2	Burrard Synchronous Condenser facility was previously the Burrard Thermal generating facility.					

- **"Key" generating facilities:** Seven "Key" generating facilities represent the largest hydro-electric facilities on the BC Hydro system and produce approximately 90 per cent of BC Hydro's average annual energy;
- **"Strategic" facilities**: Eighteen "Strategic" facilities represent all generating stations on Vancouver Island, all stations located on cascading systems, all thermal generation stations and generating stations required to provide voltage support to the transmission network. These facilities produce approximately 9 per cent of BC Hydro's average annual energy and provide significant additional value to BC Hydro due to their geographic location and system support services;
- **"Available" facilities:** Seven "Available" facilities represent those facilities that are of lower strategic importance and produce less than 1 per cent of BC Hydro's average annual energy; and
- **Waneta two-thirds:** On July 26, 2018, BC Hydro became the sole owner of Waneta. Teck Metals Ltd. continues to act as the Operator of the facility during the 20-year lease term. In that role, Teck is required to operate, manage, and maintain Waneta in accordance with the terms of the Co-Possessors and Operating Agreement (**COPOA**), which includes capital planning and operating to a prudent owner standard, exercising the degree of care and skill of an experienced dam operator and acting in accordance with Good Utility Practice.

  As Teck is the Operator of Waneta, processes that BC Hydro generally uses for internal asset management and planning purposes will not be applied. BC Hydro will retain an oversight role as part of the Waneta Operating Committee, including reviewing the annual operating plans for Waneta.

The condition of assets across BC Hydro's generation fleet is a foundational input to the planning process. BC Hydro evaluates the condition of its major equipment (turbines, generators, governors, exciters, transformers, and circuit breakers) based on the latest available maintenance test and inspection data, following BC Hydro's Equipment Health Rating methodology. This provides a systematic, objective, repeatable, and transparent assessment of equipment health. Factors influencing the Equipment Health Rating include:

- Equipment health;
- Maintenance history;
- Equipment reliability;
- Availability of spare parts;
- Availability of technical support; and
- Known equipment type design problems.

Asset health or condition information is used to assess and manage risk and to prioritize the need to make investments to preserve and sustain the generating units. Each health assessment results in a rating of Good, Fair, Poor, or Very Poor.

2.1.3 Dam Safety Investments Focus on Key Areas of Risk

BC Hydro's dams are subject to the British Columbia *Dam Safety Regulation*, which defines a "Dam" as:

(a) A barrier constructed for the purpose of enabling the storage or diversion of water diverted from a stream or an aquifer, or both; and

(b) Other works that are incidental to or necessary for the barrier described in paragraph (a).

Consistent with the *Dam Safety Regulation*, BC Hydro's Dam Safety portfolio comprises all physical features, structures and mechanisms - both constructed and natural - that retain the reservoirs and control the passage of flows past the dam.

The *Dam Safety Regulation* classifies dams according to the consequences of their failure, such as the potential for loss of life, environmental damage and economic impacts. Classifications range from “Low Consequence” to “Extreme Consequence”. These classifications dictate the required frequency of safety activities performed on the dam and are further used to guide the selection of the dam’s design and performance criteria.

Dam Safety issues and risks involve:

- The safe storage and controlled passage of water under normal conditions;
- The ability to pass floods (from the annual freshet to extreme events); and
- The ability to withstand a major earthquake without any harmful release of water.

Dam Safety risks generally have a low probability of occurrence but, if realized, a high consequence. Key drivers of Dam Safety capital investments include:

- ***Seismic Risk:*** The Canadian Dam Association Guidelines provide recommended seismic performance criteria for regulated dams based on their consequence classification. The guidelines define target performance levels in terms of an Annual Exceedance Probability (AEP). The expectation is that a dam will have no uncontrolled release of the reservoir during and following earthquake ground motions that would be expected to occur on that site no more than the frequency defined by the target AEP. Capital investments to upgrade a dam are sometimes required to improve its seismic performance to meet current Canadian guidelines.
- ***Reliability of Spillway Gates:*** A spillway is an essential component of any dam facility. It provides a means for passing sufficient quantities of water from the reservoir to the downstream water course when power generation is unavailable or insufficient to maintain required downstream flows or prevent the

reservoir from rising above its maximum safe elevation. Discharge through a spillway may also be required for emergency reservoir drawdown, such as if a defect develops within the dam and there is a need to reduce the load on the dam. Discharge through a spillway is regulated by gates located at its upstream end. BC Hydro assesses its spillway gates for design or condition-based deficiencies that impinge upon their operational reliability and which, due to their critical safety function, pose a risk. Once identified, those risks are prioritized and addressed through investments in the dam safety portfolio.

- ***Condition of Civil Structures:*** Over time and due to wear and tear the integrity or degradation of the existing civil structures poses a risk to the ability to store or pass water safely. For example, reservoir booms naturally deteriorate over time. Poorly functioning booms can allow large debris in the reservoir to reach the dam, blocking spillways and other water passages and interfering with or preventing the proper function of these critical features of a dam. These and other deficiencies are prioritized and addressed through investments in the dam safety portfolio.
- ***Condition and Function of Water Passages:*** Over time degradation of the existing water passages poses a risk to the ability to pass water safely. For example, steel penstock coatings degrade over time and, if not addressed, lead to metal loss and loss of integrity of the penstock. Furthermore, passage of water under a variety of operational and upset conditions must be managed to protect people, assets, and the environment. Upgrades to penstocks, intake gates, valves and their associated monitoring and controls are prioritized through investments in the dam safety portfolio.

2.2 Generation Bottom-Up Capital Planning Process

The following sections describe the steps of BC Hydro's bottom-up capital planning process for generation assets.

2.2.1 Step 1 - Generation Strategic Asset Management Plan

First, BC Hydro considers its Generation Strategic Asset Management Plan. This plan sets out ten-year strategies for each facility category – Key, Strategic and Available - to support appropriate resource allocations and performance targets for the facilities.

- **Key facilities:** BC Hydro has implemented a component replacement strategy for its Key facilities. Under this strategy, all major equipment at Key facilities will be restored to Good or Fair condition or will have work underway to restore them to Good or Fair condition, within ten years. This strategy means that, in aggregate, the reliability of Key facilities will be maintained at or slightly above the average of similar facilities, as reported by the Canadian Electricity Association;
- **Strategic facilities:** Equipment in "Poor" or "Very Poor" condition at Strategic facilities will either be refurbished or replaced within ten years, will have work underway to be refurbished or replaced within ten years or will have a long-term plan developed to mitigate the risk of equipment failure. This strategy means that, in aggregate, the reliability of Strategic facilities will be maintained at or restored to the average of similar facilities, as reported by the Canadian Electricity Association; and
- **Available facilities**: With the exception of Whatshan and Aberfeldie (the largest and newest Available facilities) all other Available facilities will receive minimal capital investment and will be taken out of service when they are no longer able to safely generate electricity. BC Hydro will perform regular

maintenance and inspection on these assets to keep them safe and inform investment and operating decisions. Options to re-furbish, re-develop or decommission Available energy facilities that have been taken out of service will be developed as required. Decisions on these options will be informed by BC Hydro's long-term load resource balance. Over time, this strategy may result in a gradual reduction of the energy produced by Available facilities.

2.2.2 Step 2 - Dam Safety Investment Strategy

Second, BC Hydro's level of investment in Dam Safety is targeted to address identified deficiencies in the dams and their appurtenant structures so that:

- There is no significant deterioration of BC Hydro's overall risk position with respect to these assets; and
- The overall level of risk is kept well within tolerable limits as guided by the Canadian Dam Association's Dam Safety Guidelines and the International Commission on Large Dams' Bulletin on Dam Safety Management.

In addition, BC Hydro's dam safety investments also consider qualitative judgements made, on a case by case basis, with regulators and government representatives, First Nations and stakeholders.

This targeted level of investment accounts for both the experienced and expected future wear and tear of the dams, identification of new issues, and improved understanding of previously identified issues through engineering investigations.

Identified deficiencies are rated by a "Vulnerability Index"[2] that considers:

- The extent to which the design or performance of a particular dam feature (deficiency) differs from accepted good practice;

[2] Further information on the Dam Safety Vulnerability Index is included in Appendix FF - Long-Term Dam Safety Plan.

- The extent to which that feature contributes to the safe performance of the dam;
- The frequency at which the feature is potentially stressed to the limits of its performance; and
- The effectiveness of any interim risk controls that might be in place.

At each dam, issues and risks are grouped to form a project or set of projects based on asset type, similarity of issues or solutions, and location within the facility or system. These projects are then prioritized across the system by considering:

- The potential reduction of the Vulnerability Index;
- The consequence classification of the dam;
- The cost and time to effect remediation compared to the benefits from risk reduction;
- The sequencing of required enabling projects; and
- The completeness of BC Hydro's understanding of the issue and potential remediation.

In addition to the considerations above, the Dam Safety investment strategy must provide for inclusion of investments for improvements of infrastructure deficiencies, such as those that enable access, monitoring, and management of hazards at BC Hydro's dam sites.

2.2.3 Step 3 - Growth Driven Generation Investments

Third, BC Hydro identifies opportunities to enhance the capability or increase the efficiency of existing facilities. Generation growth investments are integrated into the Capital Plan when there is an identified need for increased energy or capacity resources.

2.2.4 Step 4 - Facility Asset Plans

Fourth, BC Hydro considers the Facility Asset Plans for its hydroelectric generating facilities, thermal generating and synchronous condenser stations. Facility Asset Plans formulate, document and recommend a ten-year investment strategy for each facility, with a focus on the near years of the plan. These strategies account for the facility's role in BC Hydro's system, its Asset Health Ratings, dam safety issues and deficiencies, performance levels and targets, risks, and growth opportunities. Capital upgrade projects to implement these strategies are carefully planned so that unit outages and maintenance work are coordinated with power system requirements.

As they are developed, each Facility Asset Plan is presented to the Asset and Risk Planning Committee for agreement in principle and endorsement. This committee provides input to the Facility Asset Plan on all issues, risks and planned investments.

Facility Asset Plans are updated periodically to reflect the latest information, including changes in priorities and strategies which influence the scope and timing of facility plans and investments. A Facility Asset Plan may also be updated if new information emerges that affects the investment strategy for the facility. Between updates, BC Hydro continues to monitor the risks and issues associated with the facilities and makes adjustments, if needed.

Summaries of Facility Asset Plans are provided in Appendix K – Summaries of Capital Project, Strategies Plans and Studies.

2.2.5 Step 5 – Annual Capital Planning Review

Fifth, as part of the annual capital planning process, BC Hydro undertakes a review of the planned investments for each facility. Investments are reviewed to check that the facility asset planning process has been applied consistently, the data quality is sufficient, and the investments are appropriately prioritized and timed. These investments are then submitted into the Integrated Power System Portfolio Management process, as described in section 2.5 below.

