2 Comprising all DSM deferred operating expenditures that are relevant for DSM cost-effectiveness.

BC Hydro's DSM electricity savings since F2016 totalled 1,754 GWh/year at March 31, 2017, which equates to 105 per cent of the planned savings of 1,668 GWh/year in the F2017-F2019 RRA. DSM programs delivered 103 per cent of planned savings. Table 3 presents actual cumulative savings as a percentage of plan in F2016 to F2017.

PORTFOLIO TOTAL	**105%**

Notes:

[1] Reported savings for codes and standards and rates structures are based on planned estimates as well as evaluated results.

The cumulative portfolio DSM electricity savings since F2016 have been achieved at an average net levelized utility cost of -$20 per MWh. Table 4 presents the net levelized utility cost of actual DSM electricity savings achieved from April 1, 2015 through March 31, 2017. Net levelized utility cost is calculated by subtracting capacity benefits from gross utility costs and then dividing the resulting net utility costs by electricity savings. A negative net levelized utility cost means that the subtracted capacity benefits exceed gross utility costs.

Portfolio Total	**12.8**	**5.2**	**6.1**	**1.3**

Notes:

1 In accordance with the DSM Regulation (Ministerial Order M233/2014), the avoided cost of natural gas is valued at BC Hydro's long run marginal cost of acquiring electricity generated from clean or renewable resources in B.C converted to $/GJ in all time periods. Non-energy benefits are valued at 15 per cent of the energy and capacity benefits of electricity and natural gas.

2 While subsection 4(6) of the DSM Regulation precludes the use of the Ratepayer Impact Measure Test in determining cost-effectiveness of a demand-side measure, this benefit cost ratio is included in the table to comply with Directive 42 from the Commission decision on BC Hydro's 2008 LTAP.

3 The Total Resource Cost Test benefit-cost ratio for the Low Income program includes a 40 per cent adder to program benefits, rather than a 15 per cent value for non-energy benefits, in accordance with the DSM Regulation.

4 Mitigation Measures

Based on the experience gathered over the past few years through initiative tracking, the following are mitigation measures that have been undertaken or are planned for the future.

Codes and Standards	
Residential	Cumulative electricity savings in F2017 were approximately on plan.
Commercial	
Industrial	
Rate Structures	
Residential Inclining Block	Cumulative electricity savings in F2017 were on plan.
General Service Rate	No further conservation is forecast from the general service rate
Industrial Transmission	Cumulative electricity savings in F2017 were above plan.
DSM Programs	
Residential Sector	
Behaviour	Cumulative electricity savings in F2017 were on plan. After the success of offering a credit on customer bills as an option for receiving rebates, we are also exploring email money transfers as a means of eliminating cheques altogether as a cost saving measure.
Refrigerator Buy-Back	Cumulative electricity savings in F2017 were on plan. The program has ended per the new DSM Plan in the F2017-F2019 RRA.
Low Income	Cumulative electricity savings in F2017 were above plan. A new strategy we implemented in F2017 was using the call centre credit queue as a proactive channel for promoting the program to customers that are having bill payment issues.
New Home	Cumulative electricity savings in F2017 were on plan. The program has ended per the new DSM Plan in the F2017-F2019 RRA.
Retail	Cumulative electricity savings in F2017 were above plan. A new strategy we implemented in F2017 was a trial promotion of connected home devices through retail channel partners.
Home Energy Retrofit Offer	Cumulative electricity savings in F2017 were approximately on plan. We are working on a project that will improve data access, data analytics, customer processing time and enable creation of an online application form.
Commercial Sector	
Leaders in Energy Management - Commercial	Cumulative electricity savings in F2017 were below plan. The program has made adjustments such as streamlining the Business Energy Savings Incentive component of the program to make it easier for customers to participate and is expected to reach F2018 planned values.
New Construction	Cumulative electricity savings in F2017 were below plan. No mitigation measures are warranted as planned F2018 electricity savings are expected to be achieved based on anticipated project completions.

Industrial Sector	
Leaders in Energy Management - Transmission	Cumulative electricity savings in F2017 were above plan. New strategies that we worked on in F2017 are Energy Monitoring and Targeting systems that show energy savings from Strategic Energy Management (SEM) initiatives at the site; a Compressed Air Optimization pilot to determine if a combination of metering and system audits could result in sustained operational savings from optimizing compressed air systems; as well as launching an offer focused on smaller industrial Key Accounts who have not had access to SEM programs in the past.
Thermo-Mechanical Pulping	Cumulative electricity savings in F2017 were on plan.
Leaders in Energy Management – Distribution	Cumulative electricity savings in F2017 were approximately on plan. New strategies that we worked on in F2017 were the same as Leaders in Energy Management – Transmission and also included Strategic Energy Management Operational Energy Analytics that focused on customers and association members without access to Key Account Managers.
Load Displacement	Cumulative electricity savings in F2017 were below plan. The program has ended per the new DSM Plan in the F2017-F2019 RRA.
Capacity Focused DSM	No capacity savings were planned in F2017 as these are pilot initiatives.

5 Operating Expenditures for Fiscal 2017

BC Hydro's DSM operating expenditures in F2017 totalled $588,642.[3] Table 6 presents DSM operating expenditures in F2017.

Table 6 Operating Expenditures for F2017

	($000)
Labour	482
Consultants/Contractors/Temp Labour	8
Other	98
Total	**589**

6 Allocation of Supporting Initiative Costs to Programs

This section describes how supporting initiative costs are allocated to programs for the purpose of cost test calculations.

In accordance with Directive 61 from the Commission decision on the F05/F06 RRA, when calculating levelized costs and benefit cost ratios for this report, supporting initiative costs are allocated to DSM programs and rate structures based on their share of DSM electricity savings. F2025 has been used as the year for energy savings allocation. As an example, rate structures and programs are forecast to save roughly 530 GWh/year in F2025, so a program that is forecast to save 5.3 GWh/year in F2025

[3] DSM operating expenditures are not included in earlier tables.

represents 1 per cent of the total. In turn, 1 per cent of supporting initiative costs would be allocated to that program in each year when calculating the program's levelized cost or benefit cost ratio.

Enclosure (1)

Report on Demand-Side Management Activities for Fiscal 2018

July 11, 2018

Table of Contents

List of Tables

1 Introduction

This BC Hydro annual report to the British Columbia Utilities Commission (**BCUC or Commission**) on Demand-Side Management (**DSM**) activities provides information on DSM expenditures, electricity savings, plan performance and mitigation measures for the 2018 fiscal year, which is the twelve months ending March 31, 2018. This annual report is filed in compliance with the following Commission Directives:

- Directive 69 from the Commission Decision on BC Hydro's Fiscal 2005 – Fiscal 2006 Revenue Requirements Application (**F05-F06 RRA**);
- Directive 16 from the Commission Decision on BC Hydro's 2006 Integrated Electricity Plan and Long Term Acquisition Plan (**2006 IEP/LTAP**);
- Directives 36 and 38 from the Commission decision on BC Hydro's 2008 LTAP; and
- Directive 23 from the Commission decision on BC Hydro's Fiscal 2017 – Fical 2019 Revenue Requirements Application (**F17-F19 RRA**).

Directive 69 of the F05-F06 RRA Decision directed BC Hydro "to provide information to the Commission for on-going review of Power Smart performance through:

- Executive Summaries of milestone evaluation reports and full final evaluation reports for each program;
- Semi-annual reports on DSM activities which, amongst others, will include:
  - ► detailed breakdown of OMA expenses related to support activities carried out within the Power Smart group and in other departments that support the Power Smart organization;
  - ► detailed description of the functions of portfolio level costs and how these costs are allocated to programs;
  - ► summaries of the overall performance of Power Smart with reference to program objectives; and

- variances of fiscal year budgeted and actual deferred capital expenditures and explanation of variances."

Directive 16 of the 2006 IEP/LTAP Decision directed BC Hydro "to continue to file reports on DSM performance as described in Directive 69 of the F05/F06 RRA Decision included in Order No. G-96-04 and to file its Semi Annual Demand-Side Management Reports in the same format as the June 2005 Report with the following enhancements:

Provide annual and cumulative totals since program inception;

(i) Express these values on a per unit basis; and

(ii) Provide the benefit to cost ratios for the three DSM tests."

Directive 36 of the 2006 IEP/LTAP Decision directed BC Hydro to switch from semi-annual to annual DSM performance reports. Directive 38 from the same Decision directed BC Hydro to include in these reports:

> "metrics for each initiative, achievements in relation to milestones, and description of past or planned mitigation measures where warranted. These mitigation measures should include shifting program resources and alternative supply options for each program. Ongoing DSM performance reporting should demonstrate how BC Hydro is continuously pursuing DSM and that specific programs are cost-effective."

BC Hydro files its evaluation reports pursuant to Directive 69 of the F05-F06 RRA Decision separately.

Directive 23 of the F17-F19 RRA Decision directs BC Hydro to "include a line item in BC Hydro's Annual Report on DSM Activities to reflect the NIA activities that are tracked separately."

This annual report addresses the balance of Directives 69 and 16, as well as Directives 36 and 38 of the 2006 IEP/LTAP Decision and Directive 23 of the F17-F19 RRA Decision.

2 Expenditures and Electricity Savings for Fiscal 2018

BC Hydro's DSM expenditures[1] in fiscal 2018 totalled $82.3 million while net incremental DSM electricity savings totalled 543 GWh/year. Expenditures were $37 million or 31 per cent below the Fiscal 2018 DSM Plan presented in BC Hydro's F17-F19 RRA. Overall, net incremental electricity savings as shown in Table 1 were 61 GWh/year or 13 per cent above the DSM Plan.

Table 1 presents planned and actual DSM expenditures and net incremental electricity in fiscal 2018.

[1] Comprising all DSM-related deferred operating expenditures. DSM operating expenditures are presented in Table 7 of this report.

Table 1 Expenditures and Net Incremental Electricity Savings for Fiscal 2018

	Expenditures[1]				Net Incremental Electricity Savings

Notes:

1. Including all DSM-related deferred operating expenditures that are relevant for DSM cost-effectiveness.
2. Plan figures are from BC Hydro's F17-F19 RRA, Appendix W with Thermo-Mechanical Pulp Plan adjustments from BCUC IR 2.314.3 and subsequent Compliance filing from April 27, 2018.
3. Reported savings from codes and standards and residential inclining block and general service rate structures are based on planned estimates as well as evaluated results.

The following corresponds to the information provided in Table 1 and are explanations for the above variances:

Codes and Standards	
Residential	Expenditures were approximately on plan. Electricity savings were above plan due to an adjustment of the assumed replacement rate for incandescent lamps under the General Service Lighting (**GSL**) regulation.
Commercial	
Industrial	
Rate Structures	
Residential Inclining Block Rate	Expenditures were approximately on plan. Electricity savings were above plan due to adjustments made to the conservation forecast to reflect an update to the inflation rate and relative residential sales between Tier 1 and Tier 2.
General Service Rate	No further conservation is forecast from the general service rate as BC Hydro has revised its conservation forecast to zero due to the outcomes of the fiscal 2014 LGS/MGS evaluation report.
Transmission Service Rate	Expenditures were below plan due to deferral of the planned Transmission Service Rate evaluation, deferral of planned consultation activities for phase two of the Rate Design Application and lower than expected utilization of engineering resources for energy Customer Base Line (CBL) adjustment and determination reviews. Net incremental electricity savings were below plan in fiscal 2018 because fiscal 2017 electricity savings were higher than planned.
DSM Programs	
Residential Sector	
Behaviour	Expenditures were below plan due primarily to delays in a planned IT enhancement project. Electricity savings were above plan due to higher than forecast participation in select portions of the program, resulting largely from a strong fourth quarter (Q4) promotional campaign.
Low Income	Expenditures and electricity savings were above plan due to higher than planned participation. This was largely due to a strong response to BC Hydro bill inserts as well as leads generated through the BC Hydro call centre that led to a significant increase in the number of Energy Saving Kits being sent to customers than planned.
Retail	Expenditures and electricity savings were above plan due to the success of the lighting campaigns with strong sales of LED lighting particularly multi-packs which provided more savings than planned.
Home Energy Retrofit Offer	Expenditures and electricity savings were approximately on plan.
Sector Enabling Activities	Expenditures were below plan due to planned activities being deferred or cancelled.
Commercial Sector	
Leaders in Energy Management - Commercial	Expenditures and electricity savings were below plan due to customer decisions to delay or cancel projects. Expenditures were also below plan due to projects requiring lower incentive levels than planned.
New Construction	Expenditures were approximately on plan and electricity savings were above plan due to fiscal 2017 delayed projects completing in fiscal 2018.
Sector Enabling Activities	Expenditures were below plan due to planned activities being deferred or cancelled.

Industrial Sector	
Leaders in Energy Management – Transmission	Expenditures were below plan due to a customer cancelling a large incentive project and self-funding the project instead while maintaining planned electricity savings . Electricity savings were above plan due to energy manager's identifying and implementing more energy savings opportunities attributable to strategic energy management practices.
Thermo-Mechanical Pulping	Expenditures and energy savings are below plan due to one project being delayed. Two projects are expected to complete in fiscal 2019 and two more in fiscal 2021.
Leaders in Energy Management – Distribution	Expenditures are below plan due to projects being cancelled or deferred by customers. Electricity savings were approximately on plan due to one large project exceeding its target.
Sector Enabling Activities	Expenditures were below plan due to planned activities being deferred or cancelled.
Total Programs	Expenditures were below plan primarily due to projects not completing as planned in the Thermo-Mechanical Pulping and Commercial Leaders in Energy Management programs. Electricity savings were below plan due to project delays in the Thermo-Mechanical Pulping program.
Supporting Initiatives	
Public Awareness	Expenditures were approximately on plan.
Indirect and Portfolio Enabling	Expenditures were below plan primarily due to lower volume of IT support and enhancements.
Capacity Focused DSM	Expenditures were below plan. Projects related to distributed energy resource management systems and localized capacity were rescheduled to later time periods than previously planned to reflect a slower ramp up.
Portfolio Total	Expenditures were below plan primarily due to projects not completing as planned in the Thermo-Mechanical Pulping program and Capacity Focused DSM. Electricity savings were above plan due to an adjustment of the assumed replacement rate for incandescent lamps under the GSL regulation.

3 Non-Integrated Area Activity

Non-Integrated Area (**NIA**) activity in fiscal 2018 includes pilot project initiatives and DSM program activity. Pilot initiative objectives and activities undertaken to support NIA customers in fiscal 2018 include the following:

- Support education and skills training to build energy literacy in the community
- Facilitate access to opportunity assessments and energy efficient upgrades for homes
- Support the development and implementation of energy efficient housing policy
- Support the development of community energy plans
- Pilot a targeted Low Income Offer for First Nations communities

In addition to the pilot project initiatives, BC Hydro's NIA program activities include the Behaviour, Low Income, Home Energy Retrofit Offer, Leaders in Energy Management Commercial and Leaders in Energy Management Distribution programs. NIA customer participation in general offers such as the Retail program is not tracked separately, and hence is not included here per Directive 23. Table 2 presents expenditures, new incremental electricity savings for BC Hydro's NIA that were tracked separately as well as benefit cost ratios and net levelized cost for fiscal 2018. NIA expenditures and electricity savings included in Table 2 are also included in Table 1 within the applicable initiatives.

Table 2 NIA Activity for Fiscal 2018

	Expenditures[1]	New Incremental Electricity Savings[2]	Benefit Cost Ratios[3]				Net Levelized
	Actual $	Actual kWh/yr	Utility Test	Total Resource Cost Test	Total Resource Cost Test as modified by DSM Regulation[4]	Ratepayer Impact Measure Test	Utility Cost ($/MWh)
DSM Program Activity	$46,918	169,081	6.6	5.0	5.8	1.9	45
Pilot Project Initiatives	$522,554	n/a	n/a	n/a	n/a	n/a	n/a

Notes:

[1] Including all DSM program incentives and pilot project expenditures tracked separately as well as an allocation of Low Income Program incentives.

[2] Including all new incremental electricity savings for DSM programs tracked separately.

[3] Long Run Marginal Cost (**LRMC**) is based on NIA generation costs. Also, all components required to calculate cost effectiveness are not tracked separately therefore assumptions were developed for additional utility costs and customer cost in order to calculate cost effectiveness.

[4] For the low income components included within DSM NIA Program Activity, the Total Resource Cost Test benefit cost ratio includes a 40 per cent adder to program benefits, rather than a 15 per cent value for non-energy benefits, in accordance with the DSM Regulation.

4 Expenditures to Date

BC Hydro's DSM expenditures from fiscal 2016 through fiscal 2018 totalled $324.9 million. Table 3 presents DSM expenditures from April 1, 2015 to March 31, 2018.

Table 3 Expenditures since Fiscal 2016

Notes:

[1] Reported savings for codes and standards and rates structures are based on planned estimates as well as evaluated results.

The cumulative portfolio DSM electricity savings from April 1, 2015 through March 31, 2018 have been achieved at an average net levelized utility cost of $5 per MWh. Table 5 presents net levelized utility cost that is calculated by subtracting capacity benefits from gross utility costs and then dividing the resulting net utility costs by electricity savings. A negative net levelized utility cost means that the subtracted capacity benefits exceed gross utility costs.

Table 5 Utility Cost of Electricity Savings: Fiscal 2016 to Fiscal 2018

Portfolio Total	**n/a**	**4.9**	**5.7**	**1.3**

Notes:

[1] In accordance with the DSM Regulation, the avoided cost of natural gas is valued at BC Hydro's LRMC of acquiring electricity generated from clean or renewable resources in B.C converted to $/gigajoule (**GJ**) in all time periods. Non-energy benefits are valued at 15 per cent of the energy and capacity benefits of electricity and natural gas.

[2] While subsection 4(6) of the DSM Regulation precludes the use of the Ratepayer Impact Measure Test in determining cost-effectiveness of a demand-side measure, this benefit-cost ratio is included in the table to comply with Directive 42 from the Commission decision on BC Hydro's 2008 LTAP.

[3] BC Hydro is not solely responsible for codes and standards savings, so this benefit-cost metric is not applicable.

[4] The Total Resource Cost Test benefit-cost ratio for the Low Income Program includes a 40 per cent adder to program benefits, rather than a 15 per cent value for non-energy benefits, in accordance with the DSM Regulation.

5 Mitigation Measures

Based on the experience gathered over the past few years through initiative tracking, the following are mitigation measures that have been undertaken or are planned for the future.

Codes and Standards	
Residential Commercial Industrial	Cumulative electricity savings in fiscal 2018 were below plan. Based on market data, it is expected that as incandescent lamps subject to the General Service Lighting regulation burn out they will continue to be replaced with efficient LED lamps that meet the regulation. Replacement rate assumption has been adjusted in plans moving forward.
Rate Structures	
Residential Inclining Block	Cumulative electricity savings in fiscal 2018 were above plan.
General Service Rate	No further conservation is forecast from the general service rate.
Industrial Transmission	Cumulative electricity savings in fiscal 2018 were above plan.
DSM Programs	
Residential Sector	
Behaviour	Cumulative electricity savings in fiscal 2018 were above plan. In fiscal 2019 the program is conducting a trial to test an application for mobile devices as a means of engaging customers more easily.
Refrigerator Buy-Back	Cumulative electricity savings in fiscal 2018 were on plan. The program has ended per the new DSM Plan in the F17-F19 RRA.
Low Income	Cumulative electricity savings in fiscal 2018 were above plan. In fiscal 2019 the program will focus on coordinating with the newly developed Crisis Fund as a means of reaching customers that have sought bill relief from BC Hydro and helping them to lower their bills in the future.
New Home	Cumulative electricity savings in fiscal 2018 were on plan. The program has ended per the new DSM Plan in the F17-F19 RRA.
Retail	Cumulative electricity savings in fiscal 2018 were above plan. In fiscal 2019 the program will begin offering email money transfers for those customers that do not opt for credit on bill, further reducing costs by eliminating cheques.
Home Energy Retrofit Offer	Cumulative electricity savings in fiscal 2018 were on plan. In fiscal 2018 the program launched an online application form, greatly improving the customer experience and reducing application processing and rebate payment times by more than half.
Commercial Sector	
Leaders in Energy Management - Commercial	Cumulative electricity savings in fiscal 2018 were below plan. The program is making adjustments such as incenting HVAC control measures, launching an offer focused on social housing for multi-unit residential buildings to implement energy conservation measures and having Business Energy Advisors work with small medium businesses in order to help reach fiscal 2019 planned values.
New Construction	Cumulative electricity savings in fiscal 2018 were approximately on plan. No mitigation measures are warranted as planned fiscal 2019 electricity savings are expected to be achieved based on anticipated project completions.

Industrial Sector	
Leaders in Energy Management - Transmission	Cumulative electricity savings in fiscal 2018 were above plan. Continued development in fiscal 2018 of savings directly associated with strategic energy management has resulted in increased savings in this area.
Thermo-Mechanical Pulping	Cumulative electricity savings in fiscal 2018 were below plan. No mitigation measures are warranted as delays in large projects are possible. Two projects are currently being implemented and expected to complete in fiscal 2019. The remaining two projects are still subject to delay but currently planned in fiscal 2021. BC Hydro is in contact with the customer to ensure the best information is available for planning purposes.
Leaders in Energy Management – Distribution	Cumulative electricity savings in fiscal 2018 were on plan. A new strategy that we worked on in fiscal 2018 is the introduction of the cohort energy manager targeting medium-sized firms that completed its first full year with three cohorts in progress. This initiative will begin to deliver electricity savings in fiscal 2019.
Load Displacement	Cumulative electricity savings in fiscal 2018 were below plan. The program has ended per the new DSM Plan in the F17-F19 RRA.
Capacity Focused DSM	No capacity savings were planned in fiscal 2018 as these are pilot initiatives.

6 Operating Expenditures for Fiscal 2018

BC Hydro's DSM operating expenditures in fiscal 2018 totalled $521,043.[2] Table 7 presents DSM operating expenditures in fiscal 2018.

Table 7 Operating Expenditures for Fiscal 2018

	($000)

Total	**521**

7 Allocation of Supporting Initiative Costs to Programs

This section describes how supporting initiative costs are allocated to programs for the purpose of cost test calculations.

In accordance with Directive 61 from the Commission decision on the F05-F06 RRA, when calculating levelized costs and benefit cost ratios for this report, supporting initiative costs are allocated to DSM programs and rate structures based on their share of DSM electricity savings. Fiscal 2025 has been used as the year for energy savings allocation. As an example, rate structures and programs are forecast to save roughly 700 GWh/year in fiscal 2025, so a program that is forecast to save 7 GWh/year in

[2] DSM operating expenditures are not included in earlier tables.

fiscal 2025 represents one per cent of the total. In turn, one per cent of supporting initiative costs would be allocated to that program in each year when calculating the program's levelized cost or benefit cost ratio.

Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Appendix AA

Demand-Side Management Measurement, Verification and Evaluation

Table of Contents

1 Introduction

Measurement and verification, and evaluation are the final steps in BC Hydro's process to refine our estimates of the impacts from demand-side management (**DSM**) initiatives. Impacts include electricity savings from energy conservation initiatives, peak demand reductions from capacity-focused initiatives and fossil fuel and greenhouse gas reductions and electricity consumption increases from low carbon electrification initiatives. Evaluation also identifies opportunities to improve DSM program effectiveness or efficiency.

This appendix provides an overview of BC Hydro's DSM measurement and verification, and evaluation activities, including their purpose and objectives, the principles that guide them, the types of activities undertaken and planned work in the two-year period of fiscal 2020 to fiscal 2021. It also provides an overview of the functions' organizational structure, how the work is delivered, and our oversight process.

2 Measurement and Verification

The objective of BC Hydro's measurement and verification activities is to verify energy impacts at the project level, and by doing so, support decisions on program management and rate structure implementation, program impact evaluations and customer satisfaction.

BC Hydro's measurement and verification activities are guided by six principles: Neutrality, Professional Standards, Qualified Practitioners, Specified Selection Criteria, Business Integration and Coordination.

Measurement and verification activities fall into three major categories: data collection, data analysis and the review of a selection of customer submissions under the Transmission Service Rate.

Data collection involves a variety of sources, including BC Hydro permanent or temporary metering, customer data systems and weather data providers.

The collected data is analyzed to estimate the energy impacts of a demand-side management project. Depending on the energy measures implemented, a variety of data analysis techniques can be used, including:

- Calculating the difference between pre- and post-retrofit energy consumption and then adjusting for differences in relevant variables such as production levels;
- Regression analysis of measured energy consumption against measured drivers of electricity consumption;
- Measuring hours of lighting use and then multiplying by changes in lighting fixture wattages; or
- Calibrated computer simulation modelling of a facility or end-use equipment.

BC Hydro's measurement and verification function also supports implementation of the Transmission Service Rate for large industrial customers. Measurement and verification staff review a selection of customer submissions under the Rate to determine if the customer's electricity savings estimate claimed seems reasonable and if the customer should be required to conduct measurement and verification activities to support their electricity savings estimate.

3 Evaluation

The purpose of the evaluation function is to refine estimates of DSM impacts and identify program improvements in a rigorous and neutral manner in support of DSM and Integrated Resource Plan (**IRP**) decisions, risk management, and stakeholder confidence.

The objectives of the evaluation function are as follows:

- Support DSM investment and IRP decisions by evaluating impacts of DSM initiatives;
- Support DSM program management decisions by identifying opportunities to improve programs; and
- Fulfill Commission directives and guidelines regarding the evaluation of DSM programs and initiatives.

Evaluation activities are guided by six principles: Neutrality, Professional Standards, Qualified Practitioners, Appropriate Coverage, Business Integration, and Coordination.

BC Hydro conducts both impact and process evaluations, and these two types of evaluations are defined below.

The purpose of an impact evaluation is to estimate the impacts attributable to a DSM initiative or from a change in the efficiency of certain products within a specific timeframe that includes a change in an energy efficiency code or standard.

Evaluated gross impacts quantify impacts realized among participating customers, without determining what share of those impacts is directly attributable to a DSM initiative. Common methods for evaluating gross impacts include analyzing data for a sample of projects and extrapolating the results to the population of projects, conducting billing analysis on the population of projects, or analyzing market changes for energy efficient products based on sales data or population surveys.

Evaluated net impacts quantify impacts that are attributable to a specific DSM initiative, such as a program or rate structure. Net impacts can be estimated directly through purposely designed evaluation methods using comparison groups or econometric modelling, or using survey techniques and analysis to inform free ridership and spillover adjustments that can be applied to estimates of evaluated gross impacts.

The purpose of a process evaluation is to identify program improvements that will increase program effectiveness or efficiency. Common methods for process evaluations include analysis of program tracking data and information collected through surveys and structured interviews.

Most impact evaluations also identify opportunities for program improvements in addition to identifying gross or net impacts of a DSM initiative.

The evaluation work plan is shown in the table below. It includes the list of planned evaluations and various data collection activities that provide inputs to evaluations.

4 Organizational Structure and Work Delivery

Measurement and verification, and evaluation are an integral part of demand-side management program and conservation rate implementation. The Measurement and Verification, and Evaluation departments are located within Conservation and Energy Management, BC Hydro's DSM business unit. This supports quality and value to BC Hydro by facilitating information exchange between internal clients and staff in Measurement and Verification, and Evaluation. Measurement and verification, and evaluation staff understand BC Hydro's DSM programs, initiatives and data and, as a result, deliver better quality evaluations to support our internal client needs. Similarly, internal clients are better able to understand objectives and results of measurement and verification, and evaluation activities due to their proximity to these functions.

Independence

The independence of the measurement and verification, and evaluation functions from other functions in Conservation and Energy Management is important and established through the organizational structure. The Measurement and Verification, and Evaluation departments are separate from, and have different managers than, the departments responsible for the development and management of DSM programs and initiatives. Independence of the measurement and verification, and evaluation functions is further maintained through the oversight processes described below.

Work Delivery

BC Hydro utilizes a mix of staff and contractors to deliver measurement and verification, and evaluation work.

In measurement and verification, BC Hydro staff do all annual work planning and data collection and the majority of planning, analysis, and report writing for individual measurement and verification projects. In some situations, customers may collect data from their facility control systems and provide it to BC Hydro for measurement and verification purposes. Contractors do a minority of the planning, analysis and report writing work, particularly when the analysis requires specialized skill such as energy simulation modelling or when the volume of work exceeds staff capacity.

In evaluation, BC Hydro staff do all annual work planning and the majority of planning, analysis, and report writing for individual evaluation projects. Contractors do the majority of data collection and a minority of analysis for individual evaluation projects. Contractors are relied upon for analysis particularly when simple analytical work would be a poor use of staff time given their expertise, or when the volume of analytical work exceeds staff capacity.

Over the three years of fiscal 2016 through fiscal 2018, staff labour, contractors and other categories respectively accounted for 68 per cent, 26 per cent and 5 per cent of our total costs for measurement and verification, and evaluation.

There are several reasons behind this division of labour between staff and contractors:

1. BC Hydro is a Crown corporation without an incentive mechanism that would make it profit from DSM impacts, and thus is not in a conflict of interest with

respect to the evaluation or measurement and verification of DSM impacts. Without a DSM incentive mechanism, BC Hydro does not profit from the over-estimation of DSM impacts. This is in contrast to a number of other jurisdictions in North America, including California, where electricity is delivered by investor-owned utilities with incentive mechanisms for DSM. In these jurisdictions, utilities are in a conflict of interest with respect to the evaluation or measurement and verification of DSM impacts, since evaluation results influence incentive payments to utilities for DSM. In many of these jurisdictions, the majority of measurement and verification, and evaluation work is outsourced to contractors;

2. Costs are lower due to our use of BC Hydro staff instead of contractors. Average hourly costs for measurement and verification, and evaluation contractors are close to twice that of equivalent BC Hydro staff;

3. Quality is higher due to our use of BC Hydro staff instead of contractors. As noted above, BC Hydro measurement and verification, and evaluation staff understand BC Hydro DSM initiatives and data and, as a result, deliver better quality evaluations to support our internal client needs; and

4. Privacy requirements prevent BC Hydro from using contractors for some evaluation work. In its handling of personal information, including electricity consumption and other data pertaining to residential customers, BC Hydro must comply with the *BC Freedom of Information and Protection of Privacy Act*. The Act requires BC Hydro to safeguard personal information and contains prohibitions on the storage and access of personal information outside Canada. BC is one of only two Canadian provinces with such prohibitions (the other being Nova Scotia). These prohibitions effectively mean that BC Hydro cannot outsource evaluation analytical work on residential DSM initiatives to contractors based in the United States without Canadian subsidiaries and data

servers. This is significant since the vast majority of DSM evaluation consulting firms in North America are based in the United States.

We believe the division of labour between staff and contractors strikes the right balance for BC Hydro’s needs. Relative to an alternative scenario with more work conducted by contractors, the current division of labour results in lower costs and higher quality, and, as noted above, independence of the measurement and verification, and evaluation functions is established through the organizational structure and maintained through the oversight process described below.

Oversight

In the interest of quality and independence, both measurement and verification, and evaluation have oversight processes to ensure that their products are neutral and align with industry practice.

For measurement and verification, the oversight process includes the following steps:

1. Measurement and verification results for complex projects are reviewed by an internal measurement and verification peer; and
2. A sample of measurement and verification reports are reviewed by an external measurement and verification advisor to ensure that they utilize appropriate methodologies and align with industry practice.

For evaluation, the oversight process includes the following steps:

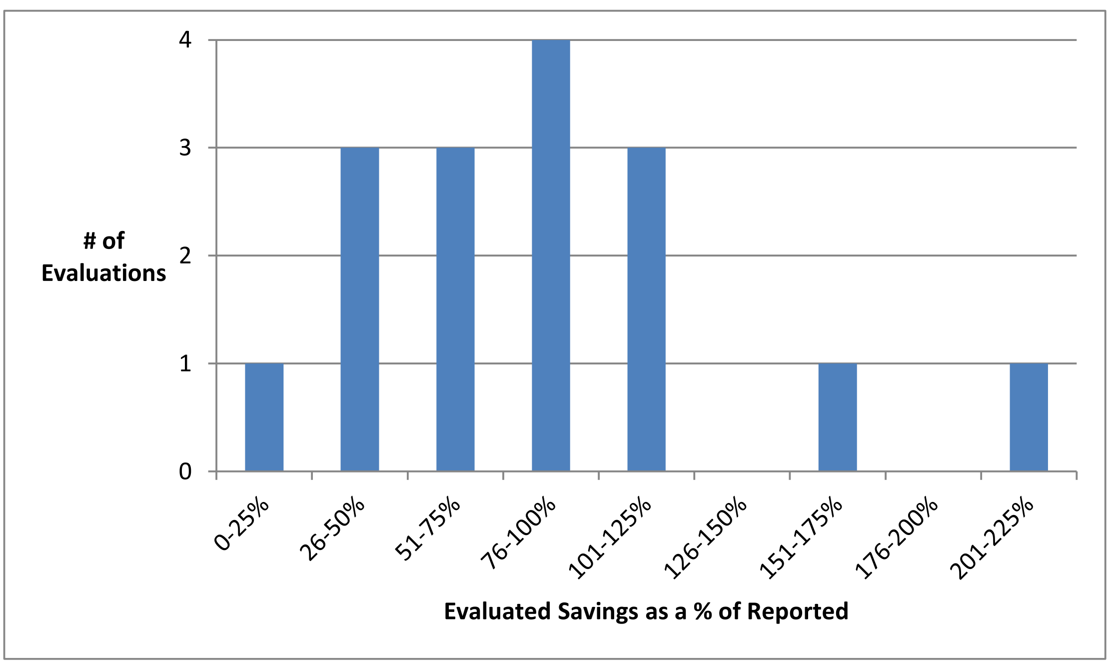
1. Evaluation plans and methodologies are reviewed by Evaluation management and evaluation peers. Evaluation plans involving new methodologies may also be reviewed by external evaluation advisors;
2. Draft evaluation reports are reviewed by two external evaluation advisors who ensure that BC Hydro evaluations utilize appropriate methodologies and align

with industry practice. Draft reports are also reviewed by Evaluation management, and evaluation results are reviewed by internal peers; and

3. Final evaluation reports are reviewed and subject to approval by an Evaluation Oversight Committee made up of BC Hydro staff representing business units with an interest in DSM and chaired by a staff person from outside the Conservation and Energy Management business unit. The external evaluation advisors participate in Evaluation Oversight Committee meetings and act as a resource to Committee members. The Evaluation Oversight Committee ensures that BC Hydro's DSM evaluations are objective, unbiased, and of sufficient quality.

Evaluation Results

The following histogram summarizes the results of 16 DSM impact evaluations conducted by BC Hydro over a five-year period from fiscal 2014 through fiscal 2018. Eleven of the 16 evaluations found electricity savings to be less than reported while five evaluations found electricity savings to be more than reported.



5 Annual Evaluation Reports to the Commission

In compliance with Directive 66 (page 197) of the Commission Decision dated October 29, 2004 on BC Hydro's Fiscal 2005 to Fiscal 2006 Revenue Requirements Application, BC Hydro submits an annual DSM Milestone Evaluation Summary Report to the Commission. Appendix AA includes the past two annual reports, covering fiscal 2017 and fiscal 2018.

Mr. Patrick Wruck
Commission Secretary and Manager
Regulatory Support
British Columbia Utilities Commission
Suite 410, 900 Howe Street
Vancouver, BC V6Z 2N3

Dear Mr. Wruck:

RE: British Columbia Utilities Commission (BCUC or Commission)
British Columbia Hydro and Power Authority (BC Hydro)
2004/05 and 2005/06 Revenue Requirements Application
Commission Decision: Order No. G-96-04, October 29, 2004, Directive 66 (page 197)

BC Hydro writes to submit its F2017 Demand Side Management Milestone Evaluation Summary Report (**the Report**), dated December 2017 in compliance with Directive 66 (page 197) of the Commission Decision dated October 29, 2004. Directive 66 directs BC Hydro to file the executive summaries of its milestone evaluation reports and full final evaluation reports for all its Power Smart programs. The Report summarizes the impact evaluations completed during F2017 for the following:

1. Residential Lighting: F2013-F2015 Q1;
2. Continuous Optimization: F2011-F2013;
3. High Performance Buildings and Commercial New Construction: F2008-F2011; and
4. Power Smart Partner - Transmission: F2012-F2014.

For further information, please contact Geoff Higgins at 604-623-4121 or by email at bchydroregulatorygroup@bchydro.com.

Yours sincerely,

Fred James
Chief Regulatory Officer

Demand Side Management Milestone Evaluation

Summary Report F2017

December 2017

This page left blank

December 2017

Table of Contents

1.0 Introduction

This report summarizes the milestone evaluations of demand-side management (**DSM**) initiatives completed by BC Hydro in fiscal year 2017 (**F2017**). It is filed in compliance with Directive 66 of the British Columbia Utilities Commission (**BCUC**) decision on BC Hydro's F05/F06 Revenue Requirements Application (dated October 29, 2004), which "*directs BC Hydro to file the executive summaries of its milestone evaluation reports and full final evaluation reports of all its Power Smart programs*" (page 197).

BC Hydro evaluates its DSM initiatives to improve its estimates of realized DSM electricity savings and to improve their effectiveness and efficiency.

DSM evaluation activities are guided by the following six principles:

- Objectivity and Neutrality: Evaluations are to be objective and neutral.
- Professional Standards: Evaluation work is guided by industry standards and protocols.
- Qualified Practitioners: BC Hydro employs qualified staff and consultants to conduct evaluations.
- Appropriate Coverage: BC Hydro strives to achieve defined coverage levels for its evaluation of DSM initiatives.
- Business Integration: The evaluation function is integrated into BC Hydro's DSM business process of planning, implementation, reporting and evaluation.
- Coordination: BC Hydro evaluation work is coordinated with FortisBC and other DSM partners where feasible.

BC Hydro DSM evaluations are subject to an independent oversight process to ensure that they are neutral and unbiased, of sufficient quality for their intended purposes, and consistent with industry standards and protocols.

1.1 Completed Evaluations

Impact evaluations summarized in this report include the following:

- Residential Lighting: F2013-F2015 Q1;
- Continuous Optimization: F2011-F2013;
- High Performance Buildings and Commercial New Construction: F2008-F2011; and
- Power Smart Partner - Transmission: F2012-F2014.

2.0 Residential Lighting: F2013-F2015 (Q1)

2.1 Introduction

The impacts and effects of BC Hydro's Residential Lighting program were evaluated for the period April 2012 through June 2014 (F2013 through the first quarter of F2015). Prior to June 2014 the program was dedicated only to residential lighting. After June, residential lighting became one component of a larger Retail Program that included a range of residential consumer products, including lighting. Prior evaluations of the Residential Lighting Program covered the period up to F2012.

The objectives of the Residential Lighting program included: (1) sustain and increase a greater market share of energy-efficient lighting in advance of regulations for more efficient lighting; (2) promote efficient lighting products not covered by regulations and newer products such as Light Emitting Diodes (**LEDs**); (3) promote and increase awareness of efficient lighting products province-wide and drive customers to retailers to purchase efficient products; and (4) provide residents province-wide with an accessible and simple lighting program.

The Residential Lighting program was first launched in 2002 and operated continuously from then until June 2014. The Residential Lighting program was initially launched as a Compact Florescent Lamps (**CFL**) pilot initiative in three communities. Bulk CFL purchases were made by BC Hydro and distributed free to customers using redeemable coupons at retail partners. The CFL pilot was later expanded to additional regions, and to include incentive coupons to encourage customers to purchase CFL torchieres rather than halogen torchieres. In October 2004 the program launched a province-wide fall campaign that focused on CFLs, seasonal LEDs and CFL torchieres. The program continued to update its product mix over the years that followed to reflect market changes. In June 2007, the program transitioned from spiral CFLs to specialty CFLs. Specialty CFLs continued to be promoted until 2013. From July 2011 to the end of the evaluation period, the program focused primarily on promoting LED lamps. CFL and LED fixtures that complied with the ENERGY STAR labelling program were also promoted. Instant in-store discounts and manufacturer buy-downs continued to be offered during time limited campaigns that ran in spring and fall. New major retail partners were added to increase market penetration of energy-efficient lighting technologies.

The program has provided retailer education for the residential lighting market since its inception. Retailer partnerships continued to be a key component of the Residential Lighting program over the period evaluated.

BC Hydro's service territory covers approximately 1.7 million residential accounts. Over the period evaluated, the program provided rebates for almost 800,000 lighting units, of which over 500,000 were LED lamps.

2.2 *Approach*

Four evaluation objectives were identified, each with specific researchable questions, as summarized in the following table:

Table 2.1. Evaluation Objectives and Research Questions

Objectives	Research Questions
1. Program effectiveness	• How did BC Hydro customer awareness, purchases, and promotion recall levels for energy-efficient lighting products compare to similar customers with a less extensive residential lighting program? • How satisfied were BC Hydro residential customers with CFL and LED lamps? • What were program participants' perceptions of program influence on their purchase decisions and their intended actions in the absence of the program? • How effective was the program in influencing retail partners' purchase and stocking decisions? • How influential was the program in encouraging retail partners to sell more energy-efficient products? • How satisfied were retail partners with the program?
2. Market trends	• What were trends in pricing and shelf space shares for lamps and fixtures? • What were trends in lamps in BC Hydro residential customer homes?
3. Evaluated gross unit electricity savings	• What were the hours of use for lamps and fixtures? • What was the peak coincidence of lamps and fixtures? • What was the power draw of the energy-efficient and baseline lighting products? • What was the installation rate for the various lighting types? • What were the unit energy savings per lighting product incented by the program?
4. Evaluated net electricity savings	• What was the free rider rate? • What was the spillover and market effects rate? • What were net energy and peak savings by lighting product type? • What were the annual, incremental evaluated savings for the program overall and how did they compare to reported savings? • What were the sources of any variances between evaluated and reported savings?

Table 2.2 summarizes, for each of the evaluation objectives, the evaluation data and methods used.

Table 2.2. Evaluation Objectives, Data and Methods

Objectives	Data sources	Method
1. Program effectiveness	• 2012 BC Hydro Residential Customer Survey (n = 601) • 2012 Comparison group survey (n = 450) • 2012, 2013, 2014 Retail Partners Surveys (n = 9, 8, 5) • • 2014 Lighting Program participant survey (n = 80)	• Cross tabulations • Trend analysis • Z-tests
2. Market trends and effects	• Annual Household Lighting Shelf Space Study from 2001 to 2014 (~ 40 stores per year) • BC Hydro residential end use surveys from 1998 to 2014 (n = 4,248 to 7,604 depending on year)	• Cross tabulations • Trend analysis
3. Evaluated gross unit electricity savings	• Program tracking data • 2010 Residential monitoring study (n = 292 lighting points) • Sales data from participating retailers • 2014 Lighting Program participant survey (n = 80) • BC Hydro Standard Procedure: Cross Effects	• Engineering algorithms • Load Shape analysis
4. Evaluated net electricity savings	• Results of objective 3 • Sales data from participating retailers • 2012 BC Hydro Residential Customer Survey (n = 602) • 2012 Comparison group surveys (n = 450) • 2014 Lighting Program participant survey (n = 80) • BC Hydro Standard Procedure: Cross Effects	• Market data analysis • Cross tabulation

2.3 Results

Results for Objective 1: Program Effectiveness

Program effectiveness was assessed using a set of residential customer surveys delivered in 2012. BC Hydro and comparison group customers had similar awareness levels for all lighting products with the exception of LED lamps. Awareness levels for LED lamps were greater for BC Hydro residential customers than for comparison group customers (73 per cent vs 66 per cent awareness, respectively) and this difference was highly statistically significant.

BC Hydro residential customers and comparison group customers were asked if they had purchased various lighting products over the past year. A greater share of BC Hydro customers had purchased halogen and LED lamps than did comparison group customers, and these differences were highly statistically significant. A lesser share of BC Hydro customers purchased incandescent lamps than did comparison group customers, and this difference was also statistically significant. BC Hydro residential customers and comparison group customers who indicated that they had purchased a particular lighting product over the past year were then asked how many they purchased. BC Hydro customers who purchased LED lamps purchased a greater number of them than did comparison group customers who purchased LED lamps (averages of eight versus five lamps, respectively). BC Hydro customers who purchased incandescent lamps purchased fewer than did comparison group customers who purchased such lamps (averages of eight versus 11 lamps, respectively).

The program's effectiveness in promoting energy-efficient product sales was examined by comparing recall of information, advertising or promotions between the treatment group and the comparison group. Recall of related promotions was higher for both CFL and LED lamps among BC Hydro customers than among comparison group customers and the differences were highly statistically significant.

BC Hydro customers reported high levels of satisfaction with LED lamps, with 92 per cent of respondents reporting being somewhat or very satisfied with them. Satisfaction levels were more mixed for specialty CFLs – with 72 per cent of respondents reporting being somewhat or very satisfied with them and 19 per cent reporting being somewhat or very dissatisfied.

Households identified as having purchased BC Hydro discounted bulbs and fixtures during the lighting campaigns were queried as to their likelihood of purchasing the units had the discount not been available. For households that purchased LEDs during the fall 2012 campaign, 55 per cent believed that they either 'definitely would have' or 'probably would have' purchased the bulbs anyway had the discount not been available. For households that purchased LEDs during the spring 2014 campaign, 61 per cent believed they 'would have purchased at least some of the bulbs anyway' had the discount not been available.

Retail partners were asked about their satisfaction with the program in each of the three years of the evaluation period. Satisfaction levels were high in each of F2013 and F2014, but declined to moderate levels in F2015.

Retail partners were also asked about the influence of the program on sales of energy-efficient lighting products. Retail partners rated the program as being more influential on sales of energy-efficient lighting products in F2013 and F2014 than they did in F2015. Retail partners viewed the program as being more influential on sales of energy-efficient lamps than on sales of energy-efficient lighting fixtures.

Results for Objective 2: Market Trends

Over the evaluation period, incandescent lamps had the largest shelf space share among residential lighting product retailers, ranging from 34 per cent to 38 per cent. CFL lamp shelf space share declined from 25 per cent to 20 per cent, while LED lamps shelf space share increased from 10 per cent in 2012 to

17 per cent in 2014. Shelf space devoted to ENERGY STAR fixtures appeared to be modest at between 4 and 7 per cent.

LED lamp prices declined from an average of $22.22 in 2012 to $16.12 by 2014. Prices for other lamp types were stable or exhibited no ongoing trend, while prices for fixtures increased.

Between 2002 (when the residential lighting program began) and 2014 the total number of lamps installed in BC Hydro residential customer homes increased from an average of 33 to 38. Over the same period, the average number of incandescent lamps per household in BC Hydro's service territory dropped from 24 to 16, while the average number of efficient lamps (CFL or LED) increased from one to 13.

Between 2012 and June 2014 (within the period covered by this evaluation), the total number of lamps installed in BC Hydro residential customer homes remained stable at 38. The average number incandescent lamps dropped from 17 to 16 per home, while the average number of LED lamps increased from one to three lamps per home. The number of CFL lamps was steady at an average of ten per home.

Results for Objectives 3: Evaluated Gross Unit Electricity Savings

Evaluated gross unit electrical savings are presented below for each of the four lighting product types rebated through the program over the evaluation period.

Table 2.3. Evaluated Gross Unit Savings

	Efficient Power Draw (Watts)	Baseline Power Draw (Watts)	Power Savings (Watts)	Annual hours	Peak Coincidence	(1 – cross effects)	Installation rate	Evaluated Gross Unit Energy Savings (kWh/yr)	Evaluated Gross Unit Peak Demand Savings (W)
	A	B	C = B - A	D	E	F	G	H = (C*D*F*G)/ 1,000	I = C*E*F*G
Specialty CFL lamps	16	54	39	934	0.31	0.95	0.76	26	9
LED lamps	10	54	45	934	0.31	0.94	0.79	31	10
LED fixtures	11	54	43	934	0.31	0.94	0.94	35	12
CFL fixtures	25	103	78	934	0.31	0.97	0.94	67	22

Free Ridership and Market Effects

Free ridership by lighting product type is presented below.

Table 2.4. Evaluated Free Ridership

	F2013 (%)	F2014 (%)	F2015 (%)
Specialty CFL lamps	58	58	N/A
LED lamps	9	9	39
LED fixtures	23	30	60
CFL fixtures	80	80	90

By analyzing differences between BC Hydro and comparison group customers, an overall estimate of the net effects of the program was developed for LED lamps and specialty CFL lamps, inclusive of market effects across the entire BC Hydro service territory. Due to limitations in the Dakotas as a representative comparison group for BC Hydro customers, the level of uncertainty associated with this estimate of the program's net effects is higher than the uncertainty associated with the free ridership estimate alone. An estimate of market effects could not be produced for ENERGY STAR fixtures.

The net-to-gross ratio inclusive of market effects was 477 per cent for LED lamps for F2013 and F2014. This result indicates that the program played an important role in accelerating awareness, purchase and installation of LED lamps across BC Hydro's service territory. Evidence presented in this evaluation indicates that the LED market is changing rapidly. As such, the market effects observed in the evaluation period may not be applicable to future periods.

The net-to-gross ratio inclusive of market effects was zero for specialty CFL lamps. The program provided rebates for specialty CFL lamps in the first part of the evaluation period only, and discontinued the offer in F2014. One explanation of an overall net-to-gross ratio of zero may be that program promotional efforts influenced customers to purchase LED lamps, instead of CFL lamps, outside the campaign period.

Results for Objectives 4: Evaluated Net Electricity Savings

The evaluated and reported net savings by year is shown below. Evaluated savings are incremental annual saving, adjusted for the fact that not all lighting products are immediately installed.

Table 2.5. Reported and Evaluated Net Energy and Peak Savings

	Energy Savings (GWh/year)			Peak Demand Savings (MW)		
	Reported	Evaluated Net Direct	Evaluated Net with Market Effects	Reported	Evaluated Net Direct	Evaluated Net with Market Effects
F2013	14.6	8.2	30.2	5.2	2.7	10.0
F2014	6.6	5.5	25.0	2.4	1.8	8.3
F2015 First Quarter	4.9	3.1	3.1	1.8	1.0	1.0
Total	**26.1**	**16.7**	**58.4**	**9.3**	**5.6**	**19.4**

Evaluated net direct savings are estimated based on the number of rebated products, the evaluated gross unit savings per lighting product, and the evaluated free ridership estimate. The level of uncertainty associated with the evaluated net direct savings is low. Evaluated net direct savings are lower than reported savings because evaluated free ridership was higher than was assumed in reported savings, and because evaluated savings include an installation rate adjustment to account for the fact that some rebated lighting products were placed in storage, whereas reported savings do not include an installation rate adjustment.

Evaluated net savings with market effects are estimated in the same manner as evaluated net direct savings for ENERGY STAR fixtures. For LED lamps and specialty CFL lamps, evaluated net savings with market effects reflect the program's impact across the entire BC Hydro service territory, and they likely include the effects of program efforts promoting LED lamps in the year prior to the evaluation period. The level of uncertainty associated with evaluated net savings with market effects is high. Evaluated net savings with market effects are higher than reported savings and evaluated net direct effects because of market effects for LED lamps.

2.4 Findings and Recommendations

Findings

1. BC Hydro's residential lighting program provided rebates for almost 800,000 lighting units over the period evaluated, of which over 500,000 were for LED lamps.
2. Over the evaluation period, the average number of LED lamps installed in BC Hydro residential customer homes more than doubled from an average of one to three lamps per home. The retailer shelf space share dedicated to LED lamps increased from 10 per cent to 17 per cent while average LED prices declined from $22.22 to $16.12.
3. BC Hydro customers had higher levels of LED lamp awareness, share of customers purchasing LED lamps, and number of LED lamps purchased relative to comparable residential customers with a less extensive residential lighting program.
4. BC Hydro customers reported high satisfaction with LED lamps, and mixed satisfaction with specialty CFL lamps.
5. The majority of BC Hydro residential customers reported that the lighting program was influential in their purchase of energy-efficient lamps.
6. Retail partner satisfaction with the program was high in F2013 and F2014, but modest in F2015. Retail partners indicated that the program was more influential on sales of energy-efficient lighting products in the earlier part of the evaluation period than the later part.
7. The reliability of gross evaluated savings would be improved with additional data on the wattage of rebated lamps and an updated metering study of lighting hours-of-use and load shape among BC Hydro residential customers. The reliability of the net-to-gross ratio would be improved with additional data on the sales of lighting products throughout the entire year.
8. The net-to-gross ratio for LED lamps including market effects was 477 per cent for F2013 and F2014. The net-to-gross ratio for specialty CFL lamps including market effects was zero. These results indicate that the program accelerated adoption of LED lamps, and that the market for CFL lamps has now matured. The net-to-gross ratio for LED lamps including market effects is not applicable past F2014.
9. High levels of free ridership were measured for LED and CFL fixtures by analyzing differences in sales. However, evidence suggests that high free ridership may be more reflective of low levels of sales of energy efficient fixtures overall, as opposed to high levels of natural conservation. Only 33 per cent of BC Hydro customers were aware of ENERGY STAR fixtures and only 2 per cent reported purchasing one.
10. Evaluated net savings including market effects over the evaluation period were 58.4 GWh/year, while reported savings were 26.1 GWh/year respectively. The main source of variance was the large evaluated estimate of market effects for LED lamps in F2013 and F2015. Lesser sources of variance were the installation rate and unit power savings.

Recommendations

Recommendations one through four are for program management, while recommendation five is for Evaluation.

1. To improve the quality and reduce the cost of future evaluations, request data on the numbers and descriptions of all lighting products sold in each month of the year, from all retail partners.
2. Given that some lamps purchased with program assistance are temporarily placed in storage, consider applying an installation rate adjustment to reported savings in periods that have yet to be evaluated.
3. The ENERGY STAR fixture offer appears to be in the early adopter stage. Relatively few residential customers were aware of, or had purchased, these fixtures. To accelerate adoption, consider reviewing the approach used to promote ENERGY STAR fixtures.
4. The evaluated estimate of market effects due to program efforts on LED lamps may reflect an acceleration of the LED market and may therefore be transitory. It is not recommended that the market effects estimate presented in this evaluation be applied as is to forecast or reported program savings beyond F2014.
5. Consider the need for and costs of an updated lighting load shape and hours-of-use metering study of BC Hydro customers.

2.5 Conclusions

From F2013 to the end of the first quarter of F2015, BC Hydro's residential lighting program saved 58.4 GWh/year of electric energy, mostly due to LED lamps. Since its inception in 2002, the program has had widespread effects on the residential lighting market in BC Hydro's service territory, resulting in an increase in awareness, installations and purchases of energy-efficient lighting products.

3.0 Continuous Optimization F2011-F2013

3.1 Introduction

Section 3.0 presents an impact evaluation of electricity savings due to BC Hydro's Continuous Optimization (**C.Op**) demand side management (**DSM**) program for fiscal years F2011 to F2013 (from April 1, 2010 through March 31, 2013). This evaluation also includes elements of a process and market evaluation.

The Continuous Optimization program began in 2009 to help commercial building owners and operators implement and maintain improvements to their energy management practices. The key focus of the program is operational conservation measures, which are often referred to as "low/no-cost" because implementation does not require the purchase and installation of new equipment, and costs are generally limited to labour. The conservation potential for operational savings in a commercial building is largely tied to improving the performance of the building's heating, ventilation and air conditioning (**HVAC**) systems, as well as lighting and refrigeration systems.

Program access was available to commercial buildings larger than 50,000 square feet and since 2010, over 500 buildings enrolled in the program, with the majority of these buildings continuing through the program stages and components further described below. Program participants have been diverse, including the following commercial segments: offices, retail, healthcare, education, hospitality and recreation. As of September 2013, the program had reached its participation goals with an estimated 35 per cent of the eligible buildings participating. The program was then considered fully subscribed and no longer accepting new applications.

The program consisted of two primary components which were fully funded by the program:
1) recommissioning the building and 2) installing an Energy Management Information System (**EMIS**).

In the recommissioning component, consultants worked with customers to identify and implement energy conservation measures, and customers were required to implement the recommended measures with simple paybacks under two years. Each customer engagement lasted up to five years, requiring ongoing customer interaction, document reviews and administration. The main steps of the recommissioning component were: studying the building, recommending low- or no-cost energy efficiency improvements, reviewing the energy conservation measures with operations staff, implementing measures, validating implementation of measures through site inspections, and conducting follow-up coaching sessions to ensure energy savings continue.

The EMIS component was an energy information tool that took interval data from the customer's whole building meter and provided analysis and reporting on the building's energy use. If the customer's utility meter measured the consumption of the whole building, BC Hydro upgraded the meter to a pulse output meter at no cost to provide the interval data. Where the utility meter did not provide whole building data, such as with large university campuses, the customer was obligated to provide their own meters to provide the interval data. The EMIS vendors then installed the EMIS and configured it to provide information allowing building operators to identify processes that had a substantial impact on energy consumption and provided a good opportunity for energy savings. The original program intent was to use the EMIS functionality for quantifying energy savings, exception reporting (a "heads up" when building consumption is unexpectedly high), load profiles, benchmarking, and billing analysis.

3.2 Approach

Four evaluation objectives were identified, each with specific researchable questions, as summarized in the following table:

Table 3. 1. Evaluation Objectives and Research Questions

Evaluation Objective	Research Questions
1. Assess program participation and energy conservation measures	• What were the most common types of participating buildings? • What were the most commonly implemented recommissioning measures? • What were the implementation rates of the various recommended measures? • How did implemented measures perform relative to expectations?
2. Understand the participant experience	• How aware are participants of key program components? • To what extent do participants' understandings of the purpose and operation of key program components match their actual purpose and operation? • How early following program enrolment did participants start to implement recommissioning measures? • What is the qualitative assessment of free ridership?[1] • To what extent did participants implement recommissioning measures at buildings that were not enrolled in the program (participant spillover)? • To what extent did participants implement hard-wired energy conservation measures as a result of the program?
3. Explore market effects and program influence	• To what extent did the number of active EMIS customers change? • What were the noticeable changes to building operating practices? • What evidence exists regarding the extent to which the above changes would have occurred in the absence of the program? • To what extent did implementation of EMIS systems and/or recommissioning studies occur outside the program?
4. Estimate net savings	• What are net electric energy savings? • What are net peak demand savings? • What is the approximate profile of energy savings during the BC Hydro system peak? • Do energy savings vary by season? • What evidence is available on savings persistence?

Table 3.2 summarizes, for each of the evaluation objectives, the evaluation data and methods used.

Table 3.2. Evaluation Objectives, Data Sources and Methods

Evaluation Objectives	Data	Method
1. Assess program participation and energy conservation measures	• Program tracking data • Project files • Measurement and Verification (**M&V**) reports	• Engineering desk review • Trends analysis
2. Understand the participant experience	• Participant interviews (22 organizations interviewed)	• Qualitative analysis
3. Explore market effects and program influence	• EMIS Vendor Interviews (3 organizations interviewed) • Recommissioning consultant interviews (5 organizations interviewed)	• Qualitative analysis
4. Estimate net savings	• EMIS hourly electricity data during F10-F15 • Program tracking data • Hourly weather data	• Quasi-experimental design: Variation in Adoption; ANCOVA statistical analysis

[1] A quantitative assessment of free ridership was not completed because the evaluation method used in Objective 4 to estimate net savings produces a direct estimate of net savings accounting for any free ridership. As a result there was no business need for a stand-alone free ridership estimate.

The first objective, related to assessing program participation and energy conservation measures, was completed using engineering desk reviews and trend analysis using three data sources: program tracking data, project files and M&V reports.

The second and third objectives, related to understanding the participant experience and exploring market effects and program influence, were addressed with qualitative research in the form of semi-structured interviews with program participants, recommissioning consultants and EMIS vendors. The twenty two participant interviewees represented 340 buildings that were enrolled in the program. The three EMIS vendors who were interviewed represented all EMIS vendors involved in the program. The five recommissioning consultants interviewed were estimated to have to have provided C.Op services to over 200 buildings that were enrolled in the program. The interviews lasted 45 to 90 minutes each, were conducted from January through March 2016 either in-person or via telephone.

The fourth objective, related to net savings, was addressed by conducting a statistical analysis of the 433 participating buildings for which quality data were available. The analysis involved five steps: 1) obtain hourly consumption and program tracking data and prepare it for analysis, 2) group the buildings by load shape, 3) set up a quasi-experiment, 4) model program effects, and 5) calculate net electricity savings. This evaluation method produces a reliable estimate of average net savings per participant. Note that the use of the EMIS modelling functionality, as well as the completion of a representative sample of M&V, were both considered for the evaluation of net savings, but were abandoned due to the cost and time involved in implementing these methods.

The method for estimating net electric energy savings was used to provide some insights into savings persistence, the average daily shape of savings and savings seasonality. Peak demand savings were calculated using the evaluated savings shape.

3.3 Results

Results for Objective 1: Program Participation and Energy Conservation Measures

Program tracking data for F2011 to F2013 revealed that four customer segments accounted for over 80 per cent of participating buildings and 77 per cent of expected savings: universities/colleges, offices, schools and hospitals. Buildings participating in the program achieved energy savings by implementing energy conservation measures related to building operations, with the most common being: reduction in excessive equipment operation (38 per cent of total measures implemented), building systems controls optimization (18 per cent) and equipment load reduction or efficiency increase (15 per cent). The majority of the energy conservation measures focused on four building systems: ventilation (67 per cent), lighting (11 per cent), boiler plants (9 per cent) and chiller plants (6 per cent).

Overall, 75 per cent of all energy conservation measures recommended by the recommissioning consultants were implemented at participating buildings. Energy conservation measures with implementation rates of 70 per cent or higher commonly involved changes to building management systems and, as such, aligned with the program intent to promote implementation of operational measures. Energy conservation measures with lower implementation rates commonly had higher capital costs and, as such, did not align with the program intent to target operational measures, but their recommendation by recommissioning consultants was not discouraged.

One of the program goals was to use the EMIS functionality for quantifying energy savings to measure savings for the program overall. That goal was ultimately not achieved because collecting and maintaining the required data was challenging for some participating buildings, and completing the required detailed investigation to validate the EMIS savings estimates was costly and slow. The EMIS did measure savings in some buildings as intended.

Ten of the buildings were selected for a detailed investigation of energy savings, using M&V. These ten buildings were selected because they appeared to have the appropriate conditions for successful application of M&V. These ten buildings are not representative of all buildings in the program and results of their M&V were not used in the estimation of net program savings presented in this evaluation. Verified savings for the ten buildings were compared to the expected savings developed by the recommissioning consultant. Across the 10 projects, the median of verified savings was 82 per cent of expected savings.

Results for Objective 2: Understand the Participant Experience

In general, there was a high level of awareness and understanding of the program among participants. Participants generally understood most of the key program milestones, and their understanding of program components generally matched the actual purpose and operation of those components. However, there was a greater range in the understanding of the role of the coaching phase, particularly between recommissioning consultants and participating customers. Experience with the individual program milestones was generally positive with the exception of the coaching phase where feedback varied widely. Overall satisfaction with the program was high with participants, consultants and EMIS vendors all reporting a very positive experience with the C.Op program.

The qualitative research suggests that minimal free ridership occurred in the C.Op program. Participants reported that little to no recommissioning measures would have been implemented without the program's support. Likewise, the recommissioning consultants reported minimal recommissioning activity before the program and minimal activity outside of the program during its operation. Although the incidence of spillover was noted to be widespread among participants and by consultants, it typically occurred at buildings that were too small to participate in C.Op or were located in regions outside B.C. (among national chains), suggesting the magnitude of spillover from this particular program within B.C. was generally small.

Results for Objective 3: Explore Market Effects and Program Influence

Multiple participants highlighted the importance of C.Op in increasing building operators' awareness of the performance of their facilities, and that checking performance with EMIS was now part of the operators' weekly activities. Many participants also noted that positive organizational changes had occurred as a result of participation, such as providing the structure for Energy Managers to work more closely with building operational staff. The EMIS also provided a tool to communicate energy performance to operators and senior managers, increasing their awareness of energy conservation and interest in making further improvements. However, there was significant variation in the reported level of engagement by operational staff.

Only a few participants owned or were even aware of the existence of EMIS prior to participation in C.Op. The EMIS vendors reported that the market for EMIS grew significantly in B.C. from the beginning of the C.Op program up to 2012 after which it plateaued, and they attributed this growth to the C.Op program. All consultants were of the opinion that there was limited recommissioning before C.Op and the market developed rapidly for recommissioning services while C.Op was in place, with the majority of this growth directly from C.Op participation. Participants expressed some uncertainty about their organizations' willingness to pay for an EMIS or for recommissioning consultants without utility funding.

Results for Objective 4: Estimate Net Savings

Results for electric energy and peak demand savings are summarized below. Results are cumulative. This means that the annual savings results include any savings achieved in earlier years that continue to persist. Values presented in the rows of the table below should not be summed.

Table 3.3. Summary of Electric Energy and Peak Demand Savings

Fiscal Year	Cumulative Energy Savings (GWh/year)		Cumulative Peak Demand Savings (MW)	
	Reported	Evaluated Net	Reported	Evaluated Net
F2011	3.3	0.0	0.5	0.0
F2012	10.7	32.4	1.5	3.7
F2013	21.6	36.5	3.0	4.2

As shown, evaluated net savings were 36.5 GWh/year by F2013, which was 171 per cent of reported. Evaluated net savings of 32.4 GWh/year in F2012 and 36.5 GWh/year in F2013 are equivalent to average annual savings per participant of 4 per cent and 5 per cent, respectively.

Analysis of changes to savings over time among the earliest participating buildings showed that an increase in savings was observed from F2011 through F2015, supporting the hypothesis that gross savings persist for at least four years. Most program savings were achieved between 7 a.m. and 7 p.m., with peak savings occurring at 11 a.m. C.Op participants achieved greatest savings during the summer season, followed by the winter season.

3.4 Findings and Recommendations

Findings

Listed below are the main findings of this study.

1. The most common energy conservation measure was to limit mechanical or lighting systems that ran longer hours than needed and ran during unoccupied periods. The majority of the energy conservation measures acted on four building systems: ventilation (67 per cent), lighting (11 per cent), boiler plants (9 per cent) and chiller plants (6 per cent).
2. Program participants had a high level of awareness and understanding of key program milestones and a generally accurate understanding of the purpose and operation of the program's components, with the exception of the coaching phase. The coaching phase also had the most varied levels of satisfaction.
3. Overall, participants, consultants and EMIS vendors reported having a very positive experience with the C.Op program. Participants also expressed very strong commendations to BC Hydro staff for designing and implementing a sound program.
4. The qualitative research suggests that program free ridership was minimal. Although the incidence of spillover was widespread among participants, it generally occurred at buildings that were too small to participate in C.Op or that were located outside of B.C., suggesting the overall magnitude of spillover in B.C. was small. Note that the net evaluated savings in this evaluation account for free ridership and spillover at participating sites.
5. Evidence suggests that suitable assignment of roles and responsibilities, including responsibility for energy management, among employees of participating organizations is a success factor for the C.Op

program. The impact analysis suggested that C.Op participants with a dedicated energy manager in place may have responded faster to the program than did participants without this position. The qualitative research revealed that although positive organizational changes had occurred at many organizations as a result of participation in the program, there was significant variation in the reported level of engagement of operational staff. Many organizations reported that engaged building operators were a key ingredient in achieving program goals, but the operators were too busy keeping the building running, were not concerned with energy efficiency or did not have sufficient training.

6. Consultants and participants expressed the importance of maintaining utility involvement in supporting recommissioning because many felt that operating practices may revert to pre-program levels in the absence of a utility-sponsored program.
7. Evaluated net savings were 36.5 GWh/year by F2013, which was 171 per cent of reported. The primary cause of the positive variance was that savings were achieved earlier than anticipated. Average net weekday savings per participant were between 4 per cent and 5 per cent, which aligns with program expectations. Savings were greater on weekdays than weekends and holidays. They were also greater during the daytime than overnight and during summer and winter than during shoulder seasons.
8. There was variation in the speed with which participants responded to the program and started to achieve savings. Universities, hospitals and hospitality buildings responded faster than did office buildings. C.Op program participants who were concurrently enrolled in another BC Hydro DSM program responded to the C.Op program faster than did those who were not.
9. The original program goal to verify program energy savings by aggregating EMIS savings estimates across participating buildings was not achieved. The EMIS savings estimates commonly had large and unexplained variances from the engineering estimates developed by the recommissioning consultants.
10. Ten buildings with suitable energy consumption and savings patterns were selected for detailed investigation using Measurement and Verification techniques. Across the 10 buildings, the median of verified savings was 82 per cent of expected savings.
11. The statistical analysis of net savings used hourly electricity consumption data collected through the EMIS. Customers and stakeholders suggested using smart metering infrastructure (**SMI**) data instead. However, SMI data would not be feasible for many participants as they operate campuses where a single utility meter covers many buildings, and not all buildings participate in the program.
12. With the trend of decreasing participation due to the program being fully subscribed, the Variation in Adoption approach applied in this impact study may not be feasible for the next impact evaluation.
13. This evaluation relied on electricity consumption data collected through the EMIS. EMIS vendors started collecting these data in 2011. BC Hydro did not request the data until 2015. This lag delayed the evaluation analysis and led to challenges in data availability and quality.