2.3 Transmission and Distribution Assets Capital Investments

The following sections describe the needs, risks and opportunities that are driving investment requirements on BC Hydro's transmission and distribution assets including substations.

2.3.1 Transmission and Distribution Assets Are Aging and Many Require Investment in the Near Term

BC Hydro's transmission and distribution assets are aging, and the asset health assessment of these assets indicate that a number of them are now at end of life.

BC Hydro's transmission and distribution assets include over 18,000 circuit km of transmission overhead lines, approximately 350 km of transmission subterranean and submarine cables, 323 substations, an integrated telecommunication system, approximately 49,000 circuit km of distribution primary overhead lines and 11,000 circuit km of distribution primary underground lines. Overall, BC Hydro has approximately four million individual transmission and distribution assets.

A large portion of the transmission system was built in the 1960s and 1970s and these assets are, or soon will be, reaching or exceeding end-of-life condition. Similarly, a large portion of the distribution system has, or soon will be, exceeding its design life. Asset Health assessments indicate that a portion of the transmission and distribution assets are in Poor to Very Poor condition, which requires either remediation work or replacement within the next ten years. This is to be expected that a certain portion of assets will be in Poor or Very Poor condition at any point in time. An overview of transmission, distribution and substation asset health is provided in Appendix M.

BC Hydro has established planning processes in place to:

- Develop transmission and distribution system plans for the safe and reliable delivery of electricity to customers;
- Connect new customers and distributed generation;
- Expand networks with existing capacity constraints to meet anticipated load growth;
- Manage asset performance; and
- Meet regulatory requirements.

Sustainment expenditures are made so that the assets perform as required throughout their lifecycle. Investments in existing assets include activities such as:

- Replacement of assets based on condition;
- Enhancements to maintain or improve customer reliability and extend asset life;
- Upgrades to mitigate risks including safety, environment, security and seismic;
- Improvements to meet evolving regulatory standards; and
- Relocations to address third-party requests.

2.3.2 BC Hydro Is Continuing to Replace Existing Assets

Assets are replaced when the equipment performance can no longer be managed due to comparatively high cost, lack of parts, or inadequate manufacturer support. Asset replacements are also required to mitigate increasing public and worker safety risks as well as environmental and regulatory risks, which could result from asset failures.

The Asset Health Index is used to assess the condition of the transmission and distribution assets. This approach considers factors such as asset age and available test and inspection data. For reporting purposes, results are presented using a common Asset Health Rating scale of Good, Fair, Poor and Very Poor. These ratings can be grouped and analyzed to assist with investment decisions.

Most replacements are the result of proactive inspections and maintenance. For example, cedar wood poles are tested and treated 20 to 29 years after initial installation and then every ten years thereafter. Units that fail the test criteria are then scheduled for replacement.

In cases where the impacts of asset failure on customer reliability are low and proactive maintenance is ineffective in extending asset life, a 'run to failure' strategy is used to minimize the life cycle costs of managing the assets. Examples of asset classes that are 'run to failure' include new LED street lights that will operate without maintenance (other than one mid-life cleaning) over their useful lives.

2.3.3 Customer Reliability Investments Are Aimed at Managing Current Reliability Levels

Customer reliability investments include upgrades to existing assets as well as adding new assets to manage reliability. Customer reliability capital expenditures are required during the test period to manage current levels of system performance. Examples of customer reliability projects include backup circuit ties to enable faster restoration in the event of customer outages as well as circuit re-locations and re-configurations to avoid potential outage causes, such as tree and vegetation contacts.

2.3.4 A Portion of the Sustainment Budget is Directed at Mitigating Other Risks

A portion of the transmission and distribution capital investment portfolio is to address a variety of other risks including public and worker safety, environment, fire, security, seismic and extreme weather. This includes:

- **Safety risk mitigation**: Examples of safety projects include the replacement of H-Frame structures in the alleys of downtown Vancouver that pose a public safety risk due to reduced clearances to buildings, and the replacement of pad mounted distribution live-front switchgear that may pose a safety hazard to employees operating them as the switchgear reaches end of life.
- **Environmental risk mitigation**: Examples of environmental projects include those to manage oil-filled equipment to address the Federal *PCB Regulations* deadline of December 31, 2025 and avoid the risk of spills as well as projects to modify structures in areas where protected bird species congregate in order to avoid electrical contact incidents.
- **Fire and security risk mitigation**: Examples of projects to address fire and security risk at substations include the installation or upgrading of fire protection systems or the installation of access detection and control, video monitoring, perimeter fencing and gate upgrades.
- **Extreme weather risk mitigation**: Examples of projects to address risks related to extreme weather include installing piles, reinforcing foundations and constructing protective structures such as retaining walls, riprap berms and debris deflectors around transmission structures and their foundations, to withstand storms, floods, landslides, and avalanches.

2.3.5 Growth Investments Have Multiple Drivers

Growth expenditures are required to expand the transmission and distribution system to accommodate load growth, to connect new customers and to mitigate other risks. This type of investment includes:

- Upgrades and additions of station equipment;
- Upgrades and additions of transmission lines and distribution feeders; and
- New service connections and upgrades.

Demand for electricity continues to increase in some areas of the province and certain parts of the BC Hydro system are reaching capacity. In certain sectors of the economy, such as the oil and gas sector in the Peace and North Coast regions, economic growth is driving the need to reinforce the system in areas that do not have the infrastructure to meet the emerging demand. In addition, new investments continue to be required to connect new customers to the BC Hydro system.

Growth investments and their timing are informed by forecast load growth, resource supply additions and existing system capacity.

Capital investments to interconnect transmission customers are also difficult to forecast. Due to uncertain timing, location and scope, only known transmission customer interconnection projects are included as specifically identified projects in the forecast capital expenditures for the test period.

BC Hydro also includes provision for emerging transmission customer interconnection projects. These amounts are aligned with the historical levels of spend and anticipated future activity. Deviations from these provisions, to respond to emerging interconnection needs, require an adjustment of the timing or scope of other projects and programs within the Capital Plan.

Distribution customer interconnection expenditures are more stable and are forecast based on historical levels.

The balance of the Growth portfolio is required to mitigate other system risks such as providing reliable service and/or allowing for the retirement of end-of-life assets. These Growth investments improve the reliability of the system or reduce the need for continued sustaining investments in assets that are at, or approaching, end-of-life. Examples include the construction of a new line to West Kelowna and a new substation in the West End of Vancouver to allow for the offloading of Dal Grauer substation. Even though these investments may be driven by the need to sustain the existing system, as is the case in the latter example, they are classified as Growth expenditures in the Capital Plan because they are adding new assets to the Power System.

2.4 Transmission and Distribution Bottom-Up Capital Planning Process

The following sections describe the steps of BC Hydro's bottom-up capital planning process for transmission and distribution assets.

2.4.1 Step 1 – Identify the System and Asset Needs

First, BC Hydro identifies system and asset needs to be considered for system reinforcement or remediation. This assessment includes reviews of system performance data to identify assets with degrading conditions, representing safety or environmental risks, not performing adequately or not meeting regulatory requirements. System and substation load forecasts are also developed to identify areas in the system that may require reinforcement. Based on these reviews, BC Hydro develops a preliminary approach and timeline for reinforcement or remediation.

The following information and data are used to assess system and asset needs:

- ***Asset Health and Performance:*** BC Hydro evaluates the condition of the Transmission and Distribution assets, based on the latest available maintenance test and inspection data, as well as engineering assessments and assigns an Asset Health Rating to each asset. The methodology provides assessments that are objective, repeatable, and consistent across asset classes. Assets with an index of Very Poor are generally considered for reinvestment within three years and assets with an index of Poor are generally considered for reinvestment within ten years. The Asset Health Index methodology and summary Asset Health Ratings for transmission and distribution assets is provided in Appendix M;
- ***Customer reliability:*** BC Hydro also reviews reliability statistics, identifies assets with poor performance and develops solutions for improvement. For example, distribution feeders are studied to determine the areas of under-performance, conduct root cause analysis and assess solutions for future investment to improve reliability;
- ***Regulatory Requirements:*** BC Hydro also evaluates the compliance of assets with the regulatory requirements of the *Workers Compensation Act*, B.C. *Wildfire Act, Canadian Environmental Protection Act* (e.g., *PCB Regulations*) and other environmental laws, as well as requirements of Mandatory Reliability Standards, Measurement Canada, and Transport Canada; compliance is addressed within the requirements of each regulation;
- ***Load and Energy Forecasts:*** BC Hydro assesses the capability of the transmission and distribution system to meet expected peak demand and accommodate forecast load and generation additions; and
- ***Other Risks:*** BC Hydro assesses the potential severity and likelihood for a range of risks including safety, seismic, environment, fire, extreme weather,

and security. High risks, as determined by BC Hydro's enterprise-wide framework for capital prioritization, are considered for remediation. The enterprise-wide framework is discussed further in section 1.4.

2.4.2 Step 2 – Determine the Scope of Strategies, Plans and Studies

Second, BC Hydro determines the scope of strategies, plans and studies to assess identified needs. Multiple needs, impacting the same parts of the system, within a similar timeframe are integrated in this step so that they can proceed through the planning process together.

In this step, identified needs are reviewed by regionally-focused cross-functional teams to determine integration opportunities. These teams consider how needs relate to each other as well as the required timelines for remediation and the risks of delay. These reviews may result in certain needs being addressed through province-wide work programs or deferred due to low risk.

Third-party interconnection requests are not typically considered for integration with other needs. These projects normally proceed individually through their respective mandated and schedule-driven processes.

2.4.3 Step 3 – Develop Strategies, Plans and Studies

Third, BC Hydro develops strategies, plans and studies to evaluate the identified needs in detail and to identify technically feasible alternatives to remediate these needs through projects or work programs. The completion of strategies plans and studies may vary from a few weeks to several years depending on the complexity of the needs and alternatives. Examples of these documents include:

- ***Area Plans:*** Area Plans are specialized technical planning studies to identify alternatives to address needs related to issues such as load growth, new generation and system reliability. The Downtown Vancouver Electric Supply

Plan and the Abbotsford Area Reinforcement Study are example of integrated Area Plans;

- ***Facility Asset Plans:*** Facility Asset Plans are developed for substations with multiple pieces of equipment that require replacement within a similar timeframe. The Barnard Substation Asset Plan is an example of a substation asset plan; and
- ***Asset Class Strategies:*** Asset Class Strategies determine the appropriate remediation approach for each asset class. Asset Class strategies include replacing the asset or continuing to perform maintenance on the existing asset.

Summaries of Area Plans, Facility Asset Plans and Asset Class Strategies are provided in Appendix K.

2.4.4 Step 4 – Annual Capital Planning Review

Fourth, as part of the annual capital planning process, BC Hydro undertakes a review of planned investments. Investments are reviewed by cross-functional teams to align investments across the portfolios. In addition, investments are reviewed to check that the data quality is sufficient and that the investments are appropriately prioritized and timed. These investments are then submitted into the Integrated Power System Portfolio Management process, as described in section 2.5 below.

2.5 Integrated Power System Portfolio Management Brings Planned and Ongoing Projects and Programs into One Portfolio

Once a year, forecasts for the planned generation, transmission and distribution projects and programs, developed through the bottom up processes described in the preceding sections, are brought together with projects and programs already being delivered. This consolidation of a single Power System capital investment portfolio begins the final stage of the preparation of the Power System Capital Plan.

The enterprise wide framework for capital prioritization, described in section 1.4, is used to categorize each investment in the initial portfolio, and assign risk to the deferral of the investments. Where labour resources have been identified as a risk to the delivery of the portfolio, the demands on the labour pool to deliver each investment are assessed and the availability of those resources are estimated.

The final step of the process is to review the Power System capital investment portfolio to determine the highest priority projects and programs within the labour and financial constraints that have been identified. These results are then reviewed with the leadership team of the Integrated Planning Business Group. This provides an opportunity for senior leaders to offer input and to align the portfolio business objectives. Once endorsed by the Integrated Planning leadership team, the Power System Capital Plan is submitted into the Enterprise Capital Planning process, which is described in section 1.4.

2.6 Planning and Delivery Processes Are Well Integrated

This section provides an overview of the collaboration and integration between planning and delivery through the annual capital planning process, work planning and the release of projects and programs to the KBUs responsible for delivery.

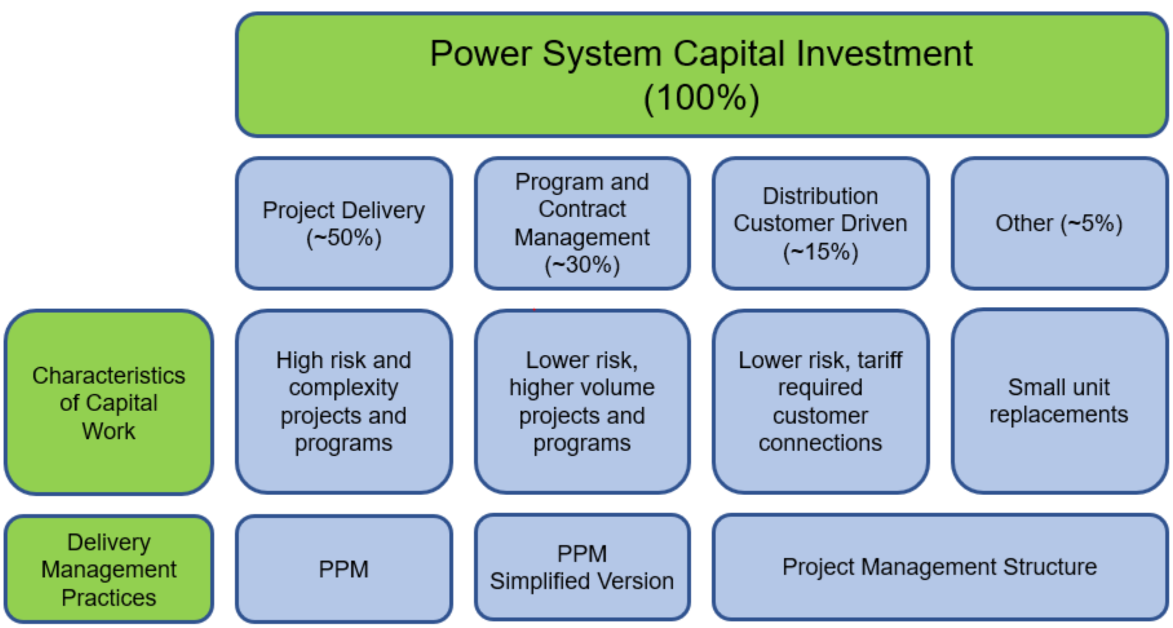
Investments associated with the Power System are delivered by three different KBUs: Project Delivery, Program and Contract Management, and Distribution

Design and Customer Connect. The processes followed by each KBU are adapted to suit the types of investment that they are responsible for delivering.

Large and complex investments generally require more rigorous delivery processes, involve a larger and broader group of internal and external stakeholders, and call for a high level of oversight and governance. Smaller projects or higher volume replacements of less complex assets require a scaled approach. Therefore, BC Hydro utilizes a range of delivery management practices to suit the range of investments that need to be delivered.

Figure N-3 below provides a summary of the Power Systems capital investments to be delivered by each KBU as well as the delivery management practice used to deliver those investments.

Figure N-3 Summary of Power Systems Capital Investments by Delivery KBU



2.6.1 Established Process Allows Early Identification of Issues and Resources

BC Hydro has an established process for early identification of issues and resources, so that work is assigned to the correct KBU with the appropriate delivery process for the nature of the investment and with resources to complete the work.

During the annual capital planning process to develop the Capital Plan for the Power System, the planning and delivery KBUs collaborate to:

- Consider labour resource availability, and validate that the Capital Plan for the Power System can be delivered with available internal and external resources;
- Determine the delivery model and assign capital investments to the appropriate KBU for delivery, considering factors such as:
  - Asset types and characteristics;
  - The size, scope, complexity, duration and costs of the projects or programs; and
  - The number of internal and external stakeholders that need to be involved.
- Review the larger and more complex projects that are proposed to be delivered by the Project Delivery KBU. This includes a review of the problem statement, possible alternatives, project scope, project duration, delivery risks and potential operational constraints.

2.6.2 Integrated Planning Remains Involved Throughout the Delivery Process

After the completion of the annual capital planning process, BC Hydro begins work planning. This involves reviews of specific investments targeted for release in the next fiscal year. The planning and delivery KBUs review the scope of planned capital investments in greater detail and consider the portfolio of planned work as well as investments already underway, to determine the appropriate time to start new work.

After work planning is complete, capital investments are prepared for release to the appropriate KBUs for delivery. This step includes final planning reviews and required financial approvals to initiate the work.

Capital investments to be delivered by the Project Delivery KBU are planned annually for release on a quarterly basis. This quarterly release plan is reviewed by the planning and delivery KBUs regularly to confirm that adequate resources are available prior to project release and may be updated in response to changing resource availability that may require the timing of work to be adjusted. Capital investments to be delivered by the Program and Contract Management KBU and the Distribution Design and Customer Connections KBU are typically released on an annual basis, prior to the start of the fiscal year. After planned capital investments have been released to the appropriate delivery group, the Integrated Planning Business Group continues to be involved throughout the delivery process and participates in key decisions and accountability meetings as the initiating group representatives.

2.7 Project Delivery KBU Uses the Project and Portfolio Management System to Deliver Larger, More Complex Projects

The Project Delivery KBU is responsible for delivering larger, more complex Power System projects. Approximately 50 per cent of the planned capital investments in the Power System are be delivered by the Project Delivery KBU.

A rigorous project delivery process is critical to delivering large or complex projects effectively. The Project Delivery KBU uses the Project and Portfolio Management System (**PPM**) system for consistent management of project risk, scope, schedule and cost.

2.7.1 Project and Portfolio Management System is Consistent with Industry Standards

PPM is BC Hydro's framework to manage engineering and construction projects that require engineering and/or project management services. It provides a consistent approach to minimize delivery risks. PPM practices are consistent with industry standards such as the Project Management Institute's Project Management Book of Knowledge and the Association for the Advancement of Cost Engineering International Recommended Practices. PPM is structured as a Quality Management System, consistent with the principles of ISO 9001, 2008 Quality Management Systems - Requirements.

There are three key components to the PPM system: practices, tools and learning. These components are described further in the sub-sections below.

2.7.2 PPM Practices Standardize the Management of Large, Complex Projects

All capital projects managed within PPM are delivered using a standard set of defined practices. BC Hydro's six defined Project Delivery Practices are:

- **Project Management** - The objective of this practice is to ensure efficiency and discipline in our work by providing a consistent framework for delivering projects and producing associated documentation. Application of these practices ensures safety for the public and employees, the quality of work delivered through the projects and our future capacity by sharing knowledge and lessons learned;
- **Design** – This practice aims to ensure efficiency and consistency in engineering design to provide facilities and equipment that are fit for purpose and will operate safely, reliably, economically and in an environmentally responsible manner, over the asset lifetime;

- **Construction and Contract Management** – This practice documents the services that we apply to construction projects, programs, and portfolios to achieve project objectives with regards to safety, security, environment, project scope, quality, schedule, cost, and Mandatory Reliability Standards;
- **Indigenous Relations** – This practice manages consultation and engagement with Indigenous Nations on BC Hydro's capital projects;
- **Procurement** – The objective of this practice is to ensure efficiency, consistency and quality in major capital project procurement by providing a framework for producing and delivering contracts that meets project requirements; and
- **BCUC Regulatory –** This practice is to provide regulatory advice to BC Hydro's business areas, and to facilitate the successful management of the company's business issues and initiatives through regulatory review processes that result in rates to BC Hydro customers that are fair, just and reasonable, and allow for the recovery of BC Hydro's revenue requirements.
- **Environment–** The objective of this practice is to strategically manage environmental risks in all life-cycle phases while ensuring regulatory compliance requirements are achieved and aligned with our Environmental Strategy and supporting BC Hydro's consent/license to operate.
- **Stakeholder Engagement -** The purpose of the Stakeholder Engagement Practice is to support the delivery of the communications, stakeholder engagement, issues management, media relations and government relations services to capital projects.
- **Properties** – The purpose of this practice is to support the delivery of Property related services to capital projects by developing and maintaining processes, tools, templates and guides to promote consistent and high quality Properties

deliverables to successfully achieve the scope, schedule, quality and cost objectives provided in the Project Statement of Objectives.

In addition to the nine Project Delivery Practices, PPM also includes Program Management and Portfolio Management Practices.

The specific objectives of the Program Management Practice are to:

- Integrate program management with other Project Delivery practices including portfolio management and project management;
- Provide a common approach to the management of programs within Project Delivery at BC Hydro;
- Support the planning and delivery of programs, including objectives, outcomes and benefits; and
- Support program managers with processes, techniques and templates.

The Portfolio Management Practice aims to establish consistent standards to support effective management of portfolios of project, program, and work program expenditures for Project Delivery projects. In particular, portfolio management guides the creation of a Portfolio Delivery Plan that describes the optimal approach to delivery of the entire portfolio, considering aggregation and coordination of opportunities and risk responses.