Recommendations

Listed below are recommendations resulting from this study, starting with recommendations for program management followed by a recommendation for future evaluations.

Recommendations for program management:

1. Consider shortening the timing between the installation of the EMIS and the reporting of savings.
2. Continue to collect building-level hourly electricity consumption data for participants to ensure the feasibility of future impact analysis given the limitations of SMI data.
3. If coaching is offered in the future, review the objectives of this component and strengthen its delivery.
4. Develop a better understanding of building operators' responsibilities, capabilities and training needs in order to better support their role in the program.
5. Some participants indicated that they may need to have the buildings go through the recommissioning process again in future as operating practices may revert to pre-program levels in the absence of the program. Therefore, the program may consider investigating the need for repeat recommissioning of participating buildings in future.

Recommendations for future evaluations:

6. Evaluation should collaborate with program management to explore, investigate and design alternative evaluation methods for future evaluations given changes in program participation trends.
7. Centralize storage and management of the EMIS data to facilitate its use in future evaluations and program administration.

3.5 Conclusions

The Continuous Optimization program was successful in achieving energy savings through building recommissioning. Evaluated net savings were 36.5 GWh/year by F2013, which was 171 per cent of reported. Program participants expressed high levels of satisfaction with the program and reported a range of organizational benefits in addition to energy savings.

4.0 High Performance Buildings and Commercial New Construction: F2008-F2011

4.1 Introduction

Section 4.0 presents an impact evaluation of net electricity savings achieved by BC Hydro's High Performance Building program and its successor the Commercial New Construction program for BC Hydro fiscal years F2008 through F2011 (from April 1, 2007 through March 31, 2011), as well as elements of a process and market evaluation. The objective of these programs (collectively referred to as the CNC program) was to accelerate the demand for and construction of energy efficient commercial buildings.

The CNC program was targeted at developers and market actors who play a role in building and expanding commercial buildings in BC Hydro's service territory. Market actors included developers, building owners, architects, engineers and consultants. The five key objectives of the CNC program were as follows:

1. Energy Efficient Design: Create energy savings by promoting the design of energy efficient buildings.
2. Energy Efficient Construction: Create energy savings by promoting the construction of energy efficient buildings.
3. Energy Efficient Operation of New Commercial Buildings: Create energy savings by providing education and support to properly operate new buildings as they were constructed and designed.
4. Training and Recognition: Enable transformation of the market by training a team of industry professionals to act as energy efficiency and conservation advocates on all new construction projects that they work on in the future. In addition, publicly recognize energy efficient design teams and projects and create a market where consumers demand energy efficient buildings.
5. Advance Building Codes: Support the transformation of the new building market to higher sustained levels of energy efficiency and improved building code compliance. Move the market towards more efficient design so that government can increase the energy efficiency requirements in the BC Building Code and Vancouver building by-law.

As noted in the fifth key objective above, the program was designed to support increases in the energy efficiency requirements in building codes. Notable changes in this regard were the 2008 and 2013 updates to the BC Building Code and Vancouver Building by-law.

4.2 Approach

Shown below are the evaluation objectives and research questions, followed by the data sources and methods.

Table 4. 1. Evaluation Objectives and Research Questions

Objectives	Research Questions
1. Assess participant experience	• What is the level of participant awareness of the various CNC program components? • How do participants rate their program experience and overall satisfaction? • How influential is the CNC program on participant decisions around energy efficiency?
2. Assess trends related to market transformation	• To what extent has the CNC program developed support for design and construction of more energy efficient buildings (beyond code requirements) among designers and builders? • How is the CNC program influencing building design practices and the new construction market, even beyond incented projects? • Did the program help designers and builders prepare for changes in the building code (2013 changes) and help improve compliance rates?
3. Assess the influence of the program on compliance and adoption of building code energy efficiency requirements	• To what extent did the CNC program influence increased compliance with the 2008 BC Building Code and City of Vancouver Building Bylaw? • To what extent did the CNC program influence the adoption of the 2013 building code by “readying the market”?
4. Estimate gross energy and peak savings	• What are gross energy and peak savings?
5. Estimate net energy and peak savings	• What are the free-ridership, participant spillover and non-participant spillover rates? • What are the net energy and peak savings for the overall CNC program?

Table 4.2 summarizes, for each of the evaluation objectives, the evaluation data and methods used.

Table 4.2. Evaluation Objectives, Data Sources and Methods

Objectives	Data sources	Method
1. Assess participant experience	• Participant survey (n = 25)	• Cross tabulations
2. Assess trends related to market transformation	• Market actor survey (15 participants and 9 non-participants)	• Cross tabulations
3. Assess the influence of the program on compliance and adoption of building code energy efficiency requirements	• Market actor survey (15 participants and 9 non-participants) • Interviews with program staff • Program documentation • Program tracking data • Expert opinion	• Delphi method
4. Estimate gross energy and peak savings	• Program tracking data • Measurement and verification (n = 14)	• IPMVP Options A, B and D • Probability Proportional to Size (PPS) ratio estimation • Peak demand savings based on peak-to-energy factor
5. Estimate net energy and peak savings	• Statistics Canada data on commercial new construction activity, F2008-F2011 • Participating building area (sq. meters) • Workshop with program administration • Results from Objective 4 • Participant survey (n = 25) • Market actor survey (15 participants and 9 non-participants) • Project files (n = 7)	• Survey based free ridership and participant spillover algorithms • Case study free ridership assessment

The first objective regarding participant experience was evaluated using the results of detailed online survey of participants delivered in spring 2013. Participants were defined as the individuals who entered into the funding agreement with the CNC program, and they most commonly held the titles project manager, property manager, developer or general manager. The total population of participants over the four years evaluated was 131. A total of 25 surveys were completed by program participants out of 73 sent.

The second objective regarding market transformation was evaluated using the results of a telephone survey of market actors delivered in February 2014. Market actors included engineers, architects, developers, energy modellers and project managers who played a role in decisions related to new construction and design. Fifteen participants and nine non-participants completed the survey.

The third objective regarding the influence of the program on building codes was evaluated using the results of a Delphi panel. The Delphi panel was made up of four local professionals and four experts residing outside B.C. The panelists were provided the results of the market actor survey, along with summary and background information on the program. The panelists first provided their responses to a questionnaire, along with an explanation behind their answer. Panelists then reviewed the results and explanations provided by their peers and had an opportunity to change their initial responses. Results were scored to produce metrics related to the program influence on the building code.

The fourth objective regarding evaluated gross savings was conducted using the results of M&V of a sample of participating buildings.[2] Nine buildings underwent Option D M&V,[3] which involves calibrated energy modelling

[2] In some cases a "building" encompassed a development made up of several parcels.
[3] As defined in the International Performance Measurement and Verification Protocol (**IPMVP**).

of an entire building, informed by energy consumption data as well as sub-metering data of individual building systems. Five buildings underwent Option A or B M&V, which involves energy calculations informed by measured results for power or hours of use. The M&V sample was designed to provide high coverage of the population in terms of energy savings, and to be representative of the population overall on that basis. The final M&V sample coverage from the 14 buildings that underwent M&V was 33 per cent of electric energy savings and 58 per cent of building area. M&V results were extrapolated to the population of all 131 participating buildings using a statistical technique called probability proportional to size ratio estimation.

The fifth objective regarding evaluated net savings, relied on the results of objective four, evaluated gross savings, as well as free ridership and participant spillover estimates derived from the participant survey described above.

4.3 Results

Results for Objective 1: Participant Experience

Awareness of the CNC program was very high among program participants at 96 per cent. Those who were aware were asked additional questions about three individual program components: the energy study, the incentive structure and the Key Account Managers role as liaisons for the program.

Seventy-four per cent of participants were aware of the basics of the energy study component of the program. Among those aware of energy studies, 61 per cent gave it positive ratings overall, and the majority (59 per cent) gave it only a ‘fair’ rating for being easy to work with and act upon, rather than an excellent (11 per cent) or good (25 per cent) rating.

Sixty-eight per cent of participants were aware of the project incentive structure of the program. Among those aware of the incentive structure, 94 per cent gave it positive ratings overall, while 61 per cent provided positive ratings for it being easy to work with and understand.

Seventy five per cent of participants were aware of Key Account Managers (**KAMs**) in general, and among those who were, all were aware of the role that KAMs play as a liaison between the CNC program and its participants. Among those who were aware of the KAM role, 100 per cent gave it positive ratings both overall, and for being easy to work with.

Among program participants, overall satisfaction with the CNC program was very high with 95 per cent of participants reporting that they were either ‘very satisfied’ (65 per cent) or ‘somewhat satisfied’ (30 per cent) with the program. In total, 100 per cent would ‘definitely’ (70 per cent) or ‘probably’ (30 per cent) recommend the program to others and in fact, 54 per cent reported already having done so.

Results for Objective 2: Market Transformation Trends

Nineteen of the 24 respondents to the market actor survey said that some portion of their buildings met or exceeded the new energy efficiency requirements in the building code prior to their introduction in December 2013. Those who indicated a portion of their buildings were meeting or exceeding the 2013 code before it took effect were asked how influential the CNC program was in this achievement. Six of the 12 participant respondents said very influential. Five of the seven nonparticipants reported the program was at least somewhat influential, and one stated it was very influential.

If the CNC program had not been in place, eight of the 24 of the respondents said overall building code compliance would have been lower in British Columbia and ten of the 24 stated that compliance would have been lower in Vancouver. Of those that thought the program affected code compliance, six of eight estimated that the program improved compliance by 20 per cent or less.

Participating market actors were asked if what they learned through the CNC program helped them comply with the building code, even on projects that did not receive a program incentive. Close to half of respondents said yes. These respondents said that the lessons learned from projects that went through the program were so useful and meaningful that they utilized this new knowledge whenever possible, even on projects outside of the program.

Results for Objective 3: Program Influence on Compliance and Adoption of Building Code Energy Efficiency Requirements

The Delphi panelists showed strong consensus around the importance of the market drivers that were identified for "Improving Compliance." All eight panelists reported that two drivers of improved compliance, "Market Awareness of Code Requirements" and "Market Awareness of Strategies and Skills to Meet Code" were *very important*.

After reading information about BC Hydro's activities related to improving compliance with the previous code, the panelists were asked to "rate the program's influence using a zero to ten scale, where zero means the program had no influence and nine means the program was very influential." Ten on the scale meant the program was so influential that it should claim all the credit (100 per cent attribution). No panelists made that determination. Panelists rated the program's influence to be greatest on the "Availability of Tools and Technologies to Demonstrate Compliance", with a mean rating of 7.6.

Table 4.3: Influence Ratings for Market Drivers of Improving Compliance with ASHRAE 90.1-2004/2007

	Market Awareness of Code Requirements	Market Awareness of Strategies and Skills to Meet Code	Availability of Tools and Technologies to Demonstrate Compliance
Mean	6.8	5.6	7.6
Mode	8	5	9
Range	5 to 8	3 to 8	5 to 9

Panelists rated the CNC program's influence on "Market Awareness of Code Requirements" as the next most influential, with a mean rating of 6.8 and four panelists providing a rating of eight. These panelists reported that they believed the program was critical to educating market actors about the code. Those who provided a lower rating noted that while the program did have a role in educating the market, it seemed the program's reach may have been low, or that other initiatives or organizations (such as LEED, the City of Vancouver, and others) were similarly engaged on this topic, and thus the contribution of the CNC program was simply one part of a much larger effort.

Panelists were also asked to rate the importance of market drivers that ready the market for the next iteration of the building code. The majority of respondents felt the identified drivers for readying the market for the 2013 update to the building code (ASHRAE 90.1-2010) were *somewhat important*. According to panelist feedback, having sufficient technical workforce capacity to design and construct buildings to meet the new code requirements was the most important driver, with three panelists reporting this as *very important* and five reporting it as *somewhat important.*

Panelists rated the program's influence on each market driver using a scale from zero to ten. Panelists rated the program's influence to be greatest on the "Technical Workforce Capacity", with a mean rating of 6.4.

Table 4.4: Influence Ratings for Market Drivers of Readying the Market

Readying the Market for the Adoption of ASHRAE 90.1-2010			
	Industry Awareness and Buy-in	**Technical Workforce Capacity**	**Availability of Tools and Technologies to Demonstrate Compliance**
Mean	5.5	6.4	5.1
Mode	5	5	2
Range	4 to 7	2 to 9	2 to 9

There were two drivers where panelists did not converge on the program's influence. These were "Technical Workforce Capacity" and "Availability of Tools and Technologies to Demonstrate Compliance" where panelists' influence ratings ranged from two to nine.

Generally, results from the Delphi panel point to a moderate influence of the program on both improving compliance with the 2008 BC Building Code as well as readying the market for subsequent code revisions in 2013.

Results for Objective 4: Evaluated Gross Electricity and Peak Demand Savings

The evaluated gross electric energy savings and peak demand savings for the CNC program from F2008 to F2011 are 48.6 GWh/year and 6.7 MW, versus the expected savings of 50.4 GWh/year and 7.0 MW. The variance between expected and evaluated gross savings is due to the program realization rate being 97 per cent. Common reasons for the variance included differences between expected and verified plug loads, operating hours, fuel mix and building envelope characteristics.

Results for Objective 5: Net Electricity and Peak Demand Savings

Evaluated net savings are summarized below.

Table 4.3: Summary of Energy and Peak Demand Savings

Fiscal Year	Energy Savings (GWh/year)		Peak Demand Savings (MW)	
	Reported	Evaluated Net	Reported	Evaluated Net
F2008	3.6	2.4	0.5	0.3
F2009	10.2	7.5	1.4	1.0
F2010	25.9	17.2	3.6	2.4
F2011	9.5	6.9	1.3	1.0
Sum of F2008-F2011	**49.2**	**34.0**	**6.8**	**4.7**

Free ridership was 31 per cent, which was higher than expected and is the reason for the negative variance between reported and evaluated savings. Participant spillover was 1 per cent.[4] Due to data limitations, a point estimate of non-participant spillover could not be produced, and non-participant spillover is not included in the net evaluated savings. Evidence collected through this evaluation suggests non-participant spillover occurred and may have been substantial.

[4] Participant spillover was defined as additional energy savings measures implemented in participating buildings, but outside the program. Because the program targeted whole building energy efficiency, participant spillover was expected to be small.

4.4 Findings and Recommendations

Findings

Key findings of this evaluation are summarized below:

1. Among program participants, overall satisfaction with the CNC program was very high with 95 per cent of participants reporting that they were either very or somewhat satisfied with the program. All surveyed participants said they would definitely or probably recommend the program to others. In fact, 54 per cent reported already having done so.

2. The aspects of the program experience that rated the highest included ‘service provided by BC Hydro’, ‘information about CNC on the website’, ‘service provided by contractors’ and ‘level of incentives offered’. Aspects which rated the lowest include ‘length of time for the project to be completed’, ‘the variety of products funded under the program’, and ‘length of time to receive the incentive’.

3. Eighty nine per cent of participants reported that the program was either ‘very influential’ or ‘somewhat influential’ on their decision to implement the energy efficient measures.

4. Responses from market actors, as well as the Delphi panel, indicate that the CNC program likely improved compliance with historical BC and Vancouver building codes. The majority of respondents said the program helped improve the compliance through financial assistance, technical assistance, or quality assurance for design and installation in participating buildings. The experts who participated in the panel rated the program favorably in terms of its effect on compliance.

5. Market actors as well as the Delphi panel found the CNC program had some influence on readying the market for the 2013 building code update. Market actors said the program was influential in helping them understand the 2013 code prior to enactment and also in building and designing buildings that met (or exceeded) the 2013 code before it went into effect, indicating that the program helped ready the market for the adoption of the regulation.

6. Measurement and verification of 14 buildings (or development parcels) revealed that most realized savings that were substantially different from expected levels. One reason for this variance was that program rules for the treatment of fuel switching were not well defined until the later part of the evaluation analysis time frame and as a result the verified fuel mix was sometimes different than expectation. Other reasons included differences in operating hours, plug load, and building envelop characteristics. These variances tended to cancel each other out, and the overall realization rate across all buildings that underwent M&V was 97 per cent.

7. The net-to-gross ratio was 70 per cent, made up of 31 per cent free ridership and 1 per cent participant spillover. Cumulative evaluated net savings from F2008 through F2011 were 34.0 GWh/year, which is 70 per cent of reported savings of 49.2 GWh/year. Free ridership was higher than expected, in part because of some of the highest saving buildings in the early part of the evaluation analysis time frame were large, high profile buildings where government and public expectation played a substantial role promoting energy efficient building design. Such buildings became less common in the later part of the evaluation analysis time frame.

8. Evidence suggests that non-participant spillover occurred during the evaluation period. However a reliable point estimate could not be produced due to data limitations. Estimates of non-participant spillover ranged from 3 per cent to 18 per cent of evaluated gross savings. Due to the high level of uncertainty, non-participant spillover is not included in the net evaluated savings estimate.

Recommendations

Recommendations from this evaluation are shown below.

1. The free ridership rate of 31 per cent presented in this evaluation was based on projects and decision making for the time period up to F2011 and may not be suitable to use for program planning and reporting purposes outside this period.

2. Given the evidence that non-participant spillover occurred, consider designing and implementing a survey of a representative, randomly selected cross section of non-participating market actors to produce an updated estimate of program effects on non-participants. The data collected should allow for the estimation of any attribution of non-participant energy efficiency savings to the CNC program, and for the estimation of the proportion of the non-participating commercial new construction market influenced by the program.

3. To achieve cost savings in future M&V, consider obtaining and retaining the participating building design and modelling files as a condition of incentive approval.

4.5 Conclusions

The Commercial New Construction Program achieved very high participant satisfaction. Cumulative evaluated net savings from F2008 through F2011 were 34.0 GWh/year, which is 70 per cent of reported savings. Evidence suggests that the program played a role readying the market, and improving compliance, with the energy efficiency requirements of the BC and Vancouver building codes.

5.0 Power Smart Partner - Transmission: F2012-F2014

5.1 Introduction

Section 5.0 presents an impact evaluation of the BC Hydro Power Smart Partner – Transmission (**PSP-T**) DSM program for BC Hydro fiscal years F2012 to F2014 (April 2011 to March 2014). This evaluation also includes elements of a process and market evaluation.

BC Hydro's Power Smart Partner – Transmission Program (renamed Leaders in Energy Management – Transmission in 2015) is a multi-year energy acquisition and market transformation initiative that encourages large industrial customers, which receive electricity supply at transmission voltage, to reduce their electricity consumption. The program's target market is BC Hydro's 75 industrial transmission customers (with facilities at 174 sites). The key program objective during the period evaluated was to partner with program participants to obtain cost-effective electricity savings by encouraging them to integrate energy efficiency into their on-going business practices and supporting them to respond to the conservation price signal delivered by the Transmission Service Rate (**TSR**). This evaluation evaluates the combined effect of the program and rate for energy efficiency and conservation projects reported through the program.

The scope of this evaluation includes electrical energy efficiency and conservation projects at industrial transmission service sites. Facility wide savings resulting from strategic energy management efforts are not included in the scope of this evaluation as they were not reported by the program during the evaluating period. This encompasses the incentive offer and enabling activities, as further described below. During the three-year evaluation timeframe, 145 energy efficiency and conservation projects were completed at 57 sites and reported under the program. Program participants included the following industrial segments: pulp & paper, mining, wood, oil & gas, chemicals, cement and transportation. The program reported projects in various end uses with a primary focus on industrial process energy efficiency improvements. The main program components and enabling activities are summarized below:

- **Incentive:** Incentives of up to 100 per cent of project costs were available for custom projects. Since F2014, smaller lighting and compressed air projects were also eligible for prescriptive incentives under the self-serve incentive program (**SIP**).
- **BC Hydro Key Account Managers:** Acted as a liaison between the program and the customer.
- **BC Hydro Alliance of Energy Professionals:** A network of energy efficiency trade professionals registered with BC Hydro, formerly known as Power Smart Alliance.
- **Energy Studies:** Identified and built a business case for the implementation of energy conservation measures; fully funded by BC Hydro.
- **Energy Managers:** Helped participants adopt strategic energy management practices; partially funded by BC Hydro.
- **Strategic Energy Management:** Provided a structured approach to improve energy efficiency, including the use of Energy Management Assessment workshops that scored current energy management practices. Supported development and implementation of energy management systems.

The program relied on two approaches to recognize savings, program enabled and incentive:

- **Program Enabled:** Customer-funded electricity conservation measures that are linked to a program-funded enabling activity such as an energy study or energy manager.
- **Incentive:** Electricity conservation measures that received an incentive from BC Hydro.

5.2 Approach

Shown below are the evaluation objectives and research questions, followed by the data sources and methods.

Table 5. 1. Evaluation Objectives and Research Questions

Evaluation Objective	Research Questions
1. Assess participant and non-participant experience and satisfaction	• What is the participant experience related to awareness, understanding, and satisfaction with the various program offers? • What are the barriers to and drivers of program participation?
2. Assess the Strategic Energy Management initiative	• What was the coverage of energy managers among program participants? Were energy managers associated with increased project activity? • What changes were observed in customer commitment to energy conservation and efficiency over time? How did customer ratings progress in key areas of Energy Management Assessments over time? • What changes were observed in the customer capability of energy conservation and efficiency over time? What changes in energy management practices among participants were observed over time?
3. Assess trends related to market transformation in the industrial sector	• Has the program shifted or transformed the market for energy efficiency services offered by trade allies registered with the BC Hydro Alliance of Energy Professionals? • Over the past five years (2011-2016), how has industry capability to deliver energy efficiency services changed? • Aside from the program, what additional drivers of demand for energy efficiency services exist among industrial customers? How have these drivers changed over time?
4. Estimate gross electrical energy and peak demand savings for incentive and program enabled projects	• What were the most common energy conservation measures by end use and customer site type for incentive and program enabled projects? • What were the evaluated gross energy and demand savings realized by PSP-T incentive and program enabled projects?
5. Estimate net electrical energy and peak demand savings for incentive and program enabled projects	• How much free ridership occurred for program enabled and incentive projects? How much participant and non-participant spillover occurred for the program overall? • What was the attribution of energy savings to the combined effect of the PSP-T program and the TSR? • What were the evaluated net energy and demand savings due to the combined effect of the PSP-T program and the TSR for incentive and program enabled projects?

Table 5.2 summarizes, for each of the evaluation objectives, the evaluation data and methods used.

Table 5.2. Evaluation Objectives, Data Sources and Methods

Objectives	Data sources	Method
1. Assess participant and non-participant experience and satisfaction	• Participant Survey (n = 28 responses covering 46 projects) • Non-Participant Survey (n = 25)	• Cross tabulations
2. Assess the Strategic Energy Management initiative	• Program tracking data • Project file reviews of four participants	• Trends analysis • Qualitative analysis
3. Assess trends related to market transformation in the industrial sector	• Trade ally interviews (11 interviews)	• Qualitative analysis
4. Estimate gross electrical energy and peak demand savings for incentive and program enabled projects	• Program tracking data • TSR tracking data • Site visits, file reviews • Measurement and Verification (n = 67) • Energy studies (n = 90)	• Engineering algorithms • Extrapolation of measurement and verification using stratified ratio estimation • Rate class average peak-to-energy factor
5. Estimate net electrical energy and peak demand savings for incentive and program enabled projects	• Results of Objective 4 • File reviews • Participant surveys (n = 28 responses covering 46 projects) • Case Studies (n = 46 projects)	• Triangulation of case study and survey based free ridership estimates • Survey based spillover algorithm • Cross tabulations • Rate class average peak-to-energy factor

5.3 Results

Results for Objective 1: Participant and Non-Participant Experience and Satisfaction

As expected, PSP-T program awareness was very high among participants, with 96 per cent indicating that they were aware of the program by name. Awareness among non/partial participants was somewhat lower, although still high, at 84 per cent. In terms of individual program components, for participants, awareness was highest for the role that Key Account Managers play as liaisons for PSP-T, energy studies and the incentive structure. Non/partial participants expressed high awareness of Key Account Managers and energy studies, but only moderate to low awareness of other program components. With the exception of training and funding for energy managers, participants expressed high levels of understanding with all individual program components. Non/partial participants expressed lower levels of understanding, particularly with energy studies and the energy manager component.

Among participants, Key Account Managers' role as liaisons for the program emerged as the highest rated component in terms of satisfaction (92 per cent 'excellent' or 'good'), followed by energy audits/studies (76 per cent). Among non/partial participants, the PSP-T incentive structure was rated the highest (80 per cent), followed much further behind by energy audits/studies (42 per cent).

Overall satisfaction with PSP-T among program participants was high with 89 per cent of participants reporting that they were either 'very satisfied' (58 per cent) or 'somewhat satisfied' (31 per cent) with the program. In terms of program experience, 'service provided by BC Hydro' was the highest rated of all service elements with 85 per cent of participants rating it as either 'excellent' or 'good'. Aspects around timing were rated the lowest of all of the program elements, with favourable ratings of only 39 per cent for 'length of time to receive the incentive' and 35 per cent for 'length of time for the project to be completed'.

Results for Objective 2: Strategic Energy Management Initiative

The strategic energy management initiative provided participants with a suite of tools and offers intended to help them build energy management into their ongoing business practices, thereby reducing operating and maintenance costs and equipment wear. The tools and offers included funding for an Energy Manager position, energy management assessment workshops that ranked participating facility's energy efficiency and provided participants with a follow-up action plan, facility monitoring and modeling, as well as energy studies and incentives.

The evidence reviewed for this evaluation indicates that Energy Managers played an important role in program participation. Coverage of energy managers among program participants was widespread. Of the 57 sites included in the scope of this impact evaluation, 39 had energy managers. Among sites at which one or more incentive projects were implemented, 20 out of 35 had energy managers, covering 64 per cent of incentive gross savings. Among sites at which program enabled projects were implemented, 19 out of 22 had energy managers, covering 85 per cent of program enabled gross savings. During the evaluation period, sites with energy managers completed twice the number of projects per site relative to those without energy managers (on average, three projects versus 1.5 projects).

Qualitative assessment of participant experience and progress in the strategic energy management initiative was conducted for four participants in the following sectors: mining, pulp & paper, wood, and cement. Each of these participants was unique, and the energy management offer was customized to their situation and opportunities. Overall, review of these four participants indicated that they had ongoing, multi-year commitment to energy management, improved their energy management capabilities over time, and adopted new energy management practices. Note that results for these four participants may not be representative of results for other participants in the strategic energy management initiative.

Results for Objective 3: Trends Related to Market Transformation in the Industrial Sector

Market trends related to market transformation were based on interviews with 11 trade allies. The trade ally respondents generally reported that the range of energy efficiency services offered by their firms had not changed due to the program, but with the experience gained through the program their level of services improved. Although energy efficiency services were not generally the main business activity of these firms, conducting the BC Hydro-funded energy studies provided opportunities for business development and improved customer service.

Responses were mixed regarding the extent to which the program led to the development of new or greater subject matter expertise over the past five years. However, most of the respondents felt that BC Hydro-funded energy studies had supported knowledge transfer among multiple groups (e.g., program technical experts, trade allies, participants and non-participants), in particular regarding analytical methods and methodologies of energy engineering that could be applied to other studies that are not funded by BC Hydro. Most interviewees noted that they rarely, if ever, received information about whether projects performed as expected and saw this as a missed opportunity to expand their expertise and improve future energy studies.

Respondents were largely of the opinion that energy studies made customers aware of new options for energy efficiency that they had not previously been aware of. However, responses varied regarding whether energy studies were motivated by energy efficiency versus other factors such as capacity, de-bottlenecking, quality, etc. About half of the respondents noted that risk avoidance was a much more important factor for customers when considering energy efficiency upgrades than any incentive amounts received or potential energy savings. Changes in customer knowledge and engagement were seen as drivers of energy efficiency services, both of which were seen as having improved as a result of the program, particularly the energy manager component.

Results for Objective 4: Evaluated Gross Electricity and Peak Demand Savings

Evaluated gross savings provide an estimate of savings achieved by program participants. Evaluated gross savings are estimated by applying a realization rate to expected savings. An overall realization rate of 0.92 was calculated for the entire evaluation period using measurement and verification results.

Table 5.3. Expected and Evaluated Gross Savings and Demand for All Participants

Period	Number of Projects	Expected Gross Energy Savings (GWh/year)	Evaluated Gross Energy Savings (GWh/year)	Evaluated Gross Peak Demand Savings (MW)
F2012	41	152.3	136.1	15.4
F2013	39	117.6	110.2	12.4
F2014	65	85.1	81.2	9.2

Results for Objective 5: Net Electricity and Peak Demand Savings

Free ridership was estimated separately for the three types of projects reported by the program: incentive, program enabled with an energy study or an energy savings prediction and program enabled without an energy study or energy savings prediction. Free ridership provides an estimate of the proportion of savings that are not attributable to the combined effect of the PSP-T and TSR. Free ridership was calculated by fiscal year. Spillover was estimated for the overall evaluation period only.

Table 5.4. Summary of Energy and Peak Demand Savings

Period	Evaluated Gross Energy Savings (GWh/year)	Evaluated Gross Peak Demand Savings (MW)	Net-to-Gross Ratio	Evaluated Net Energy Savings (GWh/year)	Evaluated Net Peak Demand Savings (MW)
F2012	136.1	15.4	0.82	111.7	12.6
F2013	110.2	12.4	0.90	99.4	11.2
F2014	81.2	9.2	1.08	87.4	9.9

The overall level of free ridership is estimated at 32 per cent, driven by high free ridership among program enabled projects without an energy study or energy savings prediction. Participant spillover was estimated at 18 per cent and non/partial participant spillover was estimated at 5 per cent for a total of 23 per cent. Together they result in a net-to-gross ratio of 91 per cent.

Evaluated net energy savings in each fiscal year were calculated using the gross savings of each project multiplied by the net-to-gross ratio of its project type. Electricity savings are presented as incremental savings achieved within each fiscal year and expressed as an annual rate of savings (also known as run rate savings). Peak demand savings were calculated using the same peak-to-energy factor as for gross demand savings. Because the distribution of project types and energy savings varied by year, so too did the yearly net-to-gross ratios. Years with greater weighting of energy savings from projects that were program enabled without an energy study or energy savings prediction saw a lower net-to-gross ratio, such as F2012 and F2013.

Table 5.5. Comparison of Reported and Evaluated Net Savings

Period	Energy savings (GWh per year)		Peak demand savings (MW)	
	Reported	Evaluated Net	Reported	Evaluated Net
F2012	125.0	111.7	14.1	12.6
F2013	109.6	99.4	12.4	11.2
F2014	77.1	87.4	8.7	9.9

The variance between reported and evaluated net savings is primarily due to the gross realization rate being lower than forecast. The evaluated net-to-gross ratio was found to be similar as forecast.

5.4 Findings and Recommendations

Findings

1. Overall satisfaction with PSP-T among program participants was high with 89 per cent of participants reporting that they were either very or somewhat satisfied with the program. A similar proportion (92 per cent) reported that they would recommend the program to others, and in fact, 46 per cent reported already having done so.
2. Research for this evaluation suggests that beyond incentives, the key aspects of the program's success in terms of satisfaction, engagement and project activity levels include Key Account Managers, energy studies and Energy Managers.
3. Among participants, the factors that emerged as the greatest motivators of conservation were minimizing operating costs, program incentives and cost-cutting measures due to economic conditions.
4. Energy Managers played an important role in program participation. Coverage of energy managers among program participants was widespread, at 86 per cent of projects. On average, sites with energy managers completed twice as many projects per site than did sites without energy managers.
5. Trade allies reported that the level of customer engagement appeared to be heavily linked to the presence of an energy manager at a company. Companies with energy managers were viewed as being much more engaged and knowledgeable than companies without one.
6. The evaluability of the strategic energy management initiative would be improved by the adoption of standardized progress monitoring of program participants, as well as adopting standardized methods for determining energy efficiency savings for strategic energy management initiatives.
7. Trade allies were largely of the opinion that energy studies made customers aware of new options for energy efficiency. Only one out of the 11 respondents felt that customers were typically aware of energy efficiency options prior to having a study done.
8. Trade allies also noted that they rarely, if ever, received information about whether projects performed as expected and saw this as a missed opportunity to expand their expertise and improve future energy studies.
9. The gross realization rate was 92 per cent, indicating that the energy conservation measures largely performed as expected. In general, smaller projects had higher realization rates than larger projects. The most common reasons why measures did not perform as expected were changes in operating conditions and inappropriate baselines.
10. Evaluated gross energy savings averaged 1.1 per cent per year of facility energy consumption across all participants, and project savings per site ranged from less than 1 per cent to over 14 per cent.
11. By including additional data sources in the evaluation review, such as TSR records and customer post-implementation data, the coverage of the gross realization rate sample was doubled from what it would have been with M&V results alone. However, the rigour of the realization rate sample was less than what it would have been with M&V results alone.
12. The overall level of free ridership is estimated at 32 per cent, driven by high free ridership among program enabled projects without an energy study or energy savings prediction. Participant spillover was estimated at 18 per cent and non/partial participant spillover was estimated at 5 per cent for a total of 23 per cent. Together they result in a net-to-gross ratio of 91 per cent.
13. Projects with an energy study or energy savings prediction were found to have a substantially lower level of free ridership than projects without one (18 per cent versus 62 per cent, respectively). The net-to-gross ratio increased over time as more and more projects had an energy study.

14. Most of the participant spillover identified in this report came from sites with an Energy Manager.
15. Evaluated net savings were 111.7 GWh/year in F2012, 99.4 GWh/year in F2013, and 87.4 in F2014, which was 89 per cent of reported savings for F2012, 91 per cent for F2013 and 113 per cent for F2014.

Recommendations

Recommendations for program management:

1. Consider providing information on project performance back to trade allies in order to improve the quality of future energy studies and the recommendations they give to customers.
2. In order to address savings discrepancies due to inappropriate baselines, the program should investigate the merits of reporting for each project the estimated remaining useful life of the baseline equipment.
3. Consider ways to increase the prevalence of energy studies or energy savings predictions among program enabled projects in order to reduce the uncertainty of the counterfactual.
4. In consultation with the evaluation department, consider ways to improve the evaluability of the strategic energy management initiative.

Recommendations for future evaluations:

1. If strategic energy management savings are reported and/or evaluated in the future using a top-down method (i.e., facility-wide regression analysis), consider the extent to which there may be double counting between the participant spillover estimate presented in this evaluation and strategic energy management savings.
2. Consider testing and adopting the Strategic Energy Management Evaluation Protocol currently being developed by the US Department of Energy’s Uniform Methods Project for determining energy efficiency savings for strategic energy management initiatives.

5.5 Conclusions

BC Hydro’s Power Smart Partner – Transmission program achieved 96 per cent of reported savings during F2012 to F2014. The program also achieved high levels of customer awareness and satisfaction.

Glossary

Baseline: A baseline is the initial condition occurring when a DSM activity begins. It may be a market share for equipment, a current standard, or a current average behavior.

Cross Effects: Cross effects (also known as interactive effects) refer to the effect that some energy conservation measures (**ECMs**) have on other electricity end uses beyond what the ECM itself produces. An obvious example is building lighting. As more efficient lighting is installed, less heat is generated by the lighting system. This means that less heat must be removed from the building by the air conditioning system during the cooling season, but more heat needs to be supplied by the heating system during the heating season.

Demand Side Management (DSM): The definition of Demand Side Management is the same as the definition of "demand-side measures" set out in section 1 of the *Clean Energy Act*, which is "a rate, measure, action or program undertaken; (a) to conserve energy or promote energy efficiency, (b) to reduce the energy demand a public utility must serve, or (c) to shift the use of energy to periods of lower demand, but does not include (d) a rate, measure, action or program the main purpose of which is to encourage a switch from the use of one kind of energy to another such that the switch would increase greenhouse gas emissions in British Columbia, or (e) any rate, measure, action or program prescribed".

End Use: The final application or final use to which energy is applied. Recognition of the fact that electric energy is of no value to a user without first being transformed by a piece of equipment into a service of economic value. For example, office lighting is an end use, whereas electricity sold to the office tenant is of no value without the equipment (light fixtures, wiring, etc.) needed to convert the electricity into visible light. End use is often used interchangeably with energy service.

ENERGY STAR®: ENERGY STAR® is the mark of high-efficiency products in Canada that meet strict technical specifications for energy performance—tested and certified. These products save energy without compromising performance in any way. Typically, an ENERGY STAR® certified product is in the top 15 to 30 per cent of its class for energy performance.

Expected Savings: Estimate of gross energy savings based on customer initially reported savings, engineering review and site inspection. These estimates represent the unverified savings.

Free Riders: Free riders are program participants who would have taken the DSM action, even in the absence of the DSM program. They are a part of the reference case. These actions are not attributable to the program.

Gigawatt Hour (GWh): One billion watt-hours; one million kilowatt hours.

Gross Savings : The change in energy consumption and/or associated demand that results directly from program-related action taken by the participants in the demand side management program irrespective of why they participated.

Market Changes: Market Changes refers to the changes in the structure or operations of markets during the course of an energy efficiency program that indicate increased levels of adoption of energy-efficient products and practices by customers and/or increased levels of promotion and delivery by suppliers.

Market Transformation: Market Transformation refers to a permanent change in the structure or functioning of markets, including more energy-efficient behaviour among customers and higher market penetration of energy-efficient products, as a result of DSM programs that reduce barriers to energy efficiency. These market changes are likely to persist in the absence of continued program activity.

Net savings: The change in energy consumption and/or associated demand that is attributable to the utility DSM program. The change in consumption or associated demand may include the effects of free riders and spillover.

Net-to-gross ratio: A factor representing net demand side management program savings divided by gross program savings that is applied to gross program impacts to convert them into net program load impacts. The factor is made up of a variety of factors that create differences between gross and net savings, commonly including free riders and spillover. Other adjustments may include rebound, cross effects and measurement and verification results.

Peak Demand - Demand refers to the amount of electricity that is consumed at any instant in time, measured in multiples of watts. Peak demand savings are the reduction in amount of electricity that is consumed at system peak demand, which for BC Hydro occurs on a winter weekday between approximately 5 p.m. and 7 p.m.

Persistence: Refers to how long the energy savings are expected to be attributable to the demand side management activity.

Realization Rate: The ratio of initial estimates of savings to savings adjusted for data errors and measurement and verification results. Does not reflect program attribution or influence on the savings achieved.

Reported Savings: Estimate of energy savings being recorded in the program tracking database. Reported savings are based on best information available from technical review of the initial engineering estimate, post implementation review of documentation and/or inspection, or measurement and verification results, as well as, a forecast net-to-gross ratio applied.

Run Rate: Run rate is the rate at which the Conservation and Energy Management programs or projects are saving electricity at a given point in time. This is usually expressed as GWh/year at the end of the month or year being reported.

Spillover: Refers to program participants and non-participants whose energy savings measures occur through actions that are not part of a program, but which were influenced by the program (also called free drivers or tag-ons). Participant spillover is the additional energy savings that occur when a program participant independently installs energy efficiency measures or applies energy savings practices after having participated in the efficiency program, as a result of the program’s influence. Non-participant spillover refers to energy savings that occur when a program non-participant installs energy efficiency measures or applies energy savings practices as a result of a program’s influence. Spillover is expressed as a fraction of the increase of energy savings due to spillover to the gross energy savings of the program participant. Spillover may not be permanent and may not continue in the absence of continued program activity.

bchydroregulatorygroup@bchydro.com

January 15, 2019

Mr. Patrick Wruck
Commission Secretary and Manager
Regulatory Support
British Columbia Utilities Commission
Suite 410, 900 Howe Street
Vancouver, BC V6Z 2N3

Dear Mr. Wruck:

RE: British Columbia Utilities Commission (BCUC or Commission)
British Columbia Hydro and Power Authority (BC Hydro)
2004/05 and 2005/06 Revenue Requirements Application
Commission Decision: Order No. G-96-04, October 29, 2004,
Directive 66 (page 197)

BC Hydro writes to submit its F2018 Demand Side Management Milestone Evaluation Summary Report (**the Report**), dated December 2018 and the final report for Evaluation of the Residential Inclining Block Rate: F2013-F2017 in compliance with Directive 66 (page 197) of the Commission Decision on BC Hydro's 2004/05 to 2005/06 Revenue Requirements Application, dated October 29, 2004. Directive 66 directs BC Hydro to file the executive summaries of its milestone evaluation reports and full final evaluation reports for all its Power Smart programs.

The Report summarizes the impact evaluations completed during F2018 for the following:

1. Residential General Service Lighting: F2012-F2017;
2. Low Income Program: F2011-F2016;
3. Power Smart Partner – Distribution Program: F2011-F2016;
4. Residential Inclining Block Rate: F2013-F2017; and
5. Residential Retail Program – Consumer Electronics and Appliance Rebate Offers: F2011 to Second Quarter F2015.

The findings from the attached final report for the Evaluation of the Residential Inclining Block Rate: F2013-F2017 show that structural savings in F2016 and F2017 were deemed to be small or zero. Accordingly, no new incremental savings are forecast for the Residential Inclining Block Rate in BC Hydro's Demand-Side Management Plan, and no further evaluations will be undertaken. BC Hydro is therefore filing the full report as the final evaluation for the Residential Inclining Block Rate in compliance with Directive 66.

For further information, please contact Geoff Higgins at 604-623-4121 or by email at bchydroregulatorygroup@bchydro.com.

Yours sincerely,

Fred James
Chief Regulatory Officer

Demand Side Management Milestone Evaluation Summary Report F2018

December 2018

This page left blank

Table of Contents

List of Tables

1 Introduction

This report summarizes the milestone evaluations of demand-side management (**DSM**) initiatives completed by BC Hydro in fiscal year 2018 (**F2018**). It is filed in compliance with Directive 66 of the British Columbia Utilities Commission (**BCUC**) decision on BC Hydro's F05/F06 Revenue Requirements Application (dated October 29, 2004), which "*directs BC Hydro to file the executive summaries of its milestone evaluation reports and full final evaluation reports of all its Power Smart programs*" (page 197).

BC Hydro evaluates its DSM initiatives to improve its estimates of realized DSM electricity savings and to improve their effectiveness and efficiency.

DSM evaluation activities are guided by the following six principles:

- Objectivity and Neutrality: Evaluations are to be objective and neutral.
- Professional Standards: Evaluation work is guided by industry standards and protocols.
- Qualified Practitioners: BC Hydro employs qualified staff and consultants to conduct evaluations.
- Appropriate Coverage: BC Hydro strives to achieve defined coverage levels for its evaluation of DSM initiatives.
- Business Integration: The evaluation function is integrated into BC Hydro's DSM business process of planning, implementation, reporting and evaluation.
- Coordination: BC Hydro evaluation work is coordinated with FortisBC and other DSM partners where feasible.

BC Hydro DSM evaluations are subject to an independent oversight process to ensure that they are neutral and unbiased, of sufficient quality for their intended purposes, and consistent with industry standards and protocols.

1.1 Completed Evaluations

Impact evaluations summarized in this report focused on the following:

- Residential General Service Lighting: F2012-F2017;
- Low Income Program: F2011-F2016;
- Power Smart Partner – Distribution Program: F2011-F2016;
- Residential Inclining Block Rate: F2013-F2017; and
- Residential Retail Program – Consumer Electronics and Appliance Rebate Offers: F2011 to Second Quarter F2015.

2 Residential General Service Lighting: F2012-F2017

2.1 Introduction

This market and impact evaluation examines changes in the market and in-home installation trends for residential lighting in British Columbia over the past six years. It also presents evaluated gross savings in the residential sector from the reduction in electricity usage of incandescent general service lamps (**GSL**) during a period of time that encompasses the introduction of energy efficiency regulations. Estimates of gross savings at industrial and commercial facilities are not included.

Phase 1 of British Columbia's GSL Regulation came into force on January 1, 2011. The GSL Regulation provided minimum energy performance standards for a range of medium base screw-type electric lamps, effectively banning 75 to 100 watt incandescent lamps. Phase 2 of the regulation came into force in January 2015 when national minimum energy performance standards for 40 to 60 watt general service lamps came into effect, which effectively banned 40 to 60 watt incandescent lamps.

BC Hydro includes gross electricity savings from the GSL Regulations in its reported and forecast DSM savings and in its load forecast after DSM.

2.2 Approach

Shown below are the evaluation objectives, research questions, data sources and methods.

Table 1 Evaluation Objectives and Research Questions

Objectives	Research Questions
1. Supply side analysis	a. What are shelf share trends by lamp type? b. What are price trends by lamp type? c. What is the level of retailer compliance with the regulation?
2. Demand side analysis	a. What are long-term trends in the types of lamps used in the home? b. How familiar are customers with various lighting products? c. How satisfied are customers with various lighting products? d. How many customers purchased and installed various lighting products? e. How many customers put various lighting products into storage?
3. Gross energy savings from conversion of incandescent la mps	a. How much conversion of 40, 60, 75 and 100 watt incandescent lamps to other lamp wattages occurred in the homes of BC Hydro customers between F2011 and F2017? b. What is the wattage of 40, 60, 75 and 100 watt replacement lamps? c. What are the gross energy savings associated with conversion of 40, 60, 75 and 100 watt lamps to other wattages? d. What are the reasons behind any variance between reported and evaluated gross savings?

Table 2 summarizes, for each of the evaluation objectives, the evaluation data and methods used.

Table 2 Evaluation Objectives, Data and Methods

Objectives	Data sources	Method
1. Supply side analysis	• Shelf space survey (n= approximately 40 stores per year for 7 years, from F2011 to F2017)	• Cross tabulations • Trend analysis
2. Demand side analysis	• Telephone surveys of residential customers for F2011, F2012 & F2013 (approximately 400 to 600 responses per survey) • Online surveys of residential customers for F2016 (888 responses) and F2017 (2,222 responses) • Residential End Use Surveys from F2002, F2004, F2007, F2009, F2011, F2013, F2015, F2017 (approximately 4,200 to 7,600 responses for the lighting section)	• Cross tabulations • Trend analysis
3. Gross energy savings from conversion of incandescent la mps	• F2011 residential monitoring study (48 homes audited) • F2014 residential audits (56 homes audited) • F2017 residential audits (233 homes audited) • Residential End Use Surveys from F2011, F2013, F2015 and F2017 • BC Hydro Annual Reports for F2011 to F2017 • BC Hydro Codes and Standards savings forecast as of spring 2017	• Engineering algorithms

Objective 1, related to supply side analysis, was completed using shelf space data. The lighting shelf space studies cover approximately 40 retail stores annually and collect a range of information on a census count of specific lighting products on the shelves of each store.

Objective 2, related to demand side analysis, was completed through cross tabulations and trends analysis of data from surveys of BC Hydro's customers. Lighting surveys collected data on consumer awareness of various lighting technologies, purchase and installation rates, satisfaction and other measures. Residential End Use Surveys collected detailed information about lighting products installed in the home.

Objective 3, related to gross savings, was completed using engineering algorithms with inputs from monitoring studies or home audits, Residential End Use Surveys and BC Hydro annual reports. The analysis involved seven steps: 1) estimate the total number of incandescent lamps installed in homes in each year of interest, 2) determine the distribution of incandescent lamp wattages installed in homes, 3) estimate the average number of incandescent lamps per home by wattage, 4) calculate the power draw of GSL replacement lamps, 5) identify hours of use and peak coincidence, 6) adjust for cross effects, and 7) calculate evaluated gross savings.

2.3 Results

Objective 1: Supply Side Analysis

The shelf space occupied by incandescent lamps dropped from 51 per cent in F2012 to 24 per cent in F2017. During this same period, shelf space occupied by LED lamps rose from 4 per cent to 40 per cent, taking over the largest share of shelf space in F2016. While compact fluorescent lamps (**CFLs**) had a fairly consistent shelf space share of about 25 per cent from F2012 to F2014, their share has steadily declined since then and reached 13 per cent in F2017. Halogen lamps have held fairly consistent shelf space since F2013, fluctuating between 17 per cent and 21 per cent.

Incandescent (60 watt A-shape) lamp prices have increased from an average of $0.85 in F2011 to $1.43 in F2017, while LED (A-shape) lamp prices have declined from an average of $24.63 in F2011 to $8.97 in F2017. Prices for CFL (13 watt spiral) lamps were generally stable, while prices for halogen (A-shape) lamps fluctuated somewhat through the period.

Within incandescent shelf space, up to 28 per cent was stocked with potentially non-compliant lamps in F2017. Compliance with the GSL regulations may be higher than indicated by this figure because the shelf space study did not record all lamp features that would have exempted lamps from the regulations.

Satisfaction ratings were collected only for CFL and LED lamps and in select years only. Satisfaction with CFL lamps in F2011 (regular and specialty lamps combined), was high at 89 per cent. In F2012 and F2013, results were available for specialty CFLs only and satisfaction was somewhat lower at 79 per cent in F2012 and 72 per cent in F2013. Satisfaction with LED lamps was high at 85 per cent in F2012 and increased to 93 per cent in F2013.

Objective 2: Demand Side Analysis

- During the evaluation period, the average total number of lamps installed per home was fairly flat at approximately 38 until F2017 when the number increased to 39.8. Incandescent lamps decreased from 17.6 lamps in F2011 to 13.1 lamps in F2017. CFLs reached their peak in F2013 at an average of 9.9 lamps, but have since decreased to 8.1 lamps in F2017. Halogen lamps fluctuated somewhat over the period, increasing in the early years from a low of 5.1 in F2011 to a high of 6.1 in F2015, but decreased to 5.4 lamps in F2017. LEDs increased rapidly from an average of less than one lamp per home in F2011 to 8.8 lamps in F2017. Fluorescent tubes were relatively stable throughout the evaluation period at approximately three tubes per home, while other lamps decreased slightly from 2.5 to 1.6.
- Based on the F2016 BC Hydro Lighting Survey, awareness of all lamp types is high, with 92 per cent of customers aware of halogens, 93 per cent aware of LEDs, 96 per cent aware of CFLs and 98 per cent aware of incandescents. In terms of

purchases over the past year, the share of customers that purchased at least one incandescent lamp has been steadily declining in recent years (from 44 per cent in F2012 to 34 per cent in F2016), as has the average number purchased (from 11.0 in F2012 to 6.8 in F2016). In contrast, the share that purchased at least one LED lamp has been steadily increasing (from 7 per cent in F2011 to 35 per cent in F2016), as has the average number purchased (from 3.7 in F2011 to 8.3 in F2016). Although the percentage of customers reporting that they had at least one incandescent lamp in storage has remained relatively flat in recent years (between 58 per cent and 65 per cent), the average number of reported lamps in storage has decreased from 10.0 in F2012 to 6.8 in F2017. This translates into approximately 7.1 million incandescent lamps in storage across BC Hydro's service territory.

Objective 3: Evaluated Gross Energy Savings

During the evaluation period, the average number of incandescent lamps installed in homes decreased from 17.6 in F2011 to 13.1 in F2017. Since the introduction of the Phase 1 regulation, the average number of 75 to 100 watt lamps per home decreased from 2.8 to 1.1, with decreases in all wattage categories covered by the regulation. Looking at the pre- to post-regulation period for Phase 2 lamps (F2014 to F2017), there was an overall decrease from 12.1 to 11.0 regulated lamps installed in the home, but decreases were not seen across all wattage categories. Decreases were only observed for lamps in the 40 to <60 watt range, but increases were observed for lamps in the 60 to <75 watt range, which were also covered by the regulation.

The power draw of replacement lamps was estimated at 12.8 watts, based on a weighted average of CFL and LED wattages installed in the home in F2017.

Evaluated gross electric energy savings in residential homes from the changes in incandescent general service lighting were 251 GWh per year in F2017, or 37 per cent of reported savings. This was made up of 226 GWh per year among lamps affected by Phase 1 of the regulation and 25 GWh per year among lamps affected by Phase 2 of the regulation. Energy savings are expressed as an annual rate of savings in F2017 due to changes since the identified baseline year (F2011 in the case of Phase 1 and F2014 in the case of Phase 2).

Table 3 Reported vs Evaluated Savings in F2017

		Energy Savings (GWh/year)		Peak Demand Savings (MW)
		Reported	Evaluated Gross	Evaluated Gross
F2017	Phase 1 lamps	300	226	75
	Phase 2 lamps	377	25	8
	Total	**677**	**251**	**83**

One of the main reasons for the variance between reported and evaluated savings, particularly for Phase 1 lamps, is a difference in assumptions used to estimate the number of regulated lamps in each of the wattage categories in F2011. Because the home audit data was not available when the reported savings model was first developed, it used shelf-space data to estimate the distribution of incandescent wattages, while this evaluation used the distribution of incandescent wattages based on home audits. The shelf-space method overestimated the relative share of 100 watt lamps and underestimated the relative share of 40 watt lamps as compared to the audit data.

The other main reason for the variance is that this evaluation found that the rate of replacement of incandescent lamps has been slower than assumed in reported savings, particularly for Phase 2 lamps. Reported savings assumed that by F2017, there would be a reduction of 15.8 million regulated lamps (approximately 5.1 million Phase 1 lamps and 10.7 million Phase 2 lamps, based on the wattage distributions from the shelf-space study). In contrast, this evaluation estimated that the reduction was in the range of 5 million lamps (approximately 3.1 million Phase 1 lamps and 1.9 million Phase 2 lamps, based on the wattage distributions from the home audits). This suggests that there are still a significant number of incandescent lamps to be replaced, and as the trend towards more efficient lighting continues, there are still significant savings to come in future years.

2.4 Findings and Recommendations

Findings

1. The shelf space of incandescent lamps has halved since F2012 (from 51 per cent to 24 per cent of total lighting shelf space), while the shelf space of LEDs has rapidly increased (from 4 per cent to 40 per cent), indicating that a shift towards energy efficient lighting has occurred in the market at the retail level.
2. The price of LEDs has been sharply declining in recent years, while the price for incandescents has been gradually increasing.
3. Within incandescent shelf space, the percentage that was stocked with potentially non-compliant lamps was estimated at a maximum of 28 per cent in F2017.
4. The number of incandescent lamps installed in the home has been decreasing steadily, while LEDs have been increasing rapidly. CFLs installed in the home appear to have peaked around F2013.
5. Although incandescent lamp purchases have declined over time, there are still a significant number of household purchasing them. In F2016, 34 per cent of households purchased at least one and among those that did, they purchased an average of 6.8 lamps.
6. Customers still have a high number of incandescent lamps in storage – an estimated 7.1 million across BC Hydro’s service territory.
7. The average number of incandescent lamps installed in the home decreased from 17.6 to 13.1 between F2011 and F2017. As of F2017, there were an average of only 1.1 Phase 1 lamps remaining in the home, but still an average of 11.0 Phase 2 lamps.
8. Evaluated gross electric energy savings in residential homes from changes in general service lighting were 251 GWh/year in F2017, which was 37 per cent of reported savings.
9. The main sources of difference between reported and evaluated savings were assumptions about the baseline number of incandescent lamps by wattage

category and the rate of replacement of incandescent lamps. The home audit data was considered to be a better representation of installed incandescent wattages in the home compared to the shelf space data.

Recommendations

1. Consider collecting additional information on lamp characteristics in the shelf space studies in order to better estimate compliance. Consider encouraging government to increase enforcement efforts on regulated lamps if compliance is found to be low.
2. Evaluation and Codes & Standards staff should periodically share information with each other on available data that can inform estimates of reported and forecast savings.

2.5 Conclusions

There have been significant changes in the market for general service lamps between F2011 and F2017, with shifts occurring from incandescent to LED lamps, both on store shelves and installed in homes. However, the rate of replacement for incandescent lamps has been slower than anticipated and there remain a considerable number of 40 to 60 watt incandescent lamps still to be replaced. Evaluated gross savings are 37 per cent of reported.

3 Low Income Program: F2011-F2016

3.1 Introduction

The evaluation encompasses two Low Income Program offers over two separate time periods: Energy Saving Kits for the period April 2010 through March 2016 (ESK: F2011-F2016) and the Energy Conservation Assistance Program – Basic Offer for the period April 2011 through March 2016 Energy Conservation Assistance Program (**ECAP**) Basic: F2012-F2016).

The Low Income Program is a BC Hydro energy acquisition initiative to help income qualifying residential customers reduce their energy bills. During the evaluation period the program provided BC Hydro income qualifying residential customers with free energy efficient products and contractor-installed energy efficiency upgrades.

The program's key objectives were to:

- Make energy efficiency more accessible to low income customers by addressing the key barriers to energy efficiency in this sector (e.g., affordability, availability and awareness).
- Provide energy savings to BC Hydro through the installation of energy efficiency measures.
- Provide low-income customers with the opportunity to reduce their energy consumption and utility bills through energy efficiency improvements.
- Increase knowledge about energy conservation among low-income customers.

The Low Income Program launched in 2008 and has operated continuously since that time.

The scope of this evaluation includes the program's two largest offers: the Energy Saving Kit (**ESK**) and ECAP Basic. Two small offers were not evaluated: the Advanced Weatherization offer and the Apartment Direct Install offer. They accounted for 2 per cent and 1.5 per cent of the program's reported electricity savings, respectively, over the evaluation period. They were not included in this evaluation for method reasons.[1]

The program was available to income qualifying residential customers. Statistics Canada's Low Income Cut Off (**LICO**) was used as the income qualification level prior to July 2014. On July 10, 2014 the income qualification level was raised to 1.3 times the LICO, and recipients of various government income and housing assistance programs were pre-qualified.[2]

The ESK is a package of basic, low-cost energy saving measures that can be installed by a homeowner or tenant. ESKs included items such as energy-efficient light bulbs, faucet aerators, window film and a refrigerator thermometer. Installation of the kit contents resulted in energy savings in lighting, space heating, and water heating.

The ECAP Basic offer was available to income qualified residential customers who lived in single family dwellings, duplexes, townhouses or mobile homes.[3] Eligible applicants received a basic home energy audit, installation of energy saving products, and education on energy saving actions from a contractor. The specific installations varied depending on the outcome of the basic audit, and included products to save on lighting, space heating and water heating. Some customers were also eligible for a refrigerator replacement.

3.2 Approach

Shown below are the evaluation objectives, research questions, data sources and methods.

[1] Participation in Advanced Weatherization was too low to enable statistical analysis. Electricity consumption data was not available for a number of Apartment Direct Install participants.
[2] BC Hydro 2015 Rate Design Application, Chapter 5.
[3] Prior to December 2013 eligibility was also based on annual energy consumption.

Table 4 Evaluation Objectives and Research Questions

Objectives	Research Questions
1. Understand the program's target market and barriers to energy efficiency	• What are the characteristics of the population of eligible program participants? • What are the barriers to energy efficiency improvements among low income customers? • How are program participants different from the general population?
2. Assess the participant experience and measures installed through the ESK offer	• What was the installation rate by kit component? • How easy were the kit contents to install? • How satisfied were participants with the ESK offer? • Would participants have purchased most of these products on their own? • Would participants recommend the ESK to someone they know?
3. Assess the participant experience and measures installed through the ECAP Basic offer	• What measures were installed through the ECAP Basic offer? • How did participants learn about the ECAP Basic offer? • Did participants take additional energy savings actions as a result of participation in the ECAP Basic offer? • How satisfied were participants with the measures installed through ECAP Basic?
4. Estimate net electric energy and demand savings for the ESK and ECAP Basic offers	• What are the net electricity savings attributable to ESK by fiscal year? • What are the net electricity savings attributable to ECAP Basic by fiscal year?
5. Assess the effect of program participation on electricity bill payment performance	• How does participation in the Low Income Program impact the bill payment performance of participating homes?

Table 5 summarizes, for each of the evaluation objectives, the evaluation data and methods used.

Table 5 Evaluation Objectives, Data Sources and Methods

Objectives	Data sources	Method
1. Understand the program's target market and barriers to energy efficiency	• 2012, 2014 Residential End Use Survey • Statistics Canada • Literature review • BC Hydro 2015 Rate Design Application	• Qualitative research
2. Assess the participant experience and measures installed through the ESK offer	• 2014-2015 ESK Apartment Participant Survey (N=460) • 2014-2015 ESK House Participant Survey (N=544)	• Cross tabulations
3. Assess the participant experience and measures installed through the ECAP Basic offer	• 2014-2015 ECAP Participant Survey (N=722)	• Cross tabulations
4. Estimate net electric energy and demand savings for the ESK and ECAP Basic offers	• Electricity consumption data • BC Hydro account data • Program tracking data • Weather data	• Quasi-experimental design with variation in adoption • ANCOVA fixed effects modelling
5. Assess the effect of program participation on electricity bill payment performance	• Program tracking data • Creditworthiness score data • Electricity consumption data	• Quasi-experimental design • ANCOVA fixed effects modelling

The first objective, related to better understanding the program's target market and barriers to participation, was addressed through a review of Statistics Canada information and data collected through BC Hydro's Residential End-Use Surveys.

The second and third objectives, related to assessing the participant experience and measures installed through ESK and ECAP Basic, were addressed using the results of BC Hydro's ESK Apartment, ESK House and ECAP Participant Surveys. The surveys were optional and mailed in to BC Hydro by the program participants throughout most of 2014 and 2015.

The fourth objective, related to net savings, was addressed by conducting statistical analysis separately for ESK and ECAP Basic using electricity consumption and other data. The analysis involved quasi-experimental design with variation in adoption and

ANCOVA fixed effects modelling. This evaluation method produced a reliable estimate of average net savings per participant by fiscal year for both ESK and ECAP Basic.

The fifth objective, related to assessing the effect of program participation on electricity bill payment performance, was also addressed by conducting statistical analysis on creditworthiness scores. The analysis involved the same techniques as objective four.

The method for estimating net electric energy savings was used to provide some insights into savings persistence, the average daily shape of savings and savings seasonality. Peak demand savings were calculated using the evaluated savings shape.

3.3 Results

Objective 1: Understand the Program's Target Market and Barriers to Energy Efficiency

The prevalence of low income families in British Columbia has been higher than in Canada as a whole for more than a decade. The 2016 Census indicated that low income individuals make up 14.4 per cent of the population in British Columbia compared to the national average of 12.8 per cent.[4] The low income population is commonly made up of single parent families and persons not living in an economic family,[5] both elderly and non-elderly. Indigenous people, recent immigrants and persons living with a disability are also at higher risk of being low income compared to the rest of the population.

Members of these vulnerable groups face considerable challenges and barriers. Statistics Canada's LICO outlines the total household income required to qualify as low income, based on the number of occupants in the home. The LICO threshold captures both the very poor and the working poor. Approximately 70 per cent of Canadians living

4 Statistics Canada, 2016 Census of Population, Statistics Canada Catalogue no. 98-400-X2016124. Accessed November 17, 2017.
5 An economic family refers to a group of two or more persons who live in the same dwelling and are related to each other by blood, marriage, common-law, adoption, or a foster relationship.

in poverty (3.1 per cent of all Canadian families) are considered to be working poor.[6] The working poor typically have precarious employment situations (e.g., contract, part-time or temporary work); make minimum wage; have limited or no benefits; and have multiple jobs to cover basic living costs. They have no liquid assets or savings to draw upon, and may be dealing with inadequate housing conditions and food insecurity issues. These challenges can lead to the following barriers to low income households participating in energy efficiency improvements: 1) initial financial outlay required to purchase the measures, 2) duration of customer pay-back from bill saving due to energy efficiency measures, 3) high proportion of renters and, 4) tendency for higher household mobility among renters.

BC Hydro estimates that approximately 11 per cent of residential customers have household incomes below the LICO threshold. With the expansion of program eligibility in 2014 to 1.3 times the LICO, an estimated 21 per cent of residential customers became eligible for the program. From 2014 on, the expansion of the income qualification criteria contributed to a 23 per cent increase in program participation, implying that program participants after that date had higher average income levels than the general population of low-income customers, defined as below LICO.[7]

The energy consumption of ESK, ECAP Basic and all BC Hydro customers was also analysed and compared. The results showed that of the three groups, ECAP Basic participants spend the largest percentage of their income on electricity (4 to 10 per cent) as compared to ESK (2 to 8 per cent) and all customers (2.5 per cent or less) and have the highest electricity consumption per square foot.

6 Lefroncois, A. Canada's Working Poor and Precarious Employment. November 2015. Accessed October 18, 2017, http://www.livingwagecanada.ca/index.php/blog/canadas-working-poor-and-precarious-employment/.
7 BC Hydro 2015 Rate Design Application, Chapter 5, pages 5-76 and 5-77.

Objective 2: Assess the Participant Experience and Measures Installed through the ESK Offer

As noted above, data for this objective was collected through separate surveys of participants living in apartments and houses. However, there was minimal variation in survey responses by dwelling type so the results were combined.

The majority of respondents agreed or strongly agreed that the products were easy to install, that they were satisfied with the products received, and that they would recommend the kits to someone they know. On the five-point agreement scale, where one is "*strongly disagree*" and five is "*strongly agree*". Respondents averaged a score of 2.5 when asked whether they would have purchased most of the products on their own.

Reported installation rates were similar between apartments and houses. The highest installation rate was found for the LED night light and the fridge/freezer thermometer, at approximately 94 per cent. This was followed by the kitchen tap aerator (79 per cent) and CFL light bulbs (76 per cent). Between 41 to 45 per cent of participants living in apartments and houses did not install any window insulator film.[8]

Objective 3: Assess the Participant Experience and Measures Installed through the ECAP Basic Offer

Approximately 50 per cent of respondents learned about ECAP Basic through mail or bill inserts. Others learned about the program through avenues such as their property manager, online, through a friend or family member or from an ECAP representative. There was a mixed response when asked whether their household would have purchased and installed products on their own. Approximately 30 per cent agreed, 25 per cent neither agreed nor disagreed and 40 per cent disagreed. Around 80 per cent of respondents indicated that they had implemented additional energy savings actions since participating in ECAP Basic and the majority of respondents agreed or strongly agreed that they were satisfied with the products installed.

[8] During the program application process, participants could opt in to receive window film or not. This install rate includes participants that requested window film and did not install it, as well as those who requested no window film at all.

A review of program tracking data showed that the most commonly installed product categories were refrigerator thermometers and lighting products, which were installed by 96 per cent and 85 per cent of participating households, respectively. Between 40 to 60 per cent of participating households installed some type of draft-proofing or water heating measure, low flow shower heads, or carbon monoxide (**CO**) detectors. Refrigerators were replaced in about 21 per cent of participating households.

The average number of measures installed per home through ECAP Basic increased in F2013, most notably for lighting products, low flow faucets and CO detectors. The average number of measures installed per home remained relatively stable in subsequent years.

Objective 4: Net Electricity Savings for ESK and ECAP Basic

The evaluated and reported net savings by fiscal year are shown below. Evaluated savings are incremental annual savings.

Table 6 Summary of ESK and ECAP Basic Net Savings F2011-F2016

	Fiscal Year	Energy Savings (GWh/year)		Peak Demand Savings (MW)	
		Reported	Evaluated Net	Reported	Evaluated Net
ESK & ECAP Basic	F2011 (ESK only)	4.7	5.3	1.0	1.1
	F2012	5.9	5.2	1.2	1.0
	F2013	3.3	4.5	0.7	0.9
	F2014	3.5	4.2	0.7	0.8
	F2015	3.1	3.6	0.6	0.7
	F2016	2.8	4.3	0.6	0.9
Total		**23.3**	**27.0**	**4.8**	**5.5**

The results for F2011 include net savings for ESK only. F2011 savings for ECAP Basic were covered in a previous evaluation.[9]

Evaluated savings from both ESK and ECAP Basic were greater than reported savings. ESK evaluated savings totaled 19.7 GWh per year or 116 per cent of reported savings

9 BC Hydro, 2012.

of 17.0 GWh per year. ECAP Basic evaluated savings totaled 7.3 GWh per year or 116 per cent of reported savings of 6.3 GWh per year. The variance is largely due to the evaluation finding that unit savings were higher than anticipated in most years of the evaluation timeframe.

As noted in the introduction, electricity savings from the program's Advanced Weatherization and Apartment Direct Install offers were not included in the scope of this evaluation and are therefore not included in the evaluated savings.