The Portfolio Management Practice also supports development of a baseline for measuring actual performance of the Portfolio Delivery Plan against the identified targets. This performance measurement allows management to understand and make more informed decisions on the interactions between projects, programs and work programs, to identify potential problems or opportunities, and to make timely interventions.

Underlying all of the Project, Program and Portfolio Practices are four “global” Practices:

- Document and Records Management – defines the framework in which documentation and records are required and dealt with for portfolio, program and project delivery;
- Performance Management – defines key performance indicators that are implemented to measure the project, including projects that are managed as part of a program;
- Reporting – provides background on reporting, its structure, the basics about the reporting process as well as what is required to develop quality reports; and
- Resource Management – ensures that resources are planned for and assigned to complete projects on schedule.

2.7.3 PPM Incorporates the Consistent Use of Technology in Project Management

BC Hydro’s PPM process uses technology solutions to manage project components. The following provides a high-level summary of these solutions and their application.

- There are two modules in the SAP system:
  - The Project Systems module provides a single system of record for work breakdown structures and financial data; and
  - The Business Warehouse module provides automated reporting on projects in the PPM process.
- The Primavera system has three components:
  - P6 software provides cost and schedule forecasts for each project;
  - Unifier is a contract management tool that is linked to the project schedules in Primavera P6; and

    - ▶ Primavera Risk Analysis performs schedule risk analysis on complex projects with a higher degree of risk.

- The PPM Workspace system (Microsoft SharePoint) provides document management functions.
- The PPM Information Centre is a web-based system that provides a record of the PPM practices.

2.7.4 PPM Includes a Learning Component to Support Best Practices

The Learning component of PPM involves the development of BC Hydro’s staff and the sharing of knowledge and experience. This is achieved through:

- **PPM Information Centre** – A website of learning and reference materials associated with Project and Portfolio Management;
- **Community of Practice** – Team sessions for all BC Hydro staff and contractors facilitated by internal and external subject matter experts;
- **Communication Hub** – an online newsletter that provides role-specific, directed communications of changes that affect how we deliver PPM projects;
- **Learning Plans** - including role-based learning available online for Document Coordinators, Schedulers and Work Package Managers to provide easy access to role specific training information;
- **Career Development site** – career pathways and progression models based on Project Delivery roles;
- **Training Sessions** – BC Hydro hosts regular Community of Practice Learning events as well the International Project Management day, where internal and external presenters share their knowledge of best practices, lessons learned and provide an opportunity to network with others; and

- **Industry Organizations** – BC Hydro participates in industry groups to share Project Management best practices, including the Project Management Institute West Coast Chapter, Western Energy Institute, Canadian Electric Utility Project Management Network and Utility Peer Group (consisting of North American utilities).

2.7.5 Project Delivery Lifecycle Involves Staged Refinement of Scope and Estimates and Gate Approvals

The delivery lifecycle of PPM projects is divided into four phases: Initiation, Identification, Definition and Implementation. Each phase is further divided into various stages. The lifecycle represents a staged approach to project definition and gate approvals.

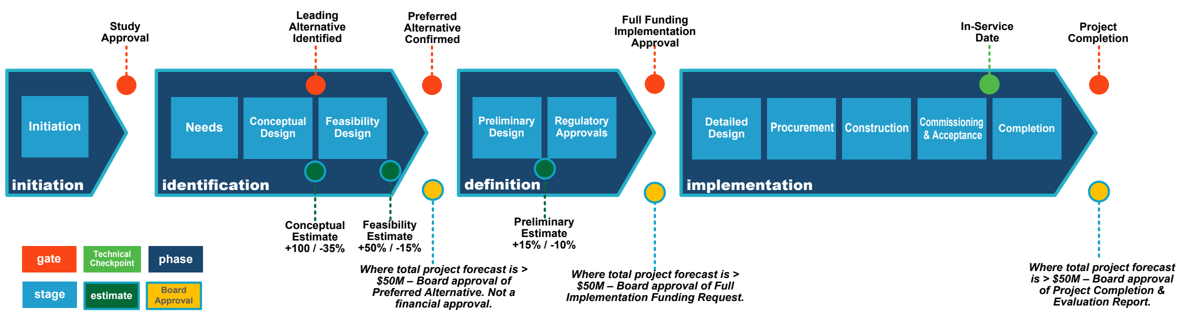
As projects move through this process, they become more defined. The increased level of definition allows for updated cost estimates to be developed. Cost estimates are provided at completion of the following stages:

- Conceptual Design: This estimate has an expected accuracy range of +100 per cent and -35 per cent;
- Feasibility Design: This estimate has an expected accuracy range of +50 per cent and -15 per cent; and
- Preliminary Design: This estimate has an expected accuracy range of +15 per cent and -10 per cent.

Gate approvals occur at defined points of the project lifecycle. Each gate is a formal approval point where key information on project cost, schedule, scope, procurement and risk is presented to the Gate Board. Further information on Gate approvals is provided in section 2.7.10 below.

Figure N-4 below provides a summary of the project delivery lifecycle. The Gates following each phase of the project lifecycle are shown as red circles, and approvals by the Board of Directors are shown in yellow circles. These project lifecycle phases and stages are non-discretionary.

Figure N-4 PPM Project Lifecycle



The following sections describe the four phases of the PPM Project Lifecycle: Initiation, Identification, Definition and Implementation.

2.7.6 Phase 1 in PPM Project Lifecycle: Initiation

The Initiation Phase begins by establishing an issue, risk or opportunity to be addressed through a planned capital project. A Study Approval Gate occurs at the end of the Initiation phase to conclude this phase and provide approval to proceed to the Needs and Conceptual Design Stages of the Identification Phase. This Gate represents the release of the project from Integrated Planning to Project Delivery. A Project Manager is then assigned to manage the specific project through to completion.

2.7.7 Phase 2 in PPM Project Lifecycle: Identification (+100/-35 per cent)

The Identification Phase consists of three stages: Needs, Conceptual Design and Feasibility Design.

- **The Needs Stage** clarifies and validates the risk, issue or opportunity to be addressed and develops a selection of high-level solution alternatives for further consideration. In this stage, an initial Work Breakdown structure, Statement of Objectives and Project Plan are developed. This includes the development of documents and systems to support the project delivery process throughout the lifecycle of the project;

- **The Conceptual Design Stage** analyzes the alternatives developed in the Needs stage and selects the alternatives to be carried forward into the Feasibility Design stage. For each selected alternative, an overall concept plan is developed including preliminary drawings of major project features, a general definition of equipment and system requirements and an overview of First Nations, stakeholder, environmental, socio-economic and procurement considerations. The selected alternatives are refined to eliminate the alternatives that do not meet the project objectives and to recommend a Leading Alternative that is technically and economically feasible and should be considered further. The main deliverable in the Conceptual Design stage is a business case which describes the alternatives considered, the methodology for evaluating those alternatives and the recommended Leading Alternative. The recommended Leading Alternative is confirmed through the Leading Alternative Identified Gate. Once this approval is provided, a conceptual design level estimate is prepared, with an expected accuracy range of +100 per cent and -35 per cent; and
- **The Feasibility Design Stage** conducts the investigations and analysis required to confirm that the Leading Alternative should be selected as the Preferred Alternative, to be carried forward to the Preliminary Design Stage of the Definition Phase. This analysis may include field and laboratory investigations as well as further evaluation of First Nations interests, environmental and other non-technical considerations. This analysis provides the required detail to prepare plans for the Definition Phase and to develop a feasibility design level estimate, with an expected accuracy range of +50 per cent and -15 per cent. At the end of the Feasibility Design stage, an

updated business case is developed and a Preferred Alternative Gate is held to confirm the Preferred Alternative. After the Gate, for projects with an Estimate at Completion greater than $50 million, the Executive Team reviews the Preferred Alternative before it proceeds to the Board of Directors for approval.

2.7.8 Phase 3 in PPM Project Lifecycle: Definition (+15/-10 per cent)

The Definition Phase defines the major project components in sufficient detail to develop a Preliminary Design cost estimate with an accuracy range of +15 per cent and -10 per cent. In this phase, implementation funding and any required regulatory authorizations are obtained. In addition, the Project Manager verifies that sufficient input has been received from First Nations via engagement and/or consultation as well as from internal and external stakeholders. To complete the Definition Phase, the Statement of Objectives, the Project Plan for the Implementation Phase and the final Business Case are examined through the Full Funding Approval Gate. Where required, projects greater than $100 million will be subject to a BCUC capital projects application. In those cases, an approval may be required prior to completing the Definition Phase. This Gate confirms that the risks associated with executing the work in the Implementation Phase are well managed and acceptable, before proceeding to that phase. After the Gate, for projects with an Estimate at Completion greater than $50 million, the Executive Team reviews the Full Funding Approval request before it proceeds to the Board of Directors for approval.

2.7.9 Phase 4 in PPM Project Lifecycle: Implementation

The Implementation Phase consists of five stages: Detailed Design, Procurement, Construction, Commissioning and Acceptance, and Completion.

- The Detailed Design stage is the final stage in the design process. This stage refines the Preferred Alternative so that it can be represented in a manner that allows work to be procured, manufactured and constructed in accordance with objectives, requirements, industry standards and accepted practices. Drawings and specifications are prepared in this stage and depending on the scale of the project, several design reviews may be required.

- The Procurement Stage initiates the sourcing process and issues tenders or requests for bids and proposal documents. In this stage, contracts are awarded for the supply, installation and construction of required work.
- The Construction Stage develops, manufactures, supplies, installs and constructs the required work in accordance with the contract specifications, drawings, and criteria.
- The Commissioning and Acceptance Stage tests and commissions the constructed facility or component in accordance with the prescribed criteria and applicable Mandatory Reliability Standards. Once the facility or component has been successfully commissioned, accepted and is fit for service, operational authority is transferred from the Project Delivery KBU to the appropriate KBU within the Operations Business Group.
- During the Project Completion Stage, the Project Delivery KBU provides a list of post-project commitments and conditions of permits, approvals and agreements to the responsible KBU within the Operations Business Group. The final deliverable in this stage is the project completion and evaluation report. Once this report is accepted, the project is classified as complete.

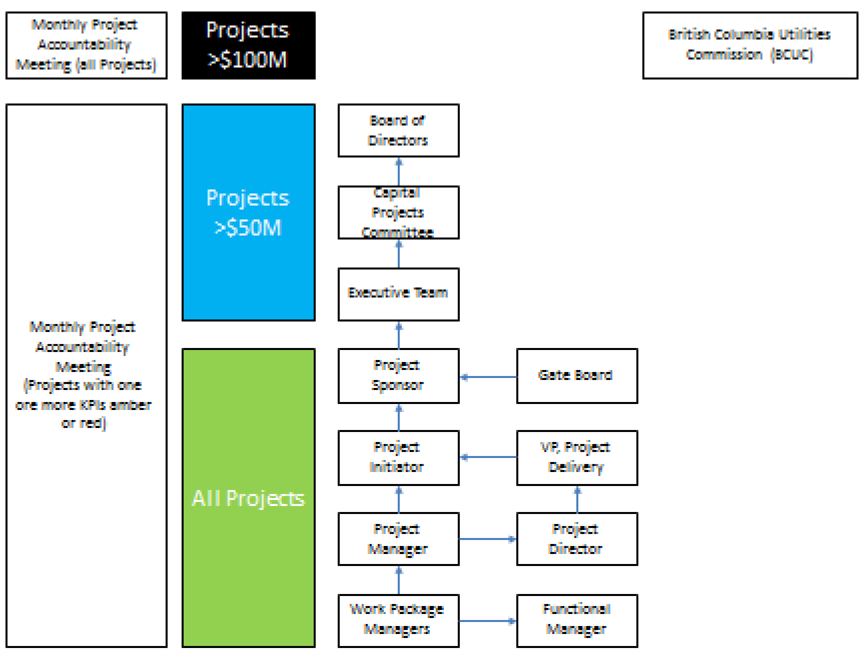
2.7.10 Project Delivery Roles and Responsibilities are Well Defined

Another important attribute of our project delivery process is that roles and responsibilities are well defined in advance. The process we employ streams projects based on their size and complexity, with additional levels of oversight for complex or higher risk projects.

BC Hydro deploys a matrix organization for resourcing and managing people assigned to capital investments delivered by the Project Delivery KBU. This means that staff are assigned to a project from various KBUs across the company to perform the required roles. Staff can be assigned to a project on a full-time or part-time basis and are accountable to the Project Manager for all project related work and decisions. The Project Manager is responsible for the day to day direction and decisions on the project. The KBUs that assign staff are responsible for setting standards, process and practices for their staff, conducting training on those practices and processes and for providing collegial support, approval of expenses and performance management.

Figure N-5 below illustrates the project governance structure for projects delivered by Project Delivery.

Figure N-5 Project Delivery KBU - Project Governance Structure



The following provides a summary of the various roles within this governance structure:

- ***Work Package Manager:*** The Work Package Manager is responsible and accountable for the planning and delivery of the Work Package within the approved scope, cost, and schedule as detailed in the Work Package Agreement. The Work Package Manager works with the Project manager and related Work Package Managers to create and develop the Work Package agreement (an element of the project scope);
- ***Functional Manager:*** The Functional Manager is responsible for the review of the Work Package agreement with the Work Package Manager to assess expectations for resource needs and review assumptions, scope, deliverables, milestones and activities related to the Work Package Agreement;
- ***Project Manager:*** The Project Manager is responsible for leading the project team to complete the objectives of the project. The Project Manager is accountable to the Project Initiator to determine the need, justification and objectives (scope, schedule and cost) of the project as well as to the Project Delivery Director for the delivery of the project against approved objectives and in accordance with approved policy and practice;
- ***Project Delivery Director:*** The Project Delivery Director is accountable to the Vice President of Project Delivery and is responsible for the execution of the projects in their portfolio against approved objectives and in accordance with approved policy and practice. The Project Delivery Directors chair the gate board meetings for projects with a cost of less than $10 million;
- ***Vice President, Project Delivery:*** The Vice President, Project Delivery is responsible for the delivery of the projects assigned to the Project Delivery KBU and is accountable to the Senior Vice President of Capital Infrastructure Project

Delivery. The Vice President, Project Delivery chairs the gate board meetings for projects with a cost of greater than $10 million;

- ***Project Initiator:*** The Project Initiator is the person with the authority to initiate work and is responsible for defining the work through the Statement of Objectives and justifying the work through the Business Case. The Project Initiator is also responsible for securing all required financial approvals. The Project Initiator sets project requirements which are then translated by the Project Manager into project scope, schedule and cost. The Project Initiator is accountable to the Project Sponsor for the definition and justification of the project; and
- ***Project Sponsor:*** The Project Sponsor supports the success of the project, by approving the project and liaising with senior management. At Gate board meetings, the Project Sponsor receives and considers Gate board recommendations to decide whether to approve key project decisions.

The following committees provide oversight of projects and endorsement of project funding requests:

- **Project Accountability Meetings:** BC Hydro conducts monthly Project Accountability Meetings to allow the Project Manager to update Gate Board members and internal stakeholders on the ongoing status of each project and provide a forum for participants to ask questions and deliver input and guidance. All projects with forecast capital costs greater than $80 million and projects under $80 million where one or more Project Key Performance Indicators are amber or red are reviewed monthly. The discussion at these meetings includes items such as project schedule, cost, scope, safety, operations, Indigenous relations, stakeholder engagement and project risks.

Table N-2 below identifies Project Accountability Meeting attendees.

Table N-2 Project Accountability Meeting Attendees

Senior Vice President, Integrated Planning	Senior Vice President, Capital Infrastructure Project Delivery
Director, Engineering Design	Executive Vice President, Operations
Director, Engineering Services	Vice President, Project Delivery (*Chair*)
Vice President, Asset Planning	Director, Indigenous Relations
Director, Stations Asset Planning	Director, Environment
Director, Dam Safety	Director, Properties
Director, Finance	Director, Stations Field Operations
Director, Interconnections	Senior Safety Advisor, Safety

- **Gate Board Meetings:** Depending on the stage of the capital project, the project's estimated cost, scope, alternatives assessment, and implementation plans are subject to endorsement by a review at a Gate Board Meeting, before a funding request is approved. The Gate Board reviews the project to determine if it is ready to progress to the next stage of its lifecycle. In addition to funding and stage progression approvals, these meetings provide an avenue for discussions with, and guidance from, key delivery partners on the status of projects and potential future issues.

  As shown in Table N-3 below, there are two types of Gate Board Meetings, depending on the cost of the capital project:

Table N-3 Types of Gate Board Meetings

Meeting Type	Capital Project Size
Major Gate Meeting	Projects ≥ \$10 million
Non- Major Gate Meeting	Projects < \$10 million

Table N-4 below identifies major and non-major Gate standing members. Additional participants may be invited when applicable.

Table N-4 Major and Non-Major Gate Board Standing Members

Major Gate Board Members	Non-Major Gate Board Members
VP of Project Delivery (Chair)	Project Director (*rotate chair between portfolios*)
SVP of CIPD	
EVP of Operations	
SVP of Integrated Planning	
VP of Asset Planning	
Directors of Engineering	Directors of Engineering
Director, Stations Asset Planning	Director, Stations Asset Planning
Director, Dam Safety	Director, Dam Safety
Director, Line Asset Planning	Director, Line Asset Planning
Director, Interconnections	Director, Interconnections
Director, Stations Field Operations	Director, Stations Field Operations
Director, Line Field Operations	Director, Line Field Operations
Senior Manager, Field Safety Assurance	Safety Manager
Director, Finance Capital Project Delivery	Finance
Director, Indigenous Relations	PMO Indigenous Relations
Director, Environment	Manager, Project Environmental Risk Management
Director of Properties	

The following additional governance roles are performed for all projects with a forecast cost greater than $50 million:

- ***Executive Team:*** The Executive Team reviews the project to determine if the project is the appropriate response to the identified risk, issue or opportunity. This review occurs at the end of the Identification Phase. The Executive Team also conducts a review at the end of the Definition Phase to determine whether the project is ready to proceed to the Implementation Phase, given the assessment of residual risks. This review supports the recommendation for approval to the Board of Directors;
- ***Capital Projects Committee:*** The Capital Projects Committee is one of the standing committees of BC Hydro's Board of Directors. This committee assists

the Board of Directors in fulfilling its obligations and oversight responsibilities related to the delivery of capital projects. Specifically, this includes, but is not limited to, dam safety, the execution of long-term capital plans and budgets, project oversight and relationships with First Nations. For capital projects with a forecast cost greater than $50 million, the Committee reviews the status of capital projects during the Identification and Definition phases, reviews and recommends the preferred alternative for approval by the Board of Directors, following the completion of the Identification Phase, and reviews and recommends financial approval by the Board of Directors, before the start of the Implementation Phase. When making its recommendations to the Board of Directors, the Capital Projects Committee reviews potential impacts to Aboriginal rights and title as well as planned mitigations and considers whether, in moving forward with a project, BC Hydro's consultations with First Nations uphold the honour of the Crown. The Capital Projects Committee meets quarterly in conjunction with the Board of Directors Meeting; and

- ***Board of Directors:*** BC Hydro's Board of Directors is appointed by and accountable to the B.C. Government. The Board of Directors is responsible for safeguarding BC Hydro's resources by approving annual operating and capital budgets as well as individual capital projects with a forecast cost greater than $50 million. For these projects, BC Hydro has established processes in place to facilitate Board of Directors review and approval of the preferred alternative, following the completion of the Identification Phase, and financial approval, prior to the start of the Implementation Phase. When considering approval, the Board of Directors reviews potential impacts to Indigenous peoples as well as planned mitigations and ensures that in moving forward with a project, the honour of the Crown is maintained.

In addition to the roles and responsibilities described above, the BCUC provides independent third-party review and approval of the need for projects greater than

$100 million or of significant public interest, unless a project has been exempted by government regulation. The BCUC also reviews the status of projects through quarterly or semi-annual progress reporting, and may undertake a prudency review of projects, once implementation is complete.

2.8 We Use a Simplified Framework for Routine Power System Investments

The Program and Contract Management KBU is responsible for delivering less complex and repetitive Power System capital investments on BC Hydro's power system. The KBU is the single point of contact for the annual delivery of the maintenance and small capital investment portfolio that is developed and optimized by the Integrated Planning Business Group.

When the annual maintenance and small capital investment portfolio is received from the Integrated Planning Business Group, the Program and Contract Management KBU develops annual program and project delivery plans in collaboration with the KBUs in the Integrated Planning and Capital Infrastructure Project Delivery Business Groups. This includes consideration of First Nations and environmental issues. Internal resource commitments to deliver the work are obtained from the Engineering, Distribution Design and Customer Connect, Line Field Operations, Stations Field Operations and Construction Services KBUs. Contracting plans are then developed to deliver the balance of the portfolio. Internal FTEs are used to deliver a significant volume of the small capital work, with external contractors being used to provide scalability due to fluctuations in demand.

The capital investments delivered by Program and Contract Management are typically “like for like” replacements of assets or system upgrades that are based on pre-defined design standards, developed by BC Hydro's Engineering KBU. Examples of capital investments delivered by the Program and Contract Management KBU include duct-bank construction, some end-of-life equipment replacement and overhead line relocations within an existing or public right-of-way. These investments are routine in nature, have a lower risk profile and require minimal, if any acquisition of property or rights of way. The standardized nature of these investments means that there are limited, if any alternatives to evaluate. Standard procedures are established to select the most feasible alternative when required.