Objective 5: Assess the Effect of Program Participation on Electricity Bill Payment Performance

Statistical analysis on a subset of program participants (those who installed both an ESK and participated in ECAP Basic) revealed improvements in electricity bill payment performance among those who had a history of late payment prior to participating in the program. On average, the creditworthiness scores of F2013 ECAP Basic program participants who previously installed an ESK and who had at least some late payments in F2012 declined (improved) by 56 per cent in F2014. This means that for these participants, the program had a statistically significant influence on their ability or willingness to pay their bills in full and on time. This evaluation did not examine whether a similar outcome would be achieved by customers who participated in other offers or initiatives (e.g., ESK only), or by customers with different demographic or other characteristics than those who were analyzed.

3.4 Findings and Recommendations

Findings

Below are the evaluation findings.

1. The prevalence of low income households is higher in BC than the rest of Canada, and is slightly higher in the Lower Mainland than the rest of BC.
2. Barriers to low income customers participating in energy efficiency improvements include the cost of energy saving products or measures, a rental situation denying

them authority or incentive to invest in energy efficiency and a higher level of household mobility.

3. The large majority of 2014 and 2015 participants found the ESK products easy to install, were satisfied with the products and would recommend the ESK to someone they knew.
4. The large majority of 2014 and 2015 ECAP participants were satisfied with the products installed and have taken additional steps to save energy since the measures were installed.
5. Between F2011-F2016, 70,475 homes registered for an ESK.
6. On average, between F2011 and F2016, ESK participants saved between 262 and 316 kWh per year per home with each kit installed. These averages apply across all regions, building types, and space and water heating fuels.
7. Analysis of F2011 ESK participants living in owned, single family dwellings in the Lower Mainland found that ESK measures saved 752 kWh per year in electric space heating, 496 kWh per year in electric water heating and 159 kWh per year in other end-uses.
8. ESK evaluated net savings between F2011 and F2016 were 19.7 GWh per year, which equates to 116 per cent of what was reported.
9. Between F2012-F2016, 9,358 homes were verified as having installed measures through ECAP Basic.
10. On average, between F2012 and F2016, ECAP Basic participants saved between 642 and 899 kWh per year per home. These averages apply across all regions, building types, and space and water heating fuels.
11. ECAP Basic evaluated net savings between F2012 and F2016 were 7.3 GWh per year, which equates to 116 per cent of what was reported.

12. The evaluated net savings for both ESK and ECAP Basic over the evaluation period was 27.0 GWh per year, which equates to 116 per cent of what was reported.
13. The average ESK unit savings in multi-unit buildings serviced by a single BC Hydro meter could not be estimated due to insufficient data.
14. Among ECAP Basic program participants in F2013 who had at least one late electricity bill payment prior to participating in the program, there was an average 56 per cent reduction (improvement) in their BC Hydro creditworthiness scores between F2012 and F2014. This indicates that among those who participated in both ESK and ECAP Basic, the program had a statistically significant influence on the ability or willingness to pay their bills on time and in full.
15. BC Hydro does not systematically archive creditworthiness score data for residential customers and this limits the ability to analyze the program's impact on bill payment performance.
16. The evaluation required extensive time to clean the program tracking data and understand the impact of program changes on the data over time which could be reduced through changes to data management practices.

Recommendations

Below are the evaluation recommendations. Recommendations 1 through 5 are for program management. Recommendation 6 is for evaluation.

1. Consider continuing to deliver periodic customer surveys if there is an interest in understanding changes in customer satisfaction and measure installation rates over time.
2. In the case of multi-unit residential building where all units share one BC Hydro account and only a portion of residents participate in the program, consider collecting information on all units in the building to increase the feasibility of evaluating this group in the future.

3. Consider systematic archiving of selected creditworthiness score data in order to support future analysis of the program's impact on the bill payment performance of income qualifying residential customers.
4. Continue to seek out opportunities to improve data quality. Actions may include, removing unused data fields in the program tracking data, creating a drop down menu for applicable information fields, developing a data dictionary and reviewing the process for crosschecking customer account ID's against the BC Hydro billing system.
5. Document relevant program changes over time in order to facilitate future evaluations.
6. Determine whether there is a need or interest in further delineation of program savings (e.g., by space or water heating fuel or by building type) to inform evaluation planning going forward.

3.5 Conclusions

The majority of Low Income Program participants were satisfied with the measures installed through the program.

The Low Income Program was successful in achieving electric energy savings among BC Hydro's low income customers. Evaluated net savings were 27.0 GWh per year by the end of F2016, which was 116 per cent of what was reported.

There is evidence to suggest that participation in both ESK and ECAP Basic influenced the electricity bill payment performance of income qualifying customers who had a history of late electricity bill payment prior to participating.

4 Power Smart Partner – Distribution Program: F2011-F2016

4.1 Introduction

This is an impact evaluation of BC Hydro's Power Smart Partner – Distribution (**PSP-D**) DSM program for BC Hydro fiscal years F2011 to F2016 (April 2010 to March 2016). This evaluation also includes elements of a process and market evaluation for the period F2011 to F2016.

BC Hydro's PSP-D program (renamed Leaders in Energy Management – Distribution in F2016) is a multi-year energy acquisition and market transformation initiative that encourages industrial customers that receive electricity supply at distribution voltage to reduce their electricity consumption. The program's target market is BC Hydro's industrial customer sites that are serviced at distribution voltage (< 69 kV). The key program objective during the period evaluated was to partner with program participants to obtain cost-effective electricity savings from capital projects by encouraging them to integrate energy efficiency into their on-going business practices and supporting the development and implementation of energy management systems.

The scope of this evaluation includes electrical energy efficiency and conservation projects at industrial distribution sites, including retrofit and new plant design and plant expansion projects, but excluding operational and procedural measures not supported by a formal sustainment plan. This encompasses the incentive offer and enabling activities, as further described below. During the six-year evaluation timeframe, 2,215 energy efficiency and conservation projects were completed at 767 participating customer sites and reported under the program. Program participants included the following industrial segments: wood, manufacturing, food and beverage, transportation and oil and gas. Similarly, the program reported projects in various end uses with a primary focus in lighting, compressed air and industrial processes.

The main program components and enabling activities in PSP-D F2011-F2016 are summarized below:

- **Custom Projects**
  - Incentives**:** Incentives of up to 75 per cent of project costs were available for custom projects.
  - Program Enabled**:** Customer-funded projects that did not receive direct capital incentive funding but were reported as a result of other program enabling activities.
- **Prescriptive incentives**: Since F2014, smaller lighting and compressed air projects were also eligible for prescriptive incentives under the self-serve incentive program (**SIP**). The Product Incentive Program (**PIP**) and Power Smart Express (**PSX**) were prescriptive programs for customers that consume less than 0.5 GWh per year and offered incentives for simple, one-for-one lighting retrofits.
- **BC Hydro Key Account Managers:** Acted as a liaison between the program and the customer.
- **BC Hydro Alliance of Energy Services Professional (formerly known as the Power Smart Alliance):** Trained and pre-qualified trade allies offering energy efficiency products and services to BC Hydro customers.
- **Energy Studies:** To identify and support a business case for implementation of energy conservation measures. Partially or fully funded by BC Hydro.
- **Energy Managers:** Helped participants adopt strategic energy management practices. Partially funded by BC Hydro.

4.2 Approach

The evaluation objectives and research questions are shown below, followed by the data sources and methods.

Table 7 Evaluation Objectives and Research Questions

Evaluation Objective	Research Questions
1. Assess participant and non-participant experience and satisfaction	What is the participant and non-participant experience related to awareness, understanding, and satisfaction with the various program offers (custom incentive, program enabled, new plant design, prescriptive incentive)? What are the barriers to and drivers of program participation?
2. Assess the program enabling activities	What proportion of the savings came from sites with a BC Hydro funded Energy Manager over time? What is the relationship between presence of energy managers and project activity? Which of the enabling activities had the greatest association with project activity, in general and over time? What could be done to improve the evaluability of the program enabling activities?
3. Estimate gross electrical energy and peak demand savings	What were the gross realization rates by end use? What were the evaluated gross energy and demand savings realized by the PSP-D program, delineated by fiscal year and by offer to the extent possible?
4. Estimate net electrical energy and peak demand savings	What are the evaluated net energy savings and demand savings realized by the PSP-D program, delineated by fiscal year and by offer to the extent possible? What factors impact free ridership among custom and prescriptive projects? How much free ridership occurred among custom and prescriptive projects? How much participant and non-participant spillover occurred in response to the program offers?

Table 8 Evaluation Objectives, Data and Methods

Evaluation Objectives	Data	Method
1. Assess participant and non-participant experience and satisfaction	• 6 waves of participant surveys covering F2011 to F2016 (n=328) • 2 waves of non-participant surveys covering F2011 to F2015 (n=206)	• Cross tabulations
2. Assess the program enabling activities	• Program tracking data	• Cross tabulations • Qualitative analysis
3. Estimate gross electrical energy and peak demand savings	• Program tracking data • Project files • Measurement and Verification results (n=297 measures) • Evaluation Review results (n=20 measures)	• Engineering calculation for measure evaluation review • Extrapolation of Measurement and Verification and Evaluation Review results using stratified ratio estimation • Rate class average peak-to-energy factor
4. Estimate net electrical energy and peak demand savings	• Results of Objective 3 • Project files • Participant survey (n=328 responses covering 341 projects) • Non-participant survey (n=206) • Case studies (n=40 projects)	• Triangulation of case study and survey based free ridership estimates • Survey based spillover algorithm • Rate class average peak-to-energy factor

4.3 Results

Objective 1: Participant and Non-Participant Experience and Satisfaction

Awareness of BC Hydro's conservation programs for industrial customers was highest among custom participants (87 per cent) and non-participants (84 per cent), as well as among SIP participants with a Key Account Manager (**KAM**) (85 per cent). Awareness was somewhat lower for SIP participants without a KAM (78 per cent), SIP non-participants (77 per cent) and Product Incentive Program or Power Smart Express (PIP/PSX) participants (79 per cent), and much lower for PIP/PSX non-participants (52 per cent). In terms of individual program components, understanding and overall ratings were highest for the role that KAMs play as liaisons of the program and the incentive structures for the SIP and custom offers.

Overall satisfaction with the custom and SIP offers was very high with 94 per cent of custom participants, 93 per cent of SIP participants with a KAM, and 91 per cent of SIP participants without a KAM rating it as excellent or good. Satisfaction was somewhat lower for PIP/PSX participants at 83 per cent. In terms of program experience, service provided by contractors and suppliers/distributors rated highly among all participant groups, as did service provided by BC Hydro personnel among those customers with a KAM. Areas which rated lowest included direct mail/email about the program (for all offers), length of time to receive project approval (for the custom incentive offer), length of time to receive incentive (for the custom incentive offer), information about the program on the website (for the SIP offer), variety of products funded by the program (for SIP and PIP/PSX) and usability of the online application (for PIP/PSX).

Among all participant and non-participant groups, the factors that emerged as the greatest motivators to conserve electricity were making operating costs as low as possible, the overall level of electricity prices, a focus on cost cutting measures due to the economic downturn or conditions, and to benefit the environment. Among participants, the individual program offers also emerged as motivators. The largest barriers to conserving electricity were lack of funds for energy efficient retrofits, other operational priorities, and a lack of financial incentives for conservation programs. Among non-participants, the main reasons for not participating in the PSP-D program were that the benefits were not worth it, the customer needed more information, and the customer thought the organization was not eligible to participate.

Objective 2: Assess the program enabling activities

Program enabling activities provided participants with a suite of tools and offers intended to help them to implement energy saving projects while also building energy management activities into their standard business practices over the long term. The tools and offers included funding for an energy manager position, energy efficiency feasibility studies, customer site investigations and plant-wide audits, end use assessments, as well as the support and expert consultation from the BC Hydro Alliance.

The evidence reviewed for this evaluation indicates that energy managers played an important role in program participation. During the evaluation period, sites with energy managers completed more than twice as many projects per site relative to those without energy managers (on average, 2.7 projects versus 1.2 projects). Also, the relative level of project savings (as a per cent of site energy consumption) was twice as high at sites with energy managers than at sites without an energy manager for small and large sites based on site energy consumption during the evaluation period.

Under the program's custom offer, 25 per cent of the projects implemented during the evaluation period, and 43 per cent of the expected energy savings, were supported by a program-funded energy study. Similarly, 34 per cent of the projects and 43 per cent of the expected energy savings were supported by a program-funded energy manager. Further, 72 per cent of expected energy savings were supported by either an energy study or an energy manager, indicating that most sites participated in either the energy manager or energy study program enabling activity but not both. Sixty per cent of energy savings occurred at sites that had previously participated in one of the program's enabling activities.

Objective 3: Estimate gross electrical energy and peak demand savings

Evaluated gross energy savings provide an estimate of savings achieved at participating sites, irrespective of whether they are attributable to the program. Evaluated gross savings are estimated by applying a realization rate derived from measurement and verification results to the expected savings by end use measure. The three samples of end use measures that were evaluated were lighting, compressed air and other end uses with realization rates and evaluated gross energy savings of 101 per cent (122 GWh/year), 112 per cent (43 GWh/year), and 89 per cent (55 GWh/year) respectively. An overall realization rate of 99 per cent was calculated for the entire program in the evaluation period, indicating that, on average, projects supported by the program achieved their expected savings. Evaluated gross energy savings averaged 8.5 per cent of site energy consumption across all participants during the six year evaluation period.

Table 9 Summary of Gross Energy and Peak Demand Savings

Period	Number of Measures	Energy Savings (GWh/year)		Peak Demand Savings (MW)
		Expected Gross	Evaluated Gross	Evaluated Gross
F2011	579	43.7	44.2	6.0
F2012	806	34.4	36.4	4.9
F2013	733	40.1	38.1	5.2
F2014	521	27.5	27.1	3.7
F2015	534	44.7	43.5	5.9
F2016	550	30.9	30.6	4.2

Objective 4: Estimation of Net Electricity Savings

Net electricity savings are the change in energy consumption and demand that is attributable to the program. They exclude free riders and include spillover. Free ridership provides an estimate of the proportion of evaluated gross energy savings that are not attributable to the program. Free ridership was estimated separately for the three types of projects reported by the program: custom, SIP and PIP/PSX with estimated free ridership of 14 per cent, 12 per cent and 18 per cent respectively. Spillover savings are additional savings that occurred due to the program's influence. Spillover was estimated at 11 per cent for the overall evaluation period among participants and non-participants. An overall net to gross ratio of 97 per cent was calculated for the entire program in the evaluation period. Evaluated net energy and peak demand savings are shown in Table 10 and average 108 per cent of reported savings, showing that the program performed better than reported.

Table 10 Summary of Net Energy and Peak Demand Savings

	Energy Savings (GWh/year)		Peak Demand Savings (MW)	
Period	Reported	Evaluated Net	Reported	Evaluated Net
F2011	41.9	43.1	5.7	5.9
F2012	31.2	35.3	4.2	4.8
F2013	35.9	36.8	4.9	5.0
F2014	23.6	26.1	3.2	3.5
F2015	37.8	41.9	5.1	5.7
F2016	27.2	29.6	3.7	4.0

The variance between reported and evaluated net savings is primarily due to the evaluated net to gross ratio being higher than what was assumed for reported savings.

4.4 Findings and Recommendations

Findings

1. Awareness of the PSP-D offers was highest among custom participants and non-participants, as well as SIP participants with a KAM. In terms of individual program components, awareness was highest for energy studies and the role that KAMs play as liaisons for the program.
2. Overall satisfaction with the custom and SIP offers was very high with over 90 per cent of participants rating these offers as excellent or good. Satisfaction was lower among PIP/PSX participants at 83 per cent.
3. Over 80 per cent of the program enabled projects (62 per cent of gross energy savings) reported through the program came from sites with an energy manager.
4. Overall, when comparing sites of similar size, the sites with energy managers completed more projects and achieved more energy savings per project. The relative level of project savings (as a per cent of site energy consumption) was twice as high at sites with energy managers than at sites without: 10 per cent versus 5 per cent for sites with energy consumption higher than 4 GWh/year, and

24 per cent versus 12 per cent for sites with energy consumption less than 4 GWh/year.

5. Forty-six per cent of the program's energy savings were supported by either or both of an energy manager or energy study. Sixty per cent of the program's energy savings occurred at sites that had previously participated in program enabling activities.
6. The lack of a standardized process for tracking customers' program enabling activities in project files made it difficult to identify and assess the influence of individual enabling activities on the project's energy savings unless the case study method was applied during evaluation.
7. The program gross realization rate calculated from M&V results was 99 per cent, indicating that the energy conservation measures largely performed as expected. Three end use level realization rates were estimated: compressed air at 112 per cent, lighting at 101 per cent and other end uses at 89 per cent with relative precision between 6 per cent and 9 per cent at 90 per cent confidence.
8. Expected energy savings averaged 8.5 per cent of site energy consumption across all participants during the six year evaluation period.
9. The average weighted persistence of measures (i.e., the length of time that the savings are reported by the program) was 13.1 years during the evaluation period.
10. The net-to-gross ratio was 97 per cent based on an overall level of free ridership of 14 per cent, participant spillover of 7 per cent and non-participant spillover of 4 per cent.
11. Evaluated net savings during the evaluation period from F2011 to F2016 averaged 108 per cent of reported savings.

Recommendations

Recommendation 1 is for program management and Recommendations 2 and 3 are for future evaluations.

1. In consultation with the Evaluation Department, consider ways to improve the evaluability of the program enabling activities through improved documentation and tracking of energy savings opportunities identified and level of influence of program enabling activities.
2. Consider using a greater sample of case studies to assess influence of program enabling activities on custom projects.
3. Should future evaluations use top-down statistical analysis of facility consumption to estimate savings from Strategic Energy Management, review the approach to evaluating participant spillover to ensure there is no double counting of savings.

4.5 Conclusions

BC Hydro's Power Smart Partner – Distribution program achieved 108 per cent of reported savings during fiscal years F2011 to F2016. The program also achieved high levels of customer awareness and satisfaction.

5 Residential Inclining Block Rate: F2013-F2017

5.1 Introduction

The Residential Inclining Block (**RIB**) rate is a two-step rate structure where BC Hydro's residential customers pay a lower price for electricity consumption up to a certain threshold, and a higher price for electricity consumption beyond the threshold.

The RIB rate went into effect in October 2008 for approximately 1.6 million residential customers. The Step 1 to Step 2 threshold was set at 1,350 kWh per two-month billing period, which was approximately 90 per cent of the median consumption of BC Hydro's residential customers. The Step 2 rate was established at BC Hydro's current estimate of the cost of new energy supply, grossed up for losses, and the Step 1 rate was calculated to achieve revenue neutrality for the residential class. The over-arching objective of the RIB rate was to use price to encourage additional electricity conservation relative to what was achievable through a flat rate structure.

The last evaluation of the RIB rate was conducted in 2013[10] and evaluated the price elasticity of consumption and the electricity conservation impacts in response to the rate's two-step structure, as well as customer awareness, understanding, and response to the RIB rate for the period from October 2008 through March 2012 (the mid-point of F2009 through F2012). This evaluation is a continuation of the 2013 evaluation, and covers April 2012 through March 2017 (F2013-F2017).

5.2 Approach

The evaluation objectives and research questions are shown on the following page.

---

[10] BC Hydro (2014) "Evaluation of the Residential Inclining Block Rate F2009-F2012", Revision 2, Power Smart Evaluation, BC Hydro.

Table 11 Evaluation Objectives and Research Questions

Objectives	Research Questions
1. Estimate Price Elasticity	• What is the price elasticity of Step 1 and Step 2 consumption? • Is there a difference in price elasticity between BCH customers and a comparable community without a RIB rate (e.g., New Westminster)? • What is the price elasticity due to natural conservation, as measured by the price response to general rate increases through F2017? • How do the results of research questions related to price elasticity compare to previous research on this topic conducted as part of the last RIB rate evaluation?
2. Estimate the Conservation Impacts of the RIB Rate	• What are the energy savings due to BC Hydro's RIB Rate from F2013 to F2017? • What are the peak demand savings due to BC Hydro's RIB rate from F2013 to F2017? • What are the energy savings due to natural conservation from F2013 to F2017, as measured by the price response to general rate increases?
3. Analyze Differences in Price Elasticity by Customer Characteristics	• Are there differences in price elasticity by region? • Are there differences in price elasticity by dwelling type? • Are there differences in price elasticity by space heating type? • How do the results of research questions related to price elasticity compare to previous research on this topic conducted as part of the last RIB rate evaluation? • Are there differences in price elasticity between winter and summer periods?
4. Evaluate the Customer Response and Understanding of the RIB Rate	• Are there differences in the characteristics or demographics of customers who are never billed in Step 2 compared to those who are sometimes or always billed in Step 2? • What is the level of customer awareness and understanding of the RIB rate? • To what degree do customers believe electricity prices provide an incentive to manage electricity consumption? • To what extent do customers believe the total electricity bill amount provides an incentive to manage electricity consumption? • What is customers' understanding of their prevailing electricity price under the RIB rate structure? • To what extent do customers believe the RIB provides an incentive to manage electricity consumption? • To what extent do RIB aware customers report energy conserving behaviours as compared to non-RIB aware customers? • To what extent do RIB aware customers report implementing longer term capital investment in energy efficiency or conservation as compared to non-RIB aware customers? • Was program participation in DSM programs different between customers aware / not aware of the RIB rate? • Did low income customers have a different perception or response to the RIB Rate? • Does the RIB rate have any impact on customers' decisions on fuel switching from electricity to thermal fuels? • Is the RIB rate perceived as a barrier to electrification? • Has customers' response/acceptance to RIB changed over time? • Do customers support the RIB rate? • Do notifications / alerts on Step 2 have an impact on customers' consumption behaviour? • How do the results of research questions related to customer response and understanding of the RIB rate compare to previous research on this topic completed as part of the last RIB rate evaluation or REUS surveys?

The table below summarizes the data sources and methods employed in this study for each evaluation objective.

Table 12 Summary of Evaluation Objectives, Data Sources and Methods

Evaluation Objective	Data Sources	Methods
1. Estimate Price Elasticity	• BC Hydro billing data from April 2004 to December 2016, including electricity consumption, space heating fuel, region and dwelling type by account • BC Hydro residential rate prices from April 2004 to December 2016 • BC Hydro DSM expenditures and savings, from 2004 to 2017 • BC Consumer Price Index data from April 2004 to December 2016 obtained from Statistics Canada • BC real disposable income from April 2004 to December 2016 from BC Stats • Heating and cooling degree days by region from April 2004 to December 2016 • New Westminster customer billing data from 2005 to 2016 and customer information on heating fuel and dwelling type	• Econometric modelling of price elasticity
2. Estimate the Conservation Impacts of the RIB Rate	• Data and results from Objective 1 • BC Hydro residential rate class load shape	• Calculation based on price elasticity and rate class load shape
3. Analyze Differences in Price Elasticity by Customer Characteristics	• Same as Objective 1	• Same as Objective 1
4. Evaluate the Customer Response and Understanding of the RIB Rate	• 2012 customer survey (n = 2,468) • 2017 customer survey (n = 3,307) • 2014 Residential End-Use Study (n=7,318) • 2017 Residential End-Use Study (n=6,929) • BC Hydro billing data from F2012 and F2017 • Data on customer sign-ups for Step 2 alerts • BC Hydro residential DSM program tracking data	• Cross tabulations of survey responses • Linking of survey responses to respondent billing history • Difference in proportions z-tests • Difference of Means Tests using Analysis of Variance

Objective 1, estimating price elasticity, and Objective 3, analyzing elasticities differences by customer characteristics, were addressed through econometric modeling which utilized a variety of data sources including electricity consumption and Statistics Canada data. Objective 2 was a calculation using the results from Objective 1.

Objective 4, related to evaluating customer response and understanding of the RIB rate, was largely addressed through analysis and comparison of the results from two similar residential customer surveys which were delivered in 2012 and 2017.

5.3 Results

Objective 1: Price Elasticity

Step 1 consumption represents the consumption of those customers whose bi-monthly usage does not exceed the 1,350 kWh threshold. The Step 1 price elasticity of these customers was estimated to be -0.14. The previous RIB evaluation in 2013 was unable to detect a Step 1 price elasticity over the F2009 to F2012 period, nor did a subsequent analysis over the F2009 to F2015 period. Due to the fact that Step 1 price elasticity could not be detected for the F2009 to F2015 period, the estimate of -0.14 was only seen to be applicable to F2016 and F2017.

Step 2 consumption represents the consumption of those customers whose bi-monthly usage exceeds the 1,350 kWh threshold. The Step 2 price elasticity of these customers was estimated to be -0.08, which is at the low end of the range estimate of -0.08 to -0.13 from the 2013 evaluation. The current estimate indicates that in comparison to the earlier years of the RIB rate, customers who were exposed to Step 2 prices in recent years may have become less price responsive—measured by percentage change in consumption—to Step 2 price increases. It also indicates that their capacity and options to conserve energy while facing price increases may have been more limited in recent years. Meanwhile, Step 1 consumption has become price sensitive in recent years.

Table 13 Step 1 and Step 2 Price Elasticity Estimates

Time Series Analyzed	Step 1 Elasticity	Step 2 Elasticity
F2005-F2012	Not statistically significant	-0.08 to -0.13***[11]
F2005-F2015[12]	Not statistically significant	Not analyzed
F2005-F2017	-0.14***	-0.08***

*** indicates statistically significant at 95% confidence level.

The price elasticity of electricity consumption under a flat rate is used to calculate the natural conservation impact that would be achieved by general rate increases as per BC Hydro's approved Revenue Requirements. This flat rate price elasticity is used to estimate the baseline conservation that would have occurred in the absence of the RIB rate. The flat rate price elasticity could not be estimated through econometric analysis. A range estimate between the Step 1 and Step 2 elasticities was adopted (-0.08 to -0.14) to calculate the natural conservation impact. Since the Step 1 price elasticity estimate of -0.14 was only applicable to F2016 and F2017, the range estimate of the flat rate elasticity was similarly applied to F2016 and F2017 only. In the absence of an empirical estimate of flat rate elasticity in the F2013 to F2015 period, the planning assumption of -0.05[13] was applied to those years.

Objective 2: Conservation Impacts of the RIB Rate

In order to evaluate additional energy conservation achieved under the RIB rate relative to the flat rate, the energy impacts of the Step 1, Step 2, and the flat rate price response were calculated separately. The baseline scenario was considered natural conservation achieved under the flat rate due to general rate increases and the RIB rate structural savings were calculated as the sum of the Step 1 and Step 2 energy impact, less the natural conservation impact. The annual incremental structural savings from the RIB rate between F2013 and F2015 are presented below. The calculations are based on the

11 BC Hydro (2014).
12 In 2016, an analysis was conducted to evaluate the Step 1 price elasticity for the period of F2005-F2015. This analysis did not produce statistically significant results. The modelling outputs from this analysis were included in Appendix D.
13 Orans, R (2008), the source and reasons for adopting this assumption were provided in the expert testimony of the 2008 BC Hydro Long-Term Acquisition Plan, Appendix E.

value of Step 1 elasticity (zero), Step 2 elasticity (-0.08) and assumed flat rate elasticity (-0.05).

Table 14 RIB Rate Savings F2013-F2015

Fiscal Year	Step 1 Price Impact (GWh)	Step 2 Price Impact (GWh)	Natural Conservationz (GWh)	RIB Structural Savings (GWh)
	A	B	C	(A + B - C)
Elasticity	**0.00**	**-0.08**	**-0.05**	**-**
F2013	-	49	24	23
F2014	-	16	13	3
F2015	-	74	62	13

Given the potential range in flat rate elasticity (-0.08 to -0.14; assuming that it lies between the estimates of Step 1 and Step 2 elasticity), natural conservation and RIB structural savings in F2016 and F2017 could not be estimated with precision. Table 15 shows the calculation of natural conservation and RIB structural savings using four different flat rate elasticities: -0.08, -0.09, -0.10 and -0.14. Based on this calculation, savings appear to decrease as flat rate elasticity increases. Based on the results derived through the range estimate, the evaluated RIB energy savings in F2016 and F2017 were deemed to be small or zero, as shown in Table 16 below.

Table 15 RIB Rate Savings F2016-F2017

	Step 1 Price Impact (GWh)	Step 2 Price Impact (GWh)	Natural Conservation (GWh)				RIB Structural Savings (GWh)			
	A	B	C				(A + B- C)			
Elasticity	**-0.14**	**-0.08**	**-0.08**	**-0.09**	**-0.10**	**-0.14**	**-0.08**	**-0.09**	**-0.10**	**-0.14**
F2016	26	45	60	67	75	104	11	4	(3)	(33)
F2017	13	23	29	33	37	52	6	2	(2)	(16)

Based on the estimates of Step 1 (-0.14), Step 2 (-0.08), and the adopted flat rate elasticity range (-0.08 to -0.014) , the energy and peak demand saving impacts attributed to the RIB rate were calculated as presented in the table below.

Table 16 Reported and Evaluated RIB Rate Savings

	Energy Savings (GWh)		Peak Demand Savings (MW)	
Fiscal Year	Reported	Evaluated	Reported	Evaluated
F2013	42	23	9	5
F2014	19	3	4	1
F2015	59	13	12	3
F2016	29	0 to 11	6	0 to 2
F2017	8	0 to 6	2	0 to 1

Two major factors contribute to the variance between reported and evaluated RIB rate savings. First, the Step 2 price elasticity of -0.08 was smaller (in absolute value) than the planning assumption of -0.1. Second, the flat rate elasticity range estimate applied to F2016 and F2017 was higher (in absolute value) than the value used in the forecast of RIB savings (-0.05).

Objective 3: Price Elasticity by Customer Characteristics

Additional analyses were conducted to determine if separate price elasticity estimates could be identified based on season or specific customer characteristics such as region, dwelling type, and space heating fuel. Those results are presented in Table 17, where each category (region, dwelling type, space heating, winter vs summer) shows the results of a separate regression analysis. The results included in Table 17 show that Step 1 and Step 2 price elasticity varied by region, dwelling type, space heating type and winter versus summer. In some instances, the elasticity estimate was not statistically significant.

Table 17 Step 1 and Step 2 Price Elasticity by Customer Characteristics

Customer Segment	Step 1 Elasticity	Step 2 Elasticity
Region		
Lower Mainland	-0.22***	Not statistically significant
Vancouver Island	-0.18***	-0.12***
Southern Interior	Not statistically significant	Not statistically significant
North	-0.23***	Not statistically significant
Dwelling Type		
Single Family Dwelling	-0.04***	-0.08***
Row/Townhouse	-0.14***	-0.10***
Apartment	-0.26***	-0.07***
Mobile Home	-0.12***	-0.09***
Space Heating		
Electric	-0.11***	Not statistically significant
Non-Electric	-0.18***	-0.17***
Winter vs. Summer	Not statistically significant	More negative by 0.05 in winter than in summer (e.g., if summer price elasticity is -0.07, winter is -0.12)

*** indicates statistically significant at 95% confidence level.

Objective 4: Customer Response and Understanding of the RIB Rate

Between F2013 and F2017, the proportion of customer households that never incurred Step 2 electricity consumption remained generally unchanged at approximately 30 per cent. However, the proportion that sometimes incurred Step 2 consumption (one to 11 months) increased from 39 per cent to 48 per cent while the proportion that always incurred Step 2 consumption (12 months) decreased from 30 per cent to 22 per cent.

Between 2012 and 2017, there was an increase from 53 per cent to 64 per cent in the proportion of customers who believed that BC Hydro's residential electricity prices were too high. In fact, for customers that never incurred electricity consumption beyond Step 1, there was no longer a majority in 2017 – as there was in 2012 – who felt that prices were ‘about right’. The largest segment of these customers now believed prices were too high.

At 49 per cent in 2012 and 47 per cent in 2017, there has been no meaningful change over the past five years in the proportion of customer respondents who knew that BC Hydro charges their consumption of electricity on an inclining block rate. For these particular customers, they believed that their total bill amounts serve as the greatest incentive to manage their consumption of electricity, followed by electricity prices and then followed by the rate structure. In fact, the RIB rate structure was seen as less of an incentive in 2017 than it was in 2012.

In the 2017 survey, customers previously aware of the RIB rate were more likely than others to have completed a home energy efficiency upgrade in the previous three years, to have participated in at least one of BC Hydro’s conservation programs, and to have outperformed other customers on many in-home conservation behaviours. However, it could not be ascertained through the research if and to what extent awareness of the rate structure led to the decisions to engage in these activities.

Customer support of BC Hydro’s RIB rate decreased from 59 per cent to 55 per cent between 2012 and 2017. Support continues to measure highest among customers who never incur Step 2 electricity consumption in a fiscal year.

5.4 Findings and Recommendations

Findings

Price Elasticity

1. The overall average Step 1 price elasticity was estimated to be -0.14 for F2016 and F2017. Previous analyses, covering the time period of F2005-F2012 and F2005- F2015, were unable to detect Step 1 price elasticity, likely due to relatively low Step 1 prices and small changes in the Step 1 price in earlier years. As a result, Step 1 price elasticity was assumed to be zero in the calculation of energy

savings for F2013 to F2015, which was the same approach used in the 2013 evaluation.

2. Step 2 price elasticity was estimated at -0.08, which is at the low end of the range from the previous evaluation (-0.08 to -0.13). This result may suggest that customer response to the Step 2 price has diminished over time.
3. A range of -0.08 to -0.14 was adopted to estimate natural conservation due to general rate increases under a flat rate in F2016 and F2017. This range spans the empirical estimates for Step 1 and Step 2 price elasticity for F2016 and F2017. In the absence of empirical estimates of flat rate and Step 1 price elasticities in the F2013-F2015 period, the planning assumption of -0.05 was applied for natural conservation in those years.
4. To obtain a proxy estimate of the flat rate elasticity, an analysis of residential consumption data from F2005 to F2016 in New Westminster, a jurisdiction serviced under a flat rate, was conducted. However, it did not produce a statistically significant estimate of flat rate elasticity.

Conservation Impacts of the RIB Rate

1. The annual incremental structural savings from the RIB rate were evaluated at 23 GWh, 3 GWh, and 13 GWh between F2013 and F2015.
2. Given the range of estimated flat rate elasticity due to general rate increases, (-0.08 to -0.14), definitive results for natural conservation and RIB structural savings in F2016 and F2017 could not be determined. Calculated RIB structural savings in F2016 and F2017 decreased as the flat rate elasticity increased. As a result, RIB structural savings in F2016 and F2017 were deemed to be small or zero.

Differences in Price Elasticity by Customer Characteristics

1. Price elasticity by region: Step 1 price elasticity was detected in three out of four geographic regions compared to none in the previous evaluation.[14] Step 2 price elasticity was detected in one region compared to all four regions in the previous evaluation. These results indicate that the Step 2 price is no longer a strong factor in determining electricity consumption in a large part of BC Hydro's service area.
2. Price elasticity by dwelling type: Step 1 price elasticity was identified in four dwelling types compared to none in the previous evaluation. Relative to the previous evaluation, Step 2 price elasticity decreased among single family dwellings and increased among row or townhouses and apartments.
3. Price elasticity by space heating type: Step 1 price elasticity was detected in households with electric and non-electric primary space heating, contrary to the previous evaluation. Step 2 price elasticity was only detected in households with non-electric primary space heating, and at a lower level than in the previous evaluation. The previous evaluation detected Step 2 price elasticity in both types of households. This finding suggests that energy savings induced by price changes from F2013 forward may have come from sources other than electric space heating.
4. Price elasticity in winter vs. summer: The analysis found no statistically significant difference in Step 1 price elasticity between winter and summer and a difference of -0.05 in Step 2 price elasticity—with elasticity being more negative in winter than in summer. This result indicates that for Step 2 consumption, the price sensitivity and price impact are greater in winter than in summer.

Customer Response, Awareness, and Understanding

1. From F2013 through to F2017, the proportion of customer households that incurred at least some Step 2 electricity consumption remained generally even at 70 per cent. Through these five years, however, there was a decrease from

[14] BC Hydro (2014).

30 per cent to 22 per cent in the proportion that were into Step 2 in each month of a fiscal year.

2. Between 2012 and 2017, there was an increase from 53 per cent to 64 per cent in the proportion of customers who felt that BC Hydro's residential electricity prices were too high. Furthermore, the extent that customers felt this way was highly correlated with their exposure to Step 2 electricity consumption.
3. For customers that never incurred electricity consumption beyond Step 1, there was no longer a majority in 2017 – as there was in 2012 – who felt that prices were 'about right'. The largest segment of these customers now believed prices were too high. Their beliefs around the price of electricity in each of the 2012 and 2017 surveys help to explain why a Step 1 price elasticity was not detected until F2016 and F2017 as customers became increasingly responsive to increases in the Step 1 price.
4. Customers' unaided awareness that BC Hydro charges household consumption of electricity on an inclining block rate has gone generally unchanged over the past five years, measuring 49 per cent in 2012 and 47 per cent in 2017.
5. For customers previously aware of the RIB rate in each of the 2012 and 2017 surveys, their total bill amounts emerged as serving more of an incentive to manage their consumption of electricity than did electricity prices or the rate structure. In fact, the inclining block rate was considered to be less of an incentive in 2017 than it was in 2012, which is consistent with the findings regarding price elasticity and conservation.
6. Customers previously aware of the RIB rate in the 2017 survey were more likely than others to have completed a home energy efficiency upgrade in the previous three years, to have participated in at least one of BC Hydro's conservation programs, and to have outperformed them on many in-home conservation behaviours. However, it could not be ascertained through the research if and to

what extent awareness of the rate structure led to the decisions to engage in these activities.

7. The total proportion of customers who support the RIB rate – including those who may have learned about it for the first time in the survey – has decreased from 59 per cent to 55 per cent over the past five years. Support continues to measure highest among customers who never incur Step 2 electricity consumption.

Recommendations

1. Consider whether the existing rate structure continues to serve BC Hydro's business objectives and meet customer needs, given that the current RIB rate structure appeared to yield little or no energy savings in F2016 and F2017.
2. Given the finding that larger consuming customers are more price responsive in the winter than in summer, consider exploring the value of a seasonal rate, with different pricing and consumption thresholds in the winter.
3. Consider the value of targeting small electricity consumers (e.g., those living in apartments) with existing or new DSM program offers, given their increased response to price changes in recent years.

5.5 Conclusions

Although awareness of the RIB rate has remained relatively unchanged over the past five years at just under 50 per cent among all residential customers, the survey analysis has shown that a greater proportion of small customers now feel that electricity prices are too high and the econometric analysis has indicated that they have become more responsive to price changes.

Overall, the RIB rate appears to have achieved its objective of encouraging conservation through the customer response to higher marginal prices. However, the effectiveness of the RIB rate in yielding electricity savings appears to have diminished over time.

6 Residential Retail Program – Consumer Electronics and Appliance Rebate Offers: F2011 to Second Quarter F2015

6.1 Introduction

This report provides the results from an evaluation of the impact of the Residential Retail Program for the period from F2011 through to the second quarter of F2015 (i.e., April 2010 through September 2014). The Residential Retail Program was a multi-year energy acquisition and market transformation initiative that facilitated the use of more energy efficient products by BC Hydro's residential customers. The focus of this evaluation report is on the Consumer Electronics offer and the Appliance Rebate Offer.

Consumer Electronics

The Consumer Electronics offer was launched in 2009 with an objective to reduce the electricity consumption resulting from the increased use of home electronics. When the offer was introduced, it consisted of two main components: new TV sales and old TV recycling. A third component involving set-top boxes was introduced in F2013.

The new TVs component provided a mid-stream incentive to participating retailers for the sale of high efficiency TVs. In-store promotional materials were made available to retailers. Training was offered to sales staff to increase their knowledge of the features and benefits of high efficiency TVs.

Recycling old TVs was promoted through advertising and outreach activities to encourage homeowners to unplug and recycle older used TVs. Outreach activities occurred in F2013 (April and January) and in F2014 (February) in selected communities inviting households to drop off their unwanted TVs at specific locations. A pick-up service was also offered in some communities in F2013 and F2014 in partnership with 1-800 Got Junk.

BC Hydro partnered with TELUS to investigate ways to increase the efficiency of set-top boxes installed by the company among its customer base. BC Hydro provided an incentive to TELUS to enable the auto-power down feature through a software update across its deployed set-top boxes in F2013, in British Columbia and Alberta. All new boxes purchased after September 2012 were also enabled with the auto-power down feature.

Appliance Rebate Offer

The objective of the appliance rebate offer was to obtain energy savings by encouraging the purchase of the most energy efficient refrigerators, freezers, clothes washers and dishwashers. The program employed a variety of promotional strategies including advertising, point of sale material and improved labelling of products. In addition, training was offered to sales staff to increase their knowledge of the features and benefits of high efficiency appliances. Rebates were provided to purchasers of qualifying refrigerators, freezers, clothes washers, and dishwashers. The appliance rebate offer was introduced in 2008 and operated on a year-round basis until the end of October 2013.

6.2 Approach

Shown below are the evaluation objectives and research questions.

Table 18 Evaluation Objectives and Research Questions

Objectives	Research Questions
1. Program Effectiveness	• How effective were each of the offers at reaching their target markets? • How influential was the program on customers' decisions to purchase high efficiency TVs or appliances, or to recycle their old TVs? • How easy was the process to apply for an appliance rebate? • How did appliance rebate participants rate the dollar value and speed of receiving the rebate? • How did retail partners rate the influence of the program on promoting sales of energy efficient TVs and appliances, and installing energy efficient set-top boxes? • How satisfied were retail partners with the consumer electronics and appliances offers?
2. Market Trends	• What were the sales trends for new TVs? • What were the stocking and price trends among energy efficient TVs and appliances? • What were trends in the types of consumer electronics and appliances installed in BC Hydro residential customer homes?
3. Evaluated net electricity savings – Consumer Electronics	• What were the gross and net electricity savings for new TVs, set-top boxes and recycled TVs? • To what extent could sales of energy efficient TVs, installation of energy efficient set-top boxes and recycling of old TVs be attributed to the Consumer Electronics offer? • To what extent was there spillover associated with the new TVs components of the offer? • How do evaluated net electricity savings compare to reported savings, and what are the reasons for any variance?
4. Evaluated net electricity savings – Appliance Rebate	• What was the rate of free ridership for each type of appliance? • To what extent was there spillover associated with the rebate offer? • What were the gross and net electricity savings for each appliance? • How do evaluated net electricity savings compare to reported savings, and what are the reasons for any variance?

Data sources and methods used to address each of the objectives are summarized in Table 19.

Table 19 Evaluation Objectives, Data Sources and Methods

Objectives	Data sources	Method
1. Program effectiveness	• 2014 Consumer Electronics Survey (n=501) • 2014 Appliance Program Participant Survey (n=1,119) • 2012, 2013, 2014 Retail Partners Surveys (n = 5, 8, 13) • 2015 Cable TV Service Provider interview (n=1)	• Frequency distributions • Cross tabulations • Qualitative analysis
2. Market Trends	• Annual Household Electronics and Appliances Floor Stock Study from 2001 to 2014 (~ 40 stores per year) • Residential End Use Surveys from 2001 to 2014 (n = 4,338 to 7,907 depending on year) • Sales data for new TVs in BC (January 2011 to December 2015)	• Frequency distributions • Cross tabulations • Trend analysis
3. Evaluated net electricity savings – Consumer Electronics	• 2014, 2015 Consumer Electronics Survey (n = 501; 500) • 2012, 2014 Residential End Use Survey (n = 7,907; 7,451) • Sales data for new TVs in BC, from January 2011 to December 2015 • Annual Household Electronics and Appliances Floor Stock Study 2001 to 2014 (~ 40 stores) • 2008 TV and Set-top Box Survey (n=641) • 2010 Residential Monitoring Study (48 homes) • 2015 Consumer Electronics Metering Study (53 homes) • Technology and Market Profile: Consumer Electronics. Marbek (2006) • 2015 Cable TV Service Provider interview (n=1)	• Engineering algorithms • Load shape analysis • Stock and flow model estimates • ARIMA modelling • Common practices baseline using market data analysis • Survey-based program attribution estimation
4. Evaluated net electricity savings – Appliance Rebate	• Program Tracking Data • Annual Household Electronics and Appliances Floor Stock Study 2001 to 2014 (~ 40 stores) • 2014 Appliance Rebate Participant Survey (n=1,119)	• Engineering algorithms • Survey-based participant free rider and spillover estimation

6.3 Results

Objective 1: Program Effectiveness

New Televisions

The program incented between 12 per cent and 30 per cent of all TVs sold annually in B.C. during the evaluation period. It also incented 94 per cent of the high efficiency TVs sold in F2012 and more than half of those sold in F2013 (55 per cent). Aggregating survey results from all years, eight out of 15 retailers indicated that the incentive was very or somewhat influential on their stocking decisions regarding high efficiency TVs. Overall, retail partners were satisfied with BC Hydro's promotions of new TVs.

Of those households that had recently purchased a new TV, 22 per cent recalled seeing promotional materials. Of those who recalled the promotion, 82 per cent purchased a high efficiency model and 94 per cent in that group indicated the promotional materials had influenced their decision to purchase that particular model.

Recycled TVs

Twenty-one per cent of respondents to the 2014 Consumer Electronics Survey reported they recalled seeing, hearing or reading BC Hydro information about recycling TVs. Of those who had recycled a TV after being exposed to the promotional information, 75 per cent reported the campaign influenced their decision to recycle.

Set-top Boxes

TELUS rated BC Hydro's encouragement and financial support as very important to enabling the auto-power down feature of their set-top boxes and the incentive provided the financial support needed to activate the auto-power down feature. As explained in the interview, TELUS had not considered energy efficiency prior to being approached by BC Hydro.

Appliances

Results of the Appliance Program Participant Survey show that 51 per cent of respondents first learned of the appliance rebate from a salesperson on the floor of the retail store, and 26 per cent learned of the rebate through in-store stickers and labels. Overall, 88 per cent of respondents reported that their experience with the program was good or excellent, including the ease of applying for the rebate. While still favourable, ratings of the speed of receiving the rebate cheque were slightly lower, with 75 per cent giving ratings of good or excellent. The total dollar amount of the rebate was rated lower with 63 per cent of participants assessing the rebate amount favourably. Reported influence of the customer appliance rebate on retailers was mixed.

Objective 2: Market Trends

Televisions

TVs were, and continue to be, a rapidly changing technology. The type of TV installed in BC Hydro customers' homes has changed substantially over the past ten years, in particular the move away from the standard CRT TV to LCD and LED-LCD TVs. The proportion of households with a CRT TV plummeted to 29 per cent in 2014 from 98 per cent in 2001. This decline was accompanied by a rapid increase in LCD models, rising from 8 per cent of households in 2006 to 76 per cent in 2014.

In terms of total TV sales in BC, there has been a declining trend from the beginning of 2011 to the latter part of 2015, and the sale of non-Energy Star televisions has been in general decline since F2012. The price of TVs with higher energy efficiency ratings tended to be slightly higher than the average of all Energy Star models.

Appliances

In 2014, almost all households (96 per cent) had at least one refrigerator, the majority of which were auto-defrost. Fifty per cent of households in the BC Hydro service territory had at least one freezer in 2014, down from 63 per cent in 2001.

In 2010, 2012 and 2014, approximately 90 per cent of households in BC had a clothes washer. The type of clothes washers installed by residential customers also changed over the evaluation period with 53 per cent of households in 2014 reported having a top-load clothes washer, down from 90 per cent in 2001. For the past ten years, slightly more than three-quarters of households in the BC Hydro service area had a dishwasher.

The average proportion of Energy-Star rated appliances on display in BC retail stores from 2009 to 2014 was 76 per cent for refrigerators, 78 per cent for clothes washers and 84 per cent for dishwashers. Energy Star freezers represented an average of 43 per cent of displayed models.

Objective 3: Evaluated net electricity savings – Consumer Electronics

New Televisions

Evaluated net savings were calculated by multiplying the total number of incented televisions by the average unit savings in each fiscal year and adjusted for cross effects. A separate analysis did not detect any lasting trends in the sales of high efficiency TVs and there was no spillover associated with the new TV sales component of the program. Note that the common practice baseline approach accounts for any free ridership that might be present. Table 20 summarizes the inputs and results for evaluated net savings as well as the reported net savings for high efficiency television sales.

Table 20 Evaluated and Reported Net Savings for New TVs

Fiscal Year	Total Units Incented	Avg. Unit Savings (kWh/year)	Cross Effect Adjustment (1-0.03)	Evaluated Net Savings (GWh/year)	Reported Net Savings (GWh/year)
F2011	58,998	34	0.97	1.9	3.2
F2012	120,360	16	0.97	1.9	6.3
F2013	74,620	31	0.97	2.2	2.8
F2014	26,098	36	0.97	0.9	1.1
Total*	**280,076**	**--**	**--**	**7.0**	**13.3**

*Columns may not sum to total due to rounding.

Evaluated net savings for the evaluation period were 7.0 GWh per year, or roughly half of the reported net savings of 13.3 GWh per year. The greatest variance between reported and evaluated savings occurred in F2012 when incented TVs accounted for 94 per cent of high efficiency TV sales in BC and when unit savings were the smallest. It is not conclusive whether the convergence of rebated and total market sales suggests high free ridership in that year or is indicative of the influence previous program efforts had on retailers to stock more of the high efficiency TVs.

Set-top Boxes

The net to gross ratio for set-top boxes was evaluated as 100 per cent, based on the results of the service provider interview. Evaluated and reported net savings for set-top boxes are presented in Table 21.

Table 21 Set Top Box Evaluated and Reported Net Savings

Fiscal Year	Evaluated Gross Savings (GWh/year)	Net to Gross Ratio	Evaluated Net Savings (GWh/year)	Reported Net Savings (GWh/year)
F2013	4.1	1	4.1	5.1
F2014	0.6	1	0.6	0.7
F2015 (Q1-Q2)	0.3	1	0.3	0.4
Total	**5.0**	--	**5.0**	**6.2**

As shown in the above table, evaluated net savings for the evaluation period were slightly lower than reported. The variance between evaluated and reported net savings is due to reported savings assuming higher unit savings and more time spent in active mode relative to evaluated results.

Recycled TVs

Program tracking data was not available for recycled TVs because this component only consisted of promotional activities. Evaluated gross savings were based on information garnered from several sources and were adjusted for a cross effect factor of 3 per cent. The gross savings were further adjusted by an attribution score to account for program influence on recycling. The attribution score was based on self-report by those who had recycled a TV and calculated to be 5 per cent. Evaluated net savings were 6.5 GWh for the evaluation period, which was almost the same as reported net savings, as summarized in Table 22.

Table 22 Evaluated and Reported Gross and Net Savings for Recycled Televisions

Fiscal Year	Evaluated Gross Savings (GWh/year)	Cross Effect Adjustment (1 - .03)	Attribution Score	Evaluated Net Savings (GWh/year)	Reported Net Savings (GWh/year)
F2011	22.4	0.97	0.05	1.1	1.1
F2012	22.4	0.97	0.05	1.1	1.9
F2013	42.9	0.97	0.05	2.1	2.0
F2014	42.9	0.97	0.05	2.1	1.6
Total	**130.6**	**--**	**--**	**6.5***	**6.6**

* Columns may not sum to total due to rounding.

Summary of Net Savings Results for Consumer Electronics

The evaluated and reported net savings for each component of the consumer electronics offer are summarized in Table 23. The share of total evaluated savings was fairly evenly split across the three components of the offer.

Table 23 Reported and Evaluated Net Savings for the Consumer Electronics Offer: F2011 - F2015, Q1-Q2 (GWh/year)

	New TVs		Recycled TVs		Set-top Boxes		Total	
Fiscal Year	Reported	Evaluated	Reported	Evaluated	Reported	Evaluated	Reported	Evaluated
F2011	3.2	1.9	1.1	1.1	--	--	4.3	3.0
F2012	6.3	1.9	1.9	1.1	--	--	8.2	3.0
F2013	2.8	2.2	2.0	2.1	5.1	4.1	9.9	8.4
F2014	1.1	0.9	1.6	2.1	0.7	0.6	3.4	3.6
F2015 (Q1-Q2)	--	--	--	--	0.4	0.3	0.4	0.3
TOTAL*	**13.3**	**7.0**	**6.6**	**6.5**	**6.2**	**5.0**	**26.2**	**18.3**

* Columns may not sum to total due to rounding.

Objective 4: Evaluated electricity savings – Appliance Rebate

Due to data limitations, an estimate of net savings attributable to the program, inclusive of the program's effect on retailers, could not be developed. Therefore, evaluated net savings have not been calculated for the appliance rebate component of the program, as program attribution could not be fully estimated.

Evaluated gross savings were calculated by multiplying average unit savings by the number of units rebated and adjusting for cross effects, where applicable. The cross effect factor applied to evaluated savings was 1.7 per cent for refrigerators and 0.5 per cent for freezers. Cross effect values used in the reported savings varied from 9.7 per cent to 1.8 per cent for refrigerators and 2.7 per cent to 0.3 per cent for freezers.

As shown in Table 24, evaluated gross savings were 19.3 GWh per year. Clothes washers achieved the largest savings, accounting for 79 per cent of the total gross savings. Evaluated gross savings were higher than reported gross savings, which were 10.2 GWh per year. The variance between evaluated and reported gross savings is largely due to the inclusion of additional energy savings from clothes drying associated with high efficiency clothes washers.

Table 24 Evaluated and Reported Gross Savings: F2011 -F2015, Q1-Q2 (GWh/year)

Fiscal Year	Refrigerators	Freezers	Dishwashers	Clothes Washers	Total Evaluated Gross Savings	Total Reported Gross Savings
F2011	0.8	0.5	0.1	4.5	**5.9**	**3.9**
F2012	0.5	0.4	0.2	4.9	**6.0**	**2.3**
F2013	0.7	0.2	0.2	3.7	**4.8**	**2.5**
F2014	0.4	0.2	<0.1	1.8	**2.4**	**1.3**
F2015 (Q1-Q2)	<0.1	--	--	0.3	**0.3**	**0.2**
Grand Total*	**2.4**	**1.3**	**0.4**	**15.2**	**19.3**	**10.2**

*Columns may not sum to total due to rounding.

The evaluation found free ridership, from the perspective of customers who received a rebate, to be in the range of 71 per cent to 76 per cent for all appliances across all fiscal years in the evaluation period. The free rider analysis captured the purchasers' perspectives of program influence on their purchase decisions and focused mainly on the rebate. Participant spillover was estimated to be negligible on an annual basis (less than 1 per cent per year) and totaled 0.1 GWh per year over the evaluation period. Data collected from non-participants were insufficient to reliably estimate non-participant spillover.

The appliances rebate offer was designed to influence both retailers and consumers. Retailer engagement, education and training activities were intended to influence retail partners to increase the stocking of high efficiency products and to improve the positioning and promotion of these products. BC Hydro's advertising and promotional activities also aimed to improve customers' awareness of high efficiency options and, in conjunction with the rebate, influence their decision to purchase high efficiency appliances. Data collected through the retailer surveys was intended to measure the indirect attribution of energy efficient appliance sales to the program via its influence on retailer stocking, pricing and selling practices. Due to data limitations, an estimate of the program's effect on retailers could not be developed.

Summary of Savings Results for the Residential Retail Program

Presented in Table 25 are the annual incremental and peak demand savings associated with the consumer electronics program component.

Table 25 Summary of Reported and Evaluated Net Energy and Peak Demand Savings for Consumer Electronics

	Net Energy Savings (GWh/year)		Net Peak Demand Savings (MW)	
Fiscal Year	Reported	Evaluated	Reported	Evaluated
F2011	4.3	3.0	1.1	0.7
F2012	8.2	3.0	2.0	0.7
F2013	9.7	8.4	2.4	2.0
F2014	4.0	3.6	1.0	0.9
F2015 (Q1-Q2)	0.6	0.3	0.1	0.1
TOTAL	**26.8**	**18.3**	**6.5**	**4.4**

*Columns may not sum to total due to rounding.

Gross peak demand savings were estimated by multiplying evaluated gross energy savings by the ratio of BC Hydro's system peak demand, in MW, to annual energy consumption, in GWh, derived from residential end-use load shapes. The reported and evaluated peak demand savings for each offer are presented in Table 26.

Table 26 Summary of Reported and Evaluated Gross Energy and Peak Demand Savings for Appliances

	Gross Energy Savings (GWh/year)		Gross Peak Demand Savings (MW)	
Fiscal Year	Reported	Evaluated	Reported	Evaluated
F2011	3.9	5.9	0.7	1.0
F2012	2.3	6.0	0.4	1.0
F2013	2.5	4.8	0.5	0.8
F2014	1.3	2.4	0.2	0.4
F2015 (Q1-Q2)	0.2	0.3	0.0	0.1
TOTAL*	**10.2**	**19.3**	**1.8**	**4.0**

*Columns may not sum to total due to rounding.

6.4 Findings and Recommendations

Findings

Program Effectiveness

1. There was evidence to suggest the program had some influence on retailers' decisions regarding stocking and display of high efficiency TVs. However, the evidence was too weak to ascribe any program effects on retailer behaviours and subsequent influences on consumer decision-making and purchases.
2. Partnerships with BC Hydro to deliver the program were successful. Retail partners reported high levels of satisfaction with the new TV and appliance rebate components of the program. The partnership with TELUS was particularly successful as BC Hydro played the key role in identifying a way for TELUS to improve the energy efficiency of set-top boxes installed in their customers' homes.
3. Survey results for the appliance rebate offer indicate that retailer activities and BC Hydro promotional activities reached the target market of residential customers thinking of purchasing a new appliance. In contrast, survey results suggest that the promotional activities of the consumer electronics offer were more limited in reach. However, the influence of the messaging among those who recalled seeing it was high for all three components.

4. Participants in the appliance rebate offer had a positive experience, rating the qualification and application processes as easy to navigate. They were somewhat less satisfied with the amount of time it took to receive the rebate and the rebate amount, but responses were positive overall.

Market Trends

1. There has been a substantial change in the types of TVs installed in BC Hydro customers' homes over the past ten years, with CRT models steadily becoming less prominent. Overall, TV sales declined over the evaluation period.
2. Characteristics of clothes washers and refrigerators have been changing since 2001. The share of households with front-load and top-load clothes washers has converged towards 50 per cent each in 2014. Overall, the percentage of households that have at least one freezer has declined, with chest freezers becoming less popular.
3. In terms of retailer showroom presence, the shares of energy efficient appliances (i.e., Energy Star) fluctuated due to changes in the Energy Star ratings. However, a high majority of refrigerators, clothes washers and dishwashers were Energy Star, as were a smaller share of freezers. No clear price trends for energy efficient appliances were identified.

Evaluated Net Electricity Savings – Consumer Electronics

1. Overall, evaluated net savings for the consumer electronics offer were 31 per cent lower than reported for the evaluation period (18.3 GWh per year as compared to 26.8 GWh per year). The largest difference between reported and evaluated savings occurred in new TVs and can be ascribed to the convergence of the energy efficiency of program qualifying TVs and the overall TV market. The rapidly changing television market made it challenging for the program to stay ahead of the market in terms of new technologies and higher levels of energy efficiency. The effect of program activities on TV retail partner stocking, positioning and sales efforts was not fully captured from the data sources available to this evaluation.

2. Using information from several different sources, the evaluation estimated a total 812,831 TVs were recycled over the period from F2011 to F2014. Approximately 5 per cent of gross savings from these recycled TVs could be attributed to program activities, as would be expected given that the initiative was limited to advertising and outreach activities.

Evaluated Electricity Savings – Appliances

1. Evaluated gross savings were close to double that of reported savings for the appliances rebate offer (19.3 GWh as compared to 10.2 GWh). Overall, clothes washers accounted for 59 per cent of appliance rebates and 79 per cent of the evaluated gross energy savings over the evaluation period. Refrigerators accounted for 20 per cent of the rebated appliances and 12 per cent of the offer's overall gross savings.

2. The variance between evaluated and reported gross savings was due mainly to differences in the unit energy savings calculated for clothes washers. Evaluated unit savings for clothes washers were higher than reported as a result of including additional savings in clothes drying associated with high efficiency clothes washers.

3. Evaluated free ridership, from the perspective of customers who received an appliance rebate, was higher than that assumed in reported savings (71 to 76 per cent as compared to 11 to 20 per cent, respectively) and evaluated participant spillover was lower than that assumed in reported (1 per cent as compared to 10 to 25 per cent, respectively).

4. It is reasonable to believe that the program induced incremental sales of high efficiency appliances by influencing retailer product stocking and sales practices (i.e., market effects) and by influencing consumers who saw the program's advertising or were aware of the rebate but did not apply for one (i.e., non-participant spillover). However, any savings through these streams were not

captured in this evaluation as the data available did not permit the development of a valid attribution score or an estimate of non-participant spillover.

5. Evaluated net savings for appliances are not reported for this evaluation due to the incomplete information about program influence on non-participants and retailers, and the indirect influence on appliance purchasers. The rationale for this decision is that it would be inappropriate to apply the free rider scores without understanding and accounting for other influences, beyond the rebate, on purchaser decision-making.

Recommendations

Recommendations 1 to 4 are for program management. Recommendation 5 is for Evaluation and Recommendations 6 and 7 are for both. The recommendations are not presented in any order of priority.

1. Explore why the speed of receiving their appliance rebates is considered less than satisfactory by a portion of applicants and how the issuance of rebates could be accelerated to improve customer ratings.
2. Continue to collect comprehensive sales data from retail partners for tracking and evaluating market trends and assessing program impacts of retail programs.
3. If clothes washers continue to be included in the appliance rebate offer, update the calculation of reported clothes washer savings to incorporate savings in clothes drying.
4. Consider options to modify the program offers or target markets to reduce free ridership.
5. For offers featuring an incentive paid to retailers, examine program influence on retailers in greater depth to better understand and account for market effects and associated energy savings.

6. Evaluation and Marketing should consider collecting additional data to enable the evaluation of non-participant spillover and market effects from the appliance offer in the future.
7. Consider the feasibility of evaluating advertising-only initiatives (like TV recycling) and how to collect the necessary data for any subsequent evaluation.

6.5 Conclusions

Evaluated savings for the Consumer Electronics offer were lower than reported, mainly due to the convergence of the energy consumption of program qualifying televisions and the television market overall. The set-top box component of the program was successful in transforming the products of a major service provider partner.

Evaluated gross savings for the appliances rebate were almost double the reported savings as a result of including savings from clothes drying. The evaluation did not estimate net savings for the Appliances Rebate offer as the effects of the program on retail partner behaviours or additional savings due to non-participant spillover and market effects were not adequately captured.

Glossary

ANCOVA: is a general linear model which blends ANOVA and regression to test the main and interaction effects of categorical variables on a continuous dependent variable, controlling for the effects of selected other continuous variables, which co-vary with the dependent.

Baseline: A baseline is the initial condition occurring when a DSM activity begins. It may be a market share for equipment, a current standard, or a current average behavior.

BC Hydro Service Area: The portion of the Province of B.C. that receives retail electricity service from BC Hydro. The service area excludes the portion of the Province of B.C. served by Aquila Networks Canada (previously known as West Kootenay Power and Utilicorp Networks Canada), FortisBC, and certain factories or communities that are not customers of BC Hydro. Approximately 75 per cent to 80 per cent of B.C.'s demand for electricity is in the BC Hydro service area and is supplied by BC Hydro.

Cross Effects: Cross effects (also known as interactive effects) refer to the effect that some energy conservation measures (**ECMs**) have on other electricity end uses beyond what the ECM itself produces. An obvious example is building lighting. As more efficient lighting is installed, less heat is generated by the lighting system. This means that less heat must be removed from the building by the air conditioning system during the cooling season, but more heat needs to be supplied by the heating system during the heating season.

Demand Side Management (DSM): The definition of Demand Side Management is the same as the definition of "demand-side measures" set out in section 1 of the *Clean Energy Act*, which is "a rate, measure, action or program undertaken; (a) to conserve energy or promote energy efficiency, (b) to reduce the energy demand a public utility must serve, or (c) to shift the use of energy to periods of lower demand, but does not include (d) a rate, measure, action or program the main purpose of which is to encourage a switch from the use of one kind of energy to another such that the switch would increase greenhouse gas emissions in British Columbia, or (e) any rate, measure, action or program prescribed”.

End Use: The final application or final use to which energy is applied. Recognition of the fact that electric energy is of no value to a user without first being transformed by a piece of equipment into a service of economic value. For example, office lighting is an end use, whereas electricity sold to the office tenant is of no value without the equipment (light fixtures, wiring, etc.) needed to convert the electricity into visible light. End use is often used interchangeably with energy service.

ENERGY STAR®: ENERGY STAR® is the mark of high-efficiency products in Canada that meet strict technical specifications for energy performance—tested and certified. These products save energy without compromising performance in any way. Typically, an ENERGY STAR® certified product is in the top 15 to 30 per cent of its class for energy performance.

Expected Savings: Estimate of gross energy savings based on customer initially reported savings, engineering review and site inspection. These estimates represent the unverified savings.

Free Riders: Free riders are program participants who would have taken the DSM action, even in the absence of the DSM program. They are a part of the reference case. These actions are not attributable to the program.

Gigawatt Hour (GWh): One billion watt-hours; one million kilowatt hours.

Gross Savings : The change in energy consumption and/or associated demand that results directly from program-related action taken by the participants in the demand side management program irrespective of why they participated.

Market Transformation: Market Transformation refers to a permanent change in the structure or functioning of markets, including more energy-efficient behaviour among customers and higher market penetration of energy-efficient products, as a result of

DSM programs that reduce barriers to energy efficiency. These market changes are likely to persist in the absence of continued program activity.

Mid-stream/upstream: The term mid-stream is used in reference to the part of the supply chain that is closer to the customer, such as retailers or contractors. The term up-stream can be used in two ways: 1) to refer to the manufacturers of products or, 2) more generically, to indicate suppliers to the purchasers.

Net savings: The change in energy consumption and/or associated demand that is attributable to the utility DSM program. The change in consumption or associated demand may include the effects of free riders and spillover.

Net-to-gross ratio: A factor representing net demand side management program savings divided by gross program savings that is applied to gross program impacts to convert them into net program load impacts. The factor is made-up of a variety of factors that create differences between gross and net savings, commonly including free riders and spillover. Other adjustments may include rebound, cross effects and measurement and verification results.

Non-energy benefits: Benefits that accrue to program participants (e.g., increased property values, decreased water and sewer bills, increased comfort, health and safety), to the utility (e.g., bill payment improvements, decreased service calls), or to society in general (e.g., improved environmental health, job creation).

Peak Demand - Demand refers to the amount of electricity that is consumed at any instant in time, measured in multiples of watts. Peak demand savings are the reduction in amount of electricity that is consumed at system peak demand, which for BC Hydro occurs on a winter weekday between approximately 5 p.m. and 7 p.m.

Persistence: Refers to how long the energy savings are expected to be attributable to the demand side management activity.

Precision: The degree to which repeated measurements under unchanged conditions show the same results.

Quasi-Experimental Design: is an empirical study used to estimate the causal impact of an intervention on its target population. Quasi-experimental research shares similarities with the traditional experimental design or randomized controlled trial, but they specifically lack the element of random assignment to treatment or control. Instead, quasi-experimental designs typically allow the researcher to control the assignment to the treatment condition, but using some criterion other than random assignment. A well designed Quasi-Experiment can control on key factors when a randomized controlled trial is not practical.

Realization Rate: The ratio of initial estimates of savings to savings adjusted for data errors and measurement and verification results. Does not reflect program attribution or influence on the savings achieved.

Reported Savings: Estimate of energy savings being recorded in the program tracking database. Reported savings are based on best information available from technical review of the initial engineering estimate, post implementation review of documentation and/or inspection, or measurement and verification results, as well as, a forecast net-to-gross ratio applied.

Spillover: Refers to program participants and non-participants whose energy savings measures occur through actions that are not part of a program, but which were influenced by the program (also called free drivers or tag-ons). Participant spillover is the additional energy savings that occur when a program participant independently installs energy efficiency measures or applies energy savings practices after having participated in the efficiency program, as a result of the program's influence. Non-participant spillover refers to energy savings that occur when a program non-participant installs energy efficiency measures or applies energy savings practices as a result of a program's influence. Spillover is expressed as a fraction of the increase of energy savings due to spillover to the gross energy savings of the program participant. Spillover may not be permanent and may not continue in the absence of continued program activity.

Evaluation of the Residential Inclining Block Rate

F2013-F2017

April 2018

Executive Summary

Introduction

The Residential Inclining Block (RIB) rate is a two-step rate structure where BC Hydro's residential customers pay a lower price for electricity consumption up to a certain threshold, and a higher price for electricity consumption beyond the threshold.