These investments generally do not require specific equipment procurement and the required materials are typically inventoried by BC Hydro's Materials Management department. When specialized services, equipment or materials are required, standing blanket services contracts or master purchasing agreements are used. Work is completed through unit-based contracts with external contractors.

The Program and Contract Management KBU applies a simplified version of the PPM practices that is suited to the lower complexity of the projects it delivers. For program investments that involve standardized units of work, the Program and Contract Management KBU applies simplified work management processes.

2.9 We Use a Standardized Process for Routine Customer Driven Work

The Distribution Design and Customer Connections KBU is responsible for work related to customer requests for new or upgraded connections to BC Hydro's distribution system. This KBU provides technical design services and project management for customer driven new connections work, under 5 MW in size. More complex projects over 5 MW or over $2 million in cost are managed by the Program and Contract Management KBU, with the Distribution Design and Customer Connections KBU providing design services.

The Distribution Design and Customer Connections KBU designs to standards, with engineering support where required, and follows a project management structure that involves standardized work order packages, with environmental, archeological, safety and job planning processes and checklists. This simplified process enables project cycle times to align with customer requirements.

The Distribution Design and Customer Connections KBU issues approximately 11,000 work order packages in support of new customer connections and customer driven improvement work. These work orders require customer interactions, design work and project coordination. A dedicated Express Connections Contact Centre within this KBU issues 37,000 service orders per year. Express service orders are simple customer connections which do not require design work.

While the Distribution Design and Customer Connections KBU plans for customer connections at a system level, individual customer connection projects depend on actual customer requests. Therefore, these projects are driven by customer timelines and are not planned in detail. Program volumes and characteristics are forecast based on historical trends. The staffing model for the Distribution Design and Customer Connections KBU includes full time regular designers, full time temporary designers and external service providers to provide flexibility and to balance internal work program and customer program demands so that customer requests are prioritized for delivery to the agreed in-service dates.

2.10 Financial Approval Policies and Procedures Apply to All Capital Investments

BC Hydro has well established Management and Accounting Policies and Procedures **(MAPP)** and Financial Approval Authority Policy (**FAAP**) that set funding approvals required for capital investments through each phase of the project lifecycle. These approval requirements and processes have been developed to balance financial controls with operational efficiency, based on the nature and risk of the capital investments. The policies and procedures apply to all groups delivering BC Hydro’s capital investments.

2.10.1 Company-Wide Approval Policies Are Documented

The policies that govern capital investment approvals are primarily included in:

- Management and Accounting Policies and Procedures 1.2.3A (Expenditure Authorization Requirements Policy);
- Management and Accounting Policies and Procedures 1.2.3B (Expenditure Authorization Requirements Procedure); and
- Management and Accounting Policies and Procedures 1.2.1B.2 (Financial Approval Authority Procedure).

The required financial approval processes set out in these documents depend on the type of capital investment. Capital investments are categorized into the following four main categories for financial approval processes:

- Phased Capital Projects;
- Non-Phased Capital Projects;
- Recurring Capital Programs; and
- Expenditure Authorization Request Exempt Capital Investments.

The financial approval processes for each category are discussed further in the sections below.

2.10.2 Phased Capital Projects Require Phase-by-Phase Funding Approval

For capital projects which are delivered using PPM phases, funding approval is required prior to the commencement of work for that stage or phase. Typically, funding is approved only for the next stage or phase once the required work for the prior stage or phase has been completed. The financial approver level is dependent on the stage or phase as well as the funding amount being requested. For projects that meet the BCUC thresholds for a Certificate of Public Convenience and

Necessity (**CPCN**) and section 44 reviews, applications are generally submitted to the BCUC during the Definition Phase.

Table N-5 below provides information on the funding approval process for phased capital projects, delivered by the Project Delivery KBU and Technology.

Table N-5 Funding Approval Process for Phased Capital Projects (Project Delivery KBU)

Phase	Primary Budget	Estimate Accuracy Level	Funding Approval Documents	Project Approvers and Finance Review	Basis of Approval	FAAP Approver
Identification Phase (Needs Stage)	O&M (CPI)[3]	N/A	• Annual Release Plan from Capital Plan • Maximum request is generally $200,000	• Project Release Committee • No Finance Review	Amount requested	Manager, Portfolio Optimization and Management
Identification Phase (Conceptual Design Stage)	O&M (CPI)	End of Stage provides +100% / -35%	• Statement of Objective (SOO) • If over $2M, business case and Expenditure Authorization Request (EAR) Form also prepared	• Project Sponsor • Project Initiator • No Finance Review unless requested amount is more than $2M	Based on cumulative O&M amount requested	Chief Executive Officer (CEO): Up to $50M Others: 25% of FAAP Planning limit
Identification Phase (Feasibility Design Stage)	Capital	End of Stage provides +50% / -15%	• SOO • Business Case • EAR Form	• Gate Board • Project Sponsor • Project Initiator • Finance Review required	Based only on capital amounts requested going forward	CEO: Up to $50M Others: 25% of FAAP Planning limit

[3] CPI refers to Capital Project Investigation cost.

Phase	Primary Budget	Estimate Accuracy Level	Funding Approval Documents	Project Approvers and Finance Review	Basis of Approval	FAAP Approver
Definition Phase	Capital	End of Stage provides +15% / -10%	• SOO • Business Case • EAR Form	• Gate Board • Project Sponsor • Project Initiator • Finance Review required	Based on cumulative capital amount requested starting from Feasibility Design Stage	CEO: Up to $50M Others: 25% of FAAP Planning limit
Definition Phase with Partial Implementation Phase costs (not including construction)	Capital	End of Stage provides + 15% / - 10%	• SOO • Business Case • EAR Form	• Gate Board • Project Sponsor • Project Initiator • Finance Review required	Based on cumulative capital amount requested starting from Feasibility Design Stage	CEO: Up to $50M Others: 25% of FAAP Planning limit
Partial Implementation Phase costs including construction	Capital	N/A	• SOO • Business Case or CPCN if applicable • EAR Form	• Gate Board • Project Sponsor • Project Initiator • Finance Review required	Total Project Estimate	Ultimate FAAP approver for Total Project Estimate
Implementation Phase	Capital	N/A	• SOO • Business Case or CPCN if applicable • EAR Form	• Gate Board • Project Sponsor • Project Initiator • Finance Review required	Total Project Estimate	Ultimate FAAP approver for Total Project Estimate

Table N-6 below provides information on the general funding approval process for phased capital projects delivered by other KBUs.

Table N-6 Funding Approval Process for Phased Capital Projects (Projects Delivered by Other KBUs)

Phase	Primary Budget	Estimate Accuracy Levels	Approval Documents	Project Approvers and Finance Review	Basis of Approval	FAAP Approver
Identification	O&M	N/A or Various	• SOO or business case or equivalent • EAR form (Technology)	• Business group dependent • Finance Review dependent on amount requested and type of capital	Amount requested or based on Total Project Estimate (Technology)	CEO: Up to $50M Others: 25% of FAAP Planning limit
Definition	Capital	Various	• Business Case • EAR Form	• Business group dependent • Finance Review required	Cumulative amount being requested or based on Total Project Estimate (Technology)	CEO: Up to $50MOthers: 25% of FAAP Planning limit
Implementation	Capital	Various	• Business Case • EAR Form	• Business group dependent • Finance Review required	Total Project Estimate	Ultimate FAAP approver for Total Project Estimate

2.10.3 Non-Phased Capital Projects Require Business Case and Authorization

Non-Phased Capital Projects are capital investments that are not delivered using project phasing but are similar to a one-time capital investment. Examples include the purchase of new equipment or office furniture. For Non-Phased capital investments over $0.5 million, an approved business case and Expenditure Authorization Request (**EAR**) form are required prior to any capital spending. These authorization documents are approved based on the total investment amount, in accordance with BC Hydro's Financial Approval Authority Policy requirements.

2.10.4 Recurring Capital Programs are Approved Annually

Recurring Capital Programs are generally completed each year, on an ongoing basis. This work is generally lower risk, involving like-for-like unit replacements, such as the annual distribution wood pole replacement program. These investments are authorized at the beginning of each fiscal year using the Recurring Capital Annual Expenditure Authorization Form.

2.10.5 Approved Work Orders Are Required for Low Cost Recurring Capital Projects

Expenditure Authorization Request Exempt Capital Investments are recurring capital projects with a low cost and high volume. Examples include work activities to connect distribution customers, which are required under the Electric Tariff and less than $1 million in cost. These investments are operationally approved through BC Hydro's Work Order system. A business case is required for any recurring capital project with a forecast cost of more than $1 million.

2.11 Portfolio Risk Adjustment Overview

BC Hydro's Capital Plan is based on project cost and schedule forecasts available at the time the Plan is developed. Variances to the planned fiscal year capital expenditures and capital additions of projects occur due to changing circumstances throughout the project lifecycle. The Portfolio Risk Adjustment is used to account for project level uncertainties to provide a more realistic portfolio level forecast (for both capital expenditures and additions) for the test period.

BC Hydro has used a Portfolio Risk Adjustment as part of our Capital Plan development since 2018 to account for the uncertainty in the schedule and cost of projects. The accuracy of project level forecast capital additions increases with the level of analysis and information on project scope, schedule and cost. Therefore, the largest uncertainties are associated with projects that are in early stages of the project lifecycle as their scope, schedule and cost are not as well defined as projects that are in later stages.

The Portfolio Risk Adjustment amount is calculated using a Monte Carlo simulation. A probability distribution is determined, based on historical project delivery performance information. The calculated Portfolio Risk Adjustment amount represents the difference (by fiscal year) between the expected value of the simulated portfolio forecast and the sum of individual project forecasts in the baseline Capital Plan.

Any differences between the forecast and actual amortization of capital additions are captured in the Amortization of Capital Additions Regulatory Account. This means that the actual amount recovered from ratepayers is ultimately based on the actual capital additions.

3 Supporting Portfolios Planning & Delivery Processes

3.1 Technology Capital Investments

The Technology KBU is responsible for the planning, design, delivery and operation of BC Hydro’s Information Technology (**IT**) systems and several Operational Technology (**OT**) systems. IT assets or systems are tools for commercial decision making, planning, business process management, and resource allocation. OT assets (or systems) provide operational monitoring and/or control of assets in the electric network in real time (or near real time).

3.1.1 Technology Planning

This section outlines the planning processes in place to understand the issues, risks and opportunities associated with these assets, and to identify the recommended capital investments. It also outlines the delivery processes in place to deliver projects and programs on time, on budget and within scope.

The Technology planning and delivery processes are integrated both within Technology and across the organization. They generally follow the same processes as described for the power systems portfolio, including both top-down and bottom-up asset planning processes.