The RIB rate went into effect in October 2008 for approximately 1.6 million residential customers. The Step 1 to Step 2 threshold was set at 1,350 kWh per two-month billing period, which was approximately 90 percent of the median consumption of BC Hydro's residential customers. The Step 2 rate was established at BC Hydro's current estimate of the cost of new energy supply, grossed up for losses, and the Step 1 rate was calculated to achieve revenue neutrality for the residential class. The over-arching objective of the RIB rate was to use price to encourage additional electricity conservation relative to what was achievable through a flat rate structure.

The last evaluation of the RIB rate was conducted in 2013[1] and evaluated the price elasticity of consumption and the electricity conservation impacts in response to the rate's two-step structure, as well as customer awareness, understanding, and response to the RIB rate for the period from October 2008 through March 2012 (the mid-point of F2009 through F2012). This evaluation is a continuation of the 2013 evaluation, and covers April 2012 through March 2017 (F2013-F2017).

Approach

The evaluation objectives and research questions are shown on the following page.

[1] BC Hydro (2014) "Evaluation of the Residential Inclining Block Rate F2009-F2012", Revision 2, Power Smart Evaluation, BC Hydro.

Table E.1: Evaluation Objectives and Research Questions

Objectives	Research Questions
1. Estimate Price Elasticity	• What is the price elasticity of Step 1 and Step 2 consumption? • Is there a difference in price elasticity between BCH customers and a comparable community without a RIB rate (e.g. New Westminster)? • What is the price elasticity due to natural conservation, as measured by the price response to general rate increases through F2017? • How do the results of research questions related to price elasticity compare to previous research on this topic conducted as part of the last RIB rate evaluation?
2. Estimate the Conservation Impacts of the RIB Rate	• What are the energy savings due to BC Hydro's RIB Rate from F2013 to F2017? • What are the peak demand savings due to BC Hydro's RIB rate from F2013 to F2017? • What are the energy savings due to natural conservation from F2013 to F2017, as measured by the price response to general rate increases?
3. Analyze Differences in Price Elasticity by Customer Characteristics	• Are there differences in price elasticity by region? • Are there differences in price elasticity by dwelling type? • Are there differences in price elasticity by space heating type? • How do the results of research questions related to price elasticity compare to previous research on this topic conducted as part of the last RIB rate evaluation? • Are there differences in price elasticity between winter and summer periods?
4. Evaluate the Customer Response and Understanding of the RIB Rate	• Are there differences in the characteristics or demographics of customers who are never billed in Step 2 compared to those who are sometimes or always billed in Step 2? • What is the level of customer awareness and understanding of the RIB rate? • To what degree do customers believe electricity prices provide an incentive to manage electricity consumption? • To what extent do customers believe the total electricity bill amount provides an incentive to manage electricity consumption? • What is customers' understanding of their prevailing electricity price under the RIB rate structure? • To what extent do customers believe the RIB provides an incentive to manage electricity consumption? • To what extent do RIB aware customers report energy conserving behaviours as compared to non-RIB aware customers? • To what extent do RIB aware customers report implementing longer term capital investment in energy efficiency or conservation as compared to non-RIB aware customers? • Was program participation in DSM programs different between customers aware / not aware of the RIB rate? • Did low income customers have a different perception or response to the RIB Rate? • Does the RIB rate have any impact on customers' decisions on fuel switching from electricity to thermal fuels? • Is the RIB rate perceived as a barrier to electrification? • Has customers' response/acceptance to RIB changed over time? • Do customers support the RIB rate? • Do notifications / alerts on Step 2 have an impact on customers' consumption behaviour? • How do the results of research questions related to customer response and understanding of the RIB rate compare to previous research on this topic completed as part of the last RIB rate evaluation or REUS surveys?

The table below summarizes the data sources and methods employed in this study for each evaluation objective.

Table E.2: Summary of Evaluation Objectives, Data Sources and Methods

Evaluation Objective	Data Sources	Methods
1. Estimate Price Elasticity	• BC Hydro billing data from April 2004 to December 2016, including electricity consumption, space heating fuel, region and dwelling type by account • BC Hydro residential rate prices from April 2004 to December 2016 • BC Hydro DSM expenditures and savings, from 2004 to 2017 • BC Consumer Price Index data from April 2004 to December 2016 obtained from Statistics Canada • BC real disposable income from April 2004 to December 2016 from BC Stats • Heating and cooling degree days by region from April 2004 to December 2016 • New Westminster customer billing data from 2005 to 2016 and customer information on heating fuel and dwelling type	• Econometric modelling of price elasticity
2. Estimate the Conservation Impacts of the RIB Rate	• Data and results from Objective 1 • BC Hydro residential rate class load shape	• Calculation based on price elasticity and rate class load shape
3. Analyze Differences in Price Elasticity by Customer Characteristics	• Same as Objective 1	• Same as Objective 1
4. Evaluate the Customer Response and Understanding of the RIB Rate	• 2012 customer survey (n = 2,468) • 2017 customer survey (n = 3,307) • 2014 Residential End-Use Study (n=7,318) • 2017 Residential End-Use Study (n=6,929) • BC Hydro billing data from F2012 and F2017 • Data on customer sign-ups for Step 2 alerts • BC Hydro residential DSM program tracking data	• Cross tabulations of survey responses • Linking of survey responses to respondent billing history • Difference in proportions z-tests • Difference of Means Tests using Analysis of Variance

Objective 1, estimating price elasticity, and Objective 3, analyzing elasticities differences by customer characteristics, were addressed through econometric modeling which utilized a variety of data sources including electricity consumption and Statistics Canada data. Objective 2 was a calculation using the results from Objective 1.

Objective 4, related to evaluating customer response and understanding of the RIB rate, was largely addressed through analysis and comparison of the results from two similar residential customer surveys which were delivered in 2012 and 2017.

Results

Price Elasticity

Step 1 consumption represents the consumption of those customers whose bi-monthly usage does not exceed the 1,350 kWh threshold. The Step 1 price elasticity of these customers was estimated to be -0.14. The previous RIB evaluation in 2013 was unable to detect a Step 1 price elasticity over the F2009 to F2012 period, nor did a subsequent analysis over the F2009 to F2015 period. Due to the fact that Step 1 price elasticity could not be detected for the F2009 to F2015 period, the estimate of -0.14 was only seen to be applicable to F2016 and F2017.

Step 2 consumption represents the consumption of those customers whose bi-monthly usage exceeds the 1,350 kWh threshold. The Step 2 price elasticity of these customers was estimated to be -0.08, which is at the low end of the range estimate of -0.08 to -0.13 from the 2013 evaluation. The current estimate indicates that in comparison to the earlier years of the RIB rate, customers who were exposed to Step 2 prices in recent years may have become less price responsive—measured by percentage change in consumption—to Step 2 price increases. It also indicates that their capacity and options to conserve energy while facing price increases may have been more limited in recent years. Meanwhile, Step 1 consumption has become price sensitive in recent years.

Table E.3: Step 1 and Step 2 Price Elasticity Estimates

Time Series Analyzed	Step 1 Elasticity	Step 2 Elasticity
F2005-F2012	Not statistically significant	-0.08 to -0.13***[2]
F2005-F2015[3]	Not statistically significant	Not analyzed
F2005-F2017	-0.14***	-0.08***

*** indicates statistically significant at 95% confidence level

The price elasticity of electricity consumption under a flat rate is used to calculate the natural conservation impact that would be achieved by general rate increases as per BC Hydro's approved Revenue Requirements. This flat rate price elasticity is used to estimate the baseline conservation that would have occurred in the absence of the RIB rate. The flat rate price elasticity could not be estimated through econometric analysis. A range estimate between the Step 1 and Step 2 elasticities was adopted (-0.08 to -0.14) to calculate the natural conservation impact. Since the Step 1 price elasticity estimate of -0.14 was only applicable to F2016 and F2017, the range estimate of the flat rate elasticity was similarly applied to F2016 and F2017 only. In the absence of an empirical estimate of flat rate elasticity in the F2013 to F2015 period, the planning assumption of -0.05[4] was applied to those years.

Conservation Impacts of the RIB Rate

In order to evaluate additional energy conservation achieved under the RIB rate relative to the flat rate, the energy impacts of the Step 1, Step 2, and the flat rate price response were calculated separately. The baseline scenario was considered natural conservation achieved under the flat rate due to general rate increases and the RIB rate structural savings were calculated as the sum of the Step 1 and Step 2 energy impact, less the natural conservation impact. The annual incremental structural savings from the RIB rate between F2013 and F2015 are presented below. The calculations are based on the value of Step 1 elasticity (zero), Step 2 elasticity (-0.08) and assumed flat rate elasticity (-0.05).

[2] BC Hydro (2014)
[3] In 2016, an analysis was conducted to evaluate the Step 1 price elasticity for the period of F2005-F2015. This analysis did not produce statistically significant results. The modelling outputs from this analysis were included in Appendix D.
[4] Orans, R (2008), the source and reasons for adopting this assumption were provided in the expert testimony of the 2008 BC Hydro Long-Term Acquisition Plan, Appendix E.

Table E.4: RIB Rate Savings F2013-F2015

Fiscal Year	Step 1 Price Impact (GWh)	Step 2 Price Impact (GWh)	Natural Conservation (GWh)	RIB Structural Savings (GWh)
	A	B	C	(A + B - C)
Elasticity	**0.00**	**-0.08**	**-0.05**	**-**
F2013	-	49	24	23
F2014	-	16	13	3
F2015	-	74	62	13

Given the potential range in flat rate elasticity (-0.08 to -0.14; assuming that it lies between the estimates of Step 1 and Step 2 elasticity), natural conservation and RIB structural savings in F2016 and F2017 could not be estimated with precision. Table E.5 shows the calculation of natural conservation and RIB structural savings using four different flat rate elasticities: -0.08, -0.09, -0.10 and -0.14. Based on this calculation, savings appear to decrease as flat rate elasticity increases. Based on the results derived through the range estimate, the evaluated RIB energy savings in F2016 and F2017 were deemed to be small or zero, as shown in table E.6 below.

Table E.5: RIB Rate Savings F2016-F2017

	Step 1 Price Impact (GWh)	Step 2 Price Impact (GWh)	Natural Conservation (GWh)				RIB Structural Savings (GWh)			
	A	B	C				(A + B- C)			
Elasticity	**-0.14**	**-0.08**	**-0.08**	**-0.09**	**-0.10**	**-0.14**	**-0.08**	**-0.09**	**-0.10**	**-0.14**
F2016	26	45	60	67	75	104	11	4	(3)	(33)
F2017	13	23	29	33	37	52	6	2	(2)	(16)

Based on the estimates of Step 1 (-0.14), Step 2 (-0.08), and the adopted flat rate elasticity range (-0.08 to -0.014) , the energy and peak demand saving impacts attributed to the RIB rate were calculated as presented in the table below.

Table E.6: Reported and Evaluated RIB Rate Savings

	Energy Savings (GWh)		Peak Demand Savings (MW)	
Fiscal Year	Reported	Evaluated	Reported	Evaluated
F2013	42	23	9	5
F2014	19	3	4	1
F2015	59	13	12	3
F2016	29	0 to 11	6	0 to 2
F2017	8	0 to 6	2	0 to 1

Two major factors contribute to the variance between reported and evaluated RIB rate savings. First, the Step 2 price elasticity of -0.08 was smaller (in absolute value) than the planning assumption of -0.1. Second, the flat rate elasticity range estimate applied to F2016 and F2017 was higher (in absolute value) than the value used in the forecast of RIB savings (-0.05).

Price Elasticity by Customer Characteristics

Additional analyses were conducted to determine if separate price elasticity estimates could be identified based on season or specific customer characteristics such as region, dwelling type, and space heating fuel. Those results are presented in Table E.7, where each category (region, dwelling type, space heating, winter vs summer) shows the results of a separate regression analysis. The results included in Table E.7 show that Step 1 and Step 2 price elasticity varied by region, dwelling type, space heating type and winter versus summer. In some instances, the elasticity estimate was not statistically significant.

Table E.7: Step 1 and Step 2 Price Elasticity by Customer Characteristics

Customer Segment	Step 1 Elasticity	Step 2 Elasticity
Region		
Lower Mainland	-0.22***	Not statistically significant
Vancouver Island	-0.18***	-0.12***
Southern Interior	Not statistically significant	Not statistically significant
North	-0.23***	Not statistically significant
Dwelling Type		
Single Family Dwelling	-0.04***	-0.08***
Row/Townhouse	-0.14***	-0.10***
Apartment	-0.26***	-0.07***
Mobile Home	-0.12***	-0.09***
Space Heating		
Electric	-0.11***	Not statistically significant
Non-Electric	-0.18***	-0.17***
Winter vs. Summer	Not statistically significant	More negative by 0.05 in winter than in summer (e.g. if summer price elasticity is -0.07, winter is -0.12)

*** indicates statistically significant at 95% confidence level

Customer Response and Understanding of the RIB Rate

Between F2013 and F2017, the proportion of customer households that never incurred Step 2 electricity consumption remained generally unchanged at approximately 30 percent. However, the proportion that sometimes incurred Step 2 consumption (1-11 months) increased from 39 percent to 48 percent while the proportion that always incurred Step 2 consumption (12 months) decreased from 30 percent to 22 percent.

Between 2012 and 2017, there was an increase from 53 percent to 64 percent in the proportion of customers who believed that BC Hydro's residential electricity prices were too high. In fact, for customers that never incurred electricity consumption beyond Step 1, there was no longer a majority in 2017 – as there was in 2012 – who felt that prices were 'about right'. The largest segment of these customers now believed prices were too high.

At 49 percent in 2012 and 47 percent in 2017, there has been no meaningful change over the past five years in the proportion of customer respondents who knew that BC Hydro charges their consumption of electricity on an inclining block rate. For these particular customers, they believed that their total bill amounts serve as the greatest incentive to manage their consumption of electricity, followed by electricity prices and then followed by the rate structure. In fact, the RIB rate structure was seen as less of an incentive in 2017 than it was in 2012.

In the 2017 survey, customers previously aware of the RIB rate were more likely than others to have completed a home energy efficiency upgrade in the previous three years, to have participated in at least one of BC Hydro's conservation programs, and to have outperformed other customers on many in-home conservation behaviours. However, it could not be ascertained through the research if and to what extent awareness of the rate structure led to the decisions to engage in these activities.

Customer support of BC Hydro's RIB rate decreased from 59 percent to 55 percent between 2012 and 2017. Support continues to measure highest among customers who never incur Step 2 electricity consumption in a fiscal year.

Findings

Price Elasticity

1. The overall average Step 1 price elasticity was estimated to be -0.14 for F2016 and F2017. Previous analyses, covering the time period of F2005-F2012 and F2005- F2015, were unable to detect Step 1 price elasticity, likely due to relatively low Step 1 prices and small changes in the Step 1 price in earlier years. As a result, Step 1 price elasticity was assumed to be zero in the calculation of energy savings for F2013 to F2015, which was the same approach used in the 2013 Evaluation.

2. Step 2 price elasticity was estimated at -0.08, which is at the low end of the range from the previous evaluation (-0.08 to -0.13). This result may suggest that customer response to the Step 2 price has diminished over time.

3. A range of -0.08 to -0.14 was adopted to estimate natural conservation due to general rate increases under a flat rate in F2016 and F2017. This range spans the empirical estimates for Step 1 and Step 2 price elasticity for F2016 and F2017. In the absence of empirical estimates of flat rate and Step 1 price elasticities in the F2013-F2015 period, the planning assumption of -0.05 was applied for natural conservation in those years.

4. To obtain a proxy estimate of the flat rate elasticity, an analysis of residential consumption data from F2005 to F2016 in New Westminster, a jurisdiction serviced under a flat rate, was conducted. However, it did not produce a statistically significant estimate of flat rate elasticity.

Conservation Impacts of the RIB Rate

5. The annual incremental structural savings from the RIB rate were evaluated at 23 GWh, 3 GWh, and 13 GWh between F2013 and F2015.

6. Given the range of estimated flat rate elasticity due to general rate increases, (-0.08 to -0.14), definitive results for natural conservation and RIB structural savings in F2016 and F2017 could not be determined. Calculated RIB structural savings in F2016 and F2017 decreased as the flat rate elasticity increased. As a result, RIB structural savings in F2016 and F2017 were deemed to be small or zero.

Differences in Price Elasticity by Customer Characteristics

7. Price elasticity by region: Step 1 price elasticity was detected in three out of four geographic regions compared to none in the previous evaluation[5]. Step 2 price elasticity was detected in one region compared to all four regions in the previous evaluation. These results indicate that the Step 2 price is no longer a strong factor in determining electricity consumption in a large part of BC Hydro's service area.

8. Price elasticity by dwelling type: Step 1 price elasticity was identified in four dwelling types compared to none in the previous evaluation. Relative to the previous evaluation, Step 2 price elasticity decreased among single family dwellings and increased among row or townhouses and apartments.

9. Price elasticity by space heating type: Step 1 price elasticity was detected in households with electric and non-electric primary space heating, contrary to the previous evaluation. Step 2 price elasticity was only detected in households with non-electric primary space heating, and at a lower level than in the previous evaluation. The previous evaluation detected Step 2 price elasticity in both types of households. This finding suggests that energy savings induced by price changes from F2013 forward may have come from sources other than electric space heating.

[5] BC Hydro (2014)

10. Price elasticity in winter vs. summer: The analysis found no statistically significant difference in Step 1 price elasticity between winter and summer and a difference of -0.05 in Step 2 price elasticity—with elasticity being more negative in winter than in summer. This result indicates that for Step 2 consumption, the price sensitivity and price impact are greater in winter than in summer.

Customer Response, Awareness, and Understanding

11. From F2013 through to F2017, the proportion of customer households that incurred at least some Step 2 electricity consumption remained generally even at 70 percent. Through these five years, however, there was a decrease from 30 percent to 22 percent in the proportion that were into Step 2 in each month of a fiscal year.

12. Between 2012 and 2017, there was an increase from 53 percent to 64 percent in the proportion of customers who felt that BC Hydro's residential electricity prices were too high. Furthermore, the extent that customers felt this way was highly correlated with their exposure to Step 2 electricity consumption.

13. For customers that never incurred electricity consumption beyond Step 1, there was no longer a majority in 2017 – as there was in 2012 – who felt that prices were 'about right'. The largest segment of these customers now believed prices were too high. Their beliefs around the price of electricity in each of the 2012 and 2017 surveys help to explain why a Step 1 price elasticity was not detected until F2016 and F2017 as customers became increasingly responsive to increases in the Step 1 price.

14. Customers' unaided awareness that BC Hydro charges household consumption of electricity on an inclining block rate has gone generally unchanged over the past five years, measuring 49 percent in 2012 and 47 percent in 2017.

15. For customers previously aware of the RIB rate in each of the 2012 and 2017 surveys, their total bill amounts emerged as serving more of an incentive to manage their consumption of electricity than did electricity prices or the rate structure. In fact, the inclining block rate was considered to be less of an incentive in 2017 than it was in 2012, which is consistent with the findings regarding price elasticity and conservation.

16. Customers previously aware of the RIB rate in the 2017 survey were more likely than others to have completed a home energy efficiency upgrade in the previous three years, to have participated in at least one of BC Hydro's conservation programs, and to have outperformed them on many in-home conservation behaviours. However, it could not be ascertained through the research if and to what extent awareness of the rate structure led to the decisions to engage in these activities.

17. The total proportion of customers who support the RIB rate – including those who may have learned about it for the first time in the survey – has decreased from 59 percent to 55 percent over the past five years. Support continues to measure highest among customers who never incur Step 2 electricity consumption.

Recommendations

1. Consider whether the existing rate structure continues to serve BC Hydro's business objectives and meet customer needs, given that the current RIB rate structure appeared to yield little or no energy savings in F2016 and F2017.

2. Given the finding that larger consuming customers are more price responsive in the winter than in summer, consider exploring the value of a seasonal rate, with different pricing and consumption thresholds in the winter.

3. Consider the value of targeting small electricity consumers (e.g. those living in apartments) with existing or new DSM program offers, given their increased response to price changes in recent years.

Conclusions

Although awareness of the RIB rate has remained relatively unchanged over the past five years at just under 50 percent among all residential customers, the survey analysis has shown that a greater proportion of small customers now feel that electricity prices are too high and the econometric analysis has indicated that they have become more responsive to price changes.

Overall, the RIB rate appears to have achieved its objective of encouraging conservation through the customer response to higher marginal prices. However, the effectiveness of the RIB rate in yielding electricity savings appears to have diminished over time.

This page left blank

1.0 Introduction

The Residential Inclining Block (RIB) rate is a two-step rate, where BC Hydro's residential customers who take electricity service under this rate pay a lower price for electricity consumption below a 1,350 kWh bi-monthly threshold and a higher price for electricity consumption above the kWh threshold.

1.1 Evaluation Scope

The previous evaluation of the RIB rate was conducted in 2013 and evaluated the price elasticity of consumption and the electricity conservation impacts in response to the rate's two-step structure, as well as customer awareness, understanding, and response to the RIB rate for the period October 2008 through March 2012 (the mid-point of F2009 through F2012). This evaluation is a continuation of the 2013 evaluation, and covers April 2012 through March 2017 (F2013-F2017).

1.2 Organization of Report

The organization of this report is as follows. Section 1 covers the evaluation scope, the organization of the report and the initiative description. Section 2 discusses the approach to the evaluation, including evaluation objectives, methodology review, data sources and methods. Section 3 provides the results organized by evaluation objective. Section 4 provides the findings and recommendations. Section 5 provides the conclusions. Additional supporting material is included in the appendices.

1.3 RIB Rate Overview

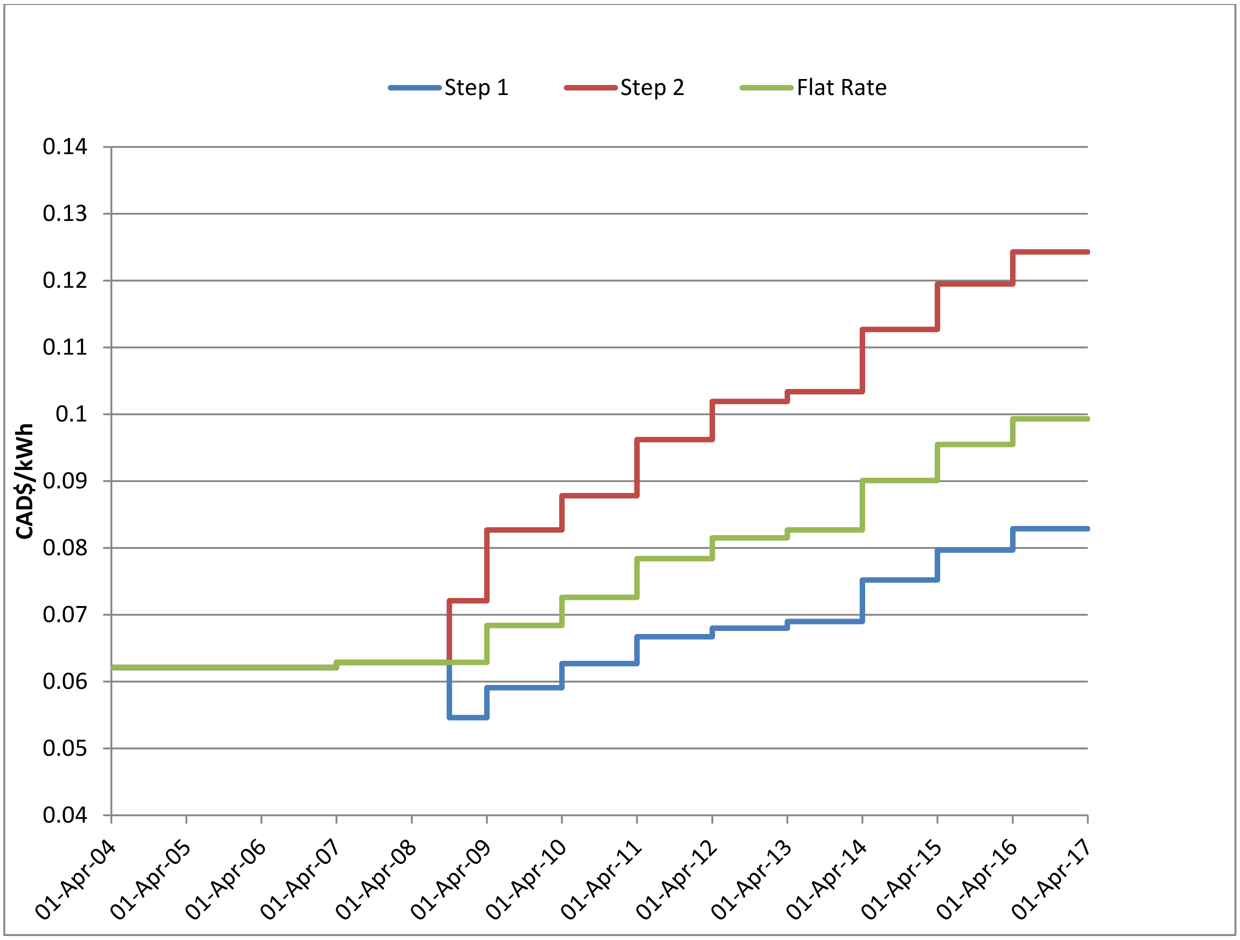
The use of conservation rate structures is one of three tools used in BC Hydro's Demand Side Management (DSM) Plan, the other two being energy efficiency programs and support for government codes and standards. The overarching objective of the RIB rate was to use price to encourage additional electricity conservation relative to what was achievable through a flat rate structure. This objective was supported by the inclining block rate design, where customers are billed at a lower (Step 1) rate for consumption below the 1,350 kWh threshold in a bi-monthly billing period, and at a higher (Step 2) rate for consumption above the threshold, thus setting a higher marginal price for large users relative to the flat rate they were billed at before the introduction of the RIB rate. Theoretically, the energy consumption of customers who rarely or never exceed the threshold may increase under this rate structure, since the Step 1 price was initially lower than the previous price. However, given that only approximately 20 percent of marginal consumption under the RIB rate was priced at Step 1, it was expected that any additional consumption by Step 1 customers would be offset and surpassed by the energy savings achieved by customers with Step 2 consumption, who were charged at a higher marginal price.

In August 2008 the British Columbia Utilities Commission (BCUC) determined that it was in the public interest for BC Hydro to implement the new RIB rate and required the new RIB rate structure to go into effect October 1, 2008 for approximately 1.6 million residential customers[6]. The Step 1 to Step 2 threshold was set at 1,350 kWh per bi-monthly billing period, approximately 90 percent of the median consumption of BC Hydro's residential customers. The 2 step price was gradually increased over time until it reached BC Hydro's estimated long run marginal cost of new energy supply. The Step 1 price was set residually to achieve revenue neutrality for the residential class.

[6] Certain residential groups were exempt from the RIB rate and continued to be charged under a flat rate, referred to as rate schedule 1151 in the BC Hydro tariff. The exempt group included farms and customers in the Bella Bella region.

Figure 1.1 below shows the nominal price changes in the RIB Step 1 and Step 2 prices, as well as the flat rate[7] that would have continued in the absence of the RIB, from F2005 through F2017.

Figure 1.1: RIB and Residential Flat Rate Energy Prices, F2005-F2017



The table below summarizes the energy prices charged to customers under the RIB rate between F2013 and F2017, and the ratio between step 2 and step 1 prices.

Table 0.1: Residential Inclining Block Rate Energy Prices between F2013 and F2017 (Nominal Dollars)

Price	F2013	F2014	F2015	F2016	F2017
Step 1 Price (¢/kWh)	6.8	6.9	7.52	7.97	8.29
Step 2 Price (¢/kWh)	10.19	10.34	11.27	11.95	12.43
Step 2 : Step 1 Ratio	1.5	1.5	1.5	1.5	1.5

Parallel Initiatives: The RIB rate operated in parallel to a number of residential DSM initiatives that were delivered to residential customers and may have had impacts on electricity consumption. These initiatives included energy efficiency programs and government codes and standards. The impact evaluation

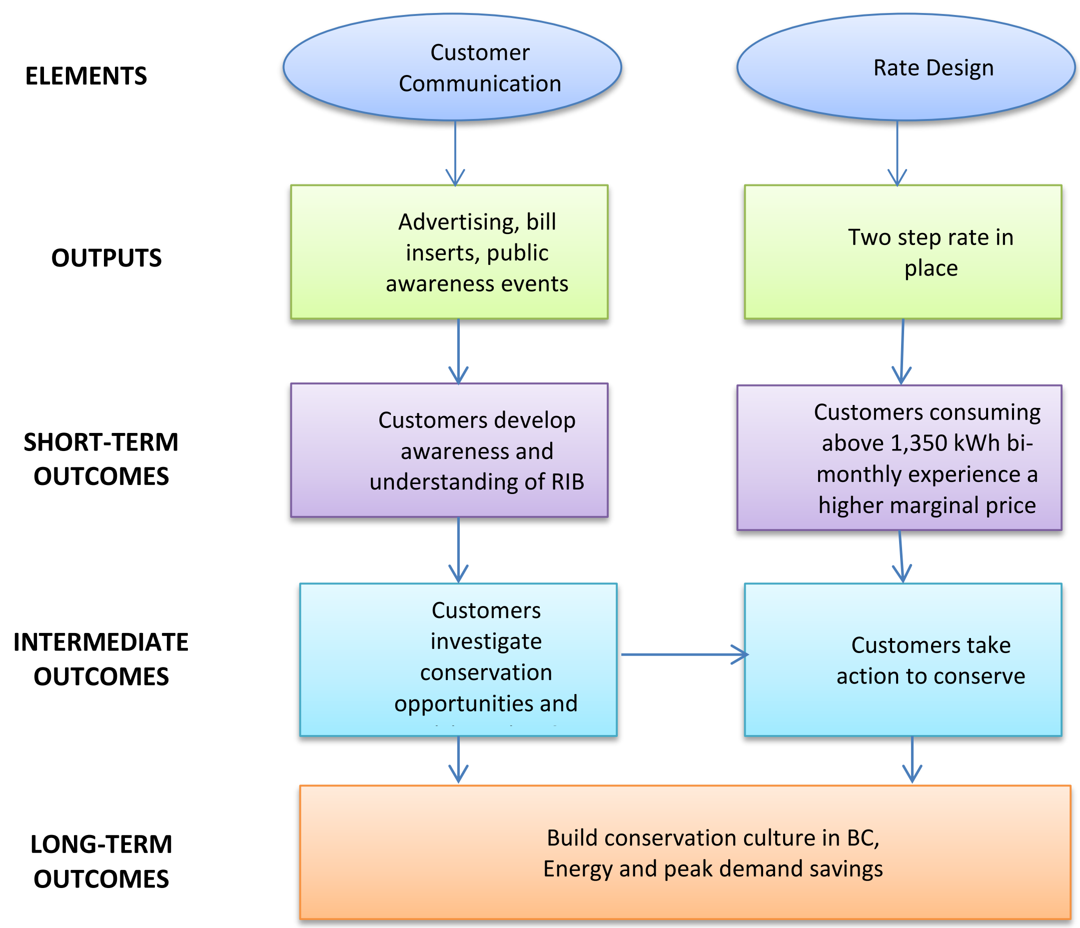
[7] The flat rate price changes included in Figure 1.1 refer to rate schedule 1151. The 1151 flat rate price was considered a proxy for what customers on the RIB rate would have been charged without the implementation of the RIB rate.

methodology used in this evaluation of the RIB accounted for the effect of these parallel DSM initiatives. Evaluated savings for the RIB do not include savings resulting from the parallel DSM initiatives mentioned above[8].

Program Logic Model: The RIB rate, through its price signals, was intended to encourage the adoption of conservation actions and encourage participation in BC Hydro's residential energy efficiency programs by improving the payback on conservation investments. Conversely, the presence of BC Hydro residential energy efficiency programs and educational initiatives was expected to elevate customers' awareness and understanding of the RIB rate, and enhance their response to the rate's price signals.

The logic model presented in Figure 1.2 illustrates how the RIB rate works toward energy conservation by dividing the initiative into its main elements or activities, and examining the logic chain for each element or activity.

Figure 1.2: RIB Logic Model



[8] The econometric analysis tests the sensitivity and influence of DSM programs and code and standard savings on the estimate of the RIB price elasticity and concludes that they do not affect the elasticity estimate. See Appendix D for the detailed econometric modelling results.

2.0 Approach

2.1 Evaluation Objectives

The overall objective of this study is to evaluate the customer response to the RIB rate and to estimate energy and peak demand savings resulting from the rate. Table 2.1 summarizes BC Hydro's evaluation objectives and research questions to be addressed.

Table 2.1: Evaluation Objectives and Research Questions

Objectives	Research Questions
1. Estimate Price Elasticity	• What is the price elasticity of Step 1 and Step 2 consumption? • Is there a difference in price elasticity between BCH customers and a comparable community without a RIB rate (e.g. New Westminster)? • What is the price elasticity due to natural conservation, as measured by the price response to general rate increases through F2017? • How do the results of research questions related to price elasticity compare to previous research on this topic conducted as part of the last RIB rate evaluation?
2. Estimate the Conservation Impacts of the RIB Rate	• What are the energy savings due to BC Hydro's RIB Rate from F2013 to F2017? • What are the peak demand savings due to BC Hydro's RIB rate from F2013 to F2017? • What are the energy savings due to natural conservation from F2013 to F2017, as measured by the price response to general rate increases?
3. Analyze Differences in Price Elasticity by Customer Characteristics	• Are there differences in price elasticity by region? • Are there differences in price elasticity by dwelling type? • Are there differences in price elasticity by space heating type? • How do the results of research questions related to price elasticity compare to previous research on this topic conducted as part of the last RIB rate evaluation? • Are there differences in price elasticity between winter and summer periods?
4. Evaluate the Customer Response and Understanding of the RIB Rate	• Are there differences in the characteristics or demographics of customers who are never billed in Step 2 compared to those who are sometimes or always billed in Step 2? • What is the level of customer awareness and understanding of the RIB rate? • To what degree do customers believe electricity prices provide an incentive to manage electricity consumption? • To what extent do customers believe the total electricity bill amount provides an incentive to manage electricity consumption? • What is customers' understanding of their prevailing electricity price under the RIB rate structure? • To what extent do customers believe the RIB provides an incentive to manage electricity consumption? • To what extent do RIB aware customers report energy conserving behaviors as compared to non-RIB aware customers? • To what extent do RIB aware customers report implementing longer term capital investment in energy efficiency or conservation as compared to non-RIB aware customers? • Was program participation in DSM programs different between customers aware / not aware of the RIB rate? • Did low income customers have a different perception or response to the RIB Rate? • Does the RIB rate have any impact on customers' decisions on fuel switching from electricity to thermal fuels? • Is the RIB rate perceived as a barrier to electrification? • Has customers' response/acceptance to RIB changed over time? • Do customers support the RIB rate? • Do notifications / alerts on Step 2 have an impact on customers' consumption behavior? • How do the results of research questions related to customer response and understanding of the RIB rate compare to previous research on this topic completed as part of the last RIB rate evaluation or REUS surveys?

2.2 Methodology Review

A literature review of electricity rate studies in DSM evaluation resources and the academic literature shows that most evaluations have been focused on the estimation of price elasticity of various rate schemes and energy or demand impact by rate design. This methodology review briefly discusses the methodologies employed in the studies or evaluations of electricity rates and the learnings gleaned for the purpose of selecting a methodology for this RIB rate evaluation.

The methodologies for evaluating rate design vary in terms of evaluation methods and data construction. These methodologies are designed to address different evaluation questions and can be classified broadly into three types: 1) qualitative study through customer surveys to assess customers' perception, acceptance and behavioral responses to the rate design, 2) quantitative evaluation of rate impacts through estimation of price elasticity, and 3) experimental or quasi-experimental design to estimate the impacts of the different rate designs on electricity consumption.

The first type of methodology is designed to gauge customers' perception and response to electricity rate design. This type of evaluation is usually conducted through surveys of a representative sample of customers. This methodology is not widely used for rate evaluations due to customer privacy issues and evaluation budget constraints. For its conservation rate evaluation, FortisBC (2014) surveyed some customers with above average electricity consumption to assess their demographic information and energy uses. Sacramento Municipal Utility District (Potter J.M. et al., 2014) also conducted customer surveys to inform its SmartPricing evaluation and to assess customer's acceptance of potential changes to its pricing plan.

The second type of methodology involves quantitative study of rate impacts on electricity consumption. Such studies mainly entail econometric analysis to estimate price elasticity—the most commonly used measure in the electricity industry when analyzing consumption changes due to rate adjustments. It provides a straightforward and easy-to-compare means to measure the price impacts on electricity consumption and the magnitude of customers' price sensitivity. Many different techniques for econometric modelling of price elasticity have been developed to treat different research issues and/or address technical shortcomings. The methodology selected is often based on the specific market conditions and available data. Most elasticity studies adopt parametric models, which are based on economic and energy consumption theories. The following examples are the econometric studies of electricity price elasticity which use parametric models:

- Fullerton T. Jr et al. (2016) estimated both short-run and long-run residential price elasticity in El Paso, Texas for the period of 1977-2014,
- Ros (2015) estimated electricity price elasticity in the USA residential, commercial and industrial sectors,
- Sacramento Municipal Utility District (SMUD) in 2014 employed econometric models to estimate price elasticity for its SmartPricing evaluation, and
- Miller and Albernini (2016) provided a comprehensive review of elasticity analyses.

Other elasticity studies adopt non-parametric models which do not have a pre-defined model specification and provide an estimation of price elasticity based on a more flexible functional form. These models are often selected when estimates of price elasticity are thought to have changed over time[9].

The third type of methodology is experimental or quasi-experimental design. These methods rely on comparative analysis between a control group and a customer group that participated in a rate design. This method requires careful selection of the control or comparison group prior to the implementation of the rate

[9] Xiao et al. (2007) used non-parametric Bayesian model to estimate price elasticity of electricity demand and compared it to the results from parametric models.

design to ensure the comparability between the two groups. Faruqui et al. (2016) used a quasi-experimental design for an impact evaluation of a Time-of-Use rate in Ontario.

2.3 Methodology

The methodology adopted to evaluate the customer response to the RIB rate and the rate-induced conservation impacts has two parts. The first part is an estimation of the conservation impacts of the RIB rate via econometric modeling of price elasticity for each of the step 1 and step 2 price. Econometric models are selected as they provide a straightforward way to measure customers' price sensitivity and the resulting impacts on electricity consumption.

The second part evaluation method used surveys of a sample of RIB rate customers. A well designed survey with good sample coverage will provide accurate information on customers' perception and response to the RIB rate with high internal and external validity. The surveys also provide information or evidence that cannot be obtained from econometric analysis. The two methods are complementary and produce multiple lines of evidence and more valid and rich evaluation results.

Table 2.2 summarizes the data sources and methods employed in this study for each evaluation objective. Further description of the proposed methodology is provided in the subsequent sections, in order of evaluation objective. Alternative methodologies that were considered for this evaluation are presented in Section 2.4.

Table 2.2: Summary of Evaluation Objectives, Data Sources and Methodology

Evaluation Objective	Data Sources	Methods
1. Estimate Price Elasticity	• BC Hydro billing data from April 2004 to December 2016, including electricity consumption, space heating fuel, region and dwelling type by account • BC Hydro residential rate prices from April 2004 to December 2016 • BC Hydro DSM expenditures and savings, from 2004 to 2017 • Statistics Canada Consumer Price Index data from April 2004 to December 2016 • BC real disposable income from April 2004 to December 2016 from BC Stats • Heating and cooling degree days by region from April 2004 to December 2016 • New Westminster customer billing data from 2005 to 2016 and customer information on heating fuel and dwelling type	• Econometric modelling of price elasticity
2. Estimate the Conservation Impacts of the RIB Rate	• Data and results from Objective 1 • BC Hydro residential rate class load shape	• Calculation based on price elasticity and rate class load shape
3. Analyze Differences in Price Elasticity by Customer Characteristics	• Same as Objective 1	• Same as Objective 1
4. Evaluate the Customer Response and Understanding of the RIB Rate	• 2012 customer survey (n = 2,468) • 2017 customer survey (n = 3,307) • 2014 Residential End-Use Study (n=7,318) • 2017 Residential End-Use Study (n=6,929) • BC Hydro billing data from F2012 and F2017 • Data on customer sign-ups for Step 2 alerts • BC Hydro residential DSM program tracking data	• Cross tabulations of survey responses • Linking of survey responses to respondent billing history • Difference in proportions z-tests • Difference of Means Tests using Analysis of Variance

The methodology employed ultimately provides an estimate of evaluated net savings. Electricity cross effects and natural conservation are accounted for within the evaluated savings results. The method is not able to provide an estimate of the magnitude of electricity cross effects or the persistence of energy savings over time. Natural gas cross effects were not evaluated.

2.3.1 Methodology to Estimate Price Elasticity

Estimating conservation of the RIB rate first required estimates of price elasticity that measured customers' responsiveness to changes in price of their electricity. Step 1 and Step 2 price elasticity was estimated separately by modelling Step 1 and Step 2 consumption using linear regression analysis. The analysis quantified Step 1 and Step 2 consumption as the average bi-monthly consumption per account among groups of RIB customers defined by different dwelling types, geographical regions and heating fuel sources. The analysis was conducted at the aggregate level instead of using customer-specific data for a representative sample of customers, mainly because BC Hydro does not maintain detailed information at the individual account level on factors affecting electricity consumption, such as occupancy, personal income and residential building characteristics. Lack of detailed information pertaining to individual accounts could potentially lead to sample selection bias and the adopted approach of conducting the analysis at the aggregate level avoids such problems.

The following steps were employed to create the econometric models:

1. Determine the explanatory variables expected to influence electricity consumption and obtain applicable data;
2. Develop a basic functional form of the regression model;
3. Develop and test alternative forms of the regression model;
4. Estimate the price elasticity for Step 1 and Step 2 consumption;
5. Estimate the price elasticity for the baseline (flat rate) scenario.

These steps are further described below.

Step 1: Determine the Explanatory Variables Impacting Electricity Consumption and Obtain Data

Many factors influence electricity consumption. It is important to capture the major factors in the regression models in order to isolate the relationship between price and consumption. Factors considered as explanatory variables include electricity prices, weather, seasonality, space heating fuel, dwelling type, region, DSM expenditure and economic factors. As discussed later, various interactions between some of the variables were also considered. This is the same suite of explanatory variables that were tested in the 2014 RIB Evaluation, which provides high comparability of the elasticity results with those from the previous evaluation.

DSM initiatives, namely BC Hydro DSM programs and government codes and standards, and their impacts were also considered in the price elasticity models. BC Hydro DSM expenditures and the energy savings attributed to programs and codes and standards were the variables tested in the price elasticity models to examine whether price elasticity estimates were impacted. Alternative models with different treatment of the DSM expenditure or savings variables were tested in Step 3.

See Appendix C for further information on the methodology and each of the expected drivers of consumption.

Step 2: Develop the Basic Functional Form of the Regression Model

The overall goal was to create a simple and transparent model that reasonably explained the changes in electricity consumption with respect to changes in electricity price over the time period of analysis. The basic model postulates that electricity consumption is a function of electricity price, space heating fuel, dwelling type, geographic region, billing period, weather, and disposable income.

Equation 1 portrays the per account consumption regression estimated using the Ordinary Least Square method. This model represents the basic form of a double-log regression with the key explanatory variables expected to affect electricity consumption.

Equation 1

$$\ln(Consumption) = \alpha + \beta \cdot Heat + \gamma \cdot Dwelling + \delta \cdot BillingPeriod + \omega 1 \cdot CDD + \omega 2 \cdot HDD + \mathfrak{z} \cdot Region + \varepsilon \cdot ln\,(Price) + \sigma \cdot ln\,(Disposable\_Income) + \varphi \cdot C + \mu$$

Where,

ln() denotes natural logarithm; natural logarithm is used for convenience, because when it is used for both the consumption and price variables it results in a regression coefficient on the price variable that can be interpreted as an elasticity without additional calculation;

Consumption is average bimonthly electricity consumption per account in kWh;

Heat is a binary indicator (dummy variable) whose value is one to indicate the presence or zero to indicate absence of electricity as the primary space heating fuel;

Dwelling is a dummy variable to indicate different residential dwelling types: single family dwelling, apartment, row house, and mobile home;

BillingPeriod is a dummy variable that represents the six bimonthly billing periods in a calendar year to capture non-weather related seasonal effects;

CDD and *HDD* represent cooling and heating degree days, respectively, which are used to represent weather impacts;

Region is a dummy variable to represent the four regions in BC Hydro's service territory: Lower Mainland, Vancouver Island, Southern Interior, and North;

Price is the real electricity price charged to residential customers. It was a single flat rate before RIB and the applicable marginal rate in the RIB period. Price elasticity is represented by the coefficient (ε) for the price variable;

Disposable_Income: per capita real disposable income (CPI deflated);

C is a correction term to account for customer selection bias[10] caused by the fact that the Step 1 regression sample is made up of customers who only had Step 1 consumption in a given billing period and the Step 2 regression sample is made up of customers who had Step 2 consumption in a given billing period.

μ is the error term.

[10] See Heckman (1979) discusses sample selection bias and related specification error. See Havranek et al. (2012), Woo and Train (1988) and Yoo et al. (2007) for the examples of using the correction term to address sample selection bias.

Electricity consumption data was drawn from BC Hydro billing records for all RIB accounts from April 2004 to December 2016 (F2005 through Q3 of F2017). The analysis commenced in early 2017 when the complete data for F2017 was not yet available.

The electricity consumption data was set up in a panel format consisting of the four regions, four dwelling types, and two space heating fuel types described above. This produced a total of 32 observations per billing period and 2,400 observations for the entire period in the regression analysis. The first four and a half years of consumption was under the flat rate schedule and another eight and one quarter years was under the RIB rate.

Step 3: Develop and Test Alternative Forms of the Regression Model

Alternative forms of the basic model were constructed to test and compare the modeling results. The alternative forms explored the effect of adding or removing explanatory variables not included in the basic form. The estimate of price elasticity and the sensitivity of the estimate with respect to DSM initiatives were explored.

The impact of DSM expenditures and savings were tested in two alternative models.

Equation 2

$$\ln(Consumption) = \alpha + \beta \cdot Heat + \gamma \cdot Dwelling + \delta \cdot BillingPeriod + \omega 1 \cdot CDD + \omega 2 \cdot HDD + ʒ \cdot Region + \theta \cdot ln\left(DSM_{Expenditure}\right) + \varepsilon \cdot ln\,(Price) + \sigma \cdot ln\,(Disposable\_Income) + \varphi \cdot C + \mu$$

Where

$DSM_{Expenditure}$ is the real (CPI deflated) BC Hydro spending on DSM initiatives (programs, codes and standards, and sector enabling activities) in the residential sector.

Equation 3

$$\ln(Consumption + DSM\ Savings) = \alpha + \beta \cdot Heat + \gamma \cdot Dwelling + \delta \cdot BillingPeriod + \omega 1 \cdot CDD + \omega 2 \cdot HDD + ʒ \cdot Region + \varepsilon \cdot ln\,(Price) + \sigma \cdot ln\,(Disposable\_Income) + \varphi \cdot C + \mu$$

Where

DSM savings refer to electricity savings in BC generated by BC Hydro's DSM programs and government codes and standards in the residential sector.

The results of the models described in Equations 2 and 3 were compared to determine whether omitting a DSM variable would introduce meaningful error or bias to the estimates of price elasticity. As shown in Appendix D, the results indicated that reliable price elasticity estimates were obtained even in the absence of a DSM variable being included in the model.

Adding interaction terms to the regression model was also considered. For example, the relationship between weather and heating fuel is expected to have a strong influence on overall consumption since households with electric heat would have higher consumption in colder weather compared to households with non-electric heat. The alternative models explored the effects of including and/or excluding variables for:

- Billing period;
- Interactions between space heating fuel and weather; and
- Interactions between dwelling type and weather.

The selection of the alternative forms of the model was based on tested economic theories of drivers of residential electricity consumption and appropriate statistical and diagnostic tests. See Appendix C for additional details on the regression models and Appendix D for the full output of regression results.

Another model was developed to identify the difference in price elasticities between summer (June, July, August) and winter (November, December, January, February) as shown in Equation 4 on the following page. This model is similar to Equation 1 but only applies to monthly consumption data of the summer and winter months.

Equation 4

$$\ln(Consumption) = \alpha + \beta \cdot Heat + \gamma \cdot Dwelling + \delta \cdot BillingPeriod + \omega1 \cdot CDD + \omega2 \cdot HDD + \mathfrak{z} \cdot Region + \varepsilon \cdot \ln(Price) + \varepsilon1 \cdot Season \cdot \ln(Price) + \sigma \cdot ln\,(Disposable\_Income) + \varphi \cdot C + \mu$$

Where,

> *Season* is a dummy variable with value being either 1 to represent winter months or 0 to represent summer months.

An interaction term $Season \cdot ln\,(Price)$ was included in the model to detect any different price influence on consumption. Its coefficient, $\varepsilon1$, indicates any difference in price elasticity between the winter and summer months.

Steps 4: Estimate the Price Elasticity for Step 1 and Step 2 Consumption

To obtain separate Step 1 and Step 2 price elasticity estimates, RIB rate customers were separated into two groups in each billing period based on bi-monthly energy consumption. The threshold between Step 1 and Step 2 consumption is 1,350 kWh in a two-month period. All RIB rate customer accounts with consumption below 1,350 kWh in a given bi-monthly billing period were analyzed as the Step 1 group. All accounts with consumption above the 1,350 kWh threshold in a given bi-monthly billing period were separately analyzed as the Step 2 group. As such, individual customers may fall in either group in different billing periods, depending on their billed consumption for specific periods. Since the Step 1 regression sample only contains the aggregate consumption of "small" customers and the Step 2 regression sample only contains "large" customers in a given bi-monthly billing period, each of the two regression models contained a correction term (as shown in Equation 1) to correct for the sample selection bias of an individual account being included in the aggregate consumption of one group or the other. See Appendix C for additional details on the regression models and Appendix D for the output of regression results.

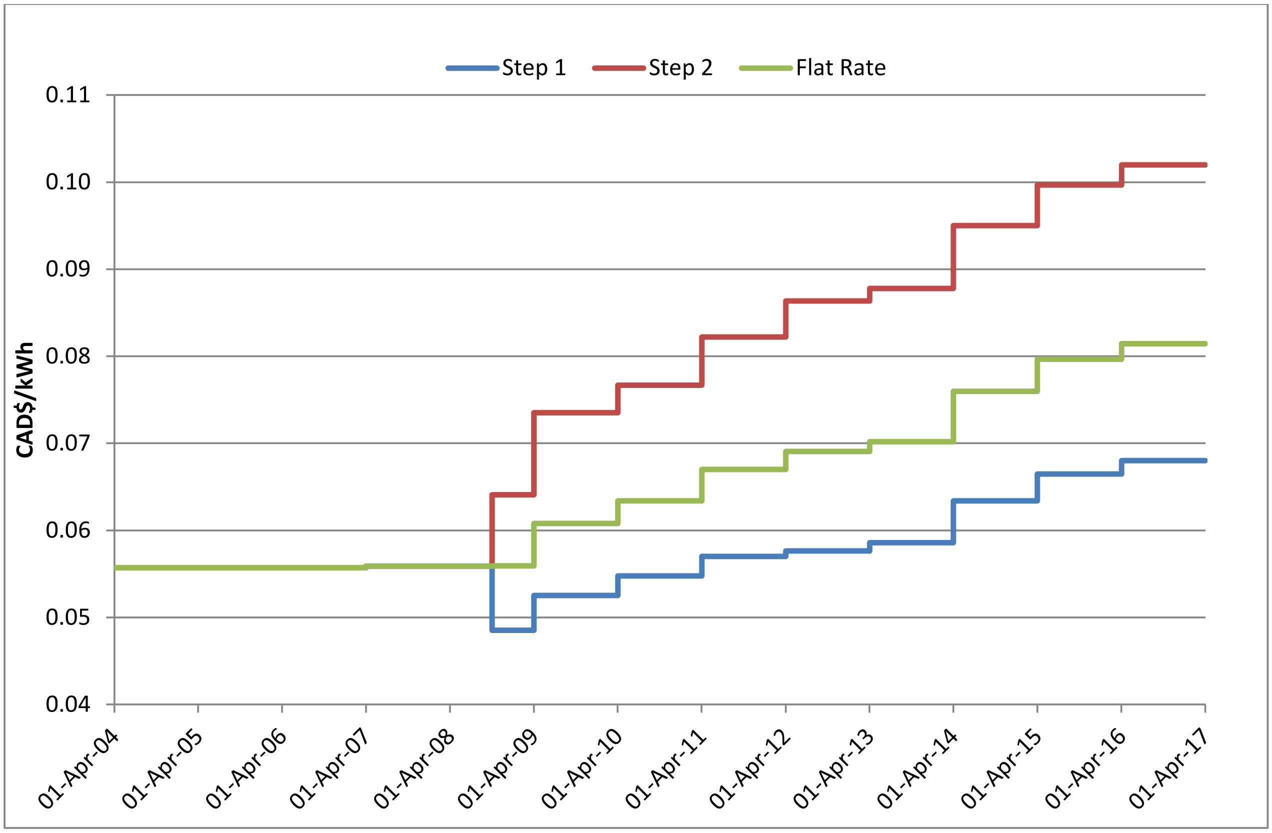
Step 5: Estimate the Price Elasticity for the Baseline Scenario

The baseline for estimating RIB rate savings was defined as a flat rate with general rate increases as per BC Hydro's approved Revenue Requirements Applications. Estimation of the price elasticity under a flat rate was required in order to estimate natural conservation due to general rate increases that would have occurred without the RIB rate structure.

BC Hydro's residential rate structure was switched from a flat rate to the RIB rate in October 2008. Since then, the flat rate has been applied only to specific customer groups under the 1151 Rate Schedule. The 1151 flat rate price was considered a proxy for what the customers on the RIB rate would have experienced without the implementation of the RIB from F2009 through F2017.

Figure 2.1 on the following page shows the real price changes after adjusting for inflation in Step 1, Step 2 and the flat rate from April 2004 (F2005) through to April 2017 (F2017).

Figure 2.1: Real Price Changes in the RIB and Residential Flat Rates after Inflation Adjustment (in 2002 dollar), F2005-F2017



The flat rate elasticity could not be empirically estimated. As a result, three options were considered for adopting a flat rate elasticity estimate. The first option was using the planning assumption of -0.05[11], which was adopted in the 2013 RIB rate application. The second option involved estimating flat rate elasticity by analyzing data from residents in New Westminster, which is another municipality in British Columbia. These customers were served by a different electric utility and charged under a flat rate. Any price elasticity estimated would then serve as a proxy for BC Hydro customers serviced under a flat rate. This analysis followed a method similar to that described in Step 1 through Step 3 above. The third option assumed that the flat rate elasticity falls somewhere in between the Step 1 and Step 2 price elasticities. This assumption was believed to be valid because the Step 1 and Step 2 price elasticity estimates are based on analysis of the same BC Hydro customers who would have been charged under a flat rate. In addition, the flat rate price falls within the range set by the Step 1 and Step 2 prices, and Step 1, Step 2 and the flat rate experienced the same annual price increases over the later part of the analysis period, as illustrated in Figure 2.1 above.

[11] Orans, R (2008), the source and reasons for adopting this assumption were provided in the expert testimony of the 2008 BC Hydro Long-Term Acquisition Plan.

2.3.2 Methodology to Estimate the Conservation Impacts of the RIB Rate

Energy and demand savings due to the RIB rate were calculated separately for Step 1 and Step 2 consumption, using the following steps, as described below:

1. Estimate total conservation for Step 1 and Step 2 consumption.
2. Estimate natural conservation under the baseline scenario.
3. Estimate structural conservation of the RIB rate as the difference between total and natural conservation.
4. Multiply total energy savings by a peak to energy ratio to estimate peak demand savings.

Step 1: Estimate Total Conservation

By definition, price elasticity multiplied by a percentage change in price yields the percentage change in consumption. The percentage change in consumption multiplied by the base year consumption gives the total change in consumption from the base year to the current year. For this evaluation, the percentage change in both Step 1 and Step 2 prices was defined as the percentage change in real price relative to the previous year. The method described in the 2008 RIB application[12] was designed to reflect estimated conservation over a phase-in period where the Step 2 rate was gradually increased, and it assumed that customer decisions were made relative to a price anchored in F2008. However, now that the RIB rate has been in place for more than nine years, it is reasonable to expect customers to adjust consumption based on the most recent price changes they experienced, rather than for example a price change relative to the flat rate that they were charged prior to the implementation of the RIB rate in 2008. This is the approach that was applied here, which is similar to what was done in the previous evaluation in 2013.

The impact of electricity consumption due to increases in each of Step 1 and Step 2 prices was calculated separately with the inputs of price elasticity and the previous year's consumption, as specified in the following equation:

Equation 5

$$\Delta\, kWh_t = \varepsilon_{price} \cdot \%\,\Delta price \;\cdot\; Electricity\ Consumption_{\,t-1}$$

Where:

$\Delta\, kWh_t$ is the consumption change (impact) in year *t* due to the change in price;

ε_{price} is the estimated price elasticity from the econometric models;

$\%\,\Delta price$ is the percentage change in real price relative to the previous year; and

$ElectricityConsumption_{t-1}$, for Step 1 impact, is the total consumption in the previous year from customer bills that do not exceed 1,350 kWh in any billing period. For Step 2 impact, it is the total consumption in the previous year from customer bills that exceed 1,350 kWh (including the first 1,350 kWh of electricity consumption per billing period billed at Step 1 price).

Total conservation is calculated as the sum of Step 1 and Step 2 impacts based on Equation 6:

[12] BC Hydro (2008) "Residential Inclining Block Application".

Equation 6

$$Total\ RIB\ Conservation\ Impact = \varepsilon_{Step\ 1\ price} \cdot \%\ \Delta Step\ 1\ price\ \cdot\ Step\ 1\ Electricity\ Consumption_{\ t-1} + \varepsilon_{Step\ 2\ price} \cdot \%\ \Delta Step\ 2\ price\ \cdot\ Step\ 2\ Electricity\ Consumption_{\ t-1}$$

Step 2: Estimate Natural Conservation

Calculations of natural conservation were based on Equation 5 with inputs of total (actual) residential sales charged at the RIB rate, the changes in the price for the 1151 Rate Schedule, and the flat rate elasticity.

Step 3: Estimate Structural Conservation

The natural conservation impacts were subtracted from the total conservation as a result of the RIB rate to arrive at the consumption impacts attributable to the structure of the RIB rate.

Equation 7

$$RIB\ Structure\ Impact = \ (Total\ RIB\ Conservation\ Impact - Natural\ Conservation\ Impact)$$

Step 4: Estimate Peak Demand Savings

Peak demand savings for the RIB rate were estimated by multiplying RIB structure energy impact, in GWh, by a peak-to-energy ratio based on the residential rate class load shape. This calculation assumes that RIB rate savings have the same shape as the total electricity consumption of the residential rate class.

2.3.3 Methodology for Analyzing Differences in Price Elasticity by Customer Characteristics

To further understand price responsiveness of different groups of customers, the data were partitioned by region, space heating fuel and dwelling type. The regression models (Equation 1) for Step 1 and Step 2 consumption used the different subsets of data to evaluate the price elasticity of different groups. The results for these models are presented in Section 3.

2.3.4 Methodology to Evaluate Customer Response and Understanding of the RIB Rate

Examination of the customer response and understanding of the RIB rate relied on customer survey data and billing data. RIB rate customer surveys were administered in January/February 2012 and in July/August 2017 to collect and track information on awareness, understanding and decision making related to the RIB rate, opinions on electricity pricing, behaviors around energy use, as well as additional demographic and housing parameters to inform the evaluation.

For the 2017 survey, a self-administered methodology – with online and print booklet options – was selected to afford respondents the time to formulate and express well considered responses to the number of complex questions being asked of them. Specifically, all randomly sampled customers were first mailed an invitation letter that served to introduce the study and to encourage their early participation in the survey by completing it online. Customers who had not completed the survey online by a specified date were then mailed a survey booklet with the option of either mailing it back in the business reply envelope, or completing it online. Lastly, customers who still had not completed the survey by a subsequent date were mailed a reminder card as a final attempt to promote participation.

The administration of the 2012 survey was very similar to that of the 2017 survey in that respondents had the two different ways of completing the survey. However, it did not utilize an initial invitation letter, and instead led directly with the survey booklet – with the option to complete online – followed by the reminder card.

The population of interest for both surveys was defined as the approximately 1.7 million customer households in BC Hydro's service territory with a residential account charged on the 1101 tariff, thereby excluding those residential in the non-integrated areas who are not charged under the RIB rate. Representative random samples of 10,000 customers were drawn from the overall population in BC Hydro's billing system with the survey correspondence subsequently sent to their households.

The 2017 survey's final sample was comprised of 3,307 customer respondents (1,792 online and 1,515 booklets) who not only completed the full survey, but also granted permission for their responses to be linked to their account history – a prerequisite for the survey analysis presented herein. This total translated to a 33 percent response rate and, at the 95 percent confidence level, a maximum margin of error of ± 1.7 percent.

The 2012 survey's final sample was comprised of 2,468 customer respondents (1,621 online and 857 booklets). This total translated to a 25 percent response rate and, at the 95 percent confidence level, a maximum margin of error of ± 2.0 percent.

Each of the two survey samples were statistically weighted by primary account holder age, housing type and region to their known population distributions to further ensure that findings were generalizable to the entire customer base of interest. These three parameters were chosen because many key areas of interest in the survey were proven to be highly correlated with them and because they are in fact among the very few parameters whose population distributions can be ascertained from the BC Hydro billing system.

Findings from BC Hydro's 2014 and 2017 Residential End-Use Studies were leveraged – due to their very large sample sizes and representativeness – to serve as population proxies in confirming the reliability of the RIB survey samples.

Refer to Appendix C for additional details on the RIB customer surveys, the Residential End-Use Studies as well as the statistical tests used in the analysis. Refer to Appendix D for the detailed RIB survey results and Appendix E for the RIB survey instrument.

2.4 Alternative Methodologies

This section describes alternative methods that were considered and rejected for this evaluation.

An intervention model is a linear regression model of bi-monthly residential electricity sales that includes a RIB rate indicator (dummy) variable to indicate the presence of the RIB rate beginning in October 2008 along with all other expected drivers of electricity consumption as described in Section 2.3.1. Theoretically, this method can produce direct estimates of the RIB rate's average conservation impact over the analysis period. However, it cannot produce a price impact for each year, nor can it take advantage of year-over-year price changes to estimate price elasticity. Since it does not produce an estimate of price elasticity, this method did not meet all the evaluation objectives and it was not adopted. Preliminary investigation into this method indicated that statistically significant savings induced by the RIB rate existed.

An experimental design using a control group was considered to estimate the flat rate elasticity as a baseline elasticity. A small number of BC Hydro residential customers that volunteered to participate in a Conservation Research Initiative ("CRI") Pilot in 2006 were excluded from the RIB rate in 2008 in order to form a control group. Preliminary analysis of customer characteristics indicated that CRI Pilot participants were not representative of the general population of RIB rate customers, so the experimental design method was rejected and further analysis was not pursued. BC Hydro dissolved the control group in 2017 with the approval of the BC Utilities Commission. As a result, a control group for the RIB rate no longer exists.

A second group of New Westminster electricity customers, who pay for their electricity under a flat rate structure, was analyzed to see if it could offer a proxy estimate of flat rate elasticity among BC Hydro customers. The econometric analysis of this group did not yield statistically significant estimates of price elasticity under a flat rate.

A separate analysis of billing data at the level of individual customer accounts for a sample of 1,000 randomly selected customers was also considered. The price elasticity estimated from such a sample of customers should be representative of the overall population. This method was rejected due to the lack of necessary and detailed demographic, socio-economic and end-use data at the individual customer level.

2.5 Uncertainty and Threats to Validity

Uncertainty and Threats to Validity: Estimates of Price Elasticity and Conservation Impacts

The method adopted for this evaluation is mainly an analysis of electricity consumption and the underlying factors driving consumption changes. As the consumption model could be specified in different functional forms, different model specifications could lead to different price elasticity estimates. The accuracy of a price elasticity estimate depends on the appropriateness of the econometric model and the availability of information and data that can be applied to the model. Models with an over-simplified specification or missing critical variables or models with irrelevant variables can both lead to biased estimates of price elasticity.

The models adopted in the evaluation cover the most important factors that influence electricity consumption to avoid biased modelling results. To address the potential for bias of price elasticity estimates, this evaluation tested alternative forms of the models, including the inclusion or exclusion of DSM savings and expenditures, to examine if such variables affect the price elasticity estimates. For this reason, the internal validity of the elasticity estimates is considered high. The external validity of Step 1 and Step 2 price elasticity estimate is also considered high given that the data used for the analysis covers the entire residential class.

The accuracy of Step 1 and Step 2 price elasticity is considered high and so are the estimates of the Step 1 and Step 2 rate impacts. However, the ability to attribute conservation effects directly to the RIB rate (an aspect of internal validity) is considered moderate as the validity of the estimate of conservation under the baseline flat rate scenario is moderate. The accuracy of the impact evaluation with this method also depends on the accuracy of the baseline or counterfactual: how much electricity would have been consumed in the absence of the RIB rate? This is difficult to estimate because it is a hypothetical scenario. This evaluation produced a range for flat rate elasticity in F2016-F2017 based on the Step 1 and Step 2 price elasticity estimates. This range was then used to estimate the conservation effects which would have occurred in the absence of the RIB rate. However, because a precise estimate of flat rate elasticity was not empirically derived, the precision of the natural conservation impact, based on the range estimate of flat rate elasticity, is not high. Prior to F2016, a planning assumption was used for flat rate elasticity, which was in turn an input into the estimation of natural conservation. As a result there is greater uncertainty associated with the estimate of natural conservation in F2013 to F2015 compared to F2016 to F2017. This in turn affects the certainty of the RIB conservation impact estimate, which has been identified as a limitation in this evaluation.

Uncertainty and Threats to Validity: RIB Surveys

The main threats to the validity of the data collection approach and accompanying findings are tied to two concepts: 1) response bias, and 2) non-response bias and representativeness.

Response bias can occur when the structure of the survey, the presentation of information in the survey, the survey questions and/or the response options influence the responses of customers away from accurate or truthful responses. This potential source of bias was mitigated by administering what is believed to be well-structured, well-ordered, unambiguous and non-leading questions together with balanced response scales that covered the potential range of customer opinion.

One particular type of response bias is 'social desirability response bias' whereby respondents provide answers that they believe an interviewer may want to hear and/or answers that they believe are consistent with the preferred outcome of the study. This potential source of bias was mitigated by utilizing a self-administered survey approach rather than an interviewer led approach.

Non-response bias can occur when subjects comprising the final survey sample are significantly different in the key exploratory parameters of interest than eligible subjects in the same population who did not complete a survey. Among a host of other possibilities, these responders may be different than non-responders on these exploratory parameters because their demographic, geographic, attitudinal or behavioural makeup is different. This can render the survey sample not wholly representative of the population.

Proving the existence or non-existence of non-response bias in a survey sample requires either 1) a follow-up survey sample of the non-responders or 2) an understanding of the true population distribution of the exploratory parameters of interest. Follow-up surveys with non-responders are very rarely conducted because they often incur additional costs, extend research timelines, and most often come with their own group of non-responders. Having an understanding of the true population distribution of the exploratory parameters before embarking on a survey is generally rare – the absence of this information is the very reason for conducting the survey in the first place.

Non-response bias was mitigated by the fact that high response rates were achieved on the surveys – the higher the response rate and the greater the coverage of a survey across different groups of subjects in the population, the lower the chance that the survey sample and its findings are not wholly representative of the population. Acceptable levels of coverage or representativeness of the survey samples were also confirmed by comparing various distributions of non-exploratory parameters in those samples (e.g. region, housing type, account holder age, education, household income, etc.) to the known distributions in the population as revealed in the customer account billing system as well as the in the Residential End-Use Studies.

3.0 Results

In this section results are organized in accordance with the evaluation objectives and research questions outlined in Table 2.1 of Section 2.1. These questions are answered using information derived from the data and methodology listed in Table 2.2.

3.1 Results for Evaluation Objective 1: Estimate Price Elasticity

Three different models[13] were explored to estimate Step 1 and Step 2 price elasticity. The price elasticity estimates from Model 1 were adopted for the calculation of RIB conservation impacts.[14] . The modelling results for all three models are listed in Appendix D.