3.1.1.1 Ongoing Technology Investment is Organized by Driver into Three Categories

BC Hydro's forecast Technology capital investments are grouped into the following three categories:

- **Manage compliance and security**: This category includes investments that address regulatory requirements, periodic foundational cybersecurity improvements, cybersecurity hardware replacements and software license renewals, and growing cybersecurity threats;
- **Manage risk and sustain productivity**: This category includes investments that address asset failure risk and new investments to help manage operational and business risks and expand information technology services as needed; and
- **Enhance business capability**: This category includes investments for new or improved business capabilities.

Table N-7 below summarizes the key capital investment drivers within each investment category.

Table N-7 Technology Investment Drivers by Category

Category	Investment Driver
Manage Compliance and Security	Regulatory compliance risk Investment toward achieving MRS, WorkSafe BC, or other compliance outcomes.
	Cybersecurity risk Investment driven by cybersecurity threats, vulnerabilities and incidents.
Manage risk and sustain productivity	Asset risk Investment to address declining asset health (including supportability), which increases the likelihood of asset failures including outages, declining performance and loss of capacity. The risk to business systems, capabilities, production and services are considered in a business-as-usual environment.
	Sustainment of productivity Investment to maintain the efficiency of IT assets, asset systems and the downstream business functions that rely on them. This includes recurring capital work programs (excluding enhancements), and software license purchases.
Enhance Business Capability	Enhancement of capability Investment to enable new or enhance existing business capabilities, to expand capacity, or to manage operational, financial, and reputational risks.

3.1.1.2 Ongoing Technology Investment is Organized Through Portfolio Management

The Executive Team provides top-down funding guidance for the Technology portfolio. Within this guidance, the Technology KBU enables desired business outcomes by sustaining the availability and security of our existing assets and providing new asset implementations and improvements as needed.

The required investments start as a list of mandatory or committed investments, and additional investment needs are prioritized into consolidated capital investment plans.

These capital investment plans address business needs and opportunities through upgrades and end of life replacements based on asset useful life or asset risk, periodic software license renewals and true-ups, enhancements to avoid functional obsolescence, capacity increases, and implementations to support new business capabilities. Individual investments are subsequently defined as projects, recurring work programs, or capital purchases.

The Technology leadership team oversees the implementation of its Capital Plan through monthly capital committee meetings. These meetings review variances between forecasts and budgets, manage risk adjustments, reallocate capital as needed to meet new priorities and business requirements and control the release of projects to delivery. Any in-year investment requests are managed through funding re-allocations and the ex-plan process.

3.1.1.3 Larger Investments undergo a Technology Benefits Realization Process

Each technology project has a business case outlining expected benefits. BC Hydro has developed a benefits realization process so that benefits claimed in business cases can be tracked and realized.

The benefits realization process monitors capital investments over $2 million in the delivery phase and once in service to help ensure the achievement of expected results. Benefits are monitored periodically over the asset life cycle.

3.1.1.4 Portfolio Risk Adjustment Overview

A portfolio risk adjustment helps provide a more accurate portfolio level forecast for the Test Period by applying a portfolio level discount to the bottom-up forecast expenditures and additions in order to offset forecasting bias.[4]

The Portfolio Risk Adjustment is assessed monthly based on project complexity, current delivery phase, distribution of forecast expenditures, and uncertainties related to specific costs.

3.1.2 Technology Portfolio Delivery Uses a Standard Framework

The capital investment portfolio consists of projects, work programs and acquisitions. Investments require approved business cases and adhere to a Technology-specific delivery framework called Information Technology Delivery Standard Practices (**ITDSP**).

3.1.2.1 We Use a Standard Technology Project Delivery Framework that Requires Approvals at Each Phase

ITDSP is used to aid managers, service providers and project teams in delivering successful technology projects. This framework was adopted in 2004 and is updated annually. The framework aligns with PPM Practices, which are discussed further in section 2.7 above and has been adapted to better support the unique character of technology projects.

[4] Bottom-up capital investment forecasts generally reflect estimation bias. This bias is visible at the portfolio level where risks associated with resource constraints are most evident. The most common bias is schedule optimism where project schedules are underestimated due to incomplete recognition of uncertainties related to project planning and delivery. A second source of risk is uncertainty of specific costs.

ITDSP uses standard PPM phases with uniquely defined stages. Gate approval points are positioned at the end of project stages so that management can confirm that the proposed project solution remains in alignment with business drivers and is ready to progress to the next phase or stage. Each gate is a formal approval point, where key information is presented to the gate board, typically related to cost, schedule, scope, procurement, and risk.

The following sections provide a high-level summary of the key activities within the project lifecycle phases.

3.1.2.2 Initiation Phase

The primary objective of the Initiation phase is the prioritization of a specific capital investment and the decision to prepare a business case. To support the decision to initiate a project, the Project Initiator is responsible for assembling a brief description of the problem or opportunity, key business drivers and any associated risks and estimated funding needs.

A decision is made to form and proceed with a project based on the understanding of the problem or opportunity and the risk to the business, support by the Project Initiator, the funding requirement, and the potential funding source.

The key outcomes of the Initiation phase are an Identification phase business case, a detailed Identification phase project plan, and firm Identification phase costs as well as an initial estimate on the overall project cost.

The Initiation phase concludes when the Identification phase business case is approved.

3.1.2.3 Identification Phase

The Identification phase includes three stages:

- **Needs Assessment** – to confirm the scope and business requirements;

- **Conceptual Design** – to review alternative solutions and select the leading alternative; and
- **Feasibility Design** – to evaluate the feasibility of alternative solutions and recommended an alternative to be taken forward to the Definition phase.

The key outcomes of the Identification phase are: approved and prioritized business requirements; an assessment of alternative solutions including a recommended solution and confirmed feasibility of the recommended solution; completion of a Process Impact Assessment; a Definition phase business case; a detailed Definition phase project plan; a firm Definition phase cost; and a refined range estimate for the overall project cost.

The Identification phase concludes when a decision is made on whether to proceed to the Definition phase (the Preliminary Approval Gate).

3.1.2.4 Definition Phase

The Definition phase includes two stages: High Level Design/Blueprint; and Regulatory Approvals.[5]

The objective of the Definition Phase is to carry out a detailed investigation of the selected alternative, and to prepare a high-level design, project implementation plan and estimate of the Implementation phase funding, including an Implementation phase business case. This phase also includes securing all required regulatory approvals as well as any key defining agreements.

The key outputs of the Definition phase are process documents, a High-Level Design/Blueprint (documented in the Architecture Definition Document), an

[5] Based on BC Hydro's Capital Filing Guidelines, the threshold for regulatory approvals is an estimated overall budget equal to or greater than $20 million.

Implementation phase business case, an Implementation project plan, and a firm overall cost estimate range to complete the project.

The Definition phase concludes when a decision is made on whether to proceed to the Implementation Phase (the Full Funding Approval Gate).

3.1.2.5 Implementation Phase

The Implementation phase includes seven stages: Detailed Design; Build; Test; User Acceptance Testing Deploy/Cut-over; Stabilization; and Completion.

The objective of the Implementation phase is to complete the detailed design, build, test and commission the solution into service.

The key outputs of the Implementation phase are a working solution, confirmed through testing, that meets project objectives and is fully transitioned into operation, and a Project Completion Report measuring success against the approved business case.

The Go Live Approval Gate represents a decision on whether to proceed to the Deploy/Cut-over stage.

The project is considered complete once the Project Initiator and Project Sponsor have accepted the project results by signing the Project Completion and Evaluation Report.

3.1.2.6 Technology Work Programs and Licenses Are Subject to Workflow Approval Processes

A Work Program is a program of high-volume sustainment or enhancements items, typically with a low cost per item, which utilizes simple workflows on highly standardized and repeatable work units to deliver an overall benefit. Work Programs are typically set up for one fiscal year at a time, for a specific asset or group of assets. As this work is less complex, the ITDSP framework and project life cycle do not apply. Similarly, capital purchases for licences and equipment are also not subject to the ITDSP framework as they are not projects.

3.1.2.7 We Optimize Internal and External Resources

Technology employs two primary delivery models to optimize the use of internal and external market-based delivery capacity:

- Projects are primarily delivered through managed teams, where BC Hydro staff or consultant project managers manage blended teams of employees, vendors and individual contractors; and
- For larger, more complex projects, BC Hydro uses an outsourced model, called the system integrator model, where teams of external service providers provide project delivery and a large number of developer resources are applied to a project.

This resourcing model is appropriate to deliver the Capital Plan in the Test Period. The use of blended teams and system integrators allows for rapid scaling of our workforce, as required.

3.1.2.8 Technology Project Delivery Governance

Governance of technology capital delivery is provided by project steering committees, project gate reviews and funding approval, the Executive Team and the Board of Directors.

- Project steering committees provide senior management level direction to projects to assist with resolving complex issues.
- Project gate reviews occur at various points of the project lifecycle. Each gate is a formal approval point where key information on project cost, schedule, scope, procurement and risk is presented to the gate board.
- The Executive Vice President approves projects greater than $6 million.

- The Board of Directors approves projects greater than $20 million.

Governance is also provided through BC Hydro's Management and Accounting Policies, which are discussed in section 2.10.

3.2 Properties Capital Investments

3.2.1 Properties Bottom – Up Asset Capital Planning Process

The Properties planning process follows a three-step bottom-up approach.

Step 1 – Identify the Asset Needs

The first step of this process is to identify the building and asset needs at each of the facilities that should be considered for remediation. This assessment includes reviews of existing asset issues and risks as well as asset condition assessments. This results in a list of proposed projects.

Step 2 – Formation of a Draft Capital Plan

The proposed projects are categorized, ranked by priority and then subjected to any funding constraints, in order to develop a draft capital plan.

Step 3 – Review the Investments in the Capital Plan Period

The draft plan then undergoes a series of reviews of the planned investments across the building portfolio to ensure that investments are appropriately prioritized and timed. This review also allows for validation of the operational requirements by Properties and BC Hydro operations and other KBUs. These reviews may result in a re-assessment of specific projects or shifting of projects within or beyond the capital plan period.

Properties proposed capital investments are subject to the BC Hydro enterprise-wide framework used to assist in prioritizing capital investment. Investments included in the BC Hydro 10-Year Capital Forecast are selected based on their prioritization score and other constraints, following the BC Hydro enterprise-wide process.

3.2.2 Properties Capital Investment Delivery Aligns with BC Hydro's Standard Approach

The delivery of Properties' capital projects are managed using both internal and external (contracted) resources following normal building construction industry practices. Properties' Capital Delivery processes align with the standard BC Hydro project lifecycle for managing projects, whereby:

- Projects progress through the four phases of delivery: Initiation, Identification, Definition, and Implementation; and
- Gate approvals are formal approval points positioned at the end of key stages in the project lifecycle to allow management to confirm that the proposed project solution remains in alignment with business drivers and that the project is delivering on key project objectives including cost, schedule, and scope.