3.1.1 Step 1 and Step 2 Price Elasticity

The previous RIB evaluation in 2013 was unable to detect Step 1 price elasticity in a statistically significant manner (at the 90% confidence level) and estimated Step 2 price elasticity to be in the range of -0.08 to -0.13 (at the 95% confidence level). In subsequent analysis in 2016 with additional data from F2013 through F2015, Step 1 price elasticity could still not be detected at the 90 percent confidence level. Step 2 elasticity was not analyzed for the period between F2005 and F2015. The current evaluation extended data up to F2017 and estimated Step 1 elasticity at -0.14 and Step 2 elasticity at -0.08 (both at the 95% confidence level or higher.)

Table 3.1: Step 1 and Step 2 Price Elasticity Estimates

Round	Time Series Analyzed	Step 1 Elasticity	Step 2 Elasticity
1	F2005-F2012	Not statistically significant	-0.08 to -0.13***[15]
2	F2005-F2015	Not statistically significant	Not analyzed
3	F2005-F2017	-0.14***	-0.08***

*** indicates the statistical significance at 95% confidence level or higher

Looking at the results of the 3 rounds of analysis shown in Table 3.1 above, the inability to estimate Step 1 price elasticity in rounds 1 and 2 is likely due to a number of factors, including a relatively low Step 1 price and relatively small changes in the Step 1 price in the F2005 to F2014 period (see Figure 2.1 in Section 2.3.1). In contrast, the current analysis had more data points and included later years when the Step 1 price experienced larger annual increases and reached higher levels. These results suggest that these latter differences in price were sufficient enough to trigger a customer response that could then be quantified by the analysis.

The 3 rounds of analysis were conducted at different points in time with slightly different model specifications. To test whether these differences in model specifications affected the analytical results, the round 3 Step 1 model was run with 2 sets of truncated data matching the time periods analyzed in the earlier 2 rounds: F2005 – F2012 and F2005 – F2015. Neither analysis produced a statistically significant estimate of Step 1 price elasticity.

Since the Step 1 price elasticity could not be detected until F2015, the estimate of -0.14 was deemed to be applicable only to F2016 and F2017. The alternative of applying the Step 1 price elasticity to the entire F2009 to F2017 period was considered but rejected due to the absence of a statistically significant estimate of Step 1 price elasticity in the first 2 rounds of analysis.

[13] See Equations 1, 2, and 3 in Section 2.3.1.
[14] Models 2 and 3 showed that DSM expenditures and savings either had no effect on the price elasticity estimate or had a coefficient with the wrong sign (e.g. positive or negative) which would bias the price elasticity estimate if left in the model. Model 1 did not have an independent variable for DSM expenditures or savings.
[15] BC Hydro (2014)

Except for this evaluation, no specific studies were found indicating that price elasticity changes over time or over a price range within a single electricity market. However, there are many studies indicating variation in price elasticity between electricity markets and across price levels and time.[16] Some academic and industry researchers have suggested that price elasticity could be non-linear within a single electricity market[17].

Model 1 estimated Step 2 price elasticity at -0.08. This estimate is at the low end of the range of price elasticity (-0.08 to -0.13) from the 2013 RIB evaluation. The latest result suggests that the customer response to the Step 2 price may have diminished with time. The current estimate indicates that in comparison to the earlier years of the RIB, customers who were exposed to Step 2 prices in recent years may have become less price responsive—measured by percentage change in consumption—to Step 2 price increases. It also indicates that their capacity and options to conserve energy while facing price increases may have been more limited in recent years. Meanwhile, Step 1 consumption has become more price sensitive in recent years.

3.1.2 Flat Rate Elasticity (Natural Conservation)

As discussed in Step 5 of Section 2.3.1, the current evaluation was also unable to produce a statistically significant estimate of flat rate elasticity and considered three options for flat rate elasticity: a) the planning assumption of -0.05, b) a proxy in the form of price elasticity in New Westminster which is served under a flat rate and c) a range of flat rate elasticity falling between the Step 1 and 2 price elasticity (e.g. -0.08 to -0.14, or a wider range if the confidence intervals on these point estimates are considered).

Option A is based on the RIB rate application in which the estimate of flat rate elasticity is low[18] and was adopted in the 2014 evaluation which was unable to produce a statistically significant estimate of flat rate elasticity. In the absence of an empirical estimate of flat rate elasticity and the Step 1 elasticity estimate being zero for the F2013 to F2015 period, the flat rate elasticity in this period is considered to be low and the planning assumption of -0.05 was applied to the F2013 to F2015 period.

With respect to option B, New Westminster is an urban municipality in the Lower Mainland with a population of approximately 70,000 that is served by a municipal electric utility and charged for electricity under a flat rate. Given the 2013 RIB evaluation was unable to produce a statistically significant estimate of flat rate elasticity among BC Hydro customers, BC Hydro attempted to estimate the flat rate elasticity among New Westminster's 32,000 residential customer accounts by analyzing their electricity consumption using the same approach as used in this evaluation. The analysis covered the period from 2005 to 2016. If the analysis was successful in producing a statistically significant estimate, the estimate could serve as a proxy for BC Hydro customers if the current evaluation was again unsuccessful in estimating flat rate elasticity in a statistically significant manner.

However, the analysis of New Westminster data did not produce a statistically significant estimate of flat rate elasticity. The flat rate elasticity estimate was -0.10 but with a low confidence level (p=0.13). This result indicated that the flat rate elasticity was in the vicinity of -0.10, but with a large error band. Other variables such as weather, dwelling type, and billing period were statistically significant drivers of electricity consumption. The results of the New Westminster analysis are provided in Appendix D.

With respect to option C, of adopting a range estimate for flat rate elasticity falling between -0.08 and -0.14, since the Step 1 price elasticity estimate of -0.14 was deemed to only be applicable to F2016 and F2017, the range of flat rate elasticity was similarly deemed to only apply to F2016 and F2017. This range estimate is considered reasonable because the range of flat rate elasticity is based on the empirically derived values for

[16] Chang (2016) constructed a time-series model to show that price elasticity of electricity consumption changes over time in four selected countries.
[17] See Alberini and Filippini (2011) and Yachew (2017) for the discussions that elasticity may change over price range and time.
[18] Orans, R (2008), the source and reasons for adopting this assumption were provided in the expert testimony of the 2008 BC Hydro Long-Term Acquisition Plan.

Step 1 and Step 2 price elasticity. Under a flat rate scheme, Step 1 and Step 2 consumption would be combined together and the flat rate elasticity would be collectively affected by both Step 1 and Step 2 price elasticity. Under the flat rate scenario, it is the same customers being analysed, therefore they would have experienced the same external factors (e.g. economy, weather, housing stock, percentage increases in electricity price each year etc.) and their price response would bear similarity to the Step 1 and Step 2 price response. This rationale lends support to the idea that the flat rate price elasticity should not fall too far from the verified Step 1 and Step 2 price elasticities.

3.2 Results for Evaluation Objective 2: Estimate the Conservation Impacts of the RIB Rate

As outlined in Steps 1 through 3 of Section 2.3.2, energy conservation is calculated separately for the impact of the Step 1 and Step 2 prices, natural conservation under the baseline scenario and the RIB rate structure.

Table 3.2 shows the annual changes in real prices for Steps 1, Step 2, and the flat rate. Refer to Table C.1 in Appendix C for the complete history of the rate schedule price changes since the beginning of the RIB Rate.

Table 3.2: Percentage Change in Real Prices (in 2002$)

Fiscal Year	Step 1	Step 2	Flat Rate
F2013	1.1%	5.0%	3.1%
F2014	1.6%	1.6%	1.6%
F2015	8.3%	8.3%	8.2%
F2016	4.8%	4.9%	4.8%
F2017	2.3%	2.3%	2.3%

The incremental structural savings from the RIB rate were evaluated at 23 GWh, 3 GWh, and 13 GWh between F2013 and F2015, as listed in Table 3.3. The calculations are based on the value of Step 1 elasticity (zero), Step 2 elasticity (-0.08) and flat rate elasticity (-0.05).

Table 3.3: RIB Rate Savings F2013-F2015

Fiscal Year	Step 1 Price Impact (GWh)	Step 2 Price Impact (GWh)	Natural Conservation (GWh)	RIB Structural Savings (GWh)
	A	**B**	**C**	**(A + B - C)**
Elasticity	**0.00**	**-0.08**	**-0.05**	**-**
F2013	-	49	24	23
F2014	-	16	13	3
F2015	-	74	62	13

After adopting a flat rate elasticity range (-0.08 to -0.14), natural conservation and RIB structural savings in F2016 and F2017 were also estimated as a range. Table 3.4 shows the calculation of natural conservation and RIB structural savings tested over four different flat rate elasticities within the range of estimates that were empirically verified for Step 1 and Step 2 price elasticity: -0.08, -0.09,-0.10 and -0.14. Based on this calculation, savings appear to decrease as flat rate elasticity increases. The evaluated RIB energy savings in F2016 and F2017 were deemed to be small or zero, as shown in Table 3.5.

Table 3.4: RIB Rate Savings F2016-F2017

	Step 1 Price Impact (GWh)	Step 2 Price Impact (GWh)	Natural Conservation (GWh)				RIB Structural Savings (GWh)			
	A	B	C				(A + B- C)			
Elasticity	-0.14	-0.08	-0.08	-0.09	-0.10	-0.14	-0.08	-0.09	-0.10	-0.14
F2016	26	45	60	67	75	104	11	4	(3)	(33)
F2017	13	23	29	33	37	52	6	2	(2)	(16)

Evaluated savings are lower than what has been reported for F2013 through F2017. Table 3.5 compares reported and evaluated savings from the RIB rate structure.

Table 3.5: Reported and Evaluated RIB Rate Savings

	Energy Savings (GWh)		Peak Demand Savings (MW)	
Fiscal Year	Reported	Evaluated	Reported	Evaluated
F2013	42	23	9	5
F2014	19	3	4	1
F2015	59	13	12	3
F2016	29	0 to 11	6	0 to 2
F2017	8	0 to 6	2	0 to 1

The evaluated peak demand savings, calculated using the peak-to-energy ratio of 0.205 MW/GWh derived from the residential rate class load shape, range from (7) MW to 6 MW during the evaluation period.

Two major factors contribute to the variance between reported and evaluated RIB rate savings. First, the Step 2 price elasticity of -0.08 (in absolute value) is less than the planning assumption of -0.1. Second, the flat rate elasticity values applied to F2016 and F2017 were higher (in absolute value) than the value used in the forecast of RIB savings (-0.05). These two reasons were the major factors contributing to the smaller savings attributed to the RIB.

3.3 Results for Evaluation Objective 3: Analyze Differences in Price Elasticity by Customer Characteristics

Price elasticity associated with different customer profiles or characteristics were further analyzed through econometric modelling by different customer segments. The analysis was broken down by region, dwelling type, and space heating fuel. Additional analysis also estimated the difference in price elasticity between winter and summer. Results are shown at the 95 percent confidence level. N/A indicates that the estimates were not statistically significant at the 95 percent confidence level.

3.3.1 Price Elasticity by Region

Price elasticity was analyzed separately for four different geographic regions in BC Hydro's service territory: Lower Mainland, Vancouver Island, Southern Interior and North. The Step 1 price elasticity estimate in each region is listed in Table 3.6. The previous evaluation was unable to detect Step 1 price elasticity in a statistically significant manner. The current evaluation was able to detect it in three out of four regions.

Table 3.6: Step 1 Price Elasticity by Region

Evaluation	Lower Mainland	Vancouver Island	Southern Interior	North
2013	N/A	N/A	N/A	N/A
2018	-0.22	-0.18	N/A	-0.23

Step 2 price elasticities by region are listed in Table 3.7. Vancouver Island was the only region where the Step 2 price elasticity was statistically significant. The current and previous evaluations indicated that Vancouver Island had the highest Step 2 price elasticity and this finding aligns with the survey results from both evaluations.

Table 3.7: Step 2 Price Elasticity by Region

Evaluation	Lower Mainland	Vancouver Island	Southern Interior	North
2013	-0.11 to -0.13	-0.15	0.08 to -0.12	-0.12 to -0.15
2018	N/A	-0.12	N/A	N/A

While the estimate of Step 2 price elasticity is significant in the BC Hydro service territory as a whole, when the analysis is conducted by region, Step 2 price elasticity is not statistically significant in 3 of 4 regions. The regional analysis indicates that price sensitivity to the Step 2 price has become unidentifiable or insignificant in many parts of BC Hydro's service territory, and that variables other than price have a stronger influence on electricity consumption in those regions.

3.3.2 Price Elasticity by Dwelling Type

Step 1 and Step 2 price elasticity for the four major dwelling types are presented in Table 3.8 and 3.9. Step 1 price elasticity by dwelling type could not be estimated in the previous evaluation, but was identified, with statistically valid estimates, in the current evaluation.

Table 3.8: Step 1 Price Elasticity by Dwelling Type

Evaluation	Single Family Dwelling	Row/Town House	Apartment	Mobile Home
2013	N/A	N/A	N/A	N/A
2018	-0.04	-0.14	-0.26	-0.12

Compared to the previous evaluation, there were changes in Step 2 price elasticity by dwelling type. Price elasticity decreased among Single Family Dwellings but increased among Row or Townhouses and Apartments.

Table 3.9: Step 2 Price Elasticity by Dwelling Type

Evaluation	Single Family Dwelling	Row/Town House	Apartment	Mobile Home
2013	-0.08 ~ -0.14	-0.06 ~ -0.07	-0.03 ~ -0.04	-0.10
2018	-0.08	-0.10	-0.07	-0.09

3.3.3 Price Elasticity by Space Heating Type

Step 1 and Step 2 price elasticity for two space heating types are presented in Table 3.10 and 3.11. The previous evaluation did not estimate Step 1 price elasticity by space heating type in a statistically significant manner. The current evaluation did. The higher elasticity value for non-electric heat suggests that the Step 1 price response comes not only from space heating but also from other end-uses.

Table 3.10: Step 1 Price Elasticity by Heating Type

Evaluation	Electric Heat	Non-electric Heat
2013	N/A	N/A
2018	-0.11	-0.18

Unlike in the previous evaluation, Step 2 price elasticity for electrically heated customers could not be identified in the current evaluation, which suggests that space heating may not be the major source of Step 2 price response among most Step 2 customers.

Table 3.11: Step 2 Price Elasticity by Heating Type

Evaluation	Electric Heat	Non-electric Heat
2013	-0.14	-0.08 ~ -0.09
2018	N/A	-0.17

3.3.4 Difference in Price Elasticity between Winter and Summer

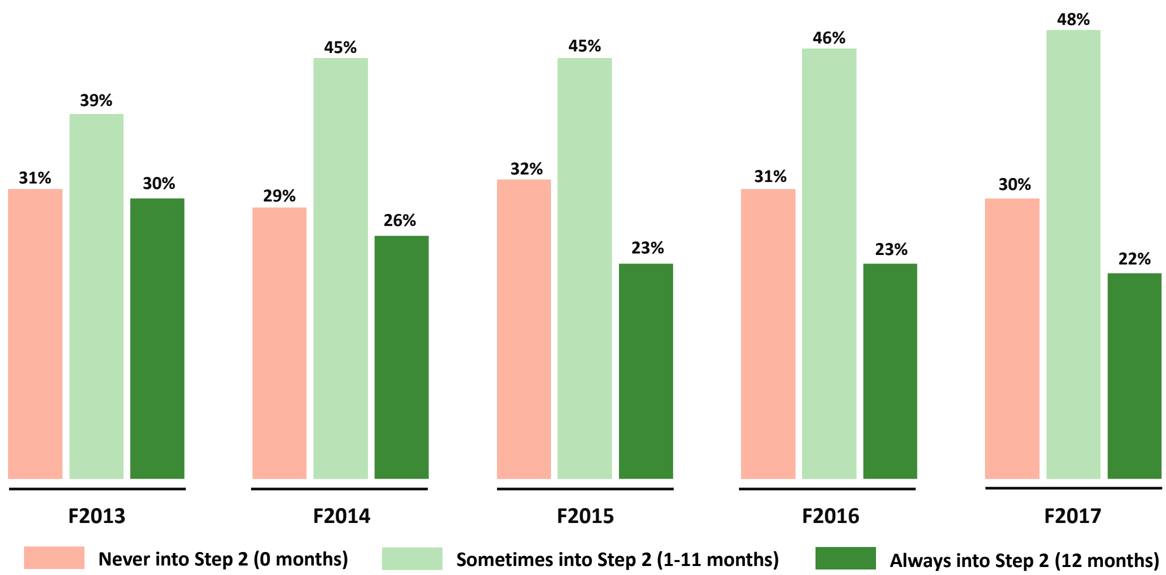
The econometric analysis of price elasticity differences between winter (November, December, January and February) and summer (June, July and August) shows no statistically significant difference in Step 1 price elasticity. For Step 2 price elasticity, the difference between winter and summer is -0.05, with Step 2 price elasticity more negative in winter than in summer. This result indicates that customers exposed to Step 2 consumption, are more price responsive in the winter compared to the summer. Due to the short time period and lack of contrast in consumption, the econometric modelling was unable to separately analyse the winter or summer period. Therefore, there was no separate estimate of winter or summer price elasticity. Based on the Step 2 elasticity estimate of -0.08 and the difference in elasticity between winter and summer of -0.05, it is expected that the Step 2 price elasticity estimate is in the vicinity of -0.05 in summer and in the vicinity of -0.11 in winter.

3.4 Results for Evaluation Objective 4: Evaluate Customer Response and Understanding of the RIB Rate

3.4.1 Customer Exposure to Step 2 Electricity Consumption

While the econometric models to estimate elasticity grouped all RIB rate customers into 'small' (Step 1 only) and 'large' (Step 2 only) consumption groups, much of the analysis presented herein uses three consumption bins to help further profile customers in terms of their exposure to Step 2 consumption through the evaluation period. For each fiscal year, Figure 3.1 details how RIB rate customers' electricity consumption distributed into the three unique consumption bins: the percentage of customer households that never (0 months), sometimes (1-11 months) or always (12 months) incurred Step 2 consumption in the twelve months of the fiscal year[19].

Figure 3.1
Incidence of Step 2 Electricity Consumption by Fiscal Year



Through the five fiscal years, the proportion of customer households that never incurred Step 2 consumption remained generally unchanged at approximately 30 percent. However, there was a change among the balance of customers in that there was an increase from 39 percent to 48 percent in the proportion that sometimes incurred Step 2 consumption while – accordingly – there was a decrease from 30 percent to 22 percent in the proportion that always incurred Step 2 consumption. The reasons for the changes are unknown, but they likely include those related to factors such as weather, changes in regulations, technological improvements, and conservation.

Incidence of Step 2 Electricity Consumption in F2017 by Region and Dwelling Type

Looking strictly at F2017, customer households on Vancouver Island were the most likely to have incurred Step 2 electricity consumption that year – 81 percent did so in at least one month of the year, including some 27 percent that always did so in all twelve months. As detailed in Appendix D, these findings reflect that nearly one-half of customers on Vancouver Island rely on electricity for both their space heating and water heating needs and that these end-uses were key determinants of Step 2 consumption.

[19] For each fiscal year, only accounts open the entire year were included in the analysis.

Customer households in the Lower Mainland were the least likely to have incurred Step 2 consumption in F2017 – only 64 percent did so in at least one month of the year. This finding is due in part to the fact the Lower Mainland is comprised of a much larger share of apartments and condominiums than other regions and the fact that these smaller dwellings – most without their own hot water heaters – are the least likely to incur any Step 2 consumption.

Table 3.12: Incidence of Step 2 Electricity Consumption in F2017 by Region and Dwelling Type

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total	Total Sometimes + Always into Step 2
Total	30%	48%	22%	100%	70%
Region					
Lower Mainland	36%	44%	20%	100%	64%
Vancouver Island	19%	53%	27%	100%	81%
Southern Interior	23%	53%	24%	100%	77%
North	22%	54%	24%	100%	78%
Dwelling Type					
Single detached house	17%	49%	34%	100%	83%
Duplex/Row house/townhouse	22%	64%	14%	100%	78%
Apartment/Condominium	65%	34%	1%	100%	35%
Mobile home/other	24%	58%	18%	100%	76%

Regional distributions are based on the billing system. Dwelling type distributions are based on the survey sample.
Row totals may not total 100% due to the rounding of values.

At 83 percent, customers living in single detached houses were the most likely to have incurred Step 2 consumption in F2017. This incidence measured slightly lower at 78 percent among customers living in duplexes, row houses or townhouses and at 76 percent among those living in mobile or other dwellings, but much lower at just 35 percent among those living in apartments and condominiums.

All of these particular patterns and differences in exposure to Step 2 consumption in F2017 – as well as those that tie to other parameters such as space heating and water heating fuels – are very similar to those first uncovered in the 2013 evaluation. Refer to Appendix D for the details pertaining to F2017.

3.4.2 Opinions of BC Hydro's Residential Electricity Prices

Several lines of questions in each of the 2012 and 2017 surveys focussed on customer opinions about the price of electricity and their electricity bills in the context of the RIB rate structure. However, in view of the possibility that not all customers think about the price of electricity in regards to the RIB rate, respondents were first asked – before seeing any RIB rate content – for their opinions about BC Hydro's residential electricity prices in a broader sense[20].

Opinion of BC Hydro's Current Residential Electricity Prices

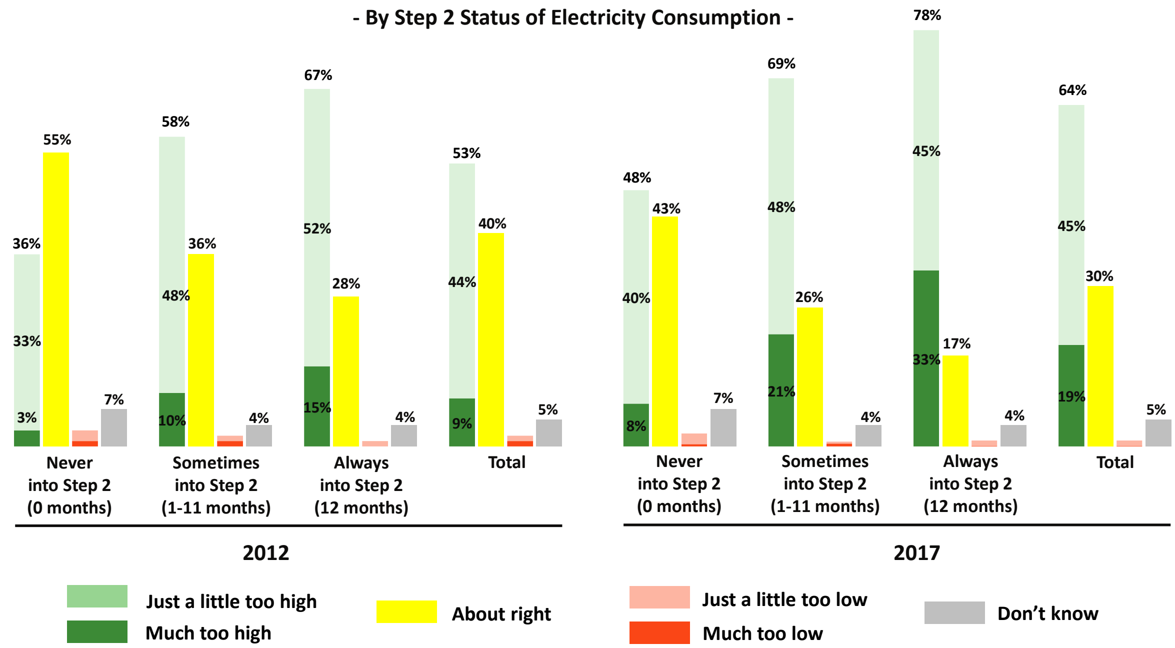
In the 2012 survey, 53 percent of customers felt that electricity prices were either 'just a little too high' or 'much too high', but this slim majority in sentiment increased to 64 percent in the 2017 survey.

In each of the two surveys, customer opinions of the current residential electricity prices varied strongly with their incidence of Step 2 electricity consumption. As illustrated in Figure 3.2 on the following page, for customers that never incurred Step 2 electricity consumption in F2012, the majority of them – 55 percent – felt

[20] Before being asked their opinion of electricity prices in the survey, respondents were first asked to rate the extent that the amount of money that their household pays for its consumption of electricity represented 'value for money'. In doing so, it is believed that their opinions about 'price' were comparably more considered and thoughtful than had the 'value for money' question not been asked.

that electricity prices were ‘about right’. To compare, the proportion who felt this way measured much lower at 36 percent among households that sometimes incurred Step 2 consumption in the fiscal year and at 28 percent among households that always did so. For these two particular cohorts, the majority of customers felt that the current electricity prices were either ‘just a little too high’ or ‘much too high’.

Figure 3.2
Opinion of BC Hydro’s Current Residential Electricity Prices
- By Step 2 Status of Electricity Consumption -



The pattern of opinions toward electricity prices identified in the 2012 survey emerged again in the 2017 survey, but with some notable shifts over the five year period. In each of the three cohorts, there were increases in the proportion of customers who felt that electricity prices were too high – including doublings in those who felt that the prices were ‘much too high’. Notably, for customers that never incurred Step 2 electricity consumption in F2017, there was no longer a majority who felt that prices were ‘about right’.

These results may help to explain why Step 1 elasticity was not detected until the third round of analysis that included data for the years F2016 to F2017. Step 1 customers who felt that electricity prices were ‘about right’ would be comparably less likely to be responsive to price increases than those who felt that prices were already ‘just a little too high’ or ‘much too high’.

Refer to Appendix D for additional findings in regards to customer beliefs in regards to price changes over the previous three years.

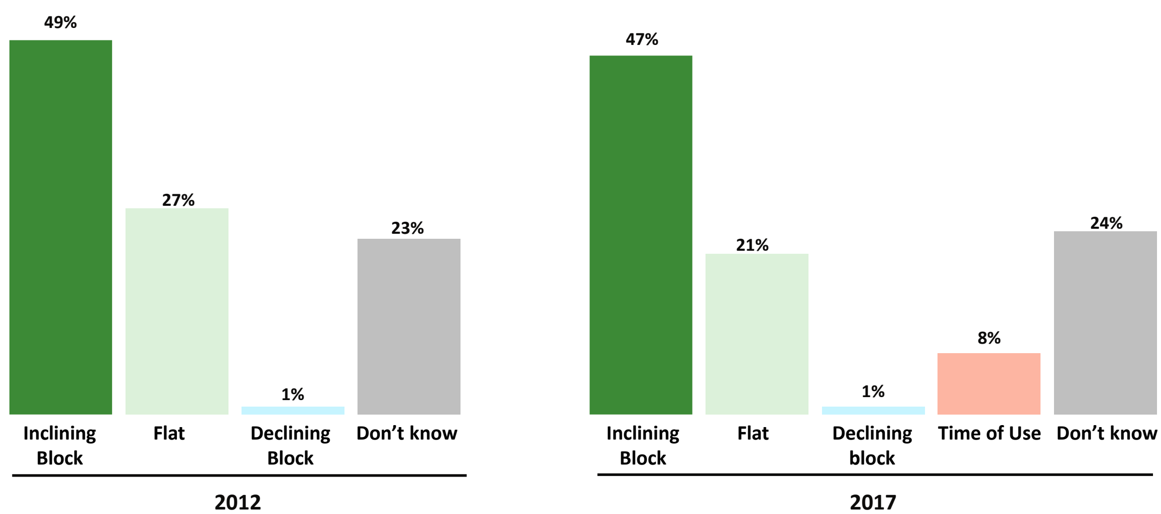
3.4.3 Awareness and Opinions of BC Hydro’s Residential Rate Structure

Unaided Awareness of BC Hydro’s Residential Rate Structure

To measure customers’ awareness of BC Hydro’s residential rate structure, a series of different rate explanations were presented in the survey and questions administered to derive their actual awareness prior to receiving the survey – that is, awareness uncontaminated by the survey content itself. It is also important to note that the context of interest was awareness of the rate structure in concept – not necessarily awareness by name such as the ‘Residential Inclining Block’ or the ‘Two-Step Residential Conservation Rate’. Figure 3.3 on the following page details the findings pertaining to 2012 and 2017.

At 49 percent in 2012 and 47 percent in 2017, there has been no meaningful change over the past five years in the proportion of customer respondents who demonstrate a previous awareness that BC Hydro charges their household's consumption of electricity on an inclining block rate – also described as a stepped rate in the survey.

Figure 3.3
Perceived Rate Structure that BC Hydro Uses to Charge for the Consumption of Electricity



The proportion of customers who believed their household's use of electricity was charged on a flat rate has dropped from 27 percent to 21 percent over the past five years. The initial finding and subsequent decrease is likely due in part to the fact that customers were charged on a flat rate prior to October 2008 – presumably, some of these respondents thinking it was still in effect. However, this decrease is also likely due in part to the fact that a time of use rate response option was added to the 2017 survey and the finding that 8 percent of respondents believed their consumption was charged in this manner. In other words, data analysis showed that many of these individuals would very likely have selected the flat rate in the 2017 survey had the time of use rate not been added as a response option[21].

Unaided awareness that BC Hydro uses an inclining block rate to charge residential customers for their use of electricity continues to be strongly tied to household consumption – the pathway very likely being via the magnitude of the accompanying bills and the extent that customers would be motivated to understand them. At 53 percent, households that always incurred Step 2 consumption in the twelve months of F2017 were the most likely to have been aware of the structure. Awareness measured slightly lower at 49 percent among households that sometimes incurred Step 2 consumption in the year and much lower at 39 percent among those that never incurred Step 2 consumption.

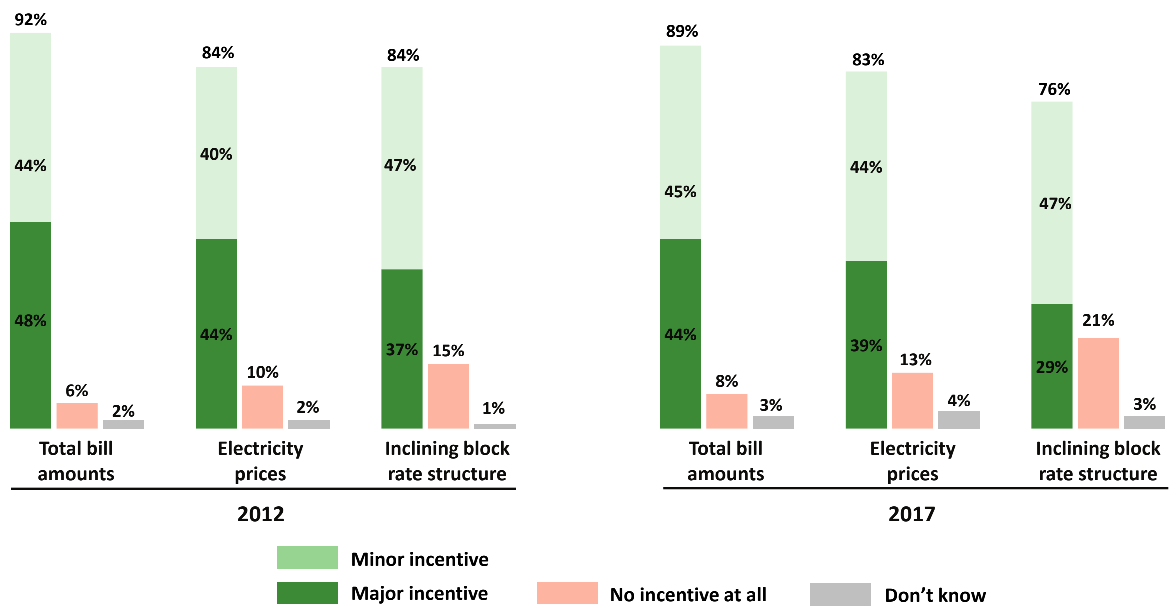
Refer to Appendix D for a complete accounting of rate awareness by all customer demographics and household sub-groups – including region, dwelling type, space heating fuel and water heating fuel.

[21] Data analysis showed that the addition of the time of use response option to the 2017 survey was not responsible for the 2-point decrease in the proportion of respondents who were coded as having a prior understanding that their consumption of electricity is charged on an inclining block rate. This is due to the rigor around the data analysis and the fact that many different lines of questions were administered in each of the 2012 and 2017 surveys to gauge and triangulate customer beliefs about the rate structure, including several strictly in regards to the inclining block rate.

Total Bill Amounts, Electricity Prices and the Inclining Block Structure as an Incentive to Manage Electricity

All customers were asked to consider – in separate lines of questions – the extent that electricity prices, their total electricity bills and the method they perceived BC Hydro uses for charging their household's consumption of electricity each served as an incentive to manage their use of it[22]. Figure 3.4 details findings from the 2012 and 2017 studies strictly among customers who correctly knew that their consumption of electricity was charged on an inclining block rate.

Figure 3.4
Extent that Total Bill Amounts, Electricity Prices and the Inclining Block Structure Serve as an Incentive to Manage Electricity
- among customer respondents with unaided awareness of BC Hydro's residential inclining block rate -



By virtue of the specific distribution of responses for each of the three factors, the total bill amounts emerged in the 2012 study as the greatest incentive to manage electricity among these customers followed by electricity prices and slightly further behind by the inclining block rate structure.

The hierarchy – the relative position of the three factors – identified in 2012 revealed itself as generally the same in 2017, but with some notable differences as detailed further below. Total bill amounts and electricity prices continued to sit in first and second position, respectively, though the specific proportion of customers assessing them as serving an incentive to manage electricity did slip marginally – the bill amounts from 92 percent to 89 percent, and the electricity prices from 84 percent to 83 percent.

The substantive change was in regards to proportion of customers who viewed the inclining block rate as an incentive to manage electricity – it decreased from 84 percent in 2012 to 76 percent in 2017. What's more, this 8-point decrease was seen entirely in the 'major incentive' response option which underscores the change in sentiment much more than had the decrease been – at least partially – in the 'minor incentive' option.

[22] In regards to electricity prices, customer respondents were reflecting on their own perception, understanding and experience with price without having been given any details about the inclining block rate – such as the Step 1 and Step 2 prices – that BC Hydro uses to charge their household for their consumption of electricity.

These changes in opinion have created sharper contrasts among the three incentive factors in 2017 than as seen in 2012. Most importantly, the inclining block rate was less seen as serving an incentive to manage electricity consumption – less in comparison to how it was viewed in 2012, and less than in 2012 in its relative comparison to total bill amounts and electricity prices.

Customer Opinion of the Price of Electricity in Relation to the RIB Rate

Customers who correctly identified that their household's use of electricity is charged on an inclining block rate may not necessarily consider or differentiate the price of electricity – as it pertains to their own household – by the Step 1 and Step 2 prices. Having been reminded that they are charged the Step 1 price for their consumption of electricity up to 1,350 kWh in an average two-month billing period and the Step 2 price for any additional consumption, these particular customers were queried in each of the 2012 and 2017 surveys as to what they considered to be their electricity price as it relates to their own household's use of it.

The single largest segment of these customers in 2017 – 46 percent – considered each of the Step 1 and Step 2 prices as being their household's price of electricity, depending on the point in time in the billing period and/or their consumption in the billing period. This is especially true for households that either sometimes or always incurred Step 2 consumption in the twelve months of F2017.

Table 3.13: Customer Opinion of the Price of Electricity in Relation to the RIB Rate - among customers previously aware of the RIB Rate in 2017 -

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
I would say that I consider the lower, Step 1 price as being my household's price of electricity in a billing period	49%	15%	7%	22%
I would say that I consider the higher, Step 2 price as being my household's price of electricity in a billing period	4%	9%	14%	9%
I would say that I consider each of the Step 1 and Step 2 prices as being my household's price of electricity, depending on the point in time in the billing period and/or our consumption in the billing period	32%	52%	48%	46%
I do not think about my household's price of electricity in any of these particular ways	13%	22%	27%	21%
Don't know	2%	2%	3%	2%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.
Binning of Step 2 status is based on electricity consumption in F2017.

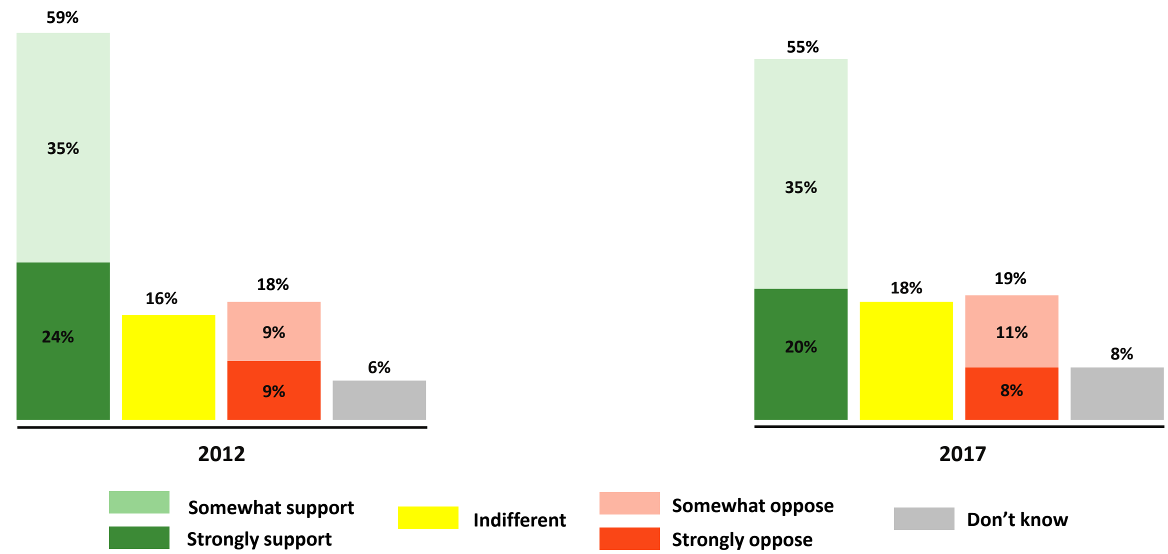
A total of 22 percent of customer contacts who correctly understood that their household's consumption of electricity is charged on an inclining block rate considered the lower, Step 1 price as being their household's price of electricity in a billing period. This sentiment increased substantially to 49 percent strictly among households that proved to have never incurred Step 2 consumption in F2017. Only a small minority of customers – 9 percent – considered the higher, Step 2 price as being their household's price of electricity in a billing period. The balance of most other customers – 21 percent – revealed that they do not think about their household's price of electricity in any of the three given ways.

A very broad view of these findings suggests that many of these customers who correctly identified that their household is on an inclining block rate have a logical understanding and view of the price of electricity. These results remain largely unchanged from the 2012 survey.

Customer Support of the RIB Rate

The total proportion of customers who support the RIB rate that BC Hydro uses to charge for their consumption of electricity – including those who may have learned about it for the first time in the survey – has decreased from 59 percent to 55 percent over the past five years. This 4-point decrease in support of the RIB rate has transferred to a 2-point increase to 18 percent in the proportion of customers indifferent about the rate and a 1-point increase to 19 percent in those opposed to it.

Figure 3.5
Customer Support of the RIB Rate



While the slip in support of the RIB rate does not mark a wholesale change in sentiment, it is statistically significant at the 99 percent level of confidence. This indicates that this change very likely occurred among the population of all RIB rate l customers – not just among those in the survey samples. Note also that this decreased support was detected in nearly all customer sub-groups (i.e. by region, dwelling type, etc.).

As found in the 2012 study, customer opinion of the RIB rate in 2017 was most correlated – and very strongly so – to their exposure to Step 2 electricity consumption. Support for the structure measured highest at 68 percent among customers who never incurred Step 2 consumption in F2017; many of them living in apartments or condominiums that often do not to breach the Step 2 threshold. Support measured much lower at 52 percent among households that sometimes incurred Step 2 consumption and at just 42 percent among those that always did so.

3.4.4 Customer Behaviour in Relation to Awareness of the RIB Rate

Electricity Consumption by Awareness of the RIB Rate

As first uncovered in the 2013 evaluation, average Step 1, Step 2 and total electricity consumption in F2017 measured higher among customer households aware of the RIB rate than among other households.

Table 3.14: ANOVA Tests: Mean Electricity Consumption in F2017 by Awareness of the RIB Rate

	Customers aware of the RIB Rate	Customers not aware of the RIB Rate	Difference between groups
Total F2017 consumption ⇒	10,447 kWh	8,707 kWh	1,740 kWh*
Total Step 1 consumption ⇒	6,305 kWh	5,777 kWh	528 kWh*
Total Step 2 consumption ⇒	4,142 kWh	2,930 kWh	1,212 kWh*

* The difference between mean consumption levels is statically significant at the 99% level of confidence.

Statistical analysis – namely, analysis of variance and linear regression – indicated a causal path whereby higher consumption leads to a greater likelihood of being aware of the rate. Refer to Appendix D for the details.

It is worthy to note that when comparing their consumption over time, households aware of the RIB rate may have lower energy consumption than had they not been aware of the rate and/or lower energy consumption than in periods prior to becoming aware of the rate.

Investments in Home Energy Efficiency Upgrades by Awareness of the RIB Rate

Customers in the 2017 survey were queried as to whether they had completed any home energy efficiency upgrades in the past three years to understand whether such investments differ by awareness of the RIB rate. Those who knew that their consumption of electricity was charged in this way were slightly more likely than others to have completed at least one of the eight upgrades investigated (52% vs. 48%), including more likely to have completed draft proofing upgrades (21% vs. 15%) and insulation upgrades (16% vs. 12%).

Table 3.15: Investments in Home Energy Efficiency Upgrades by Awareness of the RIB Rate

	Customers aware of the RIB Rate	Customers not aware of the RIB Rate	Difference between groups
	⇓	⇓	⇓
Net Total: Any of the upgrades	52%	48%	4 points*
Hot water tank installation/upgrade	30%	28%	2 points
Window upgrades	24%	22%	2 points
Draftproofing upgrades	21%	15%	6 points*
Door upgrades	17%	16%	1 point
Insulation upgrades	16%	12%	4 points*
Furnace installation/upgrade	12%	12%	0
Air source heat pump installation/upgrade	4%	3%	1 point
Ground source heat pump installation/upgrade	1%	1%	0

* Statistically significant difference between the two groups at the 95% level of confidence.

As expected, customers living in single detached or semi-attached houses were much more likely to have completed any of the upgrades than those living in apartments and condominiums. In fact, analysis showed that housing type, demographics such as income, attitudes toward energy efficiency, and awareness of the RIB rate are all factors that inform customers' likelihood of having completed such upgrades. However, due to the number of these factors and their interplay with each other, any causal relationship between awareness of the RIB rate and the decision to make such investments could not be effectively isolated and measured.

Program Participation by Awareness of the RIB Rate

BC Hydro offers several programs to its residential customers to encourage them to improve energy efficiency and to adopt more energy conscious behaviours in their homes. Customers who understood that their household's consumption of electricity is charged on the RIB rate emerged to be more likely than other customers to have participated in the Residential Behaviour Program (14% vs. 6%) and the Appliance Rebate Program (14% vs. 9%) since the rate came into effect in October 2008. In addition, these RIB aware customers were more likely to have signed-up on BC Hydro's website to be able to view their detailed electricity use by the month, week, day or even hour. Refer to Appendix D for the complete findings.

For the same reasons as given in the previous sub-section above, it could not be ascertained through the research if and to what extent awareness of the rate structure led to the decision to participate in the programs.

In-Home Behaviours by Awareness of the RIB Rate

The self-reported in-home behaviours around energy use and conservation were compared between customers who correctly understood that their household's use of electricity is charged on the RIB rate and those that did not. As found in the 2012 study, customers previously aware of the inclining block rate emerged to outperform other customers on many of the conservation behaviours related to space heating, laundry, dishwashing, lighting and other energy-using equipment.

Due to the interplay among customer demographics, attitudes toward energy efficiency, awareness of the RIB rate, etc., it was not possible to measure the causal pathway that may exist between awareness of the rate and the conservation behaviours.

Appendix D details the comprehensive list of in-home behaviours investigated in the survey, including the behavioural scores disaggregated by customers previously aware of the inclining block rate and all others.

Customer Behaviour and Electricity Consumption by RIB Step 2 Price Alerts

BC Hydro's billing system shows that a total of 5 percent of customer households have signed up online to receive email notifications that indicate when their consumption of electricity is halfway to reaching the higher Step 2 price in a billing period as well as when it has reached it.

Among these customers in the 2017 survey, 64 percent reported that they typically make more of an effort to manage their consumption of electricity when their household receives the price alerts – 35 percent do not.

In regards to the entire pool of customer households that received at least one Step 2 price alert in F2017, the analysis was not able to ascertain whether the alerts had an impact on their electricity consumption during the year.

However, for households that chose to act on the price alerts, various analyses showed – depending on the comparison scenario – that their Step 1 and/or Step 2 electricity consumption in F2017 was lower than other households. The differences were not statistically significant, however, largely because the absolute number of households in the survey that received the price alerts and acted on them was not large enough to afford a high level of confidence in the findings.

3.5 Confidence and Precision

Since the RIB conservation estimates are anchored in the estimation of price elasticity, the accuracy and confidence of the savings estimates depend on the statistical significance of the elasticity estimates. The Step 1 and Step 2 elasticity estimates have very high levels of precision (with very large t-values at the 99% confidence level). The results of the evaluated Step 1 and Step 2 price impacts have a high level of precision because they are based on the highly statistically significant Step 1 and Step 2 price elasticity estimates.

In comparison, the flat rate elasticity was not empirically derived. Instead, a planning assumption of -0.05 was applied to F2013 through F2015. For F2016 and F2017, the flat rate elasticity was estimated to fall within the range of the Step 1 and Step 2 price elasticity estimates. Due to the error band associated with the Step 1 and Step 2 elasticity estimates, the range of flat rate elasticity based on the Step 1 and Step 2 price elasticity estimates could be expanded to span, for example, the 95 percent confidence intervals of those estimates[23]. As such, the flat rate elasticity estimate is less precise than the Step 1 and Step 2 elasticity estimates because it would broaden the range of the RIB structural savings estimate, expanding it both on the positive and the negative sides and providing no more certainty over the existence of significant savings.

The calculation of natural conservation impacts are based on the flat rate elasticity planning assumption (F2013-F2015) and the flat rate elasticity range estimate with relatively low precision (F2016-F2017). Therefore, the precision of the natural conservation estimate is low. Hence, the precision of the estimated savings from the RIB rate structure, as the difference between the sum of the step rate impacts and the natural conservation impact, is moderate.

Shown below are the margins of error and the confidence levels associated with the 2012 and 2017 customer surveys used in this evaluation.

Table 3.16: Uncertainty and Margins of Error of the Survey Results

	Valid Responses	Maximum Margin of Error	Confidence Level
2012 Residential Rate Survey	2,468	± 2.0%	95%
2017 Residential Rate Survey	3,307	± 1.7%	95%

3.6 Limitations

This evaluation lacks the empirical evidence to estimate the flat rate elasticity. The certainty and precision of the evaluated conservation impact of the RIB rate is affected given that a planning assumption of the flat rate elasticity was applied to F2013 through F2015, and a range estimate was applied to F2016 and F2017.

The modelling of price elasticity also has some limitations. The current approach is limited by the availability and frequency of data. Disposable income data was only available on an annual basis while all other variables were available on a bi-monthly basis. The lower frequency and lack of variability in the income data may limit the model's ability to accurately estimate the income effect on electricity consumption. The econometric models were not able to identify the impact of energy efficiency improvements from government codes and standards on electricity consumption, as well as the impact of changes in household occupancy. A time variable which could represent these to a certain extent was tested but did not emerge as a statistically significant driver of electricity consumption.

The Step 1 price elasticity estimate in this evaluation was applied to the F2016-F2017 period only given that the analyses of previous time periods did not produce a valid Step 1 price elasticity estimate. There is a possibility that Step 1 price elasticity existed prior to F2016 but it could not be detected using the available data. This possibility is considered low but adds uncertainty to the estimate of Step 1 price elasticity. Customer survey evidence also indicated that the customer response to Step 1 was low in earlier years and has only increased in recent years.

The three rounds of Step 1 price elasticity analysis indicated that price response may change over time. However, the parametric model adopted in this evaluation alone was not able to provide direct support for non-linear price elasticity. This parametric model was based on a pre-defined consumption model, which does

[23] The range of the flat rate elasticity estimates would expand to -0.04 to -0.19 if the 95% confidence intervals of Step 1 and Step 2 price elasticity were considered.

not provide the flexibility to detect the time impact on other factors in the model (such as price elasticity or income elasticity). Any non-linear effect over time may be better estimated with a non-parametric model. However, it is not certain that a valid non-parametric elasticity model could be constructed, for the purposes of this evaluation, due to a lack of variation in the available data (e.g. income data).

As discussed in Section 2.3.1, the analysis of price elasticity was conducted at the aggregate level across all residential customers, and not at the individual customer level. It is difficult to produce more comprehensive and precise electricity consumption models at the aggregate level to better estimate price elasticity. More insights and better understanding of price elasticity could be obtained from analysis at the individual customer level, but that would require the availability of more customer-level data on end-use profiles and energy efficiency standards over the analysis period.

Finally, the use of an average peak-to-energy ratio based on the residential rate class load shape adds uncertainty to the estimates of peak demand savings. The econometric analysis is unable to determine how the customer response to the RIB rate translates into energy savings during the short time frame that defines the overall system peak.

4.0 Findings and Recommendations

4.1 Findings

Price Elasticity

1. The overall average Step 1 price elasticity was estimated to be -0.14 for F2016 and F2017. Previous analyses, covering the RIB period of F2009-F2012 and F2009-F2015, were unable to detect Step 1 price elasticity, likely due to relatively low Step 1 prices and small changes in the Step 1 price in earlier years. As a result, Step 1 price elasticity was assumed to be zero in the calculation of energy savings for F2013 to F2015, which was the same approach used in the 2013 Evaluation.

2. Step 2 price elasticity was estimated at -0.08, which is at the low end of the range from the previous evaluation (-0.08 to -0.13). This result may suggest that customer response to the Step 2 price has diminished over time.

3. A range of -0.08 to -0.14 was adopted to estimate natural conservation due to general rate increases under a flat rate in F2016 and F2017. This range spans the empirical estimates for Step 1 and Step 2 price elasticity for F2016 and F2017. In the absence of empirical estimates of flat rate and Step 1 price elasticities in the F2013-F2015 period, the planning assumption of -0.05 was applied for natural conservation in those years.

4. To obtain a proxy estimate of flat rate elasticity, an analysis of residential consumption data from F2005 to F2016 in New Westminster, a jurisdiction serviced under a flat rate, was conducted. However, it did not produce a statistically significant estimate of flat rate elasticity.

Conservation Impacts of the RIB Rate

5. The annual incremental structural savings from the RIB rate were evaluated at 23 GWh, 3 GWh, and 13 GWh between F2013 and F2015.

6. Given the range of estimated flat rate elasticity due to general rate increases, (-0.08 to -0.14), definitive results for natural conservation and RIB structural savings in F2016 and F2017 could not be determined. Calculated RIB structural savings in F2016 and F2017 decreased as the flat rate elasticity increased. As a result, RIB structural savings in F2016 and F2017 were deemed to be small or zero.

Differences in Price Elasticity by Customer Characteristics

7. Price elasticity by region: Step 1 price elasticity was detected in three out of four geographic regions compared to none in the previous evaluation[24]. Step 2 price elasticity was detected in one region compared to all four regions in the previous evaluation. These results indicate that the Step 2 price is no longer a strong factor in determining electricity consumption in a large part of BC Hydro's service area.

8. Price elasticity by dwelling type: Step 1 price elasticity was identified in four dwelling types compared to none in the previous evaluation. Relative to the previous evaluation, Step 2 price elasticity decreased among single family dwellings and increased among row or townhouses and apartments.

9. Price elasticity by space heating type: Step 1 price elasticity was detected in households with electric and non-electric primary space heating, contrary to the previous evaluation. Step 2 price elasticity was only detected in households with non-electric primary space heating, and at a lower level than in the previous evaluation. The previous evaluation detected it in both types of households. This finding

[24] BC Hydro (2014)

suggests that energy savings induced by price changes may come from sources other than electric space heating.

10. Price elasticity in winter vs. summer: The analysis found no statistically significant difference in Step 1 price elasticity between winter and summer and a difference of -0.05 in Step 2 price elasticity - with elasticity being more negative in winter than in summer. This result indicates that for Step 2 consumption, the price sensitivity and price impact are greater in winter than in summer.

Customer Response, Awareness, and Understanding

11. From F2013 through to F2017, the proportion of customer households that incurred at least some Step 2 electricity consumption remained generally even at 70 percent. Through these five years, however, there was a decrease from 30 percent to 22 percent in the proportion that were into Step 2 in each month of a fiscal year.

12. Between 2012 and 2017, there was an increase from 53 percent to 64 percent in the proportion of customers who felt that BC Hydro's residential electricity prices were too high. Furthermore, the extent that customers felt this way was highly correlated with their exposure to Step 2 electricity consumption.

13. For customers that never incurred electricity consumption beyond Step 1, there was no longer a majority in 2017 – as there was in 2012 – who felt that prices were 'about right'. The largest segment of these customers now believed prices were too high. Their beliefs around the price of electricity in each of the 2012 and 2017 surveys help to explain why a Step 1 price elasticity was not detected until the F2016 and F2017 consumption data was added to the econometric analysis.

14. Customers' unaided awareness that BC Hydro charges household consumption of electricity on an inclining block rate has gone generally unchanged over the past five years, measuring 49 percent in 2012 and 47 percent in 2017.

15. For customers previously aware of the RIB rate in each of the 2012 and 2017 surveys, their total bill amounts emerged as serving more of an incentive to manage their consumption of electricity than did electricity prices or the rate structure. In fact, the inclining block rate was considered to be less of an incentive in 2017 than it was in 2012.

16. Customers previously aware of the RIB rate in the 2017 survey were more likely than others to have completed a home energy efficiency upgrade in the previous three years, to have participated in at least one of BC Hydro's conservation programs and to have outperformed other customers on many in-home conservation behaviours. However, it could not be ascertained through the research if and to what extent awareness of the rate structure led to the decisions to engage in these activities.

17. The total proportion of customers who support the RIB rate – including those who may have learned about it for the first time in the survey – has decreased from 59 percent to 55 percent over the past five years. Support continues to measure highest among customers who never incur Step 2 electricity consumption.

4.2 Recommendations

1. Consider whether the existing rate structure continues to serve BC Hydro's business objectives and meet customer needs, given that the current RIB rate structure appeared to yield little or no energy savings in F2016 and F2017.

2. Given the finding that larger consuming customers are more price responsive in the winter than in summer, consider exploring the value of a seasonal rate, with different pricing and consumption thresholds in the winter.

3. Consider the value of targeting small electricity consumers (e.g. those living in apartments) with existing or new DSM program offers, given their increased response to price changes in recent years.

This page left blank

5.0 Conclusions

Although awareness of the RIB rate has remained relatively unchanged over the past five years at just under 50 percent among all residential customers, the survey analysis has shown that a greater proportion of small customers now feel that electricity prices are too high and the econometric analysis has indicated that they have become more responsive to price changes.

Overall, the RIB rate appears to have achieved its objective of encouraging conservation through the customer response to higher marginal prices. However, the effectiveness of the RIB rate in yielding electricity savings appears to have diminished over time.

Evaluation Oversight Committee Signoff

BC Hydro's Evaluation Oversight Committee is made up of DSM stakeholders from various parts of the company and is mandated to ensure that BC Hydro's DSM evaluations are objective, unbiased and of sufficient quality.

The F20013-F2017 RIB evaluation meets the following criteria for approval by the Evaluation Oversight Committee:

1. The evaluation complied with the defined scope.
2. The evaluation methodology is appropriate given the available resources at the time of the evaluation.
3. The evaluation results are reasonable given the available data and resources at the time of the evaluation.

Abbreviations and Glossary

BCUC: British Columbia Utilities Commission

CDD: Cooling Degree Days. A measurement to reflect the amount of energy required to cool a building derived from outdoor air temperature. Cooling degree days are defined relative to a base temperature (18°C).

CRI: Conservation Research Initiative – A pilot project started in November 2006 to investigate the capabilities of smart meters including critical peak pricing and load control components.

DSM: Demand Side Management

Evaluated Savings: Savings estimates reported after the energy efficiency activities have been implemented and an impact evaluation has been completed.

Experimental Design: Also known as a randomized controlled experiment where participants in the experiment are randomly assigned to either the treatment or control group to attempt to isolate the effects of the treatment itself from all other (unknown) sources of variation.

HDD: Heating Degree Days. A measurement to reflect the amount of energy required to heat a building derived from outdoor air temperature. Heating degree days are defined relative to a base temperature (18°C).

Natural Conservation: Refers to those efficiency improvements that would occur in the absence of any DSM activity. Natural conservation may be due to equipment efficiencies, behaviors, changes to codes and standards or simply reactions to rate increases.

OLS: Ordinary Least Squares - a method for estimating the unknown parameters in a linear regression model. This method minimizes the sum of squared vertical distances between the observed responses in the dataset and the responses predicted by the linear approximation.

Reported Savings: Savings estimates reported by a program or initiative implementer/administrator after an energy efficiency activity has been completed. Also called *claimed savings* or *tracking estimates.*

RIB: Residential Inclining Block

Quasi-experiment: In a quasi-experimental design, there is no random assignment to a treatment or control group. Treatment and comparison group members are matched on relevant characteristic(s).

Re: Evaluation of the Residential Inclining Block Rate F2013-F2017

1. What is your assessment of the quality of the research design? If you identify any shortcomings, what is your assessment of their potential risk for the validity of the evaluation results?

   The research design and objectives make sense, but the ability to get actionable results was limited by two main factors: i) better understanding of how the RIB, the absolute energy bill, and other factors played into customers' actions; and ii) getting a solid counterfactual (the flat rate case).

2. What is your assessment of the quality of the input data? If you identify any shortcomings, what is your assessment of their potential risk for the validity of the evaluation results?

   The evaluation team did a great job at drawing from a variety of data sources to optimize the cost-effectiveness of the research. Input data for the most part was good. The core difficulty was getting enough data to overcome the relatively small "signal" and large amount of "noise".

3. What is your assessment of the quality of the analytical methods? If you identify any shortcomings, what is your assessment of their potential risk for the validity of the evaluation results?

   The analytical methods were sound. The focus on determining an elasticity of demand for both the RIB and the flat rate, and then estimating savings as the difference between these made sense a priori. But it appears that due to how small the elasticities were, that about ½ of the customers' surveyed didn't know they were on RIB or what it was, resulted in much lower "signal" compared to the "noise" of other factors. The ongoing increase in rates apparently had more of an effect than the RIB. A larger focus on understanding customers' reactions to both RIB and absolute increase in their rates and how these led or not to energy saving actions would have enabled a better understanding of the influence of these and how to proceed to improve rate design.

4. How does the methodology compare to common industry practice for evaluations of similar initiatives?

   Methodology for estimating elasticities is aligned with common industry practice. Similarly, with regards to estimating savings and customer understanding of rate structures. A broader and deeper use of qualitative methods would have possibly provided a better understanding of customers' key motivating factors to take energy saving actions. For example, what were the synergistic effects of increasing rates and the RIB? Would the RIB have a larger effect if more effort were put to educate customers on it and the benefits of small reductions in energy having large effects on bills? How would customers react if their entire energy use were charged at the marginal rate they fell in the RIB (Mexico did this for a while)?

5. What are your suggestions for future evaluations of this DSM initiative?

   Future work should examine in more detail objective #4 – how well customers understand their rate structure and how changes to their energy use affect their bills, and whether these are material enough to effect increased conservation and energy efficiency actions by customers. Such research would provide more insight on what types of changes to the rate structure will be most effective at getting customers to modify their energy use (and potentially, at specific times of the day and year).

6. Do you have any other comments that you would like to make?

   This was a very difficult effort; very small "signal", lots of "noise". The evaluation team did a good job at drawing from a variety of data sources to develop elasticity and savings estimates. Findings offer elasticity results, but less on what to do in view of these, due to the uncertainty in these results and need for a deeper understanding of the reasons (i.e., customer motivators) behind the observed energy use changes.

Re: Evaluation of the Residential Inclining Block Rate F2013-F2017, April 2018

1. What is your assessment of the quality of the research design? If you identify any shortcomings, what is your assessment of their potential risk for the validity of the evaluation results?

   The research design of the evaluation is of reasonably high quality for the approach chosen. That is, given that the target program involves a rate change (*i.e.*, from a flat rate to a residential inclining block rate, or RIB), the evaluators attempted to estimate price elasticities for customers' consumption on the two pricing blocks (Blocks 1 and 2). They then calculate RIB conservation impacts by applying the elasticities to the corresponding percentage changes in prices. One potential shortcoming of this design is that estimating price elasticities for a utility can be challenging due to typically small changes in prices, which also tend to follow a trend over time, leading to relatively few independent observations on price changes. Another potential shortcoming involves the element of the design that requires estimation of consumers' price elasticity for the flat rate that would otherwise have been in place. Uncertainties surrounding this estimated price elasticity and the block price elasticities results in a somewhat wide range of estimated RIB conservation impacts that vary substantially from year to year.

2. What is your assessment of the quality of the input data? If you identify any shortcomings, what is your assessment of their potential risk for the validity of the evaluation results?

   The quality of the input data is high. BCH has extensive time-series data on their customers' bi-monthly energy consumption, weather, geographical region and rates.

3. What is your assessment of the quality of the analytical methods? If you identify any shortcomings, what is your assessment of their potential risk for the validity of the evaluation results?

   The analytical methods used to estimate price elasticities for Block 1 and Block 2 consumption are competent. However, the methods used to calculate conservation impacts of RIB implementation are needlessly convoluted, leading to considerable uncertainty regarding the estimated impacts. The problems arise from the nature of the analytical approach, which assumes that the price changes to which the estimated elasticities are applied should be year-to-year changes in the individual block prices. This assumption in turn implies the need to estimate a price elasticity for the flat rate (which customers no longer experience) so that naturally-occurring price impacts may be subtracted from RIB impacts. Lacking the ability to estimate a price elasticity for a non-existing rate, the researchers make an arbitrary assumption that it is a blend of the Block 1 and 2 price elasticities, and calculate a range of conservation impacts under alternative assumptions regarding the flat rate elasticities.

As I have suggested in previous comments, a more appropriate evaluation approach would be to calculate the relevant price changes as the percentage changes in the two block prices *relative to the flat rate* that would otherwise have applied. That is, an evaluation of any program or rate involves a comparison to a counter-factual reference case of what would have occurred had the program or rate not been offered to customers. In the case of RIB, the reference case is that customers would have faced the flat rate rather than the RIB rates. Thus, the relevant price change is the difference between the relevant RIB rate and the flat rate. As a result, Block 1 customers experience prices that are approximately 15 percent <u>lower</u> than they would have been under the flat rate, while Block 2 customers see prices that are 25 percent <u>higher</u>. Under this approach to calculating RIB impacts there would be no need to estimate a separate elasticity for the non-existing flat rate; the naturally-occurring price response would be accounted for in the relative price changes.

4. How does the methodology compare to common industry practice for evaluations of similar initiatives?

   The methodology for estimating price elasticities is comparable to common industry practice for applications such as load forecasting. However, for evaluating the impacts of the RIB rate change, other methodologies, such as those used for estimating load impacts of demand response (DR) programs and dynamic pricing are more common. These are generally intervention models in which an impact variable is used to directly estimate the effect of a rate or DR program. The binary variable takes on the value *zero* in pre-RIB billing periods and *one* following RIB implementation (the variable may be interacted with time to allow time-varying impacts), such that the coefficient on the variable represents the program impact. Such variables could be included in separate regressions using billing data for Block 1 and Block 2 consumption.

5. What are your suggestions for future evaluations of this DSM initiative?

   In future analyses I would suggest exploring two alternative research paths. One would explore intervention models of the type described above (and in the report) to estimate RIB impacts directly. The other would undertake additional analyses of price elasticities using alternative methods, particularly using dynamic models that account for possible lagged, or delayed responses to price changes. Finally, I recommend a review of the assumptions regarding the price changes that Block 1 and Block 2 customers experience compared to the counter-factual flat rate.

6. Do you have any other comments that you would like to make?

   I would suggest that future evaluations also explore the relationship between RIB impacts on residential energy consumption and the impacts of BC Hydro’s DSM conservation programs. Some initial attempts along these lines were attempted in the current evaluation and are described in the report. No statistically significant results of expected signs were found, suggesting opportunities for further exploration into data on DSM expenditures and reported savings, and on methods used in the RIB evaluation to incorporate those data.

Appendix C: Approach Details

C.1. Econometric Modeling

Price elasticity analysis started with the three electricity consumption models and their basic functional forms as shown in Equations 1, 2 and 3 in Section 2.3.1. In setting up consumption models, the following factors that are significant drivers for electricity consumption at the aggregate level were considered:

Electricity Price: Economic theory holds that price impacts consumption. Historical electricity prices for residential customers were obtained from BC Hydro Tariff documents.

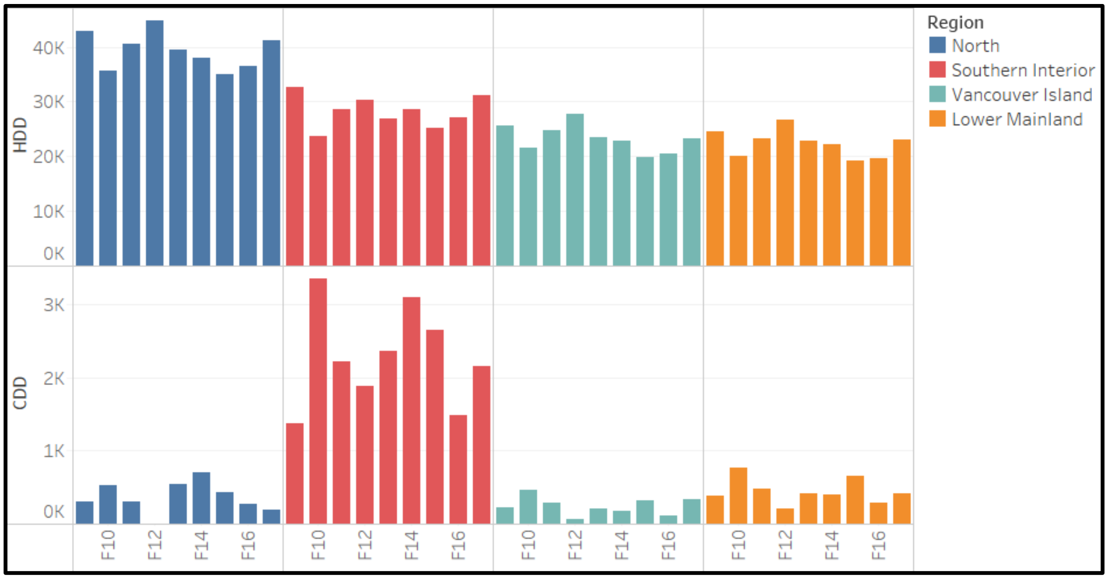
Adjusting Historical Prices using the BC CPI: Table C.1 presents a schedule of the historical prices for the Step 1, Step 2 and flat rate. The table also shows the year over year percentage change in the real price by adjusting the nominal prices for inflation, based on the consumer price index ("CPI") shown in the far-right column.

Table C.1: Historical Prices vs. Consumer Price Index

	Nominal Price (cents/kWh)			Percentage Change in Real Price from Previous Year			
Fiscal Year	Step 1	Step 2	Flat Rate (1151)	Step 1	Step 2	Flat Rate	Consumer Price Index (base year of 2002)
F2008			6.14	-	-	-	110.3
F2009	5.46	7.21	6.29	-12.8%	15.1%	0.4%	112.5
F2010	5.91	8.27	6.84	8.2%	14.7%	8.7%	112.5
F2011	6.27	8.78	7.26	4.2%	4.3%	4.3%	114.5
F2012	6.67	9.62	7.84	4.1%	7.2%	5.7%	117.0
F2013	6.8	10.19	8.15	1.1%	5.0%	3.1%	118.0
F2014	6.9	10.34	8.27	1.6%	1.6%	1.6%	117.8
F2015	7.52	11.27	9.01	8.3%	8.3%	8.2%	118.6
F2016	7.97	11.95	9.55	4.8%	4.9%	4.8%	119.9
F2017	8.29	12.43	9.93	2.3%	2.3%	2.3%	121.9

Weather: Weather affects electricity consumption through space heating, water heating and air conditioning loads. Heating Degree Days (HDD) and Cooling Degree Days (CDD) representing bi-monthly temperature variations were used to control for weather impacts on electricity consumption. Figure C.1.1 below shows the values of HDD and CDD for the four BC regions over time.

Figure C.1.1. Regional HDD and CDD from F2009 to F2017



Seasonality: Seasonality impacts electricity use through changes to the hours of daylight, seasonal holidays and other general changes in the mix of electricity end-uses based on a given time of year. Six bimonthly billing periods were used to control for seasonal impacts beyond those associated with weather.

Space heating fuel: Space heating is a large end-use of energy for BC Hydro's residential customers. Space heating in British Columbia most commonly uses natural gas or electricity followed by wood and propane. Primary space heating fuel type is estimated at the account level from the BC Hydro billing system. For the purpose of this analysis, primary space heating fuel was defined as either electric or non-electric.

Dwelling type: Dwelling type impacts electricity consumption through factors such as overall heating demand, number of appliances, number of occupants, and construction material. Dwelling type is maintained in the BC billing system using the following classifications: single family detached, row house, apartment, and mobile home.

Note that "Other" dwelling types included in the 2014 evaluation had an unusually high consumption level compared to the other categories of dwellings and showed an irregular consumption pattern in previous years. As a result, this category of residential homes (about 3% of total residential accounts) was not included in the current evaluation.

DSM Expenditures: BC Hydro's expenditures on DSM programs and sector enabling activities impacts electricity consumption by providing information and incentives for electricity conservation as well as development of codes and standards. Bi-monthly expenditures from F2005 to F2017 were obtained and allocated across the various account sub-groups (region, dwelling type, heating type) based on the number of accounts in each group. The impact of expenditures on DSM by agencies other than BC Hydro were not included because they either target different customer groups or were expected to be too small to be measured using the aggregate analysis of demand models adopted in this evaluation.

DSM Savings: Energy savings from BC Hydro's DSM programs, and federal or provincial government codes and standards have an impact on electricity consumption. Energy savings from F2005 to F2017 were collected from BC Hydro's record of DSM savings in the residential sector. Such saving impacts can be incorporated in the econometric models to test their influence on price elasticity estimate.

Economic Factors: Economic theory holds that income impacts consumption. Annual personal real disposable income in British Columbia was obtained through BC Stats. Adjustments for the impact of inflation were done using the monthly Consumer Price Index (CPI) from Statistics Canada.

Region: The BC Hydro service territory is divided into four geographic regions: Lower Mainland, Vancouver Island, Southern Interior and North. Region impacts electricity consumption through differences in demographics and lifestyle of their residents.

Interactions between variables: Adding interaction terms to the regression model may help to explain the relationships between some of the variables. For example, the relationship between weather and heating fuel type are expected to have a strong influence on overall consumption since households with electric heat would have higher consumption in colder weather compared to households with non-electric heat.

Correction Term: The bias correction term is based on the construction of a log odd regression whose dependent variable is $Y = \ln[S / (1-S)]$, where S = large user share of total accounts. Since the small user share will be (1-S), the correction term for the small user regression is based on the same log odd regression. The coefficient estimate on the correction term for the Step 2 regression is expected to be negative, based on an assumption that if a random factor causes more accounts to be in the large user group, the same factor also tends to enlarge the per account consumption. Conversely, the correction term's coefficient estimate for the small user (Step 1) regression is expected to be positive. The assumption is that if a random factor causes more accounts to be in the small user group, the same factor also tends to decrease the per account consumption.

Testing the models: Each of the econometric models was assessed for validity through:

- Statistics of the adjusted R-squared for overall regression model validity;
- Expected signs (or values) of coefficients for individual independent variables and their statistical significance;

C.2. Customer Surveys

Detailed information about the 2012 and 2017 RIB survey methodologies are presented in Section 2.3.4 of the report.

This section presents additional information in regards to the Residential End-Use Studies that were leveraged in this evaluation, an exploration of the 2017 RIB survey sample, and a description of the statistical tests used in the analysis of the RIB survey data.

C.2.1 Residential End-Use Studies

Findings from BC Hydro's 2014 and 2017 Residential End-Use Studies were leveraged – due to their very large sample sizes and representativeness – to serve as population proxies in confirming the reliability of the 2017 RIB survey sample.

As was done for the 2012 RIB survey sample in concert with the 2012 end-use study, the 2017 RIB survey sample and the distribution of customer contact demographics, household characteristics and electricity consumption were compared – and as shown in the next section, validated – to the distributions of RIB customers ascertained from the 2014 and 2017 end-use studies.

Each of the 2014 and 2017 end-use studies featured a self-administered data collection approach, and afforded respondents to complete the survey in either in a print format or online.

The 2014 study was comprised of 7,318 customer respondents on the RIB rate while the 2017 study was comprised of 6,929 customer respondents on the RIB rate.

C.2.2 2017 RIB Survey Sample Profile

This section details the distribution of the 2017 survey sample – after statistical weighting – on a number of different fronts, such as customer demographics and household characteristics, and compares the distributions to those of the population of residential customers. In doing so, a comprehensive profile of customer households is presented, and the sample is certified as being very representative of the population from which it was drawn.

Population and 2017 Survey Sample Profile of RIB Customers

Table C.2. details the population distribution of BC Hydro's 1.7 million RIB qualified customers on four known population parameters in the corporation's customer account billing system – region, dwelling type, age of primary account holder and Step 2 electricity consumption status – and the 2017 survey sample distribution of customers after statistical weighting.

The single largest segment of residential customers in 2017 – 59 percent – resided in the Lower Mainland, followed by Vancouver Island, the Southern Interior and the North. The distribution of dwelling types followed much of the same pattern in that 57 percent of customers lived in single detached houses and duplexes while most others lived in apartments and condominiums rather than in row houses and townhouses, mobile homes and 'other' types of dwellings.

Table C.2: Population and 2017 Survey Sample Profile of RIB Customers

	2017 Population*	2017 Survey Sample
Region		
Lower Mainland	59%	59%
Vancouver Island	21%	21%
Southern Interior	12%	12%
North	8%	8%
Total	100%	100%
Dwelling Type		
Single detached house/duplex	57%	57%
Row house/townhouse	9%	10%
Apartment/Condominium	28%	28%
Mobile home/other	5%	5%
Total	100%	100%
Age of Primary Account Holder		
18-24	2%	1%
25-34	11%	12%
35-44	17%	16%
45-54	21%	21%
55-64	23%	23%
65+	27%	27%
Total	100%	100%
Step 2 Consumption Status in F2017		
Never into Step 2 (0 months)	30%	31%
Sometimes into Step 2 (1-11 months)	48%	47%
Always into Step 2 (12 months)	22%	22%
Total	100%	100%

Column totals may not total 100% due to the rounding of values.
* As per BC Hydro's customer account billing system for region, dwelling type, age of primary account holder and Step 2 electricity consumption status.

As per the overall population, 71 percent of primary account holders in the 2017 survey sample were 45 years old or older, including some 50 percent who were at least 55 years old.

The distribution of customers in the 2017 survey sample also very closely followed the overall population in terms of the number of times households incurred Step 2 electricity consumption in F2017. Although most customers are billed on a bi-monthly basis and the Step 2 threshold is set at 1,350 kWh, this statistic is based on calendarized monthly consumption with the Step 2 threshold at 675 kWh.

A total of 31 percent of customers in the sample never (0 months) incurred Step 2 electricity consumption in the twelve months of F2017, 47 percent of customers sometimes (1-11 months) incurred Step 2 electricity consumption and 22 percent always (12 months) did so. This observation – underscoring the representativeness of the survey sample – is important due to the fact that customer awareness levels and opinions toward the RIB rate have proven to be highly correlated to exposure to Step 2 and overall electricity consumption.

Housing Profile of RIB Customers

As BC Hydro's customer account billing system does not include housing and demographic information beyond region, dwelling type and age, its 2017 Residential End-Use Study was leveraged to serve as a proxy for further sample comparisons to the population due to its very large sample size and representativeness. At the time of this evaluation, however, analysis of the space heating and water heating fuels in the 2017 end-use study had not been completed and, for that reason, the 2014 end-use study was instead leveraged for these two items.

Table C.3: Housing Profile of the Population and 2017 Survey Sample of RIB Customers

	2017 Population*	2017 Survey Sample
Main Space Heating Fuel		
Electricity	43%	45%
Non-Electric	57%	55%
Total	100%	100%
Main Water Heating Fuel		
Electricity	37%	35%
Non-Electric	41%	41%
No hot water tank (central)	23%	24%
Total	100%	100%
Floor Area (square feet)		
<500	1%	1%
500-1,000	24%	23%
1,001-1,500	21%	22%
1,501-2,000	17%	17%
2,001-2,500	16%	15%
2,501-3,000	10%	11%
Over 3,000	11%	10%
Average	1,869	1,857
Total	100%	100%
Year Home Built		
Before 1950	7%	8%
1950-1975	23%	24%
1976-1985	17%	19%
1986-1995	19%	16%
1996-2005	14%	15%
2006-2015	18%	17%
2016-2017	1%	1%
Total	100%	100%

Column totals may not total 100% due to the rounding of values.
* As per the distribution of RIB qualified tariff 1101 records in BC Hydro's 2017 Residential End-Use Study. Main space heating fuel and main water heating fuel as per the distribution of RIB qualified tariff 1101 records in BC Hydro's 2014 Residential End-Use Study.

Very similar to the population, 45 percent of households in the 2017 survey sample relied primarily on electricity for their space heating. A total of 35 percent of households in the 2017 survey sample relied on electricity for their home's water heating needs. It follows that 41 percent of customers relied on non-electric fuels for their hot water heating while 24 percent of customers – most of them in apartments and condominiums – received their hot water from their building's central system. The profile of survey sample in terms of dwelling floor space and vintage also very closely followed that of the overall population.

Demographic Profile of RIB Customers

The demographic composition of the survey sample was very representative of the population in terms of primary account holders being generally split by gender and by the distribution of their age (as previously shown in Table C.2.). Close to four in ten account holders had earned university degrees while the balance of others were most likely to have attended university, college, vocational or technical school.

Table C.4: Demographic Profile of the Population and 2017 Survey Sample of RIB Customers

	2017 Population*	2017 Survey Sample
Gender of Primary Account Holder		
Male	50%	48%
Female	50%	52%
Total	100%	100%
Education of Primary Account Holder		
Less than grade 12	7%	6%
High school diploma	13%	13%
Some college/vocational/technical school	18%	17%
College/vocational/technical school graduate	21%	20%
Some university	7%	7%
University/Graduate Degree	34%	37%
Total	100%	100%
Home Ownership		
Own/Co-op	80%	81%
Rent	20%	19%
Total	100%	100%
Number of Household Occupants		
1	23%	23%
2	41%	40%
3	14%	13%
4 +	22%	24%
Average number of occupants	2.5	2.6
Total	100%	100%
Household Composition		
Has children 0-5	11%	10%
Has children 6-12	12%	13%
Has young adults 13-24	19%	20%
Has adults 25-64	76%	77%
Has adults 65 +	33%	33%
Total	100%	100%

Column totals may not total 100% due to the rounding of values.
* As per the distribution of RIB qualified tariff 1101 records in BC Hydro's 2017 Residential End-Use Study.

Similar to as seen in the 2017 end-use study, a total of 81 percent of residential customers in the 2017 survey sample owned their homes.

The profile of survey respondents in terms of their household composition and household income closely followed that of all BC Hydro residential customers on the RIB rate. Households in the survey sample were comprised of an average of 2.6 people and approximately six in ten had annual earnings of $60,000 or more.

Table C.5: Demographic Profile of the Population and 2017 Survey Sample of RIB Customers (Continued)

	2017 Population*	2017 Survey Sample
Household Income		
Less than $20,000	8%	7%
$20,000 < $40,000	19%	18%
$40,000 < $60,000	17%	18%
$60,000 < $80,000	14%	14%
$80,000 < $100,000	14%	13%
$100,000 < $120,000	11%	11%
$120,000 +	19%	20%
Total	100%	100%
Low Income Status		
Yes, 'low income' household	11%	11%
No	89%	89%
Total	100%	100%

Column totals may not total 100% due to the rounding of values.
* As per the distribution of RIB qualified tariff 1101 records in BC Hydro's 2017 Residential End-Use Study.

The overall incidence of BC Hydro's RIB qualified customers in 2017 that could be classified as 'low income' as defined by Statistics Canada was estimated to have been 11 percent[25].

C.2.3 Statistical Tests

Analysis of the 2017 RIB survey sample primarily relied on frequency distributions and cross tabulations of responses. Statistical testing of differences in proportions in survey responses between groups was conducted by z-tests at the 95 percent level of confidence.

Analysis of household electricity consumption among groups of households in the survey sample was analyzed via means procedures and statistical testing of differences in means was conducted by the analysis of variance procedure at the 95 percent level of confidence.

[25] The low income cut-off (LICO) rate as defined by Statistics Canada is the percentage of families or households which fall below a low income threshold – that being, an income level whereby a family spends a larger share of its total income on the necessities of food, shelter and clothing than does an average family in an appropriate comparison group (the lower a household's income, a greater percentage of the total is tied to the necessities of living). Three variables together identify low income households of interest: annual household income, number of household occupants, and population of the household's census metropolitan area (CMA). Households with annual earnings less than the Low Income Cut-Off (LICO) for their household size and CMA population are considered low income.

Appendix D: Results Detail

D.1. Econometric Modeling Results

The results of Step 1 and Step 2 price elasticity from three econometric models are provided below. The data applied to these econometric models covered the period from April 2004 to December 2016 (F2005 through F2017).

Step 1 Price Elasticity

Model 1

Basic functional form:

$$\ln(Consumption) = \alpha + \beta \cdot Heat + \gamma \cdot Dwelling + \delta \cdot BillingPeriod + \omega 1 \cdot CDD + \omega 2 \cdot HDD$$
$$+ \mathfrak{z} \cdot Region + \varepsilon \cdot ln\,(Price) + \sigma \cdot ln\,(Disposable\_Income) + \varphi \cdot C + \mu$$

With the confidence level set at 95 percent or higher (or with the *Pr > |t|* column in the table below showing a value equal to or smaller than 0.05), the model 1 results indicate that the statistically significant (different than zero) coefficients are those associated with billing period, heating fuel type, region, dwelling type and price. Income and weather are not significant drivers for Step 1 electricity consumption as Step 1 consumption varies little with the weather or income variables.

Step 1 price elasticity is estimated at -0.14.

Model 2

Basic functional form:

$$\ln(Consumption) = \alpha + \beta \cdot Heat + \gamma \cdot Dwelling + \delta \cdot BillingPeriod + \omega 1 \cdot CDD + \omega 2 \cdot HDD$$

$$+ \mathfrak{z} \cdot Region + \theta \cdot \ln\left(DSM_{Expenditure}\right) + \varepsilon \cdot \ln(Price)$$

$$+ \sigma \cdot ln\,(Disposable\_Income) + \varphi \cdot C + \mu$$

This model tests whether adding DSM expenditure will affect the estimate of price elasticity or the coefficients of other variables.

Step 1 price elasticity is estimated at -0.14 in model 2 where BC Hydro's DSM expenditure is added in the equation. This Step 1 price elasticity result is close to the step 1 price elasticity estimate from Model 1. The results from model 2 show that DSM expenditure is not a statistically significant variable with its coefficient associated with a wrong sign and a large p-value. Adding DSM expenditure in the model only affects the coefficient estimates in a very minor way as compared to the results from model 1. These results suggest omitting DSM expenditures from the model used to estimate price elasticity does not introduce meaningful levels of uncertainty or error.

C_small	correction term: small customers	1	0.18021	0.01051	17.15	<.0001

Model 3

Basic functional form:

$$\ln(Consumption + DSM\ Savings) = \alpha + \beta \cdot Heat + \gamma \cdot Dwelling + \delta \cdot BillingPeriod + \omega 1 \cdot CDD + \omega 2 \cdot HDD + \mathfrak{z} \cdot Region + \varepsilon \cdot \ln(Price) + \sigma \ln(Disposable_{Income}) + \varphi \cdot C + \mu$$

When DSM savings were added to Step 1 electricity consumption, a statistically significant estimate of Step 1 price elasticity of -0.17 was found. This estimate is related to electricity consumption in the absence of conservation effects, therefore the price elasticity estimate in this way encompasses conservation effects generated by other DSM initiatives. In light of the conflicting result from model 2, which indicated that DSM expenditure was not a valid variable and did not affect the Step 1 elasticity estimate, it is difficult to determine how DSM initiatives affect the Step 1 elasticity estimate. The elasticity estimate from model 3 contains some DSM conservation impact in addition to price impact and is deemed not to be a true estimate of the Step 1 price elasticity.

C_large	correction term: large customers	1	-0.20262	0.01881	-10.77	<.0001

Model 2

Basic functional form:

$$\ln(Consumption) = \alpha + \beta \cdot Heat + \gamma \cdot Premise + \delta \cdot BillingPeriod + \omega 1 \cdot CDD + \omega 2 \cdot HDD$$

$$+ \mathfrak{z} \cdot Region + \theta \cdot \ln\left(DSM_{Expenditure}\right) + \varepsilon \cdot \ln(Price)$$

$$+ \sigma \cdot \ln(Disposable_{Income}) + \varphi \cdot C + \mu$$

DSM expenditures were included in Model 2, and resulted in a Step 2 price elasticity estimate of -0.10. However, the coefficient for DSM expenditures had a positive sign which indicated that increasing DSM expenditures added to electricity consumption. This is counter-intuitive and may be due to the reduction in BC Hydro's DSM expenditures in recent years that correspond to the general trend of the reduction in Step 2 price response. The positive coefficient for DSM expenditures affects the coefficients of other variables, meaning the Step 2 price elasticity from model 2 is not considered to be a true estimate of Step 2 price elasticity.

Model 3

Basic functional form:

$$\ln(Consumption + DSM\ Savings) = \alpha + \beta \cdot Heat + \gamma \cdot Dwelling + \delta \cdot BillingPeriod + \omega 1 \cdot CDD + \omega 2 \cdot HDD + \mathfrak{z} \cdot Region + \varepsilon \cdot \ln(Price) + \sigma \ln(Disposable_{Income}) + \varphi \cdot C + \mu$$

When DSM savings were added to Step 2 electricity consumption, a statistically significant estimate of Step 2 price elasticity of -0.08 was found. This estimate is close to the result from Model 1, which indicates that the inclusion of DSM savings in the model had little impact on the Step 2 price elasticity estimate. This may be attributed to relatively small changes in DSM savings as compared to Step 2 consumption.

Analysis of Price Elasticity in New Westminster

The analysis of price elasticity of about 32,000 customers in New Westminster was conducted to estimate the flat rate elasticity as a proxy for BC Hydro's flat rate elasticity. The analysis covered the period from 2005 to 2016. The elasticity analysis was built on an average bi-monthly consumption model which incorporated customer data and information available to BC Hydro.

The specific model is as follows:

$$\ln(Consumption) = \alpha + \beta \cdot HeatingCode + \gamma \cdot Premise + \delta \cdot BillingPeriod + \omega 1 \cdot CDD + \omega 2 \cdot HDD$$
$$+ \varepsilon \cdot ln\,(Price) + \sigma \cdot ln\,(Income) + \mu$$

where

ln() denotes natural logarithm;

Consumption: is the average bi-monthly consumption per account in kWh;

HeatingCode: is a binary indicator (dummy variable) whose value is one to indicate the presence or zero to indicate absence of electricity as the primary space heating fuel;

Premise: represents single detached home, high-rise building, Multiple Apartment Block, and condominium;

BillingPeriod: contains six bi-monthly billing periods which are represented by BP_1, BP_2, … and BP_5 in the model output (the default period is BP_6);

CDD and HDD: represent cooling and heating degree days, respectively, which are used to represent weather impacts;

Price: electricity price (CPI-adjusted);

Income: personal disposable income (CPI-adjusted);

μ *is the error term.*

The modelling results as shown below indicate that price, income and billing period 5 were not statistically significant variables in the model.

Root MSE	0.19857	R-Square	0.9209
Dependent Mean	6.70386	Adj R-Sq	0.9189
Coeff Var	2.96205

Analysis of Step 1 Price Elasticity in 2016

Following the 2013 RIB Evaluation, Step 1 price elasticity was analysed again in 2016 with additional data for F2013 to F2015. The data series covered F2005 to F2015. This work is referred to as Round 2 analysis in Section 3 of this Report. This analysis applied the same model used in the 2013 RIB Evaluation, which has the following functional form:

$$\ln(Consumption) = \alpha + \beta \cdot Heat + \gamma \cdot Dwelling + \delta \cdot BillingPeriod + \omega 1 \cdot CDD + \omega 2 \cdot HDD$$
$$+ \mathfrak{z} \cdot Region + \varepsilon \cdot ln\,(Price) + \sigma \cdot ln\,(Disposable\_Income) + \varphi \cdot C + \mu$$

The estimated Step 1 price elasticity was not statistically significant (*p*=0.5721).

D.2. Additional Customer Insights in Relation to the RIB Rate

This section provides more detail on customers' consumption of electricity in F2017, their opinions toward their household's consumption, the price of electricity and accompanying bills, and their awareness and attitudes toward the RIB rate.

D.2.1. Customer Exposure to Step 2 Electricity Consumption

Incidence of Step 2 Electricity Consumption by Space Heating and Water Heating Fuels

Section 3.4.1 showed that customer households on Vancouver Island and those living in single detached houses were the most likely of all customers to have incurred Step 2 electricity consumption in F2017.

The incidence of having incurred Step 2 consumption in at least one month of F2017 measured evenly at 69 percent among households that primarily rely on electricity for space heating and among those that rely on non-electric fuels such as natural gas, oil or propane.

In terms of water heating fuel, the incidence of having incurred Step 2 consumption in at least one month of F2017 measured 87 percent among households that have electric hot water heaters, 75 percent among those that have non-electric hot water heaters, and just 31 percent among those who rely on hot water from a central system. The relationship is underscored by the wide differences in the proportion of these three groups that always incurred Step 2 consumption in all twelve months of the fiscal year, measuring 33 percent, 24 percent and 1 percent, respectively.

Table D.2.1: Incidence of Step 2 Electricity Consumption in F2017 by Space Heating and Water Heating Fuels

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total	Total Sometimes + Always into Step 2
Total	30%	48%	22%	100%	70%
Main Space Heating Fuel					
Electricity	31%	50%	18%	100%	69%
Non-Electric	31%	45%	24%	100%	69%
Main Water Heating Fuel					
Electricity	13%	55%	33%	100%	87%
Non-Electric	25%	51%	24%	100%	75%
No hot water tank (central)	69%	30%	1%	100%	31%
Main Space Heating and Water Heating Fuels					
Electric Heating & Electric Water	11%	59%	30%	100%	89%
Electric Heating & Non-Electric Water	15%	57%	27%	100%	85%
Electric Heating & Central Water	62%	37%	1%	100%	38%
Non-Electric Heating & Electric Water	16%	46%	39%	100%	84%
Non-Electric Heating & Non-Electric Water	26%	50%	23%	100%	74%
Non-Electric Heating & Central Water	89%	9%	2%	100%	11%

Row totals may not total 100% due to the rounding of values.

Based on the magnitude of observed differences, it may first appear that water heating fuel was a stronger determinant of Step 2 status than space heating fuel. However, there are direct and indirect interactions between the two end-uses – as well as with other housing characteristics – that must be understood.

First, electrically heated homes are comprised of a much larger share of apartments and condominiums relying on electric baseboards. These dwellings are typically much smaller in size compared to other dwellings, lower in occupancy, have shared walls, and importantly, predominantly rely on central water heating. Second, a majority of households with electric hot water heaters also have electric space heating.

When looked at in isolation, electric space heating – in the absence of electric water heating – has a similar impact on the incidence of Step 2 consumption as does the impact of electric water heating in the absence of electric space heating. In these isolated scenarios, however, the homes with electric space heating would likely incur more Step 2 consumption in the heating season – and possibly the shoulder seasons – compared to homes with electric water heating.

Note that the incidence of having incurred Step 2 consumption climbed only marginally to 89 percent for homes that have both electric space heating and electric water heating – likely because most of these homes would already breach the threshold with only one of the two electric end-uses. However, these homes would likely incur more Step 2 consumption than those that had just one of the two electric end-uses.

Incidence of Step 2 Electricity Consumption by Household Demographics

Customers living in single detached houses have already been shown in Section 3.4.1 to have been among the most likely to have incurred Step 2 consumption in at least one month of F2017. Given the comparably higher cost of these homes and their comparably larger size, it comes expectedly that customers who own their homes, who have higher household incomes and who have the most household occupants are all among the most likely to have incurred Step 2 consumption during the year.

Table D.2.2: Incidence of Step 2 Electricity Consumption in F2017 by Household Demographics

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total	Total Sometimes + Always into Step 2
Total	30%	48%	22%	100%	70%

Row totals may not total 100% due to the rounding of values.

D.2.2. Consumption Profiles by the Incidence of Step 2 Electricity Consumption

This section presents electricity consumption patterns and insights essentially in reverse of the way presented in the previous section of this appendix. Instead of exploring customer sub-groups as to how their consumption distributes into the three unique consumption bins, each of the three consumption bins are explored as to how customer sub-groups distribute within them. Specifically, the tables detail the profiles of customer households that never (0 months), sometimes (1-11 months) and always (12 months) incurred Step 2 consumption in the twelve months of F2017.

Profile of Region and Dwelling Type by the Incidence of Step 2 Electricity Consumption

The profile of residential customers that never incurred Step 2 consumption in the twelve months of F2017 was comprised of some 70 percent of Lower Mainland households, due in large part to the greater proportion of apartments and condominiums in the region and the fact they tend to use less electricity than all other dwelling types. In fact, apartments and condominiums had a 59 percent share of all dwellings that never incurred Step 2 consumption in F2017 – 31 points higher than their overall share of dwellings in BC Hydro's service territory. Related, nearly one-half of these customers were single occupant households.

Given the breadth of the consumption bin, it comes expectedly that the profile of residential customers that sometimes incurred Step 2 consumption in F2017 generally followed that of the overall customer base.

Table D.2.3: Profile of Region and Dwelling Type by the Incidence of Step 2 Consumption in F2017

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	All Customers
Region				
Lower Mainland	70%	55%	51%	59%
Vancouver Island	15%	23%	26%	21%
Southern Interior	9%	13%	13%	12%
North	6%	9%	9%	8%
Total	100%	100%	100%	100%
Dwelling Type				
Single detached house	29%	57%	86%	54%
Duplex/Row house/townhouse	9%	17%	8%	13%
Apartment/Condominium	59%	20%	2%	28%
Mobile home/other	4%	6%	4%	5%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.

The pool of residential customers that always incurred Step 2 consumption in F2017 was comprised of a somewhat greater share of households outside the Lower Mainland – especially on Vancouver island – as compared to their share in the population overall. This consumption bin, however, was more prominently characterized by its dwelling composition by virtue of the fact that 86 percent were single detached houses – 32 points higher than their 54 percent share across the entire service territory.

Profile of Space Heating and Water Heating Fuels by the Incidence of Step 2 Electricity Consumption

The profile of households that never incurred Step 2 consumption in the twelve months of F2017 was largely comprised of households that do not rely on electricity for either of their space heating or water heating needs.

As for households that always incurred Step 2 consumption, the share of main space heating fuels measured 39 percent electric and 61 percent non-electric. This group's profile by water heating fuel does not follow that of the overall population as it is 18 points over-represented by households with electric hot water tanks (53%) and 23 points under-represented by households without any hot water tanks at all (1%). As detailed in this appendix, these findings reflect a complex interplay of factors that influence customer exposure to Step 1 and 2 prices, including space heating, water heating, dwelling and other demographic parameters.

Table D.2.4: Profile of Space and Water Heating Fuels by the Incidence of Step 2 Consumption in F2017

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	All Customers
Main Space Heating Fuel				
Electricity	46%	48%	39%	45%
Non-Electric	54%	52%	61%	55%
Total	100%	100%	100%	100%
Main Water Heating Fuel				
Electricity	14%	41%	53%	35%
Non-Electric	33%	44%	45%	41%
No hot water tank (central)	53%	15%	1%	24%
Total	100%	100%	100%	100%
Main Space Heating and Water Heating Fuels				
Electric Heating & Electric Water	8%	29%	32%	23%
Electric Heating & Non-Electric Water	2%	5%	5%	4%
Electric Heating & Central Water	35%	14%	1%	18%
Non-Electric Heating & Electric Water	6%	11%	21%	12%
Non-Electric Heating & Non-Electric Water	31%	39%	40%	37%
Non-Electric Heating & Central Water	18%	1%	<1%	6%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.

Profile of Household Demographics by the Incidence of Step 2 Electricity Consumption

Compared to the population of all residential customers, households that always incurred Step 2 consumption in F2017 were more likely to own their homes (91% versus 81% overall) and to have reported annual earnings of at least $80,000 (60% versus 44% overall). These findings simply reflect the fact that this consumption bin is largely comprised of single detached houses.

Table D.2.5: Profile of Household Demographics by the Incidence of Step 2 Consumption in F2017

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	All Customers

No	84%	90%	93%	89%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.

D.2.3. Customer Opinions about Managing Electricity Consumption

This section presents findings in regards to customers' opinions around managing their consumption of electricity, including their reported ease of doing so, their current effort and their change in effort over the past three years.

Ease in Managing Household Electricity Consumption

As a way to 'ease' customer respondents into the rates-related content of the 2017 survey, they were first queried about the management of their household's electricity use. Customers were reminded that they can manage their consumption of electricity by changing behaviour, purchasing energy-efficient products, making energy-efficient home upgrades and by participating in conservation programs.

Under the premise that they want to manage their use of electricity, a total of 75 percent of customers reported that it is either 'very easy' or 'somewhat easy' for them to manage their use of electricity. As detailed in Table D.2.6, this proportion measured 84 percent among customers who never incurred Step 2 electricity consumption in F2017, 74 percent among customers who sometimes incurred Step 2 electricity consumption and 64 percent among those who always did so.

Table D.2.6: Reported Ease or Difficulty in Managing Household Electricity Consumption

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total very easy + somewhat easy	84%	74%	64%	75%
Very easy	34%	20%	14%	23%
Somewhat easy	50%	54%	50%	52%
Somewhat difficult	13%	22%	31%	21%
Very difficult	2%	4%	5%	4%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.
Don't know responses have been excluded from all calculations.

Current Effort in Managing Household Electricity Consumption

A total of 67 percent of customers in the 2017 survey reported that their household was currently making either 'a great deal of effort' or 'a fair amount of effort' to manage its consumption of electricity.

Table D.2.7: Reported Effort in Managing Household Electricity Consumption

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total a great deal of effort + a fair amount effort	67%	68%	65%	67%
A great deal of effort	17%	14%	12%	14%
A fair amount of effort	50%	53%	53%	52%
A little effort	26%	28%	32%	28%
No effort at all	6%	3%	2%	4%
Not applicable – there is little opportunity to do so	1%	1%	1%	1%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.
Don't know responses have been excluded from all calculations.

Change in Effort over the Past Three Years in Managing Household Electricity Consumption

The majority of customer households – 57 percent – reported that they were currently making either 'much more of an effort' or 'a little more of an effort' to manage their consumption of electricity as compared to three years ago. This proportion measured lowest at 49 percent among customers who never incurred Step 2 electricity consumption in F2017 and highest at 63 percent among those who always did so.

Table D.2.8: Reported Change in Effort over the Past Three Years in Managing Electricity Consumption

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total much more of an effort + a little more of an effort	49%	60%	63%	57%
Much more of an effort	16%	20%	21%	19%
A little more of an effort	33%	40%	42%	38%
No change	49%	37%	34%	40%
A little less of an effort	2%	2%	3%	2%
Much less of an effort	<1%	<1%	<1%	<1%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.
Don't know responses have been excluded from all calculations.

D.2.4. Customer Opinions about Electricity Prices and their Bills

This section presents additional findings in regards to customers' opinions around their perceived price of electricity and their accompanying bills.

Electricity Prices – Value for Money

Customer respondents in the 2017 survey were asked to think about the amount of money their household pays for electricity every month, every two months or even over the course of a year, and to consider the benefits they receive in return. In total, 79 percent of customers believed that the amount of money represents either 'excellent', 'good' or 'fair' value for money. Customer opinions in this regard varied strongly with their Step 2 consumption status in F2017, measuring highest at 90 percent among customers who never incurred Step 2 electricity consumption in F2017 and lowest 67 percent among those who always did so.

Table D.2.9: Perceived Value for Money Household Pays for its Electricity Consumption

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total excellent + good + fair	90%	77%	67%	79%
Excellent value for money	12%	4%	2%	6%
Good value for money	31%	22%	14%	23%
Fair value for money	46%	52%	51%	50%
Poor value for money	5%	16%	24%	14%
Very poor value for money	1%	3%	5%	3%
Don't know	4%	4%	4%	4%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.

Total Electricity Bill

The majority of customers in the 2017 survey reported that they look over their household's electricity bill either 'at least once a month' or 'once every two months'.

Table D.2.10: Frequency of Looking over Electricity Bill (Print or Online Version)

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total at least once a month + once every 2 months	78%	80%	81%	80%
At least once a month	36%	40%	39%	39%
Once every 2 months	42%	40%	43%	41%
Once every 3 months	5%	6%	5%	6%
Once every 4 to 6 months	4%	4%	4%	4%
Once or twice a year	4%	5%	4%	4%
Never – we just pay it	8%	5%	5%	6%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.
Don't know responses have been excluded from all calculations.

Attitudes toward Household Electricity Consumption and Bills

Table D.2.11 below details customer agreement levels on four attitudinal statements related to their household's electricity consumption and the accompanying electricity bills.

Table D.2.11: Attitudes toward Household Electricity Consumption and Bills (Table 1 of 2)

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
I spend more time looking over bills I receive than my BC Hydro bill				
Total strongly agree + somewhat agree	38%	32%	27%	33%
Strongly agree	16%	14%	13%	14%

Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.

Reported Change in Total Electricity Bill Amounts

A total of 79 percent of customers believed that the total dollar amount of their electricity bills have either 'increased a great deal' or 'increased just a little' over the past three years. This proportion stepped up through the three consumption bins, from a low of 69 percent among customers who never incurred Step 2 electricity consumption in F2017 to a high of 86 percent among those who always did so.

Table D.2.13: Reported Change in Total Electricity Bill Amounts over the Past Three Years

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total increased a great deal + increased just a little	69%	81%	86%	79%
Increased a great deal	16%	34%	46%	31%
Increased just a little	54%	47%	40%	48%
Stayed about the same	20%	10%	7%	12%
Decreased just a little	2%	3%	2%	3%
Decreased a great deal	1%	1%	1%	1%
Don't know	8%	5%	4%	5%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.

Perceived Reasons for Change in Total Electricity Bill Amounts

Among customers who believed the total amount of their electricity bills had increased over the past three years, 78 percent believed the increase was due to changes in the overall price they pay for electricity while 28 percent (also) believed the increase was due to changes in their household's consumption level.

Table D.2.14: Perceived Reason for Change in Total Electricity Bill Amounts over the Past Three Years

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
For those who reported increases in bills				
Due to changes in the overall price we pay for electricity	76%	79%	78%	78%
Due to changes in our consumption level	25%	31%	26%	28%
Don't know	10%	6%	10%	9%
For those who reported decreases in bills				
Due to changes in our consumption level	86%	85%	83%	85%
Due to changes in the overall price we pay for electricity	9%	16%	15%	14%
Don't know	7%	10%	8%	9%

*Totals may be greater than 100% due to multiple mentions.

Among customers who believed the total amount of their electricity bills had decreased over the past three years, 85 percent believed the decrease was due to changes in their household's consumption level while 14 percent (also) believed the decrease was due to changes in the overall price they pay for electricity.

D.2.5. Awareness and Opinions of BC Hydro's Residential Rate Structure

This section provides more detail on customers' prior awareness, understanding and opinions of BC Hydro's residential rate structure.

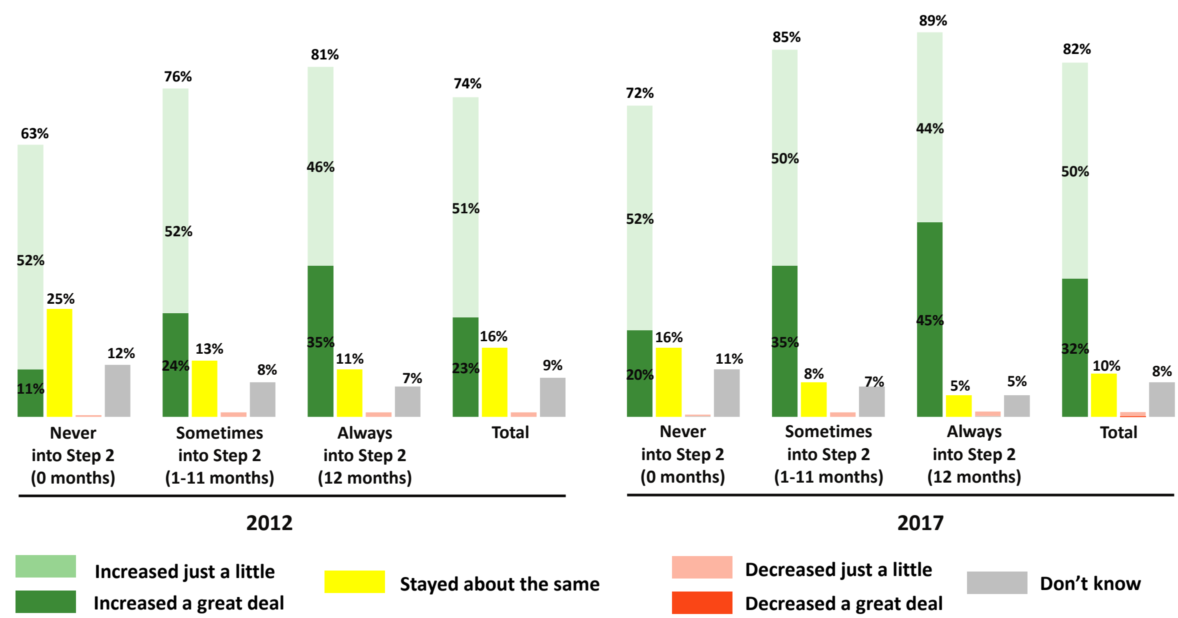
Perceived Change in BC Hydro's Current Residential Electricity Prices over the Past Three Years

In each of the 2012 and 2017 surveys, customers were also asked about the extent to which they believed residential electricity prices had changed – if at all – over the previous three years.

As illustrated in Figure D.1, 63 percent of customers that never incurred Step 2 electricity consumption in F2012 believed that electricity prices had increased over the previous three years. To compare, this proportion climbed to 76 percent among those that sometimes incurred Step 2 electricity consumption in the fiscal year and further to 81 percent that always did so.

Different insights and perspectives can be gained by bundling the 'increased just a little' and 'stayed about the same' responses during analysis. By doing so, it can be said that 77 percent of those that never incurred Step 2 electricity consumption in F2012 felt that prices had increased little – if at all – over the previous three years. To compare, this proportion measured lower at 65 percent among customers that sometimes incurred Step 2 electricity consumption and at 57 percent among those that always did so.

Figure D.1
Perceived Change in BC Hydro's Residential Electricity Prices over the Past Three Years
- By Step 2 Status of Electricity Consumption -



The findings in the 2012 survey are intuitively consistent with the actual change in electricity prices dating back to October 2008 when the RIB rate was implemented. As shown in Figure 2.1, at the time of the 2012 survey, the Step 1 price had existed for roughly 3.5 years and had been lower than the pre-RIB flat rate price for 2.5 of those years. This group would be expected to be less cognizant of price increases in these years and to be less responsive to them as compared to the two other cohorts. Analysis presented in an earlier section showed this in that a Step 1 price elasticity pertaining to that period was not detected with a high degree of confidence whereas a Step 2 price elasticity was.

The pattern of opinions toward the perceived change in electricity prices by Step 2 status identified in the 2012 survey emerged again in the 2017 survey, but with some shifts over the five year period. In each of the three Step 2 cohorts, the proportion of customers who felt that electricity prices had 'increased a great deal' over the previous three years measured higher in 2017 than in 2012. In particular, the proportion nearly doubled from 11 percent to 20 percent among the cohort that was never into Step 2. It is reasonable to believe, therefore, that this group of customers would have become comparably more responsive to an increase in electricity prices than they were five years earlier. This belief is backed by the fact that a statistically significant Step 1 price elasticity was ascertained once the F2016 and F2017 consumption data was added to the econometric analysis.

Unaided Awareness of BC Hydro's Residential Rate Structure by Region, Dwelling and Step 2 Consumption

As explained in Section 3.4.3., unaided awareness that BC Hydro uses an inclining block rate for charging residential households for their consumption of electricity measured highest at 53 percent among customer households that always incurred Step 2 electricity consumption in F2017. It follows that prior awareness of the inclining block rate continues to measure highest – 58 percent currently – among customers on Vancouver Island. These households were previously shown to have been the most likely to incur Step 2 consumption in F2017 and by extension, the most likely to have had the highest electricity bills.

Interestingly, the results of the analysis of regional elasticities in Section 3.3.1 also that showed Vancouver Island customers were more responsive to the Step 2 price than customers in other regions.

Table D.2.15: Unaided Awareness of BC Hydro's Residential Rate Structure by Region, Dwelling and Step 2 Status

	Inclining block rate	Flat rate	Declining block rate	Time of Use	Don't know	Total
Total	47%	21%	1%	8%	24%	100%
Region						
Lower Mainland	42%	23%	1%	8%	26%	100%
Vancouver Island	58%	15%	1%	7%	19%	100%
Southern Interior	49%	19%	1%	7%	25%	100%
North	45%	21%	1%	7%	26%	100%
Dwelling Type						
Single detached house	53%	19%	1%	7%	20%	100%
Duplex/Row house/townhouse	43%	20%	<1%	10%	27%	100%
Apartment/Condominium	37%	25%	1%	8%	29%	100%
Mobile home/other	49%	12%	1%	6%	31%	100%
Step 2 Consumption Status in F2017						
Never into Step 2 (0 months)	39%	23%	1%	9%	28%	100%
Sometimes into Step 2 (1-11 months)	49%	20%	1%	7%	23%	100%
Always into Step 2 (12 months)	53%	19%	<1%	8%	20%	100%

Row totals may not total 100% due to the rounding of values.

Consistent with findings tied to education and income, unaided awareness of the inclining block rate measured highest among customers who own single detached houses – the most expensive of the dwelling types, and typically the highest in consumption.

Unaided Awareness of BC Hydro's Residential Rate Structure by Household Demographics

Unaided awareness of the inclining block rate was strongly correlated to level of education, spanning 21 points from a low of 34 percent among customers who have earned no more than a high school diploma to a high of 55 percent among those who have attained university degrees. Related, awareness was also tied to annual income, spanning 19 points from a low of 37 percent among those with household earnings less than $40,000 to a high of 56 percent among those with household earnings of at least $120,000. Note that educated and affluent consumers are among the most likely to live in single detaches houses which have been shown to be the most likely of all dwellings to incur Step 2 electricity consumption. These customers are also known to be comparably more likely than others to be regular readers of public affairs information – conventionally in newspapers, but also online – in which electricity issues and rates are often covered.

Table D.2.16: Unaided Awareness of BC Hydro's Residential Rate Structure by Household Demographics

	Inclining block rate	Flat rate	Declining block rate	Time of Use	Don't know	Total
Total	47%	21%	1%	8%	24%	100%
Home Ownership						
Own/Co-op	49%	20%	1%	8%	22%	100%
Rent	36%	24%	1%	7%	33%	100%
Age of Primary Account Holder						
18-34	47%	23%	1%	6%	22%	100%
35-54	46%	23%	1%	8%	22%	100%

$120,000 +	56%	25%	<1%	6%	13%	100%
Low Income Status						
Yes, 'low income' household	33%	20%	2%	10%	34%	100%
No	48%	21%	1%	7%	23%	100%

Row totals may not total 100% due to the rounding of values.

Consistent with other BC Hydro research, approximately 10 percent of the customer households in the 2017 surveys were classified as 'low income'. Among these customers, unaided awareness of the RIB rate measured 33 percent.

Unaided Awareness of BC Hydro's Residential Rate Structure by Heating Fuels

There was no meaningful difference in unaided awareness of the inclining block rate among customers who rely on electricity to heat their homes versus those who rely on natural gas, oil or propane (46% versus 47%). However, at 54 percent, customers who rely on electricity for their water heating were more likely than others to have been aware of the rate. To compare, this proportion decreased to 47 percent among customers with non-electric hot water tanks and further to 36 percent among those with central water heating. As previously explained, all of these findings reflect a complex interplay of factors that influence customer awareness of electricity rate structures, including space heating, water heating, dwelling and other demographic parameters.

Table D.2.17: Unaided Awareness of BC Hydro's Residential Rate Structure by Heating Fuels

	Inclining block rate	Flat rate	Declining block rate	Time of Use	Don't know	Total
Total	47%	21%	1%	8%	24%	100%
Main Space Heating Fuel						
Electricity	46%	19%	1%	7%	27%	100%
Non-Electric	47%	22%	1%	8%	22%	100%

Non-Electric Heating & Central Water	36%	31%	<1%	10%	22%	100%

Row totals may not total 100% due to the rounding of values.

Understanding of the RIB Rate

After first soliciting their awareness of the method BC Hydro uses for charging their household's consumption of electricity, the survey informed respondents that an inclining block rate is indeed the method that BC Hydro uses. In doing so, the method was also introduced as BC Hydro's Two-Step Residential Conservation Rate and the Step 1 to Step 2 threshold and prices were detailed.

Table D.2.18: Understanding of the RIB Rate by the Incidence of Step 2 Electricity Consumption in F2017

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total excellent + good + fair	37%	47%	51%	44%
Excellent	7%	14%	16%	12%
Good	19%	21%	24%	21%
Fair	11%	12%	11%	11%
Poor	1%	2%	2%	2%
Very poor	<1%	<1%	<1%	<1%
Don't know	<1%	<1%	<1%	<1%
Not aware of the RIB rate	61%	51%	47%	53%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.

Having read the details about BC Hydro's Two-Step Residential Conservation Rate, a total of 44 percent of customers felt they actually had either an 'excellent', 'good' or 'fair' understanding of the rate prior to receiving the survey – this included some 33 percent professing either an 'excellent' or a 'good' understanding of it. These findings are generalizable to the entire population of BC Hydro's residential customers charged on this rate because the figures are fully based – the 53 percent of customers identified as not being previously aware that their consumption of electricity is charged on the RIB rate have not been excluded.

Closely following unaided awareness that residential electricity consumption is charged on an inclining block rate, the extent that customers understood the details of the RIB rate increased with the frequency of exposure to Step 2 consumption. While a total of 37 percent of customer households that never incurred Step 2 consumption in the twelve months of F2017 emerged to have either an 'excellent', 'good' or 'fair' understanding of the rate, this proportion increased to 47 percent among customers that sometimes incurred Step 2 consumption and further to 51 percent among customers that always incurred Step 2 consumption during this period.

Reported Change in 'Mindfulness' of Electricity Consumption over the Past Three Years

Among customers previously aware of the RIB rate, a total of 48 percent of them report that they have become either 'much more mindful' or 'somewhat more mindful' over the past three years of their consumption of electricity in relation to the Step 1 and Step 2 prices and thresholds.

Table D.2.19: Reported Change in 'Mindfulness' of Electricity Consumption over the Past Three Years

- among customers previously aware of the RIB rate –

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total much more mindful + somewhat more mindful	43%	52%	46%	48%
Much more mindful	11%	13%	13%	13%
Somewhat more mindful	32%	38%	33%	35%
No change	55%	47%	52%	51%
Somewhat less mindful	1%	1%	1%	1%
Much less mindful	1%	0%	1%	<1%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.
Don't know responses have been excluded from all calculations.

Awareness that the RIB Rate was Designed to Encourage Conservation

Among customers who correctly identified the inclining block rate as the method that BC Hydro uses for charging their household's consumption of electricity, 77 percent reported having been previously aware that the rate was designed to encourage conservation.

Table D.2.20: Awareness that the RIB Rate was Designed to Encourage the Conservation of Electricity

- among customers previously aware of the RIB rate -

	Yes, previously aware	No, not previously aware	Total
Region			
Lower Mainland	77%	23%	100%
Vancouver Island	80%	20%	100%
Southern Interior	75%	25%	100%
North	73%	27%	100%
Step 2 Consumption Status in F2017			
Never into Step 2 (0 months)	79%	21%	100%
Sometimes into Step 2 (1-11 months)	79%	21%	100%
Always into Step 2 (12 months)	73%	27%	100%
Education of Primary Account Holder			
High school or less	73%	27%	100%
College/vocational/technical/some university	74%	26%	100%
University/Graduate Degree	82%	18%	100%
Low Income Status			
Yes, 'low income' household	74%	26%	100%
No	77%	23%	100%

Row totals may not total 100% due to the rounding of values.

Awareness that the RIB rate was designed to encourage the conservation of electricity was correlated to education level, stepping up from a low of 73 percent among those who have attained no more than a high school diploma to a high of 82 percent among those who have earned university degrees. Again, this may reflect the fact that the most educated consumers are known to be more regular readers of newspapers in which electricity issues and rates are often covered.

How the RIB Rate Provides an Incentive to Manage Electricity

In each of the 2012 and 2017 surveys, customers who correctly identified the inclining block rate as the method that BC Hydro uses for charging their household's consumption of electricity and said it serves as an incentive to manage their use of it were further queried as to just how the rate acts as a motivator.

The single largest segment of these customers in 2017 – 32 percent – reported that the difference between the Step 1 and Step 2 prices acts as an incentive to their household to manage its consumption of electricity. These customers indicated that if they can manage their use of electricity effectively in a billing period, then they can have most of it charged at the lower, Step 1 price, perhaps even avoiding Step 2 consumption and the higher, Step 2 price altogether. This sentiment measured even higher at 37 percent specifically among customers that sometimes incurred Step 2 consumption in F2017 – possibly reflecting success in this regard.

One in five customers – specifically, 21 percent in 2017 – continued to say that the lower, Step 1 price on its own acts as an incentive to their household. They consider the lower, Step 1 price as being the price applicable to all of their electricity consumption in a billing period, and they try to manage their consumption of electricity on that basis. At 41 percent, it comes intuitively that this was the most prevalent view specifically among households that never incurred Step 2 consumption in F2017.

Table D.2.21: How the RIB Rate Provides an Incentive to Manage Electricity - among customers previously aware of the RIB Rate and who said it serves as an incentive in 2017 -

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
The lower, Step 1 price on its own incents our household…	41%	14%	8%	21%
The higher, Step 2 price on its own incents our household…	4%	12%	17%	11%
The difference between the Step 1 and Step 2 prices incents our household…	28%	37%	26%	32%
The consumption threshold on its own incents our household…	15%	17%	18%	17%
The stepped rate does not incent my household in any of these particular ways…	9%	17%	25%	16%
Don't know	2%	3%	6%	4%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.
Binning of Step 2 status is based on electricity consumption in F2017.

Just 11 percent of customers with proven awareness of the inclining block rate in 2017 felt that the higher, Step 2 price on its own serves as an incentive to their household to manage its use of electricity. As was the case in 2012, these customers consider the higher, Step 2 price as being the price applicable to the part of electricity consumption in a billing period that they have control over, and they try to manage their use of electricity on that basis.

A total of 17 percent of customers reported that price does not manifest itself in any of these ways as an incentive to them to manage their use of electricity; instead, they point to the consumption threshold. For these customers, regardless of the difference in the Step 1 and 2 prices and the amount they pay on their bill, they compare their household's consumption to the Step 1 to Step 2 threshold simply because they like to keep their consumption as low as possible compared to it.

Although they understood that their household's consumption of electricity is charged on an inclining block rate and they said that the rate serves as an incentive to their household to manage its use of it, 16 percent of customers in 2017 subsequently reported that the rate does not incent their household to manage its consumption of electricity in any of the four ways as presented. It is not clear if these particular customers are indeed incented by the rate in some different way, or if they were inconsistent in their responses.

Once again, results from the 2012 survey were by and large the same as those in the 2017 survey.

Customer Support of the RIB Rate

High level findings in regard to customer opinion of the RIB rate were reported in Section 3.4.3. Table D.2.22 below details the findings by region, dwelling type, Step 2 consumption status in F2017 and low income status.

Table D.2.22: Customer Support of the RIB Rate

	Don't know	Strongly oppose	Somewhat oppose	Indifferent	Somewhat support	Strongly support	Total	Total support

Reported Change in Support of the RIB Rate over the Past Three Years

Among customers who were previously aware of the RIB rate in the 2017 survey, the majority – 58 percent – said that there had been 'no change' over the past three years in their opinion of it. On the other hand, a total of 19 percent said that they had become more supportive of it while 20 percent said that they had become more opposed to it. As detailed in the table below, customers who had never incurred Step 2 electricity consumption in F2017 were the most likely to have become more supportive of the RIB rate.

Table D.2.23: Reported Change in Support of the RIB Rate over the Past Three Years

– among customers who correctly identify being charged on the RIB rate –

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total much more supportive + somewhat more supportive	28%	18%	12%	19%
Much more supportive of it	9%	5%	3%	5%
Somewhat more supportive of it	19%	13%	10%	14%

Column totals may not total 100% due to the rounding of values.

D.2.6. Customer Behaviour in Relation to Awareness of the RIB Rate

This section presents detailed findings of how electricity consumption, investments in home energy efficiency upgrades and conservation program participation levels differ among RIB-aware and RIB-unware customers.

Electricity Consumption by RIB Rate Awareness

As a first investigation into the relationship between consumption and awareness, an ANOVA (analysis of variance) statistical test showed that the pool of customer households previously aware of the RIB rate incurred significantly higher average consumption in F2017 than the pool of customers not previously aware of the rate (10,447 kWh versus 8,707 kWh). In fact, while the differences were not always statistically significant at the 95 percent confidence level, RIB-aware customers incurred higher consumption in every scenario shown Table D.2.24. As customers aware of the rate would likely never choose to deliberately consume more electricity, the findings uncover a causal path: greater consumption leads to a greater likelihood of being aware of the rate.

Table D.2.24: ANOVA Tests: Mean Electricity Consumption in F2017 by RIB Rate Awareness

	Customers aware of the RIB Rate (kWh)	Customers not aware of the RIB Rate (kWh)	Difference between groups (kWh)	F Statistic of Difference	Significance
All Customers					
Total F2017 consumption ⇒	10,447	8,707	1,740	44.38	0.000*
Total Step 1 consumption ⇒	6,305	5,777	528	49.26	0.000*
Total Step 2 consumption ⇒	4,142	2,930	1,212	30.94	0.000*
Customers Never into Step 2 (0 months)					
Total F2017 consumption ⇒	3,517	3,339	178	3.37	0.067**
Total Step 1 consumption ⇒	3,517	3,339	178	3.37	0.067**
Total Step 2 consumption ⇒	-	-	-	-	-
Customers Sometimes into Step 2 (1-11 months)					
Total F2017consumption ⇒	9,858	9,159	699	12.67	0.000*
Total Step 1 consumption ⇒	6,886	6,726	160	7.59	0.006*
Total Step 2 consumption ⇒	2,972	2,433	539	10.52	0.001*
Customers Always into Step 2 (12months)					
Total F2017 consumption ⇒	19,083	17,806	1,277	3.08	0.080**
Total Step 1 consumption ⇒	8,122	8,122	0	0.00	1.000
Total Step 2 consumption ⇒	10,960	9,684	1,277	3.08	0.080**

* The difference between mean consumption levels is statically significant at the 95% level of confidence.
** The difference between mean consumption levels is statically significant at the 90% level of confidence.

In a second investigation, a linear regression was conducted with consumption as the dependent variable. The independent variables consisted of rate awareness as well as various combinations of region, dwelling type, heating fuel, floor area, income, household occupants, and saturation levels of some major end-uses.

The coefficient for the awareness variable always emerged positive in the models, but typically not statistically significant at the 95 percent level of confidence. This meant that in the estimation of a household's electricity consumption using these models, the estimate would sometimes increase – but never decrease – if the household was aware of the inclining block rate. As gleaned from both investigations, awareness of the rate does not directly lead households to having lower consumption as strictly compared to households unaware of the rate.

However, compared over time, households aware of the RIB rate may have had higher energy savings in F2017 than had they not been aware of the rate and/or higher energy savings than in periods prior to becoming aware of the rate. To investigate this, a much larger dataset of customer accounts would be required, including a long time series of consumption history both before and after households became aware of the RIB as disaggregated by a finely specified date variable.

Investments in Home Energy Efficiency Upgrades by Awareness of the RIB Rate

Those who knew that their consumption of electricity was charged on the RIB rate were slightly more likely than others to have completed at least one of the eight upgrades investigated (52% vs. 48%), including more likely to have completed draft proofing upgrades (21% vs. 15%) and insulation upgrades (16% vs. 12%).

Table D.2.25: Investments in Home Energy Efficiency Upgrades by Awareness of the RIB Rate

	Customers aware of the RIB Rate	Customers not aware of the RIB Rate	Difference between groups
Net Total: Any of the upgrades			
All customers	52%	48%	4 points*
Low income customers	44%	34%	10 points
Hot water tank installation/upgrade			
All customers	30%	28%	2 points
Low income customers	15%	15%	0 points
Window upgrades			
All customers	24%	22%	2 points
Low income customers	23%	17%	6 points
Draftproofing upgrades			
All customers	21%	15%	6 points*
Low income customers	19%	14%	5 points
Door upgrades			
All customers	17%	16%	1 point
Low income customers	12%	12%	0 points
Insulation upgrades			
All customers	16%	12%	4 points*
Low income customers	15%	4%	11 points *
Furnace installation/upgrade			
All customers	12%	12%	0
Low income customers	5%	8%	(-3) points
Air source heat pump installation/upgrade			
All customers	4%	3%	1 point
Low income customers	1%	0%	1 point
Ground source heat pump installation/upgrade			
All customers	1%	1%	0
Low income customers	0%	1%	(-1) point

* Statistically significant difference between the two groups at the 95% level of confidence.

Low income customers previously aware of the RIB rate were more likely than other low income customers to have completed some home energy-efficiency upgrades. Once again, the differences were not always statistically significant because the absolute number of low income households in the survey was not large enough to afford a high level of confidence in the findings.

Program Participation by RIB Rate Awareness

BC Hydro offers several energy conservation initiatives and rebate offerings to its residential customers to encourage them to improve energy efficiency and to adopt more energy conscious behaviours in their homes. An investigation into these programs was conducted to assist in understanding whether there were differences in program participation among those who correctly understood their use of electricity was charged on the RIB rate as compared to other customers.

This procedure relied on customer program participation markers from BC Hydro's billing system, strictly since the implementation of the RIB rate in October 2008, and customer awareness of the RIB rate.

Table D.2.26: Program Participation since RIB Rate Inception by Awareness of the RIB Rate

	Customers aware of the RIB Rate	Customers not aware of the RIB Rate	Difference between groups
Net: Any of the Programs (excludes Energy Visualization Portlet)			
All customers	32%	22%	10 points*
Low income customers	30%	25%	5 points
Appliance Rebate Program			
All customers	14%	9%	5 points *
Low income customers	8%	4%	4 points
Refrigerator Buy-Back Program			
All customers	7%	7%	0 points
Low income customers	7%	5%	2 points
Low Income Program			
All customers	4%	4%	0 points
Low income customers	16%	13%	3 points
HERO Program			
All customers	<1%	<1%	0 points
Low income customers	0%	0%	0 points
Team Power Smart Residential Behavior Program			
All customers	14%	6%	8 points *
Low income customers	14%	7%	7 points *
Energy Visualization Portlet			
All customers	29%	15%	14 points *
Low income customers	27%	14%	13 points *

* Statistically significant difference between the two groups at the 95% level of confidence.

Customers who understood that their household's consumption of electricity is charged on the RIB rate emerged to be more likely than other customers to have participated in the Residential Behaviour Program (14% vs. 6%) and the Appliance Rebate Program (14% vs. 9%) since the rate came into effect in October 2008. In addition, these RIB aware customers were more likely to have signed-up on BC Hydro's website to be able to view their detailed electricity use by the month, week, day or even hour.

Low income customers previously aware of the RIB rate were more likely than other low income customers to have participated in some conservation programs. The differences were not always statistically significant because the absolute number of low income households in the survey was not large enough to afford a high level of confidence in the findings.

In-Home Behaviours by RIB Rate Awareness

The customer survey was comprised of several banks of questions about in-home conservation behaviours. The tables in this section of the report document the self-reported frequency that individuals and/or their households typically exhibit. Findings are detailed for those aware of the RIB rate and those unaware of the rate – within the entire customer class as well as among low income customers. Statistical testing was based on aggregated or pooled data.

Frequency scores in the tables are based on the 4-point scales ('always', 'usually', 'occasionally', 'never') extensively utilized in the surveys. For any behaviour, statistical testing focused on the difference between the RIB-aware and RIB-unaware customer groups in the top-box score ('always') as well as the top-two box score ('always' + 'usually') as it is the difference in these categories that might help illuminate what might be behind any differences in the groups' actual energy consumption.

Given the large sample size for the entire customer class, statistically significant differences can emerge between RIB-aware and RIB-unaware customers for the smallest of gaps – even 2 percentage points. With this in mind, it is important to note that statistically significant differences in scores do not necessarily equate to meaningful differences in behaviours.

On the other hand, the pool of low income customer households is comparably smaller, and as such differences between RIB-aware and RIB-unaware customers were not always statistically significant because the absolute number of low income households in the survey was not large enough to afford a high level of confidence in the findings.

Plug-Load Behaviours

Table D.2.27: Plug-Load Behaviours

	Never	Occasionally	Usually	Always	Total	Total Always + Usually
Turn off the TV when no one is in the room or actively watching a program						
All Customers

** Statistically significant difference between the two groups' top-two box score ('always' + 'usually') at the 95% level of confidence.

Customer Behaviour and Electricity Consumption by RIB Step 2 Price Alerts

BC Hydro's billing system shows that a total of 5 percent of customer households have signed up online to receive email notifications that indicate when their consumption of electricity is halfway to reaching the higher Step 2 price in a billing period, as well as when it has reached it. This incidence increased through each of the three consumption bins, having measured 2 percent among households that never incurred Step 2 electricity consumption in F2017, 6 percent among customers that sometimes incurred Step 2 consumption in that year and 7 percent among customers that always did so.

Table D.2.35: Incidence of Customers Signed-Up to Receive Step 2 Price Alerts

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Signed-up to receive Step 2 price alerts	2%	6%	7%	5%
Not signed-up	98%	94%	93%	95%
Total	100%	100%	100%	100%

Incidences ascertained from the customer account billing system.

Among customers in the 2017 survey that have signed up to receive the price alerts, 64 percent reported that they typically make more of an effort to manage their consumption of electricity when their household receives the price alerts – 35 percent do not.

At 52 percent, the majority of customers that always incurred Step 2 electricity consumption in F2017 reported that they do make more of an effort to manage their consumption when they receive the price alerts, but this proportion measured 14 to 17 points lower than the other two customer groups.

Table D.2.36: Effort in Managing Household Electricity Consumption When a Step 2 Price Alert Received

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total much more of an effort + a little more of an effort	66%	69%	52%	64%
Much more of an effort	52%	30%	18%	29%
A little more of an effort	14%	39%	34%	35%
No change	34%	30%	45%	35%
A little less of an effort	0%	0%	0%	0%
Much less of an effort	0%	0%	0%	0%
Not Applicable – never received a Step 2 price alert	0%	1%	2%	1%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.
Don't know responses have been excluded from all calculations.

Understanding the extent that the Step 2 price alerts assisted customers to manage their electricity consumption was difficult because these customers were among those with the highest consumption to begin with whereas others had comparably lower consumption. Such understanding was best ascertained by comparing the pool of customers who received and acted on the price alerts to a pool of customers that did not receive the alerts, but were nonetheless as similar as possible in other ways, especially in their Step 2 status.

Table D.2.37: ANOVA Tests: Mean Electricity Consumption in F2017 by Step 2 Price Alerts

	Received and acted on a Step 2 price alert (kWh)	All others (kWh)	Difference between groups (kWh)	F Statistic of Difference	Significance
Customers that were sometimes (1-11 months) or always into Step 2 (12 months)					
Total F2017 consumption ⇒	11,528	12,334	806	0.824	0.364
Total Step 1 consumption ⇒	7,137	7,219	82	0.378	0.539
Total Step 2 consumption ⇒	4,391	5,115	724	0.768	0.381
Customers that were always into Step 2 (12 months)					
Total F2017 consumption ⇒	17,885	18,520	635	0.159	0.690
Total Step 1 consumption ⇒	8,122	8,122	0	0.000	1.000
Total Step 2 consumption ⇒	9,763	10,398	635	0.159	0.690
Customers in single detached houses that were always into Step 2 (12 months)					
Total F2017 consumption ⇒	18,406	18,859	453	0.072	0.789
Total Step 1 consumption ⇒	8,122	8,122	0	0.000	1.000
Total Step 2 consumption ⇒	10,284	10,737	453	0.072	0.789

For households that chose to act on the Step 2 price alerts, various analyses showed – depending on the comparison scenario – that their Step 1 and/or Step 2 electricity consumption in F2017 was lower than other households. The differences were not statistically significant, however, largely because the absolute number of households in the survey that received the price alerts and acted on them was not large enough to afford a high level of confidence in the findings.

Extent that the RIB Rate was a Factor in Purchasing a Non-Electric Item

Customers aware of the RIB rate were asked if they had purchased any natural gas, oil or propane equipment or appliances in the past three years and, if they had done so, how much of a factor the rate was in their decision to purchase it as opposed to one powered by electricity.

Table D.2.38 details the purchase rates for the six non-electric items and for each, the extent that customers said the RIB rate was a factor in choosing non-electric type rather than one powered by electricity.

Table D.2.38: Extent that the RIB Rate was a Factor in Purchasing a Non-Electric Item in the Past Three Years

- among customers previously aware of the RIB rate and who purchased the item –

		Extent that the RIB Rate was a factor in the purchase decision					
	Purchased	Don’t know	No factor at all	Minor factor	Major factor	Total	Total major + minor factor
Gas/Propane Fireplace	4%	2%	38%	15%	46%	100%	61%
Gas/Oil Furnace	6%	<1%	40%	21%	39%	100%	60%
Gas Range/Cooktop	4%	1%	42%	22%	35%	100%	57%

Gas/Propane Patio Heater	3%	2%	46%	20%	33%	100%	53%
Gas Lawnmower	7%	0%	63%	18%	18%	100%	36%

Row totals may not total 100% due to the rounding of values.

D.2.7. Customer Support of a Flat Rate

To close out the section on rate structures in the 2017 survey, customer respondents were asked their opinion of a flat rate. The question was prefaced with a statement that BC Hydro may one day consider altering its method of charging customers for their consumption of electricity to address changes in energy policy and objectives. Customers were also reminded that under a flat rate, the price per kilowatt hour (kWh) of electricity is constant regardless of the amount of electricity used in a billing period.

A total of 33 percent of customers reported that they would support a flat rate, 20 percent would be indifferent towards it, and 38 percent would be opposed to it. At 44 percent, support for a flat rate measured highest among customers households who always incurred Step 2 electricity consumption in F2017.

Table D.2.39: Customer Support of a Flat Rate

	Never into Step 2 (0 months)	Sometimes into Step 2 (1-11 months)	Always into Step 2 (12 months)	Total
Total strongly support + somewhat support	22%	34%	44%	33%
Strongly support	8%	12%	19%	12%
Somewhat support	15%	22%	25%	21%
Indifferent	20%	20%	19%	20%
Somewhat oppose	25%	21%	18%	22%
Strongly oppose	24%	15%	8%	16%
Don’t know	9%	10%	11%	10%
Total	100%	100%	100%	100%

Column totals may not total 100% due to the rounding of values.

July/August 2017

Dear Customer:

As per the invitation letter previously sent to your household, you have been selected at random from all BC Hydro customers to be part of this Residential Rate Survey. If you have already completed your survey on the Internet, then we thank you for doing so and you may discard this booklet.

New technologies, population increases, industrial growth and energy policies are all factors that determine how much electricity B.C. will need in the future. Understanding our residential customers' opinions about electricity and electricity rates also plays a role in this regard and as such, your participation in this survey is extremely important.

The Mustel Group, an independent research company based in B.C., is assisting us to conduct it. Your responses will be held in strict confidence by BC Hydro's Evaluation department and will be compiled with those of other customers for the research and planning purposes identified above.

<u>Please ensure that your survey responses refer to the residence located at the service address as shown above.</u> The survey should be completed by either the primary or joint account holder.

You may complete this printed survey and return it in the postage paid envelope provided or, alternatively, you may access the electronic version of the survey on the Internet by typing the website address below into a browser's address bar and using the survey ID and pass key shown at the top of this page.