3.3 Fleet Capital Investments

Fleet Services Asset Planning identifies and ranks vehicles and equipment for replacement using asset information (asset age/remaining life, mileage, maintenance costs, utilization rates, observed downtime frequency), input from fleet maintenance staff and end-users on asset condition, criticality and operational requirements. End-users also can identify requirements for upgraded or additional fleet assets. This information is used to assemble a list of vehicles and equipment for acquisition planning. The process is initiated in advance of the expected end-of-life replacement criteria (i.e., for a vehicle with a ten-year life replacement planning is started at approximately the seven-year mark). The general fleet replacement criteria are established based on historical data, as well as the suggested useful life in a commercial application as determined by BC Hydro fleet data, industry benchmarks and vehicle manufacturers. In addition, the work application and the environmental conditions in which the assets are operated are considered as they have an impact on the actual life of the vehicle.

Through the application of the enterprise-wide framework for capital prioritization, top-down planning and expenditure guidelines and other constraints, the list of vehicles for replacement, upgrades and vehicle additions are prioritized. Recommended acquisition plans are then vetted through senior management.

New in Fiscal Year 2021

Technology Strategy

Business mindset

Value fast

Forward thinking

Our strategy is to support BC Hydro in meeting its Service Plan objectives by optimizing our investments, delivering outcomes early and often, and leveraging future technology.

Over the past year we have made significant progress against the 5-Year Plan as well as in implementing the principles of the strategy. Our focus last year was on “making it easier to get work done” and using our principle of “delivering outcomes early and often” to rapidly make a difference for our front-line workers. We achieved this through mobile app development, deployment of robotic process automation and the introduction of rapid, iterative delivery methods where appropriate.

Two important areas of focus have emerged that require us to bring forward some elements of the plan. The first is the need to adapt to the COVID-19 pandemic and working from home. The second is the need to improve compliance outcomes related to Mandatory Reliability Standards (MRS) and NERC Critical Infrastructure Protection (CIP).

This year we are developing a compliance technology roadmap to identify areas for short and long- term improvements to our systems in support of compliance outcomes as well as advancing the deployment of collaboration tools such as WebEx for virtual meetings, training and events and Microsoft Teams.

To put our strategy into action, we continue to prioritize our investment. Our first priority is to ensure sufficient investment in cybersecurity and compliance, our second is to sustain our existing assets and capabilities, and our third is to support new business functionality. The majority of our capital funding is invested in sustainment. One of the largest sustainment investments we will make over the next 5 years is to move our SAP core systems onto the next generation SAP platform and database.

The 2020 BC Hydro 5-year strategy identifies digitizing work management as an objective for achieving cost effectiveness. Pre-initiation work on enterprise asset and work management is underway to determine our approach to achieving this objective.

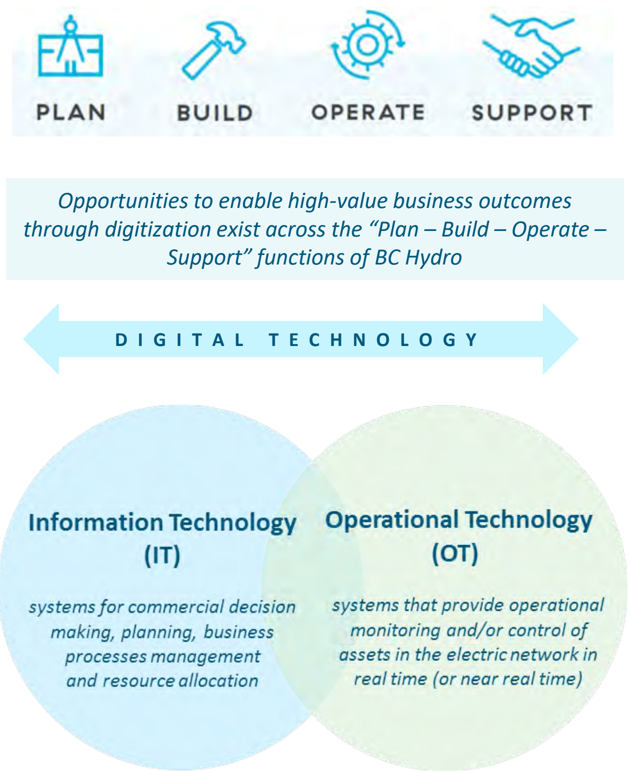
BC Hydro
Power smart

Introduction

Technology plays a critical role in the operation of BC Hydro and is embedded in virtually everything we do; from enterprise business systems, to the monitoring and controlling of field assets, to mobile devices in the hands of workers. Global trends, business competition, and high consumer expectations are driving rapid advances in technology. In the utility industry, the application of digital technology is viewed as essential in meeting future business objectives.

For BC Hydro, investment in technology can help us achieve our service plan objectives to provide reliable and responsive service, maintain affordable rates, continue to support clean, renewable energy and focus on safety above all else.

In this document, “technology” refers to digital technologies encompassing *information technology* (IT) as well as *operational technology* (OT). Traditionally separate domains in the electric utility business, the digital technology environments of IT and OT are now converging as the trend continues towards automation of all aspects of the power systems and the use of grid system data for business decision-making. New capabilities using rapidly evolving digital technologies such as cloud computing, mobility, internet of things, and machine learning, are being implemented as utilities modernize towards a more intelligent grid – this is the digitization of the utility industry.



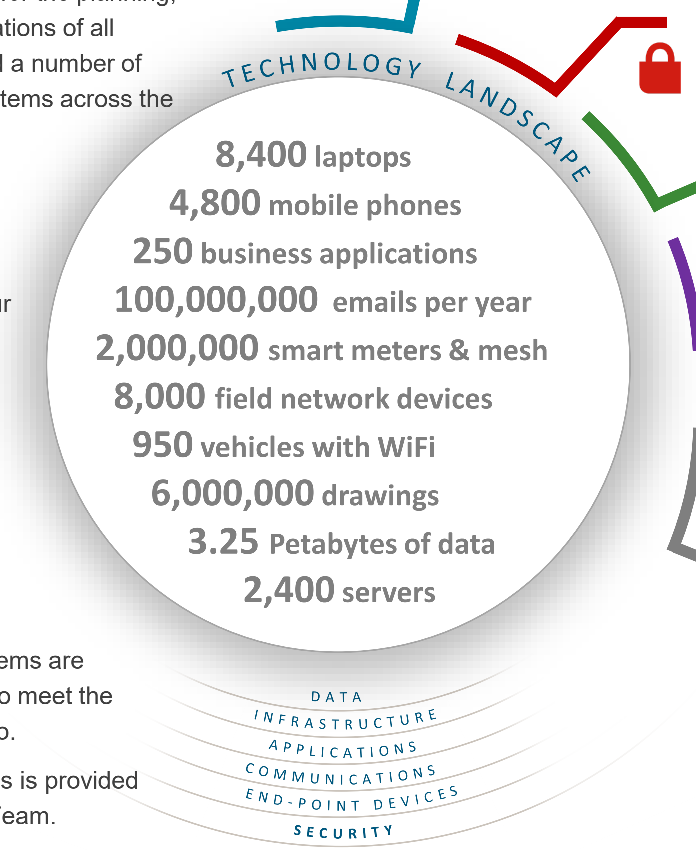
Introduction
Our role

Technology is responsible for the planning, design, delivery, and operations of all information technology and a number of operational technology systems across the enterprise.

We provide technology leadership and oversight across BC Hydro. We actively collaborate with our organization to understand current and future needs. We are responsible for the enterprise technology architecture, and selection of appropriate technology solutions to deliver strong business outcomes.

Our work ensures our systems are reliable, secure, and able to meet the growing needs of BC Hydro.

Governance of our activities is provided by BC Hydro's Executive Team.



Planning and operating our complex environment

Technology investment planning, architecture and design, performance management, data and information governance, portfolio and resource management, service management, service desk, systems monitoring, maintenance and support, incident response and recovery

Protecting our systems and information

System-wide cybersecurity, system design, monitoring and response, testing, education, policy, compliance, detection and protection tools, vulnerability assessment, securing perimeters, privacy protection, security risk management, records management, information protection, drawings management, library and archive services

Ensuring the resilience of our systems

Service continuity planning and response, disaster recovery, risk management, high-availability architecture, cloud-based services, internal capabilities for critical functions, asset maintenance and health management

Enabling new business capabilities

Engaging with the business to understand their current and future needs, managing our capital investments and on-going sustainment, delivering high value projects on-time, on-scope and on-budget

Improving operational efficiency

Effectively managing vendors and contracts, retiring legacy assets, balancing internal and external resources, modernizing tools and processes, introducing agile methods, use of cloud, out-of-the-box solutions

BC Hydro
Power smart

Introduction

About this document

This Technology Strategy and 5-Year Plan is the result of extensive collaboration across BC Hydro. Its primary goal is to provide guidance and direction for future technology investments to meet compliance and security objectives, sustain and modernize our existing operations, and enable new business capabilities.

Our strategy is to support BC Hydro in meeting its service plan objectives by optimizing our investments, delivering outcomes early and often, and leveraging future technology.

A clear strategy and plan is essential to inform the direction of future investments, but the approach looking forward must be flexible in order to adapt to, and exploit, the ever-changing technology landscape as well as to address new business opportunities as they arise. Given the rapid advancements in technology, and the continuing evolution of BC Hydro's business needs, the 5-Year Plan will be refreshed annually.

Our investment in technology is aligned with our capital plan over the next five years. The 5-Year plan describes the major investments we anticipate, however each will be supported by its own business case and initiated based on changing priorities, available funds and resources.

The purpose of this document is to:

- ✓ **Articulate BC Hydro's technology investment objectives**
- ✓ **Describe our strategy to meet these objectives**
- ✓ **Communicate the 5-Year Plan to guide investment and inform current and future regulatory submissions**

Context

- Our strategic objective
- Drivers for our strategy
- Digital value streams for electric utilities

BC Hydro

Technology Strategy

Our strategic objective

This Technology Strategy and 5-Year Plan is designed to support BC Hydro in achieving its Service Plan Objectives:

- ✓ **Safety above all**
- ✓ **Set the standard for reliable and responsive service**
- ✓ **Help keep electricity bills affordable for our customers**
- ✓ **Help make renewable, clean power British Columbia's leading energy source**

Implementation of technology solutions has the potential to advance each of these objectives, for example:

- By maintaining the health, stability and security of our digital systems we assist in ensuring the reliability and responsiveness of our service.
- Providing tools to streamline workflows, optimize work and asset management, and inform decision making all enable productivity improvements that lead to affordable rates.
- Mobile applications can provide location and job specific information to assist with improving safety outcomes for field workers.