The online survey has been optimized for completion on a smartphone, but completion on a computer or tablet – should you have one – will be made easier due to their larger screens and the survey's layout.

www.web-research-online.com/bchydro.html ⇐ type this address in; do not use a search engine.

Please complete the survey by August 18, 2017, and for doing so, you can enter your name in a draw for one of four $250 gift cards to a home improvement retailer of your choice. If you complete the survey on the Internet, your name will be entered in the draw one additional time. Also, if your completed survey is received (in the mail or submitted via the Internet) by August 8, your name will be entered in the draw one additional time.

Contact information is detailed on the inside cover of this booklet should you have any questions about how to complete the survey or why BC Hydro has commissioned it.

Thank you for your cooperation and prompt response. The information you provide is extremely important to us.

Yours truly,

Anthea Jubb

Anthea Jubb
Senior Regulatory Manager, Tariffs

Residential Rate Survey

You and your household have been randomly selected from all BC Hydro residential customers to participate in this Residential Rate Survey. Your participation in this survey and your accompanying opinions are very important because you will be representing – in effect – as many as 500 other customers who might be similar to you, but have not been randomly selected to participate.

Questions?

The Mustel Group, an independent research company based in B.C., is assisting us to conduct this survey. If you have any questions about how to complete or return your survey, please contact Matt Shepherd, Project Manager at mshepherd@mustelgroup.com or toll-free at 1-866-742-2242.

If you have questions about why BC Hydro is conducting this research, please contact Marc Pedersen, Senior Evaluation Specialist at marc.pedersen@bchydro.com.

Please complete and return the survey by August 18, 2017.

The information gathered in this survey is being collected in furtherance of BC Hydro's electricity conservation mandate under the *Clean Energy Act*.

In consideration of privacy issues, do not reference any individuals' names in your responses.

Thank you for your participation and prompt response.

BC Hydro
333 Dunsmuir Street, Vancouver BC V6B 5R3
www.bchydro.com

Important…

Work your way through the survey from front to back, carefully following the applicable instructions. By doing so, you may be instructed to skip past some of the questions not relevant to you and your household.

Managing Electricity Use

1. Customer households can manage their consumption of electricity by changing behaviour, purchasing energy-efficient products, making energy-efficient home upgrades or by participating in conservation programs.

Assuming you wanted to do so, how easy or difficult is it for your household to manage its consumption of electricity?

☐1 Very easy
☐2 Somewhat easy
☐3 Somewhat difficult
☐4 Very difficult

☐99 Don't know

2. How much of an effort does your household currently make to manage its consumption of electricity?

☐1 A great deal of effort
☐2 A fair amount of effort
☐3 A little effort
☐4 No effort at all

☐99 Don't know

☐97 Not Applicable – there is little opportunity at this time to manage our household's consumption of electricity

3. Compared to three years ago, would you say your household is making more of an effort to manage its consumption of electricity, less of an effort, or has there been no change?

☐1 Much more of an effort
☐2 A little more of an effort
☐3 No change
☐4 A little less of an effort
☐5 Much less of an effort

☐99 Don't know

Electricity Prices

4. Please think about the amount of money your household pays for electricity every month, every two months, or even over the course of a year, and consider the benefits you receive in return.

Would you say that the amount of money your household pays for its consumption of electricity represents…

☐1 Excellent value for money
☐2 Good value for money
☐3 Fair value for money
☐4 Poor value for money
☐5 Very poor value for money

☐99 Don't know

5. Thinking of things in a slightly different way, would you say that BC Hydro's residential electricity prices are…

☐1 Much too high
☐2 Just a little too high
☐3 About right
☐4 Just a little too low
☐5 Much too low

☐99 Don't know

6. Compared to three years ago, do you think that BC Hydro's residential electricity prices have…

☐1 Increased a great deal
☐2 Increased just a little
☐3 Stayed about the same
☐4 Decreased just a little
☐5 Decreased a great deal

☐99 Don't know

7. Regardless of your household's current effort to manage its consumption of electricity, to what extent do BC Hydro's residential electricity prices serve as an incentive to your household to manage its consumption of electricity?

☐1 Major incentive
☐2 Minor incentive
☐3 No incentive at all

☐99 Don't know

Total Electricity Bill

8. How often do you look over your household's electricity bill (either the print version or the online version)?

☐1 At least once a month
☐2 Once every 2 months
☐3 Once every 3 months
☐4 Once every 4 to 6 months
☐5 Once or twice a year
☐6 Never – we just pay it

☐99 Don't know/not sure

9. For the following set of statements, please check (✓) the response option that most accurately reflects your agreement or disagreement with the statement.

		Strongly agree	Somewhat agree	Neither agree nor disagree	Somewhat disagree	Strongly disagree	Don't know
a.	I spend more time looking over other bills I receive than my BC Hydro bill.	☐1	☐2	☐3	☐4	☐5	☐99
b.	I have a good understanding of the factors that cause changes in my household's consumption of electricity.	☐1	☐2	☐3	☐4	☐5	☐99
c.	My BC Hydro bill is easy to understand.	☐1	☐2	☐3	☐4	☐5	☐99
d.	I usually pay my BC Hydro bill without looking over its consumption details.	☐1	☐2	☐3	☐4	☐5	☐99

10. Compared to three years ago, would you say the total dollar amount of your household's electricity bills have…

- ☐1 Increased a great deal
- ☐2 Increased just a little
- ☐3 Stayed about the same ⇒ **check the box, then skip to question 12**
- ☐4 Decreased just a little
- ☐5 Decreased a great deal

- ☐99 Don't know ⇒ **check the box, then skip to question 12**

11. Thinking about your response in question 10 above, which of the following statements do you believe describes the reason(s) for the change in the total dollar amount of your electricity bills over the past three years. (check all that apply)

- ☐1 I believe the change in our bills has been due to changes in the overall price we pay for electricity.
- ☐2 I believe the change in our bills has been due to changes in our consumption level.

- ☐99 Don't know/not sure

- ☐97 Not applicable – our electricity bills have 'stayed about the same' (your previous response to question 10)

12. Thinking of your own experience, to what extent does the total dollar amount of your electricity bills serve as an incentive to your household to manage its consumption of electricity?

- ☐1 Major incentive
- ☐2 Minor incentive
- ☐3 No incentive at all

- ☐99 Don't know

As a reminder…

- **Mail the completed survey in the postage paid envelope provided, or complete the electronic version by August 18.**
- **For completing your survey, you can enter your name into a draw for one of four $250 gift cards to the home improvement retailer of your choice.**
- **If you complete the survey online, your name will be entered in the draw one additional time. Also, if your survey is received (in the mail or submitted via the Internet) by August 8, your name will be entered in the draw one additional time.**
- **Official rules can be viewed online at: www.web-reseach-online.com/bchydro_rules.html**

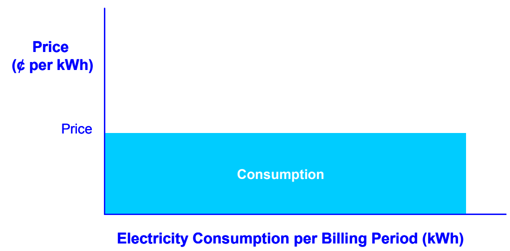
BC Hydro
Power smart

Rate Structures

In this section of the survey, we would like to explore your awareness and understanding of rate structures – that is, the various methods that can possibly be used to charge customers for their consumption of electricity, which is measured in kilowatt hours (kWh). Please review the four most common methods in the illustrations below.

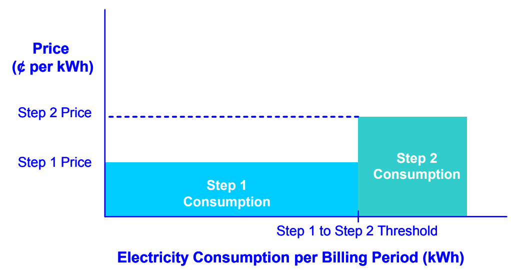
Flat Rate

1. **The price per kilowatt hour (kWh) of electricity is constant regardless of the amount of electricity used in a billing period.**



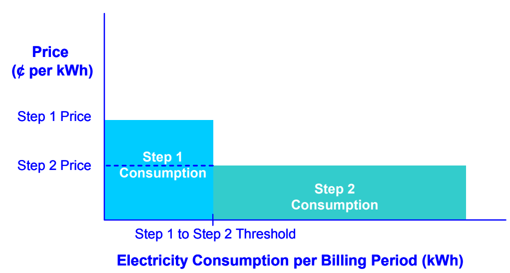
Inclining Block Rate / Stepped Rate

2. **The price per kilowatt hour (kWh) of electricity is lower for the first portion of electricity used, and steps up to a higher price for any additional consumption beyond a specified threshold in a billing period. The inclining block rate is also known as a stepped rate.**



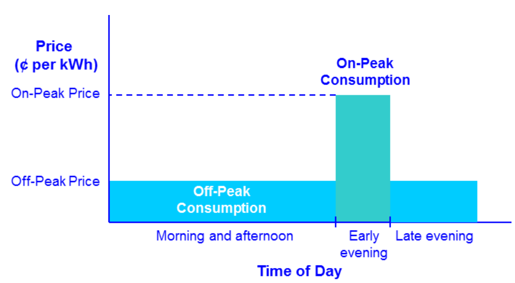
Declining Block Rate

3. **The price per kilowatt hour (kWh) of electricity is higher for the first portion of electricity used, and steps down to a lower price for any additional consumption beyond a specified threshold in a billing period.**



Time of Use Rate

4. **The price per kilowatt hour (kWh) of electricity varies by the time of day, typically higher during the early evenings than during all other hours of the day.**



You may review the explanation of rate structures and the accompanying illustrations on the adjacent page before proceeding with question 13.

13. Prior to receiving this survey, were you aware – in concept – of the flat rate method that can be used to charge customers for the consumption of electricity?

☐1 Yes
☐0 No

☐99 Don't know

14. Prior to receiving this survey, were you aware – in concept – of the inclining block rate (also known as a stepped rate) that can be used to charge customers for the consumption of electricity?

☐1 Yes
☐0 No

☐99 Don't know

15. Prior to receiving this survey, were you aware – in concept – of the declining block rate method that can be used to charge customers for the consumption of electricity?

☐1 Yes
☐0 No

☐99 Don't know

16. Prior to receiving this survey, were you aware – in concept – of the time of use rate that can be used to charge customers for the consumption of electricity?

☐1 Yes
☐0 No

☐99 Don't know

17. Prior to receiving this survey, which one of the four common methods did you believe BC Hydro currently uses for charging its residential customers for their consumption of electricity?

☐1 Flat rate (the price per kilowatt hour (kWh) of electricity is constant regardless of the amount of electricity used in a billing period)

☐2 Inclining block rate (also known as a stepped rate, the price per kilowatt hour (kWh) of electricity is lower for the first portion of electricity used, and steps up to a higher price for any additional consumption beyond a specified threshold in a billing period)

☐3 Declining block rate – (the price per kilowatt hour (kWh) of electricity is higher for the first portion of electricity used, and steps down to a lower price for any additional consumption beyond a specified threshold in a billing period)

☐4 Time of use rate – (the price per kilowatt hour (kWh) of electricity varies by the time of day, typically higher during the early evenings than during all other hours of the day)

☐99 Don't know/not sure

18. Thinking about your response to question 17 above – the method you believe BC Hydro currently uses for charging its residential customers – to what extent does the method serve as an incentive to your household to manage its consumption of electricity?

☐1 Major incentive
☐2 Minor incentive
☐3 No incentive at all

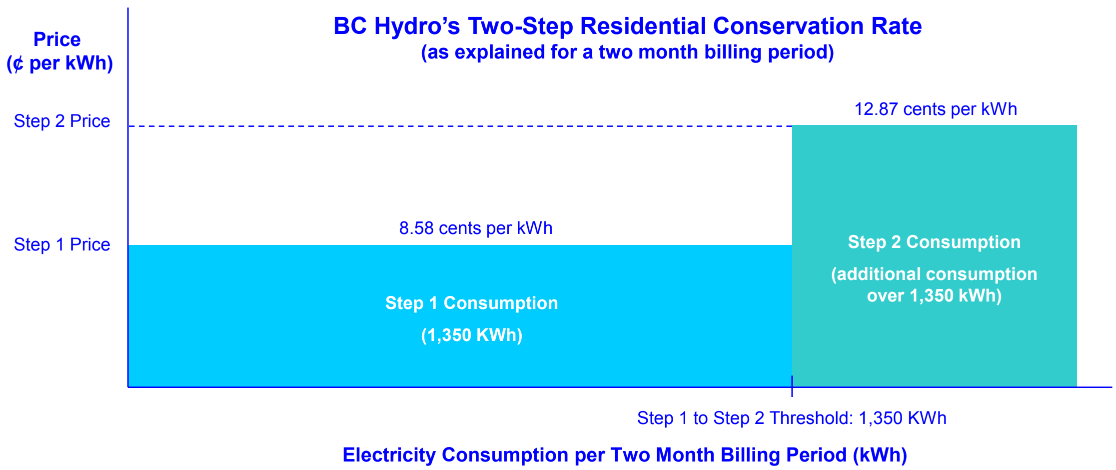
☐99 Don't know

BC Hydro's Residential Rate Structure

The method that BC Hydro charges its residential customers for their consumption of electricity is an inclining block rate – also known as a stepped rate.

Under this rate structure, customers who are billed every two months currently pay 8.58 cents per kilowatt hour (kWh) for the first 1,350 kWh used. This first portion is called Step 1. Above that amount, these households pay 12.87 cents per kWh for the balance of the electricity used during the billing period. This second portion is called Step 2. For customers billed on a monthly basis, the Step 1 to Step 2 threshold is set at 675 kWh, but with the same prices in the billing period as noted above.

This rate structure is designed to encourage conservation and, as such, some customers may also know it as the Two-Step Residential Conservation Rate.



Please read about the Two-Step Residential Conservation Rate – as above – before proceeding with question 19.

19. Which of the following statements best describes your awareness of BC Hydro's method of charging its residential customers for their consumption of electricity?

- ☐[1] Prior to this survey, I was fully aware that residential electricity consumption is charged on a stepped rate (also known as an inclining block rate).
- ☐[2] Now that it has been mentioned, I had heard that residential electricity consumption is charged on a stepped rate (also known as an inclining block rate).
- ☐[3] Prior to this survey, my understanding was that residential electricity consumption is charged on a flat rate.
- ☐[4] Prior to this survey, my understanding was that residential electricity consumption is charged on a declining block rate.
- ☐[5] Prior to this survey, my understanding was that residential electricity consumption is charged on a time of use rate.
- ☐[6] Prior to this survey, I did not know how residential electricity consumption is charged.
- ☐[99] Don't know

20. Having read a little more about the stepped rate method that BC Hydro uses for charging residential electricity consumption, how easy or difficult would you say it is to understand how the rate works?

- ☐[1] Very easy
- ☐[2] Somewhat easy
- ☐[3] Somewhat difficult
- ☐[4] Very difficult
- ☐[99] Don't know

21. How much of an understanding would you say you actually had – prior to receiving this survey – about the stepped rate method that BC Hydro uses for charging its residential customers?

- ☐[1] Excellent understanding
- ☐[2] Good understanding
- ☐[3] Fair understanding
- ☐[4] Poor understanding
- ☐[5] Very poor understanding

- ☐[99] Don't know

- ☐[97] Not applicable – I was not previously aware of the stepped rate method that BC Hydro uses ⇒ **check the box, then skip to question 30**

22. Although your household is charged the Step 1 price for its consumption of electricity up to 1,350 kWh in a two-month billing period and the Step 2 price for any additional consumption, you may not necessarily think about the price of electricity in this way as it applies to your own household.

How do you think about the price of electricity as it applies to your own household? (check only one)

- ☐[1] I would say that I consider the lower, Step 1 price as being my household's price of electricity in a billing period.
- ☐[2] I would say that I consider the higher, Step 2 price as being my household's price of electricity in a billing period.
- ☐[3] I would say that I consider each of the Step 1 and Step 2 prices being my household's price of electricity, depending on the point in time in the billing period and/or our consumption in the billing period.
- ☐[4] I do not think about my household's price of electricity in any of these particular ways.
- ☐[99] Don't know

23. Thinking of your own experience, to what extent does the stepped rate that your household's electricity is charged serve as an incentive to your household to manage its consumption of electricity?

- ☐[1] Major incentive
- ☐[2] Minor incentive
- ☐[3] No incentive at all **check the box, then skip to question 25**

- ☐[99] Don't know **check the box, then skip to question 25**

24. Which one of the following statements/scenarios best describes how the stepped rate incents your household to manage its consumption of electricity? (check only one)

- ☐[1] The lower, Step 1 price on its own incents our household: I consider the lower, Step 1 price as being the price applicable to all our electricity consumption in a billing period, and we try to manage our consumption of electricity on that basis.
- ☐[2] The higher, Step 2 price on its own incents our household: I consider the higher, Step 2 price as being the price applicable to the part of electricity consumption in a billing period that we have control over, and we try to manage our consumption of electricity on that basis.
- ☐[3] The difference between the Step 1 and Step 2 prices incents our household: If we can manage our consumption of electricity effectively in a billing period, we can have most of it charged at the lower, Step 1 price, perhaps even avoiding Step 2 consumption and the higher, Step 2 price altogether.
- ☐[4] The consumption threshold on its own incents our household: Regardless of the difference in the Step 1 and 2 prices and the amount we pay on our bill, we compare our household's consumption to the Step 1 to Step 2 threshold (675 kWh for monthly billing; 1,350 kWh for bi-monthly billing) simply because we like to keep our consumption as low as possible compared to the threshold.
- ☐[5] The stepped rate does not incent my household to manage its consumption of electricity in any of these particular ways.
- ☐[99] Don't know

25. Compared to three years ago, would you say your household is more mindful of its consumption of electricity in relation to the Step 1 and Step 2 prices and thresholds, less mindful, or has there been no change?

☐1 Much more mindful
☐2 Somewhat more mindful
☐3 No change
☐4 Somewhat less mindful
☐5 Much less mindful

☐99 Don't know

26. Customers can sign-up online to receive email notifications that will indicate when their consumption of electricity is halfway to reaching the higher Step 2 price in a billing period as well as when it has reached it.

Which of the following reflects your awareness and use of these Step 2 price alerts?

☐1 My household is currently signed-up to receive these alerts

☐2 I was previously aware of these alerts, but have never signed-up to receive them **check the box, then skip to question 28**

☐3 I was not previously aware of these alerts **check the box, then skip to question 28**

☐99 Don't know **check the box, then skip to question 28**

27. When your household receives Step 2 price alerts, does it typically make more of an effort to manage its consumption of electricity, less of an effort, or is there typically no change in effort?

☐1 Much more of an effort
☐2 A little more of an effort
☐3 No change
☐4 A little less of an effort
☐5 Much less of an effort

☐99 Don't know

☐97 Not Applicable – Our household has never received a Step 2 price alert

28. BC Hydro would like to understand if the stepped rate has been a factor in customer decisions to purchase any gas, oil or propane equipment/appliances instead of those that are powered by electricity.

For each gas, oil or propane equipment/appliance item listed, first indicate if your household has purchased one in the past three years. Next, for each item that you did purchase, indicate how much of a factor the stepped rate was – possibly, your desire to limit or avoid Step 2 electricity consumption – in your decision to purchase it as opposed to purchasing one powered by electricity.

If your household did not purchase any of the items, check here (   ), then skip to question 29.

			The stepped rate was a …			
Purchased in the past 3 years?	Yes, purchased		Major factor in the purchase decision	Minor factor in the purchase decision	No factor at all in the purchase decision	Don't know
a. Gas, oil or propane furnace	☐1	⇒	☐1	☐2	☐3	☐99
b. Gas range and/or gas cooktop	☐1	⇒	☐1	☐2	☐3	☐99
c. Gas, oil or propane water heater	☐1	⇒	☐1	☐2	☐3	☐99
d. Gas or propane fireplace	☐1	⇒	☐1	☐2	☐3	☐99
e. Gas or propane patio heater	☐1	⇒	☐1	☐2	☐3	☐99
f. Gas lawn mower	☐1	⇒	☐1	☐2	☐3	☐99

29. Prior to receiving this survey, were you aware that the stepped rate is designed to encourage the conservation of electricity?

☐[1] Yes
☐[0] No

☐[99] Don't know

30. Even though you may have just learned about it, overall, would you say you generally support the stepped rate method that BC Hydro uses to charge its residential customers for their consumption of electricity, oppose it, or are you indifferent about it?

☐[1] Strongly support
☐[2] Somewhat support
☐[3] Indifferent
☐[4] Somewhat oppose
☐[5] Strongly oppose

☐[99] Don't know

31. Thinking about your response to question 30 above, for what reasons do you feel that way? (In consideration of privacy issues, please do not reference any individuals' names.)

32. Compared to three years ago, would you say you have become more supportive of the stepped rate, more opposed to it, or has there been no change in your opinion?

☐[1] Much more supportive of it
☐[2] Somewhat more supportive of it
☐[3] No change
☐[4] Somewhat more opposed to it
☐[5] Much more opposed to it

☐[99] Don't know

☐[97] Not Applicable – I was not aware of the stepped rate three years ago or was not previously aware at all

Other Rate Structures

33. To address any changes in energy policy and objectives, BC Hydro may one day consider altering its method of charging residential customers for their consumption of electricity.

One option might be changing from the stepped rate to a flat rate whereby the price per kilowatt hour (kWh) of electricity is constant regardless of the amount of electricity used in a billing period.

Would you say you would generally support a flat rate, oppose it, or are you indifferent about it?

☐[1] Strongly support
☐[2] Somewhat support
☐[3] Indifferent
☐[4] Somewhat oppose
☐[5] Strongly oppose

☐[99] Don't know

Current In-Home Behaviours

In this section, BC Hydro would like to understand your behaviours related to electricity use in this home.

Please check (✓) the response option that best describes what you normally do when you are at the property at the service address as shown on the cover page of this booklet.

However, if you own the property but rent it out to tenants, or if the property typically goes unoccupied such as a pump house, then complete this section in regards to your behaviours in the home that you personally live in.

Be sure to check (✓) the 'Not Applicable' box if the statement does not apply to your household.

34. Lighting Behaviours

	Always	Usually	Occasionally	Never	Not Applicable
a. Only have the minimum number of lights on in a room for what I am doing	☐1	☐2	☐3	☐4	☐97
b. Turn off lights when no one is in the room	☐1	☐2	☐3	☐4	☐97
c. Purchase the most energy-efficient light bulbs, even if they are more expensive	☐1	☐2	☐3	☐4	☐97

35. Space Heating Behaviours (during winter months)

Check the 'Not Applicable' box in row e if you do not have a dog or cat.

	Always	Usually	Occasionally	Never	Not Applicable
a. Use a communicating/programmable thermostat or manually turn down the heat at night	☐1	☐2	☐3	☐4	☐97
b. Use a communicating/programmable thermostat or manually turn down the heat when no one is home	☐1	☐2	☐3	☐4	☐97
c. Reduce temperature in unused rooms by closing vents or turning down thermostats	☐1	☐2	☐3	☐4	☐97
d. Dress more warmly in cold weather and reduce/keep the thermostat to 20° Celsius (68° Fahrenheit) or below	☐1	☐2	☐3	☐4	☐97
e. Maintain the temperature of your home specifically for your dog(s) or cat(s) when no one is home	☐1	☐2	☐3	☐4	☐97

36. Space Cooling Behaviours (during summer months)

If this home does not have air conditioning, check here ( ), then skip to question 37.

	Always	Usually	Occasionally	Never	Not Applicable
a. Have the air conditioning come on only when it is 26° Celsius (79° Fahrenheit) or higher during the summer to save energy	☐1	☐2	☐3	☐4	☐97
b. Draw the window coverings during hot weather to reduce heat in the dwelling	☐1	☐2	☐3	☐4	☐97
c. Clean the air conditioning filter and coils at least once per season	☐1	☐2	☐3	☐4	☐97
d. Cool only the rooms to be occupied rather than the whole home	☐1	☐2	☐3	☐4	☐97
e. Use air conditioning only when very hot and natural ventilation is insufficient	☐1	☐2	☐3	☐4	☐97

37. Please indicate the location of the laundry appliances that your household typically uses.

☐[1] In my own home
☐[2] In a laundry room in another part of my building (i.e., the laundry appliances are shared with other suites)
☐[3] In another building or at a laundry business

38. Laundry Behaviours (please complete the table below regardless of where you do your laundry)

	Always	Usually	Occasionally	Never	Not Applicable
a. Only do laundry with full loads	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]
b. Use cold water wash & rinse when doing laundry	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]
c. Clean the lint filter before drying clothes	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]
d. Use the temperature/moisture sensor to turn off the dryer rather than use the timer	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]
e. Hang clothes to dry rather than machine dry	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]

39. Dishwasher Behaviours

If the home does not have an automatic dishwasher, check here ( ), then skip to question 40.

	Always	Usually	Occasionally	Never	Not Applicable
a. Only turn on the dishwasher when it is full	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]
b. Air dry the dishes in the dishwasher rather than use the dry cycle	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]

40. Water Use Behaviours

Check the 'Not Applicable' box in row 'a' if the home does not have its own water heater.

	Always	Usually	Occasionally	Never	Not Applicable
a. Turn off the water heater when no one is in the home for more than 2-3 days	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]
b. Keep shower times to no more than 5 minutes each	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]

41. Plug Load Behaviours

Check the 'Not Applicable' box if the home does not have the item.

	Always	Usually	Occasionally	Never	Not Applicable
a. Turn off the TV when no one is in the room or actively watching a program	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]
b. Turn off the computer and printer when not in use OR use the power-save mode	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]

42. How often do you perform the following actions?

	Always	Usually	Occasionally	Never	Not Applicable
a. Pay more for products that are environmentally friendly	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]
b. Think about ways to save energy	☐[1]	☐[2]	☐[3]	☐[4]	☐[97]

Attitudes toward Electricity and the Environment

For the following sets of statements, please check (✓) the response option that most accurately reflects your agreement or disagreement with the statement.

43. This first set of statements relate to your awareness and opinion of energy conservation as an issue.

	Strongly agree	Somewhat agree	Neither agree nor disagree	Somewhat disagree	Strongly disagree	Don't know
a. I have a good understanding of the reasons given for conserving electricity in this province.	☐1	☐2	☐3	☐4	☐5	☐99
b. I am in support of the reasons given for conserving electricity in this province.	☐1	☐2	☐3	☐4	☐5	☐99
c. We could all use a lot less energy than we do and if many people conserved, we could all make a big difference overall.	☐1	☐2	☐3	☐4	☐5	☐99
d. I am knowledgeable about ways to save electricity around my home.	☐1	☐2	☐3	☐4	☐5	☐99

44. These statements relate to your habits around electricity and conservation.

	Strongly agree	Somewhat agree	Neither agree nor disagree	Somewhat disagree	Strongly disagree	Don't know
a. I am an active energy conserver who looks for opportunities to save energy in everything I do.	☐1	☐2	☐3	☐4	☐5	☐99
b. Conserving energy is second nature to me – I've always done it, and know how to do it.	☐1	☐2	☐3	☐4	☐5	☐99
c. When I do make efforts to conserve electricity at home, it is more about saving money on my bill than helping to save the environment.	☐1	☐2	☐3	☐4	☐5	☐99
d. By making my home more energy-efficient, I am helping to do my part for the environment.	☐1	☐2	☐3	☐4	☐5	☐99

45. These final four statements are a mixture of issues.

	Strongly agree	Somewhat agree	Neither agree nor disagree	Somewhat disagree	Strongly disagree	Don't know
a. Climate change is a serious problem.	☐1	☐2	☐3	☐4	☐5	☐99
b. I really do not care much about energy and see little reason to conserve.	☐1	☐2	☐3	☐4	☐5	☐99
c. I believe my household's usage of electricity is currently at or near its lowest possible level.	☐1	☐2	☐3	☐4	☐5	☐99
d. Regardless of whether it makes a difference, everyone has a moral obligation to do the best they can to conserve energy.	☐1	☐2	☐3	☐4	☐5	☐99

Your Relationship to the Property

Important…

In these next sections of this survey, when we ask about your home, we are referring to the area covered by your BC Hydro bill at the service address as shown on the cover page of this booklet.

For some customers, this service address pertains to a seasonal home, a rental property or even an unoccupied structure such as a pump house rather than a primary residence. Whatever the case may be, please ensure your survey responses are in relation to the service address as shown on the cover page of this booklet.

46. Please indicate (✓) which of the following best describes your relationship to the property located at the service address as detailed on the cover page.

- ☐1 I (co)own and live (full-time or part-time) in the property at this service address
- ☐2 I (co)own and live in this Co-op property at this service address
- ☐3 I (co)own the property at this service address, but rent it out to tenants
- ☐4 I am a renter living in the property at this service address
- ☐98 Other (please specify): ____________________________

47. Regardless of whether it is owner or renter occupied, what type of residence is this property? (check only one)

- ☐1 Primary residence
- ☐2 Seasonal, vacation or weekend residence
- ☐98 Other (please specify): ____________________________

48. How many weeks or months in 2016 was this property left completely unoccupied?

______ weeks OR ______ months **if 0 weeks unoccupied in 2016, then check this box:** ☐0 0 weeks

49. Who is the BC Hydro account holder associated with the property at the service address?

- ☐1 Property owner(s)
- ☐2 Renter(s)
- ☐98 Other (please specify): ____________________________

50. Do you (or your landlord) pay maintenance fees to a building management company or a strata corporation in regards to this property?

- ☐1 Yes
- ☐0 No
- ☐99 Don't know

51. If you pay rent or maintenance fees, which of the following are included? (check all that apply)

- ☐1 Heat
- ☐2 Hot water
- ☐3 Natural gas for fireplace
- ☐4 Natural gas for cooking
- ☐5 Rent or maintenance fees are paid in regards to this property, but none of these items are included
- ☐97 Not Applicable – rent or maintenance fees are not paid in regards to this property
- ☐99 Don't know

About the Home Structure

52. What type of home structure is this? (located at the service address as detailed on the cover page)

- ☐[1] Single detached house
- ☐[2] Duplex
- ☐[3] Row/townhouse (3 or more units attached, each with separate entrance)
- ☐[4] Apartment/condominium
- ☐[5] Mobile home/manufactured home

- ☐[98] Other (please specify): ____________________________

53. When was this home built?

- ☐[1] Before 1950
- ☐[2] 1950-1975
- ☐[3] 1976-1985
- ☐[4] 1986-1995
- ☐[5] 1996-2005
- ☐[6] 2006-2015
- ☐[7] 2016-2017

- ☐[99] Don't know

54. What is the total floor area of this home? Include all floors covered by your BC Hydro bill, the basement and unfinished areas. Exclude the garage/carport and all other floors of apartment/condominium buildings.

_______________ square feet OR _______________ square meters ☐[99] Don't know

55. Does your BC Hydro bill cover only your household, or are there other households or suites on the same account?

- ☐[1] My household only
- ☐[2] Other households or suites as well ⇒ How many other households or suites? _______________

56. Which of the following energy efficiency upgrades – if any – has your household completed at the service address in the last three years? (check all that apply)

- ☐[1] Door upgrades
- ☐[2] Draft proofing upgrades
- ☐[3] Insulation upgrades
- ☐[4] Window upgrades
- ☐[5] Air source heat pump installation/upgrade
- ☐[6] Ground source heat pump installation/upgrade
- ☐[7] Furnace installation/upgrade
- ☐[8] Hot water tank installation/upgrade

- ☐[98] Other (please specify): ____________________________

- ☐[0] None of the above

- ☐[99] Don't know

Water Heating Equipment and Fuels

57. Please indicate (✓) the main type of hot water heating equipment in this home. (check only one)

If you live in an apartment or condominium, be sure to consider whether your water is heated by equipment in your own suite or by a central system located elsewhere in your building.

- ☐[1] Home does not have its own hot water equipment – the water is heated centrally elsewhere in the building and shared with other units

- ☐[2] Hot water tank (conventional storage tank)

- ☐[3] Heat pump water heater

- ☐[4] Tankless, on-demand water heater (not a small instant hot water dispenser in the kitchen)

- ☐[0] None – this property does not have access to running hot water

- ☐[99] Don't know

58. What is the main fuel used for the hot water heating equipment in this home?

- ☐[1] Electricity
- ☐[2] Natural gas
- ☐[3] Oil
- ☐[4] Wood
- ☐[5] Bottled or tanked propane
- ☐[6] Piped-in propane
- ☐[7] Solar

☐[98] Other (please specify): ____

☐[99] Don't know

☐[97] Not applicable – the home does not have its own hot water equipment

Home Heating Systems and Fuels

59. What is the main system used to heat the home at the service address? (check only one)

- ☐[1] Both central forced air furnace AND electric baseboards *
- ☐[2] Forced air furnace – single fuel
- ☐[3] Forced air furnace – dual fuel (without a heat pump)
- ☐[4] Forced air furnace – with a heat pump (all-in-one unit)
- ☐[5] Electric baseboard(s)
- ☐[6] Electric fireplace
- ☐[7] Electric radiant ceiling(s) or floor(s)
- ☐[8] Electric portable heaters (including ceramic, infrared)
- ☐[9] Electric wall heater(s)
- ☐[10] Heat pump – air source (not with all-in-one furnace)
- ☐[11] Heat pump – ground source (not with all-in-one furnace)
- ☐[12] Hot water baseboard(s)
- ☐[13] Hot water radiator(s)
- ☐[14] Hot water radiant floor(s)
- ☐[15] Natural gas fireplace
- ☐[16] Wood stove / wood fireplace

☐[98] Other (please specify): ____________________

☐[99] Don't know

* Typically these homes have central heat on the main floor and electric baseboards upstairs and/or downstairs.

60. In the first column in the grid below, please indicate the main heating fuel used with the main heating system you specified in question 59. In the second column, please indicate any other heating fuels used in the home.

- **If the home's main heating system is 'both a forced air furnace and electric baseboards', then the fuel used for the furnace should be indicated as the main heating fuel (in the 1st column), and electricity should be indicated as the other heating fuel for the electric baseboards (in the 2nd column).**
- **Note that hot water is not a fuel. We're interested in what fuel is used to heat the hot water.**

	Main Heating Fuel (check only one in this column) ⇓	Other Heating Fuels (check all that apply in this column) ⇓
Electricity	☐[1]	☐[1]
Natural gas	☐[2]	☐[2]
Oil	☐[3]	☐[3]
Wood	☐[4]	☐[4]
Bottled or tanked propane	☐[5]	☐[5]

District energy fuel(s) (produced by municipality)	☐[7]	☐[7]
Other (please specify):____________________	☐[98]	☐[98]
No Other Fuels (home has only one fuel)		☐[0]
Don't know	☐[99]	☐[99]

You and Your Household

The collection of demographic information in this section serves two very important purposes. First, it assists us in determining the extent that the sample of completed surveys provides a representative cross-section of all residential customers. Second, the information allows a better understanding of how awareness levels, opinions and behaviours differ among certain groups of customers.

61. Your age is:

☐1 18 to 24 years of age
☐2 25 to 34
☐3 35 to 44
☐4 45 to 54
☐5 55 to 64
☐6 65 or older

62. You are:

☐1 Female
☐2 Male

63. Your education is:

☐1 Less than Grade 12
☐2 High school diploma
☐3 Some college, vocational or technical school
☐4 College, vocational or technical school graduate
☐5 Some university
☐6 University/graduate degree

64. Which of the following describe your current status? (check all that apply)

☐1 Employed/self-employed – full-time
☐2 Employed/self-employed – part-time
☐3 Homemaker
☐4 Retired
☐5 Unemployed
☐6 Student
☐7 Short-term or long-term disability

☐98 Other (please specify): ___________________________

65. Please indicate the number of people living in this household on a full-time basis, in the following age categories. Please include any boarders or renters who do not have a separate BC Hydro account.

If the service address on the cover page pertains to a seasonal dwelling, then complete the table below in relation to the time(s) of the year when the dwelling is typically occupied.

	Number of people
a. Children 0 - 5 years of age	_______
b. Children 6 - 12	_______
c. Young adults 13 - 24	_______
d. Adults 25 - 64	_______
e. Adults 65 or older	_______
f. Total	= __________

66. Please indicate the combined total income before taxes for your household in the last year. The reason we ask is that, in analyzing groups of customers, we often find that energy use is related to total household income.

Your income information will never be associated with your name or household in any analysis or reporting.

☐[1] Under $20,000	☐[7] $70,000 to under $80,000
☐[2] $20,000 to under $30,000	☐[8] $80,000 to under $90,000
☐[3] $30,000 to under $40,000	☐[9] $90,000 to under $100,000
☐[4] $40,000 to under $50,000	☐[10] $100,000 to under $110,000
☐[5] $50,000 to under $60,000	☐[11] $110,000 to under $120,000
☐[6] $60,000 to under $70,000	☐[12] $120,000 or over

☐[99] Prefer not to say

67. Do you or anyone in your household use the property at the service address for farm use where income is generated from agricultural production (crops and/or livestock)?

☐[1] Yes ⇒ If Yes: Is your property at this service address assessed as a farm for tax purposes? ☐[1] Yes ☐[0] No
☐[0] No

68. Does anyone in your household conduct business activities in the home either on a full-time or part-time basis?

☐[1] Yes, full-time
☐[2] Yes, part-time
If Yes: How many hours per week are business activities conducted in the home? ____ hours

☐[0] No

Suggestions?

69. Is there anything BC Hydro can do to make the Two-Step Residential Conservation Rate more effective in encouraging your household to manage its consumption of electricity efficiently and to conserve? (In consideration of privacy issues, please do not reference any individuals' names.)

Permission for Linkage to Account Consumption

70. A key objective of this survey is to collect the necessary information to assist in our evaluation of the Two-Step Conservation Rate, including how customers' consumption of electricity may vary with their awareness, understanding and attitudes toward the rate.

To facilitate this, it is important to analyze customers' consumption of electricity at their current address for the past year as well as the next year as a 'time series' of consumption data helps us to better control for year-to-year changes in the weather, the economy, etc.

Rather than asking you to estimate how much electricity your home has and will consume over these periods, BC Hydro's Evaluation department would like to access this information from your account history and link it to your responses in this survey. We will not access nor review any of your bill payment information.

☐1 Yes
☐0 No

Incentive Prize Draw

71. Please provide your name and contact information below if you wish to be entered into the draw for one of four $250 gift cards to a home improvement retailer of your choice.

You can view the official rules and regulations at www.web-reseach-online.com/bchydro_rules.html

	Name:	Telephone:	Email Address:
☐1 Yes ⇒	______________________	____________	______________________
☐0 No thanks			

Thank You!

Your time and effort in completing this survey is very much appreciated and will help in planning electricity services for your community and the province as a whole.

If you completed this survey in this booklet rather than online, please fold it in half and place it in the postage paid business reply envelope provided. Upon receiving your survey booklet via Canada Post, the Mustel Group will keypunch and compile your responses with those of other customers.

RE: Ministry of Energy, Mines and Petroleum Resources (MEMPR or Ministry)
British Columbia Hydro and Power Authority (BC Hydro)
Greenhouse Gas Reduction (Clean Energy) Regulation Reporting
Fiscal 2018 Annual Report

BC Hydro writes to submit the Business Information and Declaration (Attachment 1), and the Fiscal 2018 Greenhouse Gas Reduction Regulation (**GGRR**) Annual Report (**Report**) (Attachment 2). The Report includes, where applicable, results for the period from April 1, 2017 to March 31, 2018 (**Fiscal 2018**) for BC Hydro's prescribed undertakings as defined in section 4 of the GGRR.

Under section 18 of the *Clean Energy Act*, a public utility implementing prescribed undertakings defined in the GGRR, must submit to the MEMPR a report respecting the prescribed undertaking. Specifically, section 18(5) states that "a report to be submitted under section (4) must include the information the minister specifies and be submitted in the form and by the time the minister specifies."

In April 2018, Ministry staff issued the GGRR reporting requirements. The reporting requirements state that an annual report is due by June 30, of each year. On June 28, 2018, BC Hydro notified the Ministry and the British Columbia Utilities Commission (**BCUC**) it was unable to meet the June 30, 2018 deadline, and that it expects to file the Report no later than July 31, 2018.

BC Hydro is redacting customer-specific information in this version of the Report. An un-redacted version of the Report is being filed with the Ministry and BCUC only under separate cover.

Greenhouse Gas Reduction (Clean Energy) Regulation Reporting

Attachment 2

Fiscal 2018 Annual Report No. 1

April 1, 2017 to March 31, 2018

PUBLIC

Table of Contents

List of Tables

1 Executive Summary

This is BC Hydro's first annual report regarding its programs and projects that are "prescribed undertakings" under the *Clean Energy Act* (**CEA**). It is provided in response to the April 2018 "British Columbia Greenhouse Gas Reduction (Clean Energy) Regulation Reporting Requirements" provided to BC Hydro by the Ministry of Energy, Mines and Petroleum Resources. The report covers the period from April 1, 2017 to March 31, 2018 (**Fiscal 2018**).

BC Hydro provided supporting resources for three Low Carbon Electrification (**LCE**) Demand-Side Management (**DSM**) studies which were completed in Fiscal 2018. These studies are expected to contribute towards customers' business cases for project implementation, as well as provide key inputs on barriers, costs, and benefits that BC Hydro will consider in future program development and design. As reported in Table 2, the actual expenditure for LCE DSM in Fiscal 2018 was $0.22 million.

BC Hydro also made significant progress on the Peace Region Electricity Supply (**PRES**) Project. In Fiscal 2018, actual expenditure on the PRES Project was $10.7 million in the period with a cumulative cost of $21.5 million over the life of the project.

In all cases, it is premature to report any avoided greenhouse gas emissions or ratepayer impacts.

2 State of the Market and Program Planning

2.1 Background

British Columbia's Climate Leadership Plan sets out actions to enable the Province to meet its greenhouse gas (**GHG**) emission targets by 2050. Among other things, the plan calls for BC Hydro to make investments in infrastructure to power natural gas production projects with clean electricity and to initiate programs to encourage customers to switch from fossil fuels to electricity in order to reduce greenhouse gas (**GHG**) emissions.

In August 2017, the Minister's Mandate Letter to BC Hydro included an expectation for BC Hydro to continue to provide leadership in advancing the government's climate action strategies, through fuel switching and electrification initiatives in the transportation, oil and gas, and other sectors; initiatives to further reduce emissions in the transportation sector; and policies and programs to increase the energy efficiency of buildings. This expectation has also been reiterated in the April 2018 Minister's Mandate Letter to BC Hydro.

Subsection 18(1) of the CEA empowers the Lieutenant Governor in Council to prescribe, by regulation, classes of undertakings for the purpose of reducing GHG emissions. Public utilities that choose to engage in undertakings that are within one or more prescribed class of undertaking are assured of being able to recover the costs of the undertaking in their rates, and may not be prevented by the Commission from engaging in the undertaking. The Greenhouse Gas Reduction (Clean Energy) Regulation (**GGRR**) was first issued in 2012, but was amended in 2017 to include eight new classes of electrification undertakings. Together, CEA section 18 and the GGRR provide one of the statutory pillars of the Province's GHG emission reduction policy.

The eight new classes of electrification undertaking prescribed by GGRR section 4 can be divided into two broad categories: those that are program based, similar to BC Hydro's demand-side management programs,[1] and those that are infrastructure based.[2] BC Hydro refers to its undertakings that fall within one of the classes in the former category as LCE DSM Project/Programs, and to its undertakings that fall within one of the classes in the latter category as LCE Infrastructure Projects. This

[1] Being the classes of undertaking prescribed by subsections 4(3)(a)(i); 4(3)(a)(ii); 4(3)(b)(i); 4(3)(b)(ii); 4(3)(c) and 4(3)(d) of the GGRR.

[2] Being the classes of undertaking prescribed by subsections 4(2) and 4(3)(e) of the GGRR.

nomenclature corresponds to the "Electrification Programs" referred to in subsection 6.8 of the GGRR Reporting Requirements, and "Transmission, Distribution and Generation" referred to in subsection 6.9 of the GGRR Reporting Requirements, respectively.

As noted, one of the legal consequences of the public utility program or project being a "prescribed undertaking" is that the public utility is entitled to recover the costs of the program or project in its rates. That legal consequence is meaningful only if the costs associated with particular programs and projects that are prescribed undertakings can be identified and thus are accounted for by the public utility.[3] Accordingly, the prescribed undertakings described in this Fiscal 2018 GGRR Annual Report are those programs and projects with recorded costs in Fiscal 2018.

2.2 State of the Market Discussion

The GGRR Reporting Requirements ask for a "state of the market" discussion that includes consideration of program data, performance metrics, underlying assumptions regarding the metrics, ratepayer impacts and environmental benefits. As Fiscal 2018 is the first year in which it is contemplated by the GGRR that public utilities would engage in electrification undertakings, BC Hydro has little aggregated or generalized information to provide; such information as it currently has on these topics is set out in the LCE DSM Project/Program and LCE Infrastructure Project discussions which follow. However, BC Hydro can say, generally, that it is forecast to be in an energy surplus position until Fiscal 2033. During this surplus period, the LCE-driven incremental electricity sales will increase BC Hydro’s revenues and can make rates lower than they otherwise would have been due to the expected positive differential between domestic electricity rates and forecast export prices. Such incremental electricity sales are also expected to reduce GHG emissions from what they otherwise would have been, thus having an environmental benefit.

[3] BC Hydro notes that the costs it incurs in regard to its LCE DSM Project/Programs are all deferred to the DSM Regulatory Account, pursuant to Order in Council No. 100, issued March 1, 2017. Generally, the costs it incurs in regard to its LCE Infrastructure Programs are capitalized.

The GGRR Reporting Requirements also requests a report by a Fairness Advisor on the competitiveness of any call process held during the reporting period. BC Hydro confirms that in Fiscal 2018 it did not hold any call processes in regard to its LCE DSM Project/Programs or its LCE Infrastructure Projects.

3 LCE DSM Project/Programs

3.1 Overview

BC Hydro is leveraging over 25 years of experience in conservation-focussed DSM and its substantial knowledge about market transformation, customer barriers, and market response to develop cost-effective LCE DSM Project/Programs. It is envisioned that BC Hydro's LCE DSM Project/Programs will fall within three customer sectors – residential, commercial, and industrial - with a focus on opportunities in industrial process, transportation, and space heating.

3.2 Fiscal 2018 LCE DSM Project/Programs

In Fiscal 2018, BC Hydro incurred expenditures in regard to three LCE DSM Project/Programs as described below. There were five additional projects with which BC Hydro made preliminary funding commitments of approximately $30.5 million, but there are no expenditures in BC Hydro's financial reporting for Fiscal 2018. As such, these expeditures will be detailed in future GGRR reports.

(i) [redacted]

[redacted] has been investigating options that would allow them to produce a wide variety of new products. As part of this exploration an assessment of process heating requirements was completed. Process heating is typically supplied by natural gas or propane. This study investigated if an opportunity exists to use electricity in place of fossil fuels. The study was completed and found that pilot testing and further analysis would be required to determine if electrification would be a viable option. The electrification study was an undertaking within the class of prescribed undertakings set out in section 4(3)(c) of the GGRR.

(ii) [redacted] The focus of this project was to explore low-carbon electrification [redacted] materials-handling methods. The current materials-handling method for [redacted] removal involves use of diesel fueled equipment to remove the [redacted], and [redacted] trucks (diesel-fueled) to transport [redacted]. The project examined a potential electrified system to [redacted]. The study is complete and found that a reduction in carbon dioxide equivalent (CO2e) could be made. Based on the assessment in the study it was recommended to proceed with a detailed feasibility study to further develop the concepts and establish a preliminary design and corresponding capital cost estimate. It is also an undertaking within the class of prescribed undertakings set out in section 4(3)(c) of the GGRR.

(iii) [redacted] This [redacted] project was the first phase of investigations into ways low-carbon technologies could be introduced into the local transportation network to reduce carbon emissions. [redacted] refers to transporting goods [redacted] via (diesel-fueled) ground freight. The study is complete and found that there are many inherent challenges when considering the implementation and promotion of new technologies into the fragmented and competitive [redacted] However, it is recommended that the [redacted] continue to maintain a broad outlook towards each of the low-carbon technologies identified in the study as being suitable for reducing carbon in the [redacted] industry. It is also an undertaking within the class of prescribed undertakings set out in section 4(3)(c) of the GGRR.

(iv) BC Hydro Program Staff Labour: BC Hydro provided internal support resources to the three projects described above, as well as to other projects and programs under development or related to preliminary funding commitments for projects expected to be reported in future periods. The associated expenditures are an undertaking within the class of prescribed undertakings set out in section 4(3)(c) of the GGRR.

3.3 Verification Methods

Depending on the program, project or activity, there can be up to four distinct areas of activity that BC Hydro may use to review and verify electrification and emission reduction estimates. These are technical review, site inspection, measurement and verification, and evaluation. Results from each area will be used in project and contract management to ensure that BC Hydro receives the expected project benefits. BC Hydro will be selective in the use of these processes, and focus its efforts where warranted to improve the accuracy of estimates and reduce exposure to risk. This approach will mirror BC Hydro's current approach to demand-side management electricity savings, and provide estimates for both additional electricity demand and greenhouse-gas emission reductions. BC Hydro will provide details of its verification efforts in future annual reports when they are employed.

3.4 Performance Metrics

The LCE DSM Projects/Programs described above were studies into the use of electrical technology, and the expenditures associated with supporting resources. Such studies are critical in enabling customers to build the business case for project implementation as well as providing key inputs on barriers, costs, and benefits into program development and design. Performance metrics for these studies include the following elements:

1. Yield information which could inform and improve accuracy of the project modeling assumptions;

2. Yield information which could inform and improve understanding of market barriers and customer drivers; and
3. Yield site specific investigation and engineering analysis at a level sufficient to determine if advancing the project would provide tangible benefits that would make business sense for the customer and BC Hydro to continue supporting the project.

The three studies were completed in Fiscal 2018 and the associated supporting resources met these performance metrics.

3.5 Cost-Effectiveness

Undertakings are in a class of undertakings prescribed by subsections 4(3)(a) to 4(3)(b) of the GGRR if they satisfy a cost-effectiveness test defined in subsection 4(1) of the GGRR. That cost-effectiveness test requires that each undertaking that is an undertaking within the class of undertakings prescribed by subsections 4(3)(a) or 4(3)(b) of the GGRR must have a positive net present value (**NPV**), with the measure of a program's NPV being that of all of the programs that fall within the class of undertakings described in subsections 4(3)(a) and 4(3)(b) of the GGRR. Furthermore, the GGRR cost-effectiveness test is measured only at the time BC Hydro decides to carry out the program. The cost-effectiveness test in the GGRR is not applicable to this Fiscal 2018 Annual Report as BC Hydro did not incur expenditures in regard to any undertaking defined by a class of undertakings in subsections 4(3)(a) to (b) of the GGRR in Fiscal 2018. There is no other cost-effectiveness test applicable to prescribed undertakings.

3.6 Results Table - Explanation of Terms

Table 1 includes a description of the information provided in Table 2 below in regard to LCE DSM Projects/Programs.

Table 1 LCE DSM Project/Program Results Table: Explanation of Terms

Column	Heading	Descriptions
A	GGRR	Applicable section of the GGRR
B	Project / Program/Contract / Expenditure	Low-carbon electrification activities to encourage or enable the use of electricity in place of other sources of energy that produce more greenhouse gas emissions.
C	Actual Cost ($ million)	Costs incurred at the end of the current reporting fiscal
D	Cost Effectiveness ($ million): NPV to 2030 (Fiscal 2031)	The present value of the costs and benefits are determined using a discount rate equal to BC Hydro's weighted average cost of capital. The present value of the costs are subtracted from the present value of the benefits from the project start year to last year in the calculation period (Fiscal 2031) to determine the net present value for the project.
E	Cost Effectiveness ($ million): GGRR NPV to 2030 (Fiscal 2031)	The calculation of the GGRR NPV is based on costs and benefits as defined in the GGRR. Per that definition, benefits mean **all** revenues BC Hydro expects to earn as a result of implementing LCE programs falling under subsections 4(3)(a) or 4(3)(b), less revenues that would have been earned from the sale of that electricity to export markets. Costs mean **all** the costs BC Hydro expects to incur to implement LCE programs falling under subsections 4(3)(a) or 4(3)(b), including development and administration costs.
F (i)	Actual: Additional Energy Consumption (MWh/year)	The average annual additional energy consumption estimated to be delivered from the project in the current reporting fiscal period.
F (ii)	Cuml.: Additional Energy Consumption (MWh/year)	The sum of the successive average annual additional energy consumption estimated to be delivered from the project as at the end of the reporting fiscal period.
G (i)	Actual: Additional Capacity Demand (MW)	The total energy demand added
G (ii)	Cuml.: Additional Capacity Demand (MW)	Sum of the successive energy demand addition
H (i)	Actual: Estimated GHG Emission Reductions (tonnes CO2e/year)	The average annual tonnes per year of carbon dioxide equivalent reductions from the project in the current reporting fiscal period.
H(ii)	Cuml.: Estimated GHG Emission Reductions (tonnes CO2e/year)	The sum of the successive additional average annual tonnes per year of carbon dioxide equivalent reductions from the project as at the end of the reporting fiscal period.

3.7 Results Table

Table 2 summarizes information regarding the three LCE DSM Programs/Projects that are prescribed undertakings as described above. The reasons for the numerous indications of "n/a" is due to the nature of the projects, as described above. The GGRR Reporting Requirements requests graphical depictions (e.g., pie charts or bar charts) of the distribution by region in the Province and the distribution by customer sector where possible. Given that the Fiscal 2018 LCE DSM Programs/Project volume consisted of three projects, it was determined that a graphical depiction may not be meaningful and as such was not included in this report. In future years with a larger number of LCE DSM Programs/Projects, meaningful graphical depictions can be developed and included.

4 LCE Infrastructure Projects

4.1 Overview

Northeast British Columbia is forecasted to experience a significant increase in natural gas production and processing primarily in the Montney region. In the absence of adequate electricity supply, much of this development will be powered by natural-gas fired production processes. Meanwhile, BC Hydro's local and area transmission system in this region is constrained. Further, the transmission system's ability to supply new loads in the South Peace region at all, even with a reduced level of reliability, is expected to be exceeded in summer 2021. Accordingly, BC Hydro will construct and operate new transmission and distribution facilities, and/or provide for temporary generation pending the completion of such facilities, to avoid incremental GHG.

4.2 Fiscal 2018 LCE Infrastructure Projects

As of March 31, 2018, the only infrastructure project for which BC Hydro has incurred expenditures for the purpose of reducing GHG emissions is the Peace Region Electricity Supply (**PRES**) Project. BC Hydro has also entered into an agreement valued at about $12 million with respect to temporary generation facilities until the PRES Project is in service, but there were no expenditures incurred or recorded in Fiscal 2018 in that regard. Expenditures incurred and recorded in future fiscal years will be described in the applicable future GGRR annual report.

The PRES Project is in the South Peace region of British Columbia. The PRES Project consists of two parallel 230 kV transmission lines that will connect the future Site C South Bank substation to the existing Shell Groundbirch substation using mainly wood pole construction and upgrades at each station. The proposed transmission lines will be 58 km long. As of March 31, 2018, BC Hydro has incurred $21.5 million in capital expenditures on developing the PRES Project, of which $10.7 million was incurred in Fiscal 2018. During Fiscal 2018, the PRES Project team carried out a detailed investigation of the preferred alternative and began the process of securing required licences and permits to be able to advance this project to the construction stage.

The PRES Project will enable natural gas producers and processors to electrify their existing and new operations, rather than self-supplying with natural gas. This includes natural gas producers and processors as defined in GGRR paragraphs 4(2)(a)(i) and (ii). The PRES Project will reduce greenhouse gas emissions in British Columbia.

As of March 31, 2018, BC Hydro had not yet determined whether the PRES Project should proceed to implementation. The PRES Project was approved by BC Hydro's Board of Directors for implementation in June 2018 and has an expected in-service date prior to December 31, 2022. Therefore, it is a prescribed undertaking pursuant to GGRR section 4(2).

4.3 Quantitative Data – Methodology & Assumptions

BC Hydro has developed criteria to qualify customer loads for inclusion in its estimates for GHG emissions reduced or avoided due to the PRES Project. To qualify the customer load:

- Must be a new natural gas processing plant (including associated gas gathering and wellpad facilities) or existing plant converting to take grid service which takes, or commits to take, electricity service from BC Hydro in Fiscal 2018 or later;
- Would have used natural gas for power supply in the absence of BC Hydro's commitment to construct and operate new facilities; and
- Will be served by the PRES Project once it is placed in service.

4.4 Performance Metrics

The GGRR performance metrics for the PRES Project are listed in Table 3 below.

Table 3 PRES Project: GGRR Performance Metrics

Type of Facility	Project(s)	Performance Metrics
Transmission & Distribution	PRES Project	1. New load served 2. GHG Emissions Reduction

A key benefit of the PRES Project is to provide a clean, reliable source of electrical power supply to existing and new natural gas processing operations. In the absence of PRES, there would be no grid service alternative. These plant operations would otherwise need to use natural gas (or other fossil fuels) for power supply. Since greenhouse gases are emitted when fossil fuels are burned to create power, the PRES Project will reduce GHG emissions in British Columbia for any existing plant, or prospective new plant, that elects to take grid service rather than self-supply using natural gas. BC Hydro will estimate the impact the PRES Project will have on GHG emission reductions in British Columbia based on the assumptions and methodology set out below:

Assumptions

- The N-0 supply capability of the Dawson Chetwynd Area Transmission (DCAT) system, which currently serves customers in the South Peace region, is 413 MW;
- BC Hydro is unable to supply any new customer loads above this limit until the PRES Project is constructed;[4]
- For any customer load that elects to self-supply using natural gas, the average heat rate for gas-fired power is 10.0 GJ/MWh and the average emissions intensity factor is 518 tonnes per GWh;[5] and

[4] BC Hydro will use temporary generation to supply any new customer loads above the 413 MW limit of DCAT, prior to PRES being in-service.

- The average load factor for a natural gas processing plant is 85 per cent.

Methodology

- For every 100 MW of customer load, the average annual energy consumption is determined by the formula: 100 MW x 8,760hrs/year x 0.85 = 745 GWh/year
- For every 100 MW of customer load that makes the permanent decision to use natural gas for power supply rather than connect to the BC Hydro transmission system, the GHG emission impact is: 745 GWh/year x 518 tonnes GHG per GWh = 385,910 tonnes GHG/year
- Assuming an average operating plant life of 25 years, the total GHG emission impact for every 100 MW of load not served by BC Hydro is:
  385,910 tonnes GHG/year x 25 years = 9,647,750 tonnes GHG.

4.5 Results Table - Explanation of Terms

Table 4 includes a description of the information provided in the results table for LCE Infrastructure Projects. The reasons for the indications of "n/a's" is due to the nature of the PRES Project as of March 31, 2018, as described above.

[5] Average heat rate and emissions intensity represents the efficient operation of an LM6000 SCGT gas engine. Actual load-following heat rates and emissions for natural gas-fired power supply at a customer plant may differ.

Table 4 LCE Infrastructure Projects Results
Table: Explanation of Terms

Column	Heading	Descriptions
A	Prescribed Undertaking	Type of prescribed undertaking.
B	Name	Project, program, or customer name.
C (i)	Actual ($ million)	Actual costs in millions incurred at the end of the current reporting fiscal.
C (ii)	Cumulative Costs ($ million)	Cumulative actual costs in millions incurred from first year of expenditure to the end of the current reporting fiscal.
C (iii)	Forecast Total ($ million)	Transmission & Distribution: Total Definition phase estimated forecast cost range in millions (AACE class 4 estimate accuracy range).
D	Capacity of Facility (MW)	Planned facility capacity in megawatts at N-1 and N-0.
E	Total Capacity Committed/Secured (MW)	Cumulative total capacity committed and secured until the end of the current fiscal year in megawatts.
F	Total Customer Load(s) Served (MW)	Cumulative total customer loads served as at the end of the current fiscal year in megawatts.
G	Total Energy Provided to Customers (MW/h)	Cumulative total energy provided to customers as at the end of the current fiscal year in megawatts per hour.
H (i)	Actual: GHG Emissions Reduction Estimates (tonnes CO2e/year)	Actual GHG Emissions Reduction at the end of the current fiscal period in tonnes of carbon dioxide equivalent per year.
H (ii)	Cumulative: GHG Emissions Reduction Estimates (tonnes CO2e/year)	Cumulative GHG Emissions Reduction as at the end of the current fiscal period in tonnes of carbon dioxide equivalent per year.
I (i)	Type: Fossil Fuel(s) Avoided Or Displaced	Type of fossil fuels avoided or displaced or likely to be avoided or displaced.
I (ii)	Amount: Fossil Fuel(s) Avoided Or Displaced	Amount of fossil fuels avoided or displaced or likely to be avoided or displaced.

Introduction and Methods

BC Hydro commissioned Cadmus to examine how various jurisdictions in North America attribute or determine the share of energy savings[1] to credit energy efficiency program administrators (PAs) for supporting codes and standards (C&S). This study is in response to a directive to BC Hydro from the B.C. Utilities Commission in their F2017-F2019 Revenue Requirements Application that asked BC Hydro to review the industry practice for attribution of C&S savings.

Program Administrators' Support for Codes and Standards

Building energy codes and appliance efficiency standards can offer cost-effective opportunities to produce significant energy-savings (Edison Foundation; Stellberg et al. 2012). Program Administrators (PAs), including utilities, are in a strong position to support C&S; however, without appropriate policies that credit PAs with savings, PAs are disincentivized from supporting C&S because this raises the baseline from which traditional programs' energy savings are derived (Cadmus et al. 2013; Drexler 2012; Cooper and Wood 2013).

Jurisdictions are recognizing the potential for PAs to support codes and standards in conjunction with developing policies that incentivize PAs to take the following actions:

- Support the adoption of new C&S by helping design new codes or standards, increasing the market share of energy-efficient products or practices through their programs and promoting the adoption of new C&S.
- Enhance compliance with and enforcement of new C&S by offering code training programs, supporting third-party inspectors and plan reviewers, spreading awareness, and listing and publicizing complying products (Cooper and Wood 2013).

Public utility commissions have an interest in ensuring that ratepayer dollars are spent on cost-effective programs and activities to influence the market, but adopting new C&S is a complex process that involves multiple stakeholders and key players.[2] Also, it is not always clear how much PAs impact the adoption of new regulations, and whether those regulations would have been adopted at the same time absent PA efforts. When PAs sponsor programs to support code and standard compliance, it may seem simple to attribute impacts since the PA is responsible for the program activities; yet, determining the share of savings credited to PA programs can be challenging due to multiple non-programmatic influences such as local enforcement efforts or building industry education campaigns. However, these

[1] Quantifying the energy impacts from codes and standards is beyond the scope of this study, although the attribution process is often closely related to the other steps for determining savings.

[2] Depending on the code or standard, stakeholders could include those from the federal government (Natural Resources Canada) or provincial government, energy efficiency advocates, the BC Association for Advancement of Conservation and Efficiency, nongovernmental organizations such as Pembina or Sierra Club, and other utilities such as FortisBC or FortisElectric.

non-programmatic influences are also increasingly complicating the determination of attribution for traditional utility programs "because multiple agents contribute to a decision-maker's awareness and deliberation; these agents are diffused throughout the community and are themselves subject to numerous influences, including program administrator efforts" (Peters and McRae 2008).

Industry Drivers for Attribution

As noted in subsequent sections, the involvement of PAs in C&S activities, as well as the interest in and methods for attributing energy savings to such activities, is changing over time. Several factors are influencing PAs to assess C&S savings and claim energy savings; however, the drivers for each PA can differ and often depend on the specific regulatory framework for each PA. These drivers include:

- *State and local legislated policy targets*. Energy savings targets for PAs, often included in a statewide energy efficiency resource standard (EERS), provide an incentive for PAs to claim C&S savings towards their energy reduction goals.[3]
- *Effect of more stringent C&S on program savings*. Existing codes and standards usually provide the baseline against which PA program savings are measured. As the stringency of codes and standards increases, the options for achieving savings targets through incentive programs decline. PAs can reduce this challenge if they are able to claim some of the C&S savings.
- *Cost-effectiveness of incentive programs*. A corollary of the effect of C&S on savings from incentive programs is the effect on cost-effectiveness. If conventional programs increase the market readiness for C&S, attributing part of the C&S savings to the programs could improve their cost-effectiveness. We are unaware of any jurisdiction where this has been implemented, though the California utilities have proposed considering it.
- *Accurate program savings and load estimation*. If C&S are used as the baseline for estimating incentive program savings but compliance is less than 100%, program savings and load forecasts will be inaccurate. In addition, C&S savings are estimated for the purpose of determining the net load forecast.
- *C&S program impact.* PAs are using attribution assessments to demonstrate the impact of code compliance support programs on code compliance and to estimate the energy savings resulting from increased code compliance. This effort highlights the importance of funding C&S programs.

British Columbia Context and the DSM Regulation

In British Columbia (BC), a key driver for determining C&S savings is to reflect the impact in the net load forecast. However, Section 4(1.4) of the Demand-Side Measures (DSM) regulation (Province of British Columbia, Utilities Commission Act 2008) provides that the British Columbia Utilities Commission (BCUC)

---

[3] The California Public Utilities Commission has taken a unique position regarding savings from utility support of C&S. They have set specific savings targets for C&S separate from the rest of the portfolio. C&S program costs and benefits are not included in the overall cost-effectiveness calculation and utilities are awarded a given percentage management fee for their C&S advocacy activities.

may determine the cost-effectiveness of a measure proposed in an energy efficiency plan or portfolio by increasing the benefit of the measure if the measure increases the use of an item that will be regulated by a future building code or appliance efficiency standard.[4] The adjustment can be applied if there is either a specified standard that has not yet commenced, or a specified proposal.

The guidance provided for the regulation (Province of British Columbia 2014) explains that the BCUC can attribute a portion of the savings that will result from the standard to a program that includes the measure and helps transform the market for the measure. The BCUC can determine what share of savings from the standard will be attributed to the program and for what period.

This regulation is unique in that it seeks to account for the effect of programs on readying the market for standard adoption and advancing the effective date of standards. The intent of the regulation is to bolster the cost-effectiveness of a program, rather than to claim the energy savings within that program, (i.e., to attribute "benefits" but not attribute energy savings). The regulation and guidance do not provide any direction for how the BCUC should determine the amount of benefits to be attributed to the program.

Methodology

Cadmus reviewed policies and practices in 27 jurisdictions outside of British Columbia to understand how C&S savings are attributed to utility or PA efforts. Table 1 lists the two other provinces in Canada and numerous jurisdictions in the United States Cadmus examined.

4 BC's DSM regulation was enacted in 2008 and amended in 2011, 2014, and again in 2017. Section 4(1.4) has been unchanged since 2011.

Table 1. Reviewed Jurisdictions

Jurisdictions	
Canada	
Manitoba	Ontario

California	Colorado
Connecticut	District of Columbia
Hawaii	Illinois
Iowa	Massachusetts
Minnesota	Missouri
Nevada	New Hampshire
New Jersey	New York
Pacific Northwest (ID/MT/OR/WA)	Pennsylvania
Rhode Island	Texas (Austin)
Utah	Vermont
Arizona	

Three main sources of data were used to support this study:

- Publicly filed reports
- Communications with stakeholders in various regions
- Literature review of papers and presentations discussing PA involvement with C&S

Cadmus examined whether each jurisdiction has program activities related to codes, standards, or both. We then characterized each jurisdiction based on the type(s) of activity we observed: support for new C&S or compliance enhancement efforts. Lastly, we outlined whether savings attribution is determined in each jurisdiction and, if so, the process for determining attributable savings.

We have categorized the attribution process in each jurisdiction depending on how substantive and formal it is. Although the process in most jurisdictions fits a specific category well, we found a few processes that were combinations or hybrids of different processes, so were difficult to assign to a single category. Also, we found the process in several jurisdictions had not been fully defined yet. In both these cases, we decided which categorization fit best and explained our rationale.

This report builds on previous Cadmus attribution research. In 2014, Cadmus examined and summarized the attribution efforts of 14 jurisdictions across North America (Cadmus 2014). Comparisons to Cadmus' previous research are made throughout the document and many conclusions are based on notable changes and trends.

We have made every effort to be as comprehensive as possible, but the involvement of PAs in C&S activities is changing over time so any review is a snapshot of the situation at a point in time. In addition, entities other than PAs have primary responsibility for most activities associated with building codes and appliance standards so there is not much documentation of the role of PAs that are involved. However, Cadmus believes that the jurisdictions and PAs covered here capture the full range of energy savings and attribution approaches that exist.

The next section of this report presents the findings for building codes. The section after presents our findings for appliance standards. More PAs have programs that support building codes than appliance standards. Of 18 jurisdictions where PAs are involved in building energy codes, nine also support appliance standards.[5] In recent years, there has been a trend toward PAs supporting code compliance enhancement rather than building code adoption, and the number of PAs supporting standards activities has grown recently.

[5] For accounting purposes, this report treats the Pacific Northwest—Oregon, Washington, Idaho, and Montana—as a single jurisdiction because of the high degree of coordination and integration provided by the Northwest Energy Efficiency Alliance and other regional bodies.

Building Codes Policy Results by Jurisdiction

Summary of Findings

Table 2 provides a high-level overview of the role PAs play in building codes in several jurisdictions, including whether PAs support code adoption and support efforts to increase compliance with codes, and how savings are or are not attributed to PAs for their building code activities. We did not find any other jurisdictions that followed BC's DSM regulation approach of attributing benefits to DSM programs prior to the adoption of a code or standard that regulates a measure or measures included in the DSM program.

Table 2. Summary of Building Code Results

Jurisdiction	Status	Activity for Adopting Codes?	Activity for Compliance Enhancement?	Program Administrator Attribution Method
Formal Attribution Approach				
California	Program and attribution process in place more than 10 years	✓	✓	Use evidentiary record, expert panel; focused on code adoption only
Pacific Northwest	Attribution process in place 10 years	✓	✓	Use evidentiary record; attribution based on share of funding for regional market effects program; focused on code adoption only
Massachusetts	Attribution completed in 2018		✓	Use evidentiary record, expert panel; focused on compliance enhancement
Rhode Island	Attribution completed in 2017		✓	Use evidentiary record; focused on compliance enhancement
New York	Process established; attribution not yet completed	✓	✓	Use evidentiary record, expert panel; focused on compliance enhancement only
Arizona – Salt River Project	Attribution process in place several years and multiple analyses completed	✓	✓	Use evidentiary record, evaluate attribution percentage, not-to-exceed 50%; focused on code adoption
Illinois	Process established; attribution not yet completed		✓	Use evidentiary record, expert panel; focused on compliance enhancement
District of Columbia	Process not developed yet		✓	Considering California and others
Deemed Attribution Approach				
Arizona – Investor Owned Utilities	Program and attribution process authorized for eight years	✓	✓	Evaluate portion of maximum allowable attribution percentage
Texas (Austin)		✓	✓	Deemed savings are claimed

Jurisdiction	Status	Activity for Adopting Codes?	Activity for Compliance Enhancement?	Program Administrator Attribution Method
Pennsylvania	Attribution permitted in late 2018		✓	Evaluate portion of maximum allowable attribution percentage
Full Savings Without Determining Attribution				
Ontario				No support for codes; regional savings goal
Manitoba		✓		No attribution; claim full territory savings as a result of advocacy efforts
Attribution Permitted: No Approach Specified				
New Jersey	Attribution permitted in mid-2018		✓	No approach specified
Minnesota	Permitted since 2007		✓	No approach specified
No Attribution: Codes Savings Considered Non-Resource[a]				
Vermont			✓	No attribution; code program is non-resource
New Hampshire			✓	No attribution; code program is non-resource
Missouri			✓	No attribution; code program is non-resource
Iowa			✓	No attribution; code program is non-resource
Colorado			✓	
Utah			✓	No attribution; code program is non-resource
Hawaii		✓	✓	No attribution; code program is non-resource

[a] The term non-resource refers to programs that are not expected to result in direct savings but contribute to the acquisition of energy efficiency through education, outreach, training, or other general approaches.

Formal Attribution Approach

In 2014, Cadmus found that while many jurisdictions recognized energy savings arising from building energy codes, only two instituted a formal assessment of attribution—California and Massachusetts—and Massachusetts' process was in the pilot stage. More recently, three additional states have proposed or initiated formal attribution processes: Rhode Island, New York, and Illinois. Additionally, Cadmus determined the Pacific Northwest's attribution process was better categorized as a formal approach for this report. The following sections detail how each state is claiming or proposes to claim savings for their code adoption support or compliance enhancement programs.

California

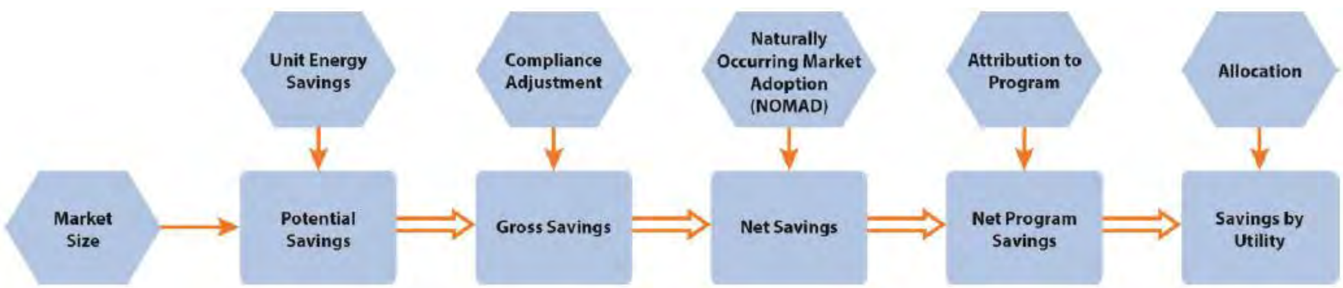
California investor-owned utilities' (IOUs') Codes and Standards program supports technical and market research of new technologies and practices, advocates for the adoption of more efficient regulations, and provides compliance enhancement support of California's Building Energy Standards (Title 24) and Appliance Standards (Title 20), as well as federal appliance and equipment standards implemented by the Department of Energy's Building Technologies Office. According to a recent report (California Public Utilities Commission [CPUC] 2018), "Savings from Codes and Standards are consistently the most cost-effective savings available to IOU efficiency programs, since these programs impact all new buildings constructed and appliances purchased in the state."

The California IOUs initiated their efforts to support codes and standards in the late 1990s and treated them as a non-resource program (that is, they claimed no savings from their efforts). For the 2006-2008 program cycle, the CPUC authorized IOUs to claim and receive credit toward their savings goals for C&S activities. Because this was the first time C&S savings were analyzed and accredited, the CPUC directed that the savings be discounted by 50%. For the 2010-2012 and 2013-2015 program cycles, IOUs received full evaluated savings credit for the program using the California Codes and Standards Advocacy Program Evaluation Protocol.

California Evaluation Protocol

The California Codes and Standards Advocacy Program Evaluation Protocol, illustrated in Figure 1, shows the steps and major factors used to identify program attributable net savings for efforts advocating for new C&S (Cadmus and DNV GL 2016).

Figure 1. Codes and Standards Advocacy Program Evaluation Protocol



Source: (Cadmus and DNV GL 2016)

The potential energy savings attributable to the C&S program is based on the estimated unit energy savings and the number of those units (building code measures or appliances) entering the market each year. To derive gross energy savings, evaluators apply a compliance adjustment to potential savings. Net savings result from adjusting the gross savings by the naturally occurring market adoption (NOMAD) of measures or appliances meeting the code or standard that would have occurred in the absence of the code or standard. Net program savings that are credited to the statewide C&S program are then determined by applying an attribution score; each of the four IOUs is then allocated net savings attributable to the program based on their share of the statewide energy market (for electricity or gas).

In California, the California Energy Commission has responsibility for adopting new codes or standards. The rationale for including the attribution step is that the statewide C&S program is designed to influence which C&S are adopted and at what level, so a portion of the credit for the C&S savings can be attributed to the utilities' efforts. For each technology or building practice, the evaluator must establish the percentage of savings resulting from program efforts. As there are no limits on the proportion of savings that are attributable to C&S initiatives, scores can range from 0% to 100%.

The process of determining attribution is formally done through an attribution panel consisting of independent C&S experts. The evaluator's process of determining attribution entails the following steps:

1. The evaluator collects information and compiles documentation on stakeholder activities from a range of sources, including rulemaking dockets, code change theory reports (written by the IOUs), and stakeholder interviews. [6]
2. A panel of independent C&S experts assesses the information compiled by the evaluator on the program's contributions to the adoption of each C&S based on a careful and systematic review of the evidence. Having independent experts evaluate program contributions lessens concerns about potential biases from having utility representatives directly involved in determining credit for their own efforts.
3. The evaluator researches and estimates the relative effort necessary to adopt a new code or standard based on three general factor areas required for adoption: (1) development of compliance determination and other special analytic methods, (2) development of technical information, and (3) stakeholder outreach and feasibility of code or standard. The evaluator then applies these relative measures of effort to the contribution made by the program in each area to produce a weighted attribution score for each C&S (Cadmus and DNV GL 2017).

To date, the IOUs have claimed and received energy savings credit for only advocating for adoption of building codes. However, they have engaged in an ongoing program to enhance code compliance for several years, so are likely to pursue getting credit for savings from this program as well. When that occurs, the current evaluation and attribution methodology will need to be modified as needed.

Since California's protocol has been in practice the longest, it is often referenced by other states and jurisdictions.

Code Compliance Savings from New Construction Program Spillover

The California IOUs have argued unofficially that their incentive programs for new buildings should receive some credit for savings from building codes because they "ready the market" for new codes. This claim was the only case we found in our research that relied on logic similar to that presented in the

[6] The California IOUs provided Code Change Theory Reports to evaluators, which provided the IOU perspective about the C&S team's contributions to rulemaking. This information from the reports is used in the determination of program credit for applicable standards and building codes.

BC DSM regulation. The CPUC has not accepted that position, however, because the IOUs are receiving savings credit directly from their statewide C&S program.

In an October 2007 Decision (D.07-10-032), though, the CPUC issued a directive to explore possible market effects of building programs on code compliance rates and the ability to credibly quantify and credit such nonparticipant spillover. When the decision was issued, the IOUs' residential new construction (RNC) programs encouraged high-performance building designs that exceeded the 2005 Title 24 energy-efficiency requirements by 15% or more, while also aiming to increase the adoption and installation of individual high-efficiency measures (KEMA 2010). Using market data and two Delphi panels, a consultant's study estimated that the IOUs' 2006-2008 RNC programs were responsible for approximately 23% of the gross electricity savings from achieving code compliance in non-program homes (Massachusetts Group and NMR Group, Inc. 2010). Although these savings could, in theory, be attributed to the RNC program, they would be accounted for in the C&S program evaluation and the CPUC has not authorized any crediting of the savings to the incentive program.

Pacific Northwest (Idaho, Montana, Oregon, and Washington)

The Northwest Energy Efficiency Alliance (NEEA), a regional nonprofit organization, manages the Pacific Northwest's market transformation efforts, which include work supporting building codes and appliance standards. From NEEA's website: "The long-term goal of NEEA's market transformation programs is often to lock in energy savings through progressively effective energy codes and standards. NEEA supports regional stakeholders in energy code development and adoption, training and implementation. Program staff serve as technical experts during U.S. Department of Energy rulemakings to encourage the adoption of federal appliance and equipment efficiency standards." NEEA has been supporting regional building codes since 1997 and, recently, has become more active in efforts to adopt national model energy codes. After the adoption of a code, NEEA provides technical support and training for regional compliance.

NEEA is classified as having a formal attribution approach as it has conducted studies to quantify attribution to NEEA's efforts in the past, though NEEA has not continued to update these analyses. As with some other jurisdictions, the approach in the region is a hybrid involving a mix of formal attribution, allocation, and integration of savings with the load forecast.

In 2008, Cadmus (formerly Quantec) developed and implemented a method for assessing attribution of energy code savings to NEEA's regional efforts to support code adoption and implementation. We did not find any information documenting a more recent assessment of attribution. The assessment used the following approach:

- Estimate regional energy savings from code adoption.
- Calculate net savings as a portion of total regional savings by subtracting the market baseline (typically estimated through independent evaluations) that would occur naturally without NEEA or programmatic intervention.
- Subtract savings claimed by sponsors' efficiency programs (to avoid double counting).

- Estimate attribution to NEEA's efforts by counting the number of times various entities are mentioned in response to open ended questions regarding organizations that influenced code adoption in each state.

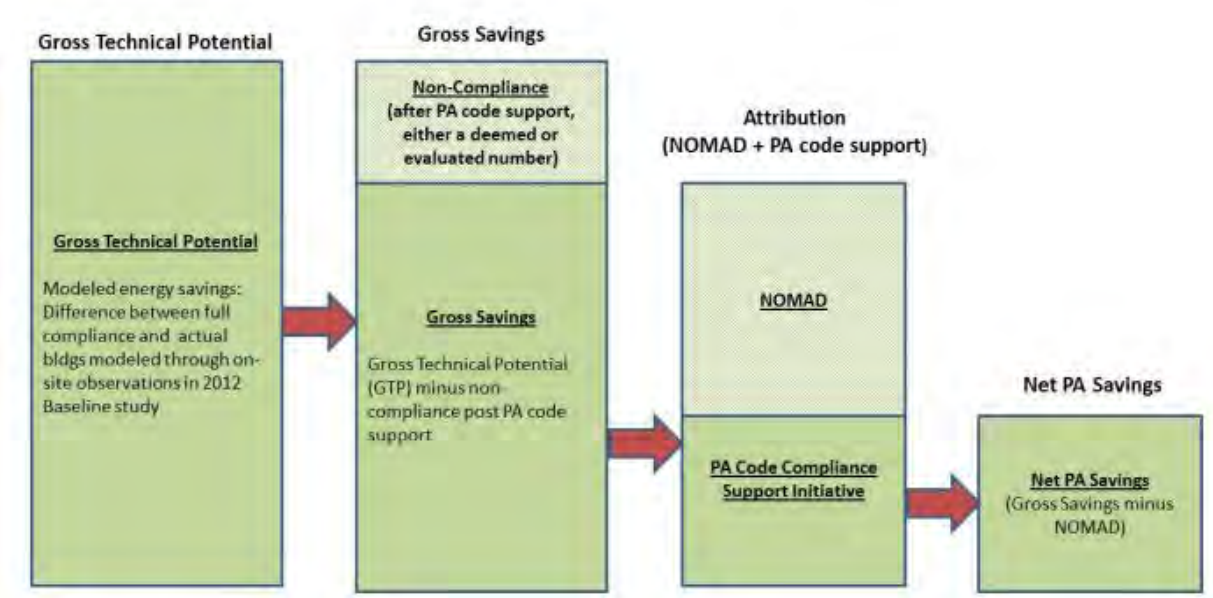
NEEA's energy savings are claimed by its funding partners (Bonneville Power Administration, public utilities, etc.) in proportion to the amount of funding provided to NEEA. This is a reasonable way to allocate savings among regional parties and similar to the approach agreed to by the California IOUs.

Utilities in the Pacific Northwest usually do not try to claim savings outside of NEEA efforts because of the increased level of scrutiny that would invite, and because of the additional documentation requirements such as providing sales data.

Massachusetts

Since 2014, the Massachusetts PAs have funded the Code Compliance Support Initiative (CCSI), a compliance enhancement effort aimed at educating code officials and building professionals on the residential and commercial building energy codes implemented throughout the Commonwealth of Massachusetts. The program initially ran as a pilot (through 2015) with no claimed savings (described later as a non-resource program). A preliminary savings methodology for evaluating the PAs' effort was developed by the PAs in 2015 and presented to the Massachusetts Department of Energy Resources. The methodology, as shown in Figure 2, calculated gross savings and net energy savings, or the portion attributable to the CCSI, after considering such factors as non-compliance and NOMAD (Massachusetts Program Administrators 2015).

Figure 2. Massachusetts PA Preliminary Net Savings Calculation Methodology



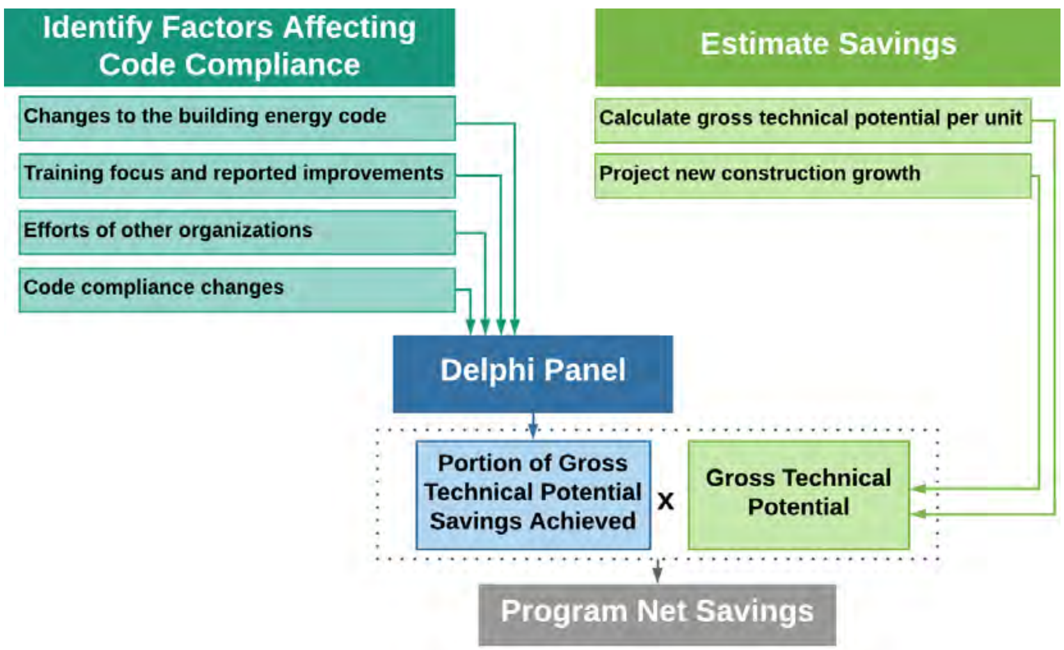
Source: (Massachusetts Program Administrators 2015)

In 2018, the Massachusetts PAs and the Energy Efficiency Advisory Council consultants contracted with the Massachusetts Cross-Cutting Research Area evaluation team to estimate prospective savings attributable to the PAs from the code compliance enhancement efforts of the CCSI. The evaluation teams used the net savings calculation presented to Massachusetts Department of Energy Resources as the starting point for the commercial and residential attribution assessments, as discussed in subsequent sections.

Commercial New Construction and CCSI Attribution Assessment

To develop an attribution score and project CCSI net savings for 2019-2021 for new commercial buildings, the Massachusetts Cross-Cutting Research Area evaluation team (NMR and Cadmus) used a Delphi panel approach modeled after the California protocol. For this evaluation, a panel of code experts reviewed documentation on CCSI activities and provided estimates of code compliance over the period under two scenarios: (1) with CCSI activities continuing at a similar level to previous efforts and (2) without implementation of the CCSI. Figure 3 illustrates the process used by evaluators to assess attribution and calculate estimated savings from the CCSI.

Figure 3. Massachusetts Attribution Study Approach



Source: (NMR and Cadmus 2018)

The first step in the process was to identify and provide to the expert panel the factors affecting code compliance. Documentation supplied to the panel included the following:

- Background information on the initiative
- Baseline and follow-up compliance study results
- Key changes to energy code requirements
- Reported impacts of training and technical assistance

- Gross technical potential modeling results for compliance enhancement
- Compliance enhancement efforts of other organizations throughout the state

From this documentation, the Delphi panel estimated compliance under two scenarios: (1) with the CCSI continuing code enhancement activities in the future at a similar level to historical efforts and (2) with the CCSI never having been implemented. The Delphi panel deliberated compliance in two rounds. In the first round, panelists provided estimates and their rationale for compliance under the two scenarios. In the second round, the panelists reviewed a compilation of their peers' first-round estimates and revised their estimates, if desired.

The team then estimated the gross technical potential using the baseline technical potential and projected commercial building new construction. Finally, to estimate program net savings, we multiplied the CCSI attribution as determined by the Delphi panel by gross technical potential, as shown in the following equation:

$$Program\ Net\ Savings_{year} = Program\ Attribution_{year}\ x\ Gross\ Technical\ Potential_{year}$$

The evaluation team provided the Massachusetts PAs and the Energy Efficiency Advisory Council with estimated program net savings for 2019-2021 program period (Cadmus and NMR Group, Inc. 2018).

Residential New Construction and CCSI Attribution Assessment

Using a methodology similar to the commercial attribution assessment, NMR forecasted net-to-gross (NTG) ratios for the low-rise RNC program and the residential portion of the CCSI for the 2019-2021 program period. [7] The assessment covered both programs, which target the single-family residential new construction market, together to avoid double counting savings and to ensure all savings attributable to the PAs were documented (NMR Group, Inc. 2014).

The evaluation team calculated a retrospective NTG ratio for the 2015 program year and prospective NTG estimates for 2019-2021. To estimate retrospective NTG ratios, the team conducted the following activities:

- A Delphi panel of codes experts estimated measure-level efficiencies as if the RNC and CCSI programs never existed (referred to as the counterfactual scenario) in two rounds.
- The energy consumption of program and non-program homes was modeled as constructed (referred to as the as-built scenario) and under the counterfactual scenario determined by the Delphi panel.
- Evaluator estimated retrospective net savings and NTG estimates using analysis of the as-built and counterfactual energy consumption.

To develop prospective NTG estimates, the team then produced and presented to the Delphi panel an internal forecast of the impact of the programs in 2019-2021. The Delphi panelists, in a third-round,

[7] The methodology was consistent with NMR's 2014 Residential New Construction Net Impacts Study.

suggested changes to the forecasted estimates, which the team used to adjust retrospective findings and develop NTG ratios for 2019-2021 (NMR Group, Inc. 2018).

Rhode Island

National Grid, the only IOU in Rhode Island, implements a code enhancement program like Massachusetts' CCSI; the Code Compliance Enhancement Initiative (CCEI) provides trainings, circuit rider[8] technical assistance, third-party inspection support, and other code compliance tools and resources covering both the residential and commercial energy codes. The CCEI also focuses on stakeholder engagement activities, such as attending local code official meetings and industry or trade group events, and program implementers visit each building department throughout the state. These CCEI activities, which began in 2013, have been National Grid's initial short-term focus and are a part of National Grid's larger C&S initiative, which encompasses four components: code compliance through CCEI; appliance standards development and advocacy; stretch code development; and base code advocacy.

In December 2012, National Grid, with the support of the Energy Efficiency Resource Management Council, developed a model for attribution that was approved by the Rhode Island Public Utilities Commission. In 2017, NMR estimated the savings in the residential and commercial new construction markets attributable to the CCEI in the 2018-2020 period due to its code compliance enhancement efforts.

Figure 4 illustrates the iterative attribution approach used by the evaluators. This approach is like the approaches used in California and Massachusetts in that a broad range of resources, including baseline compliance studies, reported impacts of training, and NOMAD estimates, were used to determine an attribution score. However, unlike California and Massachusetts, the attribution score was determined solely by the evaluation team rather than a Delphi panel (NMR Group, Inc. 2017).

8 An energy code circuit rider provides statewide energy code training, technical support, and code interpretations to design and building professionals, permitting departments, and code officials.

Figure 4. Rhode Island Attribution Assessment Approach

New York

The Energy Conservation Construction Code of New York State (ECCCNYS) is updated regularly by the State Fire Prevention and Building Code Council. The New York State Department of State Division of Building Standards and Codes serves as secretariat to the Building Code Council; the Building Standards and Codes administers the energy code, provides training and education, and supports local code enforcement (New York Department of State 2018). The New York State Energy Research Development Authority (NYSERDA) also serves as the program administrator for code compliance and enforcement programs, including the Advanced Energy Codes and Standards Program and the Clean Energy Fund.

Advanced Energy Codes and Standards Program

In 1996, the New York State Public Service Commission established a System Benefits Charge (SBC) to fund initiatives that serve all energy consumers throughout New York State. The SBC was renewed several times over the last two decades, with the most recent extension ending in December 2016. The SBC program was primarily administered by NYSERDA, and the 2012-2016 order funded a Technology and Market Development Portfolio comprising nine initiatives, including the Advanced Energy Codes and Standards Program (New York State Energy Research Development Authority 2013).

The Advanced Energy Codes and Standards Program aimed to reduce energy use by increasing compliance with the ECCCNYS; developing a voluntary stretch code for local adoption; and contributing to the development of appliance and equipment standards, specifically those not covered by federal standards. Through the energy codes component of the program, NYSERDA coordinated code enhancement services and resources for code officials, design professionals, and third-party energy professionals; these included training opportunities, technical assistance, plan review and inspection support, and code enforcement and implementation tools.

To date, NYSERDA has not claimed savings from its code activities. However, two process evaluations on NYSERDA's energy code training efforts have been completed and an impact evaluation to attribute energy savings to the program's code enhancement activities is underway (Industrial Economics, Incorporated 2016 and 2017). The impact evaluation consists of two separate Delphi panels. The first Delphi panel,[9] completed in 2015, established an energy code compliance baseline and the second, expected to be completed in 2018, will evaluate the program's effectiveness and estimate the change in compliance between the two points in time (ERS and Industrial Economics, Incorporated 2016). The Delphi panel will be asked to estimate the change in compliance and how much of the change can be attributed to NYSERDA's efforts, natural market changes, and technology progress. This information will feed into a model that considers the construction volume and estimated energy savings due to code changes to estimate the energy savings attributable to NYSERDA's activities.

Clean Energy Fund

Currently, NYSERDA has 25 Clean Energy Fund Investment plans intended to reshape the energy efficiency landscape in New York by providing clean energy and energy innovation programs to a wide range of consumers and help meet the state's commitment of 50% renewable energy by 2030 (NYSERDA 2016). The Codes Chapter of the Clean Energy Fund, issued November 2017, is designed to support compliance with and enforcement of the ECCCNYS, advance the development of stretch energy codes, and provide technical assistance and other services to support the enactment of state and local energy codes. Code to Zero, the first initiative of the Codes Chapter, has three main goals:

- Code compliance reaches 90% throughout New York
- 20% of jurisdictions adopt a stretch code

---

9 The process for the first Delphi panel consisted of three rounds of one-on-one interviews.

- Jurisdictions that adopt alternative code enforcement structures or receive training and supplemental services report improved enforcement of the energy code (NYSERDA 2017)

For each goal, NYSERDA has established performance metrics that will be analyzed over the length of the initiative, including the number of training attendees and percentage of market complying with the energy code. Although the evaluation plan has not been finalized, NYSERDA anticipates using a Delphi panel process to establish a compliance baseline, estimate NOMAD, and measure the impact of the initiative over time. Additionally, it is expected that the evaluation team will conduct ongoing interviews with representative jurisdictions to compare to the Delphi panelists' responses. NYSERDA will use these evaluations to quantify long-term, indirect energy savings impacts attributable to the Code to Zero initiative.

Arizona—Salt River Project

Salt River Project (SRP), a community-based not-for-profit electric provider in Phoenix, claims savings for supporting C&S adoption and implementation activities. As described later, the Arizona Corporation Commission (ACC) adopted rules that allow IOUs to claim savings from codes and standards, but as a political subdivision of the State of Arizona, SRP is not regulated by the ACC (Cadmus September 9, 2018). SRP's board, however, decided to allow the utility to claim up to 50% of the savings from a code or standard if it demonstrates influence over the adoption of the new code or standard (Cadmus 2012).

SRP's Building Energy Code Initiative offers education, training, and support to city councils and the state legislature to influence the adoption and enforcement of building energy codes within the cities and code jurisdictions SRP serves (SRP 2018). Aside from working with local code officials to drive adoption and consistent enforcement practices across the Phoenix metropolitan area, SRP leverages its governmental status and voting rights to influence the development of new building energy codes at the national level to better serve Arizona and the Southwest region.

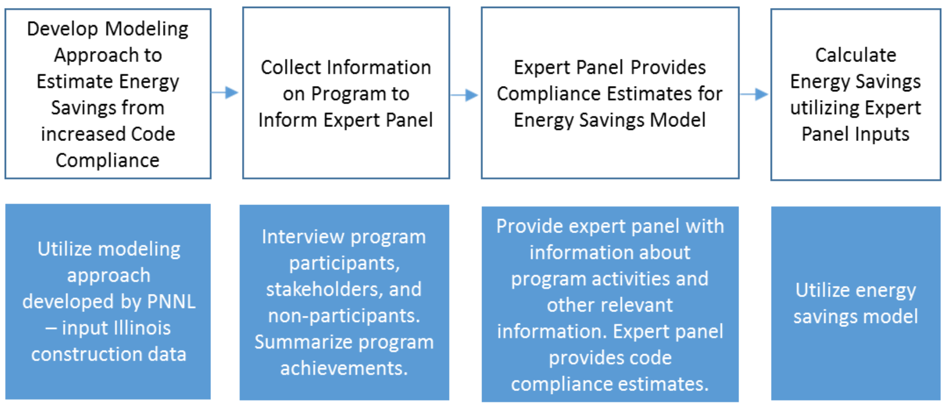
SRP has worked with Cadmus and other third-party evaluators to document the initiative's influence and attribute the appropriate amount of energy savings from building codes to its portfolio. SRP modeled its attribution approach after California and Massachusetts, with modifications to make it more applicable to home rule states. Evaluation activities have included interviews with stakeholders and jurisdictions, and assessments of materials developed by SRP to determine the influence SRP has had on the process. Cadmus has used building simulation data to estimate code savings and implemented an innovative billing data analysis to estimate residential code savings (Bonesteel 2017).

Illinois

For several years, the Illinois Department of Commerce and Economic Opportunity (DCEO) administered the Building Energy Codes Education and Technical Assistance Program, a comprehensive program aimed at supporting the adoption, implementation, compliance, and enforcement of the Illinois Energy Conservation Code. The program effectively ended in 2016 due to a lengthy impasse over the state budget, with energy efficiency program administration responsibilities shifting to the utilities.

At the request of DCEO, Cadmus, as a subcontractor to ADM Associates, evaluated the impact of the program on energy savings for the 2014, 2015, and 2016 calendar years and for program years 7, 8, and 9; each program year ran from June 1 to May 31 (Cadmus 2017). Cadmus' formal approach, summarized in Figure 5, utilized a panel of experts to estimate the difference in the level of compliance due to the program. Cadmus calculated the energy savings estimates for both the residential and commercial sectors using input from the expert panelists and Pacific Northwest National Laboratory's energy consumption models.

Figure 5. DCEO Energy Codes Education and Technical Assistance Analysis Approach



Illinois' Future Energy Jobs Act (FEJA) became effective in June 2017 (MEEA August 2018), requiring significant energy savings by the state's electric utilities.[10] To meet the savings goals, FEJA requires utilities to include proposals for C&S programs, as shown below (State of Illinois Public Act 099-0906 2016*)*.

Excerpt from FEJA:

> *In submitting proposed energy efficiency and demand-response plans and funding levels to meet the savings goals adopted by this Act the utility shall:*
>
> 1. *Demonstrate that its proposed energy efficiency and demand-response measures will achieve the requirements that are identified in subsections (b) and (c) of this Section, as modified by subsections (d) and (e).*
> 2. ***Present specific proposals to implement new building and appliance standards that have been placed into effect. (****Note: emphasis added by Cadmus).*

[10] The bill, passed in December 2016, amended the Public Utilities Act and the Illinois Power Agency Act. It requires Ameren Illinois to attain 16% and Commonwealth Edison Company to attain 21.5% cumulative annual persisting savings by 2030. Gas utility targets, as determined by 2009 amendments to the Illinois Power Agency Act, were unaffected.

Additionally, utility procurement plans must include an analysis of "the impact of energy efficiency building codes or appliance standards, both current and projected," along with opportunities to expand the programs.

In response to savings and C&S program requirements, Illinois gas and electric utilities have joined together for a potential statewide code compliance enhancement program. The utilities are currently involved in the Illinois Energy Codes Compliance Collaborative and are funding the Midwest Energy Efficiency Alliance (MEEA) and Cadmus to complete pre-program residential and commercial field studies; the studies will establish a compliance baseline and identify opportunities for improved compliance. The utilities will use results from the field studies to design and implement an Integrated Compliance Support Program, a suite of programs targeted at improving the compliance issues observed in the field. Savings from the programs will be verified through post-program studies and used to meet the utilities' savings targets, but the specific attribution analysis method has not been defined yet (MEEA September 2018).

District of Columbia

The District of Columbia Department of Energy and Environment (DOEE) oversees the DC Sustainable Energy Utility (DCSEU). Created as part of the Clean and Affordable Energy Act of 2008, DCSEU implements energy efficiency and renewable energy programs in the DC area (DOEE 2008). "The DCSEU operates under a performance-based contract with DOEE, with input and recommendations from the SEU Advisory Board, and oversight from the Council of the District of Columbia" (DOEE October 2018).

In a 2017 presentation developed by the DCSEU Advisory Board, savings attribution was included as a new strategy for efficiency savings. Per the presented material, attribution "accounts for the numerous ancillary service offerings the DCSEU offers to customers in addition to incentives" and it is noted that attribution was recommended in the 2016 draft of DC's energy and climate action plan, Clean Energy DC (DCSEU Advisory Board 2017).

Clean Energy DC was finalized in August 2018. The plan recommends that DCSEU invest in compliance enhancement efforts and receive credit for associated savings:

> *The DCSEU should assist DOEE, DCRA [Department of Consumer and Regulatory Affairs], the Green Building Advisory Council and the Construction Code Coordinating Board to develop and implement building-code improvements. The DCSEU should also design outreach and incentive programs for building owners, designers, and contractors with an eye to laying the foundation for future building code improvements. To incentivize such investments, the DCSEU should be credited for a portion of any energy savings attributable to the adoption of energy-saving building code improvements, as is the case in Arizona utilities. To maximize the energy savings realized from building code improvements, the DCSEU should invest resources in training, outreach, technical assistance, design assistance, marketing, explanatory materials, and other efforts to increase compliance with building codes. As codes become more ambitious, the DCSEU should receive credit for bringing poor performing buildings up to code. As the District has little history of crediting a demand-side management administrator for code-related energy savings …*

> *this would need to be resolved through an evaluation, measurement, and verification review and the subsequent development of appropriate guidelines.*

The plan also notes: “other jurisdictions, such as California, also provide utilities attribution for energy code adoption, but the Arizona model is most appropriate for a small jurisdiction like the District (DOEE August 2018).”

Staff at the Institute for Market Transformation (IMT), DCSEU’s subcontractor for code compliance trainings, and the DCRA, the department that supports code compliance and enforcement activities, indicated that they are actively working on an appropriate attribution approach. Per our correspondence with IMT staff: "Attribution is indeed being considered in association with the DC Sustainable Energy Utility’s work on building code development and implementation. These plans are still at a formative stage and will require further development, then extensive review before approval. Therefore, it’s premature to present details” (Cadmus October 3, 2018).

DCRA receives funding for code enhancement, as it is available, from DCSEU and is interested in helping DCSEU achieve its savings target through savings related to these activities. According to correspondence with DCRA staff, the department has proposed a baseline study that follows a building project from plan review to inspection to certificate of occupancy, and notes compliance issues throughout the process. Programs designed specifically to address the issues in compliance will then be proposed, with savings associated to the programs attributed to DCSEU. DCRA staff noted, “the traditional utility program has to transition to a world where the energy code is the law and support those laws through compliance support” (Cadmus October 2, 2018). Attribution details are still being developed.

Deemed Attribution Approach

Through our research, we identified three jurisdictions —Arizona (investor owned utilities), Austin, Texas, and Pennsylvania—that use a deemed approach to estimate energy savings attributed to PA energy code programs (that is, the deemed savings specify what portion of the savings are attributable to the PAs). The following sections detail how each state or jurisdiction is claiming savings for their code adoption support or compliance enhancement programs.

Arizona—Investor Owned Utilities

In 2010, the ACC adopted rules (Docket No. OOOOOC-09-0427) that require IOUs and rural electric cooperatives to achieve annual energy savings of at least 22% by 2020 (Southwest Energy Efficiency Alliance 2016). As a result, the regulated electric utilities, Arizona Public Service (APS) and Tucson Electric Power Company (TEP), have developed energy efficiency programs from which they can claim savings. The ACC allows the regulated utilities to claim electricity savings from building codes and gas savings from both building codes and appliance standards. The regulations do not establish an attribution process that is purely formal or purely deemed. The rules state that utilities can claim up to one-third of the savings generated by the codes or standards, but they must be quantified through a measurement and evaluation study conducted by the utility (ACC 2018).

TEP’s 2018 Energy Implementation Plan and APS’ Amended 2018 Demand Side Management Implementation Plan both include a codes and standards component. The objectives of TEP’s Energy Codes and Standards Enhancement Program, approved by the ACC most recently in Decision No. 75450, are to improve compliance with current energy codes and standards and support the adoption of newer codes and standards (TEP 2017). TEP claims savings from its codes and standards program but has not allocated budget to conduct an evaluation of the program. APS’ DSM plan includes the Building Codes and Appliance Standards Initiative, which offers compliance enhancement support to code officials, building professionals, and other market actors. APS claims significant electricity savings from the initiative (APS 2017), which are reviewed and verified annually as part of APS’ Measurement, Evaluation, and Research Reports. Per an interview with a consultant working on APS’ attribution, savings are estimated using publicly available sales data, field research within the APS territory, and market baselines (Cadmus October 9, 2018).

The 2017 APS Codes and Standards Report states that the savings “*reflect increased adoption of federal, state, and jurisdictional codes and standards (C&S) that are directly influenced by APS' portfolio of demand-side management (DSM) programs. This increased adoption results in more efficient baselines that, in addition to driving greater savings for C&S programs, reduce the savings potential for measures currently incentivized by APS' DSM programs. Therefore, each year APS adjusts its savings accordingly to reflect these baseline changes, which drives APS to pursue new program opportunities focused on the latest, most efficient technologies”* (Navigant 2018).

Texas (Austin)

The Austin City Council adopted the Austin Climate Protection Plan in 2007. The resolution includes goals for energy codes, including a goal in the 2012 update to the resolution to “implement the most energy efficient building codes in the nation” (Austin Energy 2012). Austin Energy, a publicly owned electric utility in Texas, administers many energy efficiency programs in support of the Climate Protection Plan, including the Austin Energy Green Building (AEGB) program. The program has been providing support to the design and construction communities to reduce building energy use and meet the climate protection goals of the city since 1990. AEGB oversees the City of Austin’s energy code; every three years, the program amends the code to reflect innovation in construction materials and practice, as well as any policy changes (Austin Energy Roadmap).

Austin Energy reports significant savings from the AEGB, with the greatest share due to code efforts (Austin Energy 2018). Cadmus did not find documentation indicating that an attribution analysis of code savings was conducted for this publicly owned utility. Instead, per email correspondence with Austin Energy’s Evaluation and Development Group, deemed savings factors based on energy models of various prototypical buildings are applied to building permits. The deemed savings factors represent the kW and kWh savings of the energy code to which the building is permitted over the baseline energy code in effect in 2007 (2001 International Energy Conservation Code [IECC] and by reference, ASHRAE 90.1-2001) (Cadmus September 21, 2018). A similar approach was proposed to evaluate AEGB’s Multifamily Rating Program, but Cadmus could not locate documentation of this effort (Reed 2014).

Pennsylvania

Pennsylvania is the most recent state to permit PAs to claim savings resulting from energy code programs. Per the General Assembly of Pennsylvania, Senate Bill No. 1235, September 2018 amendment to Title 66 (Public Utilities) of the Pennsylvania Consolidated Statutes, Pennsylvania utilities may claim up to one-third of the energy savings resulting from their involvement in building energy codes. The statutory language (shown below) is very similar to that in the regulation promulgated by the Arizona ACC:

Excerpt from Senate Bill No. 1236:

> *(3) The term includes up to one third of the energy savings and reductions resulting from energy efficiency building codes, provide that:*
>
> > *(i) The electric distribution utility played a direct role in achieving the savings and reductions through program implementation.*
> >
> > *(ii) The savings and reductions are quantified and reported throughout an independent measurement and evaluation study.*
> >
> > *(iii) The savings and reductions are commensurate with the direct role that the affected utility played to achieve the savings and reductions.*

Senate Bill No. 1236 ensures savings from code efforts can be applied to the energy reduction goals of Pennsylvania's seven major electric distribution companies, as required by Act 129 of 2008 (The General Assembly of Pennsylvania, House Bill No. 2200).

We did not find any details yet on whether the savings would be counted for code adoption or compliance enhancement efforts, or both. Also, there is no information available yet on whether attribution would be assessed, or utilities would just be able to claim one-third of resulting energy savings without having to quantify attribution.

Full Savings without Determining Attribution

In Ontario and Manitoba, code and standard savings are counted in a PA portfolio or regional savings model, without consideration of attribution. For perspective, this is the approach that BC Hydro takes, with the savings estimates subsequently used to develop a net load forecast.

Ontario

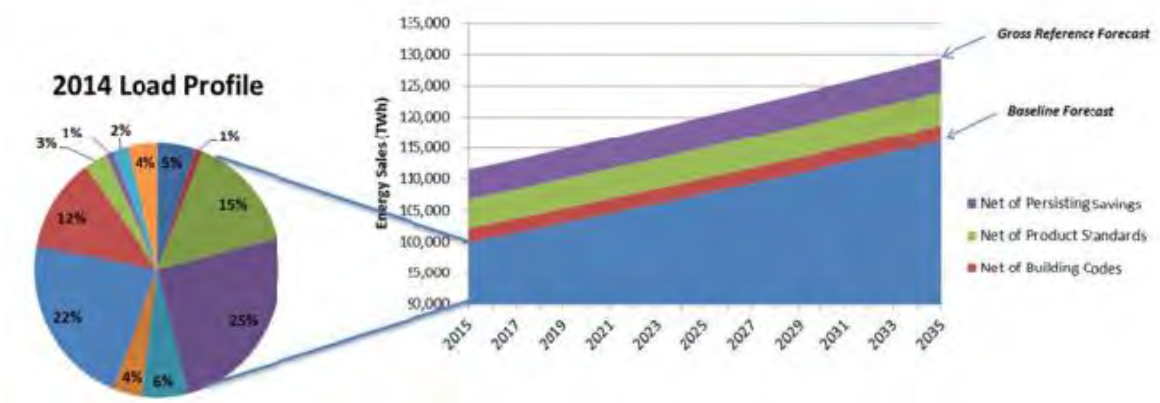
In 2015, Ontario Power Authority merged with the Independent Electricity System Operator (IESO), which oversees Ontario's local distribution companies (LDCs) and electricity market (IESO Power Authority Amalgamate 2018). IESO supports the LDC's conservation programs and aids with meeting the required savings targets outlined in the Conservation First Framework (IESO Conservation Delivery Tools 2018).

Savings are not estimated for C&S programmatic efforts claimed as contributing to each LDC's Conservation First Framework targets. They are addressed by subtracting forecast codes and standards savings from top-line gross load forecasts to develop a reference forecast for each LDC, with the result being a lower target. This process is explained in IESO's *2016 Achievable Potential Study: Short Term Analysis* report (Nexant 2016):

> *Subtract codes and standards and persisting savings from gross forecast: Nexant worked with IESO's staff to obtain the respective energy savings through the long term study horizon anticipated by end use due to the adoption of more stringent building codes (e.g. HVAC and lighting) and the adoption of more efficient product standards (e.g. appliances). Data provided by IESO summarized the persistent savings by measure from 2015, and Nexant allocated the appropriate persistent savings by LDC, by sector, and by end use and subtracted the savings from the gross reference forecast. These codes and standards, and persistent savings were subtracted from the top-line gross reference forecast to establish the baseline forecast.*

Figure 6 illustrates how each LDC's baseline load forecast was determined with consideration for codes and standards; the baselines reflect codes and standards savings regardless of an LDC's energy code efforts. IESO documents do not provide any assessment of possible LDC involvement in building code adoption or compliance enhancement.

Figure 6. IESO Illustration of Baseline Load Forecast Development by LDC



Source: (Nexant 2016)

Manitoba

Manitoba Hydro is the primary electric and gas utility in Manitoba, Canada. Its *2014-2017 Power Smart Plan* indicates that DSM targets include savings from C&S, which are considered separate from electric and natural gas DSM programs (Manitoba Hydro 2015). Per Manitoba Hydro's DSM plan for the 2016/17 fiscal year, "Manitoba Hydro's overall DSM strategy involves taking a broad approach to capturing energy efficiency opportunities: education to build awareness and understanding, creating foundations through the support of standards, motivating customers with the aid of financial tools, and entrenching energy savings through the support of federal and provincial codes and regulations" (Manitoba Hydro 2016).

The *Power Smart Plan* acknowledges: "A code or a regulation ensures permanent market transformation for the specific energy efficiency opportunity since a potential always exists that the market could revert back to the non-efficient option once Power Smart has reduced or eliminated its program support."

Manitoba Hydro's code activities include market intervention strategies, such as being an "aggressive and active participant" on provincial and national energy efficiency codes and standards committees. "Manitoba Hydro is heavily engaged in both Federal level and Provincial level committees that work to establish ongoing updates to minimum energy performance standards for technologies and to determine the appropriateness of their adoption into a code or a regulation."

The national commitment to update the 1997 National Energy Code for Buildings (NECB) was initiated in Manitoba by the Energy Code Advisory Committee which was led by Manitoba Hydro. Manitoba Hydro also chaired the national Building Energy Code Collaborative, which was formed in response to the recommendations provided by the Energy Code Advisory Committee. Manitoba was instrumental in getting jurisdictions across Canada to undertake the work to update the 1997 NECB. The Province still moved forward with its own energy strategy and, in January 2011, the energy efficiency amendments developed for the Manitoba building code were approved by the Building Standards Board of Manitoba and the Minister of Labour. Manitoba Hydro Power Smart staff contributed to the process of adopting specific amendments for Manitoba and staff continues to contribute to the national process for the development of the 2015 edition of the NECB.

Manitoba Hydro's influence on codes and standards is shown in the following example from the *2014-2017 Power Smart Plan:*

> *Effective December 1st, 2010, Manitoba implemented changes to the building and plumbing codes that increased energy and water efficiencies. These changes were the result of extensive consultations by the Office of the Fire Commissioner involving new homebuilders, contractors and technical experts. The new efficiencies incorporated into new construction and homes undergoing extensive renovations included:*
>
> - *specifying minimum energy-efficiency requirements for windows,*
> - *eliminating the pilot light in gas fireplaces,*
> - *increasing the required level of attic insulation to R50,*
> - *requiring a minimum 94 per cent fuel-efficiency rating for furnaces,*
> - *specifying a mid-efficient heat-recovery ventilator, and*
> - *introducing energy-modeling software that will allow builders to model alternatives to the code requirements.*
> - *Requiring a maximum flow rate for primary showerheads to 1.75 GPM*
>
> *Through its close working relations with key industry stakeholders and the Power Smart New Home Program offering, Manitoba Hydro succeeded in advancing these changes to the Manitoba Building code. In fact, a majority of the technologies adopted by the Manitoba Building Code for the December 1, 2010 update were part of the aforementioned Power Smart Gold Home standard requirements. Without the program*

> *providing information, education, training, and incentives for these technologies and building practices, the industry would have been less likely to adopt these technologies and transform the market. The program created demand for these technologies, provided builders an opportunity to gain experience using them, and provided trades and contractors training opportunities to advance their expertise and knowledge of the technologies.*

Manitoba Hydro prepares an annual forecast of the expected influence of currently implemented regulated and nonregulated codes and standards; the forecast is used to adjust Manitoba Hydro's system load forecast. The full savings are counted toward the utility's savings goals without any estimation of attribution.

Attribution Permitted: No Approach Specified

Utility interest in claiming C&S energy savings is increasing and the initial framework necessary to claim savings is emerging in various jurisdictions. Cadmus identified two states that permit attribution, but that have not yet defined exactly how savings are credited.

New Jersey

In May 2018, New Jersey's Act Concerning Clean Energy (Clean Energy Act), Bill A-3723, was signed into law. The act, effective immediately, requires utilities to establish energy efficiency and peak demand reduction programs to be approved by the Board of Public Utilities (BPU). Load reduction targets vary by gas and electric public utilities (The Senate and General Assembly of the State of New Jersey 2018). Gas utilities will be required to achieve, within five years of program implementation, reductions of at least 0.75% of the average annual usage in the prior three years; electric utilities must achieve reductions of at least 2% under the same scenario (Day Pitney Alert 2018).

Within one year of the Clean Energy Act, the BPU must adopt performance indicators for each public gas and electric utility to "establish reasonably achievable targets for energy usage reductions and peak demand reductions and take into account the public utility's energy efficiency measures and other non-utility energy efficiency measures including measures to support the development and implementation of building code changes, appliance efficiency standards, the Clean Energy program, any other State-sponsored energy efficiency or peak reduction programs, and public utility energy efficiency programs that exist on the date of enactment of P.L.2018, c.17 (C.48:3-87.8 et al.)."

To achieve the targets established by the board, the Clean Energy Act permits utilities to "apply all energy savings attributable to programs available to its customers, including demand side management programs, other measures implemented by the public utility, non-utility programs, including those available under energy efficiency programs in existence on the date of enactment of P.L.2018, c.17 (C.48:3-87.8 et al.), building codes, and other efficiency standards in effect, to achieve the targets established in this section."

It is unclear at this time how savings will be attributed to codes and standards programs.

Currently, the BPU is also administering New Jersey's Clean Energy Program, a statewide program that offers energy efficiency programs, incentives, and services. The BPU does not count energy code savings in its savings reporting except for the incremental amount above current code, determined by the Protocols to Measure Resource Savings (State of New Jersey Board of Public Utilities 2018). According to correspondence with a senior policy advisor from BPU, the gas and electric utilities with programs supplementary to the New Jersey's Clean Energy Program account for energy savings in the same manner (Cadmus September 27, 2018).

Minnesota

In 2007, Minnesota passed the Next Generation Energy Act with a goal of reducing emissions by 80 percent by 2050. The policy allows utilities to claim savings credit for building codes and appliance standards toward the annual energy savings target (State of Minnesota 2017).

Excerpt from the Next Generation Energy Act of 2007:

> ***Sec. 4. [216B.2401] ENERGY CONSERVATION POLICY GOAL.***
>
> *It is the energy policy of the state of Minnesota to achieve annual energy savings equal to 1.5 percent of annual retail energy sales of electricity and natural gas directly through energy conservation improvement programs and rate design, and indirectly through energy codes and appliance standards, programs designed to transform the market or change consumer behavior, energy savings resulting from efficiency improvements to the utility infrastructure and system, and other efforts to promote energy efficiency and energy conservation.*

Minnesota's electricity and natural gas utilities administer the Conservation Improvement Program ([CIP]; Minnesota Department of Commerce 2018). Historically, CIP program policies did not allow programs to claim savings for code efforts; however, "numerous developments within the last several years have suggested that CIP-funded programs that increase code compliance could be given credit for energy savings in Minnesota" (Center for Energy and Environment 2018).

In March 2018, the Center for Energy and Environment (CEE) provided the Minnesota Department of Commerce, Division of Energy Resources (DER) with a summary of opportunities for CIP-funded code compliance programs and recommendations for an approach to estimating savings for code efforts.

CEE recommended that energy savings for code programs be based on a third-party impact evaluation but did not provide a detailed approach. However, CEE proposed guidelines to "meet the need for utilities to have confidence in the ability to claim savings while also providing a degree of rigor in the savings quantification process." These guidelines include the following:

- "Utilities should be encouraged to file for cost-effective code-compliance programs, and to work collaboratively with the DER and other utilities to come up with an appropriate evaluation plan in their filing.

- During program implementation, the evaluation should be carried out by a third party. Evaluation contractors could either be directly contracted by DER with program funds provided by the utility, or at least have the evaluation firm credentials approved by DER.
- Utilities should be encouraged to work together to jointly implement programs that would be evaluated together as well. In addition to having the benefit of being able to be more easily evaluated, it would also be a more efficient use of ratepayer dollars.
- During program development, each individual utility (or ideally, a group of utilities) is responsible for contracting directly with a DER approved evaluation firm to develop the evaluation plan, in a form that will provide for competitive bidding of the implementation evaluation. The integration of savings evaluation planning into the program development process is meant to provide utilities with a degree of confidence that a proposed program will be able to count an appropriate level of savings.
- DER approval of evaluation firms should be based on minimum standards for experience with program evaluations and with energy code compliance programs, and be a third party (i.e. a firm cannot evaluate a program it is delivering). Certain, reasonable limits on claiming savings could also be established by DER through the TRM [Technical Resource Manual] (e.g. a limit of 30% of savings compared to the previous code for general education only programs). As precedents for specific types of compliance programs are established through individual program approvals, the TRM can be updated with guidance for future, similar programs."

According to correspondence with a MEEA policy manager, the state has not yet acted on CEE's recommendations.

No Savings: Codes Considered Non-Resource

Most utilities, PAs, and regulators do not treat building energy codes as a reliable energy efficiency resource. Consequently, PA programs supporting code adoption and compliance enhancement are referred to as non-resource programs, and the PAs do not claim savings from them. Further, many states throughout the U.S. do not have an energy efficiency resource standard (EERS), or a quantitative, long-term energy savings target for utilities (American Council for an Energy-Efficient Economy 2018); states without an EERS are likely not claiming savings. The following section provides a high-level overview of the non-resource efforts in the U.S. by region and identifies states that have an EERS.[11]

C&S Non-Resource Efforts by Region

Cadmus corresponded with representatives from each of the regional energy efficiency organizations, shown in Figure 7, to better understand utility and PA code activities.

---

[11] All information on state Energy Efficiency Resource Standards is from the American Council for an Energy-Efficiency Economy EERS database.

Source: Building Codes Assistance Project

Northeast

Massachusetts, Rhode Island, New York, and Washington D.C. are leading the attribution efforts in the Northeast. The Northeast Energy Efficiency Partnerships (NEEP) actively works to help educate utilities and PAs on attribution approaches. In its 2017 *Building Energy Codes for a Carbon Constrained Era: A Toolkit of Strategies and Examples,* NEEP recommends strategies to advance energy code development and adoption and to improve energy code administration to ensure performance levels are achieved. One such recommendation is to allow PAs to claim savings for compliance support activities. NEEP is also working on an exemplar of Massachusetts attribution efforts (Cadmus September 14, 2018).

National Grid, whose service territory spans Massachusetts, New York, and Rhode Island, is also a champion of attribution for code programs and has developed many resources for utilities and PAs to consider when looking to claim savings for code programs. Among those is the recent 2018 American Council for an Energy-Efficient Economy (ACEEE) paper, *Polishing a Hidden Gem: A Novel Evaluation Method for Energy Codes & Standards Programs* (Na'aim et al. 2018).

Every state in the Northeast has an EERS, although the EERS in Delaware is voluntary.[12] Many utilities and PAs also provide some form of support or funding for energy code education; however, with the exception of the Northeast states highlighted throughout this report, the efforts are considered non-resource. According to an interview with a NEEP senior policy manager, New Jersey Natural Gas provides robust energy code training; Vermont utilities support C&S through Efficiency Vermont; and New Hampshire utilities support energy code training by providing funding to NHSaves. Vermont and New Hampshire, described in greater detail below, have the most defined non-resource C&S efforts in the Northeast.

Vermont

Efficiency Vermont's (EVT's) 2018-2020 Triennial Plan (Vermont Energy Investment Corporation 2017) outlines the services and activities necessary to achieve the goals of the Vermont General Assembly's 2008 Energy Efficiency and Affordability Act and the 2016 Comprehensive Energy Plan (Efficiency Vermont 2018). Under the 2018-2020 plan, Efficiency Vermont will provide energy code training, market partner support, and technical assistance; distribute code materials; support energy code updates; and provide code assistance to various agencies, committees, and customers.

EVT has offered code support services for many years as part of its development and support services. According to the plan, "these efforts continued to be essential to Efficiency Vermont's efforts to deepen energy savings and to have a lasting, positive impact on Vermont households, businesses, institutions, and communities." EVT's 2017 savings claim summary does not indicate that EVT received credit for savings associated with the development and support services (Efficiency Vermont 2017). According to NEEP's *2013 Attributing Building Energy Code Savings to Energy Efficiency Programs* report: "the [Department of Public Safety] and [EVT] have had a long history of explorations of the concept of claiming energy savings from code support. Neither organization has found it necessary or worthwhile to endeavor to evaluate and assign savings for this activity" (Cadmus et al. 2013).

New Hampshire

New Hampshire's energy efficiency programs and policies are administered by NHSaves, a program jointly operated by New Hampshire utilities with oversight from the New Hampshire Public Utilities Commission. In 2016, the commission approved Order Number 25,932, establishing an EERS. In response to the EERS, NHSaves submitted the 2018-2020 New Hampshire Statewide Energy Efficiency Plan (New Hampshire's Electric and Natural Gas Utilities 2018).

The 2018-2020 plan details the "comprehensive customer outreach and education" New Hampshire utilities offer in support of energy codes. These activities include offering classroom and in-field training courses and disseminating educational materials to builders, inspectors, installers, contractors, real estate professionals, auditors, and Home Energy Rating System raters. The educational programs are

---

[12] Northeast states include Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, Vermont, and Washington D.C.

intended to "raise awareness of the benefits of energy-efficient products, homes, and businesses and establish a foundation for a more positive customer experience." No energy savings are attributed to PAs for these programs.

Southeast

The Southeast has made perhaps the least progress implementing utility C&S programs. According to a phone interview with a senior staff from the Southeast Energy Efficiency Alliance, utilities in the Southeast do not typically have a large role in the code adoption process and, while there has been some limited funding provided by utilities to support training, there are no utility energy code enhancement programs either (and as such, no utilities are claiming savings) (Cadmus September 17, 2018).

Two states in the Southeast, Arkansas and North Carolina, have an EERS. Virginia also has an EERS, but energy savings targets are considered voluntary since there are currently no regulatory requirements in place for energy efficiency programs. There is no EERS in Alabama, Florida, Georgia, Kentucky, Louisiana, Mississippi, South Carolina, or Tennessee.

Midwest

While no attribution approaches have been finalized in the Midwest, Illinois and Minnesota are moving toward claiming savings for code support efforts. Cadmus interviewed a senior policy manager at MEEA who reinforced that while many utilities and state agencies support some level of code training or education, none are currently claiming savings (Cadmus September 13, 2018).

Five states in the Midwest have an EERS: Illinois, Iowa, Michigan, Minnesota, and Ohio. Missouri and Kentucky have a voluntary EERS and the remaining states (Indiana, Kansas, Nebraska, North Dakota, South Dakota, West Virginia, and Wisconsin) do not have an EERS.

Missouri and Iowa, as described below, have included recommendations for code programs or initiatives in their energy efficiency plans. It is unclear if the utilities will seek attribution.

Missouri

Ameren Missouri's 2019-24 Missouri Energy Efficiency Investment Act plan proposes an "aggressive expansion of the portfolio," and includes six new education programs. One of these programs, the Home Building Code Compliance Education Program, is designed to provide energy code training and education to builders and other market actors "focused on high-energy impact measures that are commonly missed in residential code compliance." While the draft plan is publicly available, the appendices, which include draft program evaluation plans, are not (Ameren Missouri 2018).

Iowa

The 2016 Iowa Energy Plan, developed by the Inova Energy Group for the Iowa Economic Development Authority and the Iowa Department of Transportation, recommends the Department of Public Safety "work with local jurisdictions, utilities and other energy stakeholders to identify sources for long-term monetary support and resources for ongoing energy code education and training of local inspectors." It also cites the attribution efforts in Illinois as a way to claim savings for compliance enhancement as part of their programs (Inova Energy Group 2016).

South-Central

Oklahoma and Texas are the two South Central states that are supported by SPEER, the South-central Partnership for Energy Efficiency as a Resource. As stated on the organization's website, SPEER's purpose is "to advance the understanding and adoption of energy efficiency as a low-cost energy resource." SPEER currently administers an Energy Code Compliance Program that supports compliance by providing energy code training, outreach, and peer support to building professionals and code officials in Oklahoma and Texas. Savings from the program are not currently being claimed.

Texas was the first state to adopt an EERS in 1999; Oklahoma does not have an EERS.

Southwest

Arizona's deemed savings attribution approach has been the Southwest's flagship for claiming energy savings. Cadmus corresponded with the Southwest Energy Efficiency Partnership's (SWEEP's) buildings efficiency program director on the status of attribution in the Southwest. SWEEP confirmed that Arizona is the only state claiming savings for codes although each state, except Wyoming, has an EERS.

Utilities in Nevada, Colorado, and Utah currently provide funding for code trainings, although savings for these efforts are not being claimed. In 2018, according to its website, the Nevada Governor's Office of Energy, NVEnergy, and Southwest Gas have collaborated to fund energy code training. Efforts in Colorado and Utah are described in greater detail in the following sections.

Colorado

Since 2011, Colorado's Strategic Compliance Plan has served as the framework for energy code adoption and compliance throughout the state. The plan outlines strategic outreach and training efforts, including the role utilities and state departments play in the funding and implementation of such programs (Colorado Department of Local Affairs 2011).

According to Colorado Energy Office's website, Colorado has two IOU electric utilities, Black Hills Energy and the Public Service Company of Colorado (also known as Xcel Energy), regulated by the Public Utilities Commission. Through the State of Colorado's proceeding number 16A-0512EG, Xcel Energy agreed to co-fund energy code training in 2017 and 2018 with other stakeholders. Xcel Energy included the training in its 2017 DSM Annual Report, but no savings were claimed (Xcel Energy 2018). Energy code training is offered by other utilities and organizations as well, such as Garfield Clean Energy and Clean Energy Economy for the Region. The Colorado Energy Office also offers code training and technical assistance, as cited in ACEEE's State and Local Policy database. No attribution efforts are currently underway for code or standard support from these organizations either.

According to Colorado's Strategic Compliance Plan: "As a fellow home rule state that does not have a statewide mandatory energy code, Arizona's work to incorporate energy code implementation efforts into its energy efficiency targets offers a model for Colorado to consider."

Utah

Utah's 10-Year Strategic Energy Plan, published first in 2011, includes a recommendation for a statewide energy consumption reduction program with an energy code training component "supported through partnerships with Rocky Mountain Power and Questar [Dominion Energy] in conjunction with utility DSM programs" (Utah Office of Energy Development 2014).

In support of the plan, per the Utah Governor's Office of Energy Development's (OED's) website, OED has partnered with Rocky Mountain Power and Dominion Energy to offer the Building Talks Program. The Building Talks Program provides residential and commercial energy code training to builders, design professionals, code officials, and other building professionals, as well as other energy code resources. While there is little available information about the Building Talks program, a reference to the program is included in OED's 2018 budget (FY2018 Base Budget Presentation); Rocky Mountain Power has included energy code training as part of its 2017 portfolio level expenditures (Rocky Mountain Power 2018); and Dominion Energy lists "State Energy Program (SEP) Codes Training" in its 2018 budget notes (Dominion Energy 2017). SWEEP indicated that neither Rocky Mountain Power nor Dominion Energy are claiming savings for training efforts and this was confirmed through correspondence with the Managing Director of Energy Efficiency and Renewable Energy: "Presently, no savings are being claimed from this effort. It has been an ongoing discussion and the utilities are interested in the prospect of attribution, but it would require a [Public Service Commission] decision (and potentially state legislation)" (Cadmus October 1, 2018).

Northwest

The code support efforts of the Northwestern states are described in detail in the Pacific Northwest (Idaho, Montana, Oregon, and Washington) section above. Two of the four states, Washington and Oregon, have an EERS; Idaho and Montana do not have savings targets.

Hawaii

The State of Hawaii has committed to an aggressive clean energy goal of 100% by 2045. Under contract with the Hawaii Public Utilities Commission, Hawaii Energy acts as a PA and offers a suite of energy efficiency programs aimed at helping the state achieve its Energy Efficiency Portfolio Standards goal of a 4,300 GWh reduction by 2030 (Hawaii Energy 2018). A key feature of Hawaii Energy's 2018 Annual Plan is "advocacy and outreach support for advanced building energy codes and standards." C&S support is included as part of Hawaii Energy's Market Transformation Program "to drive energy savings in both public and private sectors" through adoption support at the county-level, code compliance improvement, and standards advocacy.

Since 2014, Hawaii Energy has participated in State Building Code Council monthly meetings, completed several code compliance studies, developed and distributed educational materials, offered circuit rider trainings, provided written and oral testimony in support of the 2015 IECC, created (and currently chairs) the State Building Code Council, Energy Efficiency Code Coordination Investigative Committee, advocated for county-level code adoption, and advocated for enhanced appliance standards through legislation.

To understand the savings associated with a more stringent energy code, Hawaii's Department of Business, Economic Development, and Tourism commissioned an energy impact forecast, completed in 2016, for the 2015 IECC with Hawaii amendments (Cadmus 2016). The savings forecast was used, in part, to inform a review "on behalf of the Public Utilities Commission to try to understand opportunities for energy savings from codes and standards activities in Hawaii, and what role the Hawaii Energy programs might be able to play in achieving these savings" (Mitchell-Jackson et al. 2016).

Hawaii Energy's team has since developed a logic model that "will guide how the Program will measure and propose energy savings attributable towards [its] resource acquisition goals." The team is actively researching attribution approaches that may be applied to their program (Cadmus, Hawaii Energy September 27, 2018).

Appliance Standards Policy Results by Jurisdiction

Summary of Findings

Table 3 provides a high-level overview of the role PAs play in appliance standards in several jurisdictions, including whether PAs support standards adoption, whether they support efforts to increase compliance with standards, and how savings are or are not attributed to PAs for their appliance standards activities.

Table 3. Summary of Appliance Standards Results

Jurisdiction	Status	Activity for Adopting Standards?	Activity for Compliance Enhancement?	Program Administrator Attribution Method
Formal Attribution Approach				
California	Program and attribution process in place more than 10 years	✓	✓	Evaluation using evidentiary record, expert panel; focused on adoption only
Pacific Northwest (ID/OR/MT/WA)	NEEA program in place for several years; attribution analyzed in recent years	✓		Attribution determined for energy efficiency advocates using evidentiary record and expert panel or evaluator
Massachusetts	Program in discussion	Proposed, likely in 2019		To be developed; likely to follow approach similar to codes
Rhode Island	Program likely following Massachusetts implementation	Likely		To be developed; likely to follow approach similar to codes
Arizona—SRP	Savings credited to program for several years	✓		Used deemed approach; method is being revised to analyze attribution
Deemed Attribution Approach				
Arizona—IOUs	Savings credited to program for several years	✓		Attribution limited to one-third of savings; evaluation required, but no information available
Full Savings Without Determining Attribution				
New York	Program supports adoption	✓		Counted without attribution
New Jersey	Program accounts for standards			No information available on attribution
Illinois	Utilities required to account for standards			None

Jurisdiction	Status	Activity for Adopting Standards?	Activity for Compliance Enhancement?	Program Administrator Attribution Method
Minnesota	Utilities can claim savings from standards			No information available
Hawaii	Hawaii Energy provides support	✓		No information available
Ontario	Standards subtracted from forecast load			No attribution
Manitoba	Utility supports appliance standards	✓		No analysis of attribution
No Attribution				
Vermont	State adopted new standards			No attribution

Evidence, such as the results of evaluations of California IOUs' C&S program, suggests that appliance standards offer a very large potential for energy savings, likely more than the savings possible through energy code upgrades and building code compliance enhancement efforts. Consequently, appliance standards could be a largely untapped resource from which PAs could harvest energy savings through efforts supporting standard adoption.

Activities to adopt standards at the state level have ramped up in recent years, while the process of adopting standards at the federal level has slowed. A recent study by the Appliance Standards Awareness Project (ASAP) and ACEEE identified a large number of standards that could be adopted by states, and some states have moved ahead to adopt some of these standards (Mauer et al. 2017). Much of the information in this section was provided through an interview with a representative of ASAP (Cadmus September 18, 2018).

The same study notes that most states have to adopt standards through legislation, so any effort by PAs to influence standard adoption would have to be directed at the legislative process. This policy issue could require PAs to take on an unaccustomed role and could be an obstacle to some advocating for appliance standards. California is one major exception to standards being adopted through legislation because the California Energy Commission has the authority to adopt state appliance standards (as well as building codes). This has made it more feasible for PAs in California to engage in efforts to support appliance standards and get energy savings credit.

Given the relatively recent state activities adopting standards and the usual process of requiring adoption through legislation, PA involvement has been modest to date, and processes for attributing savings credit to PAs have been limited.

Formal Attribution Approach

Overall, fewer jurisdictions attribute energy savings from standards than building energy codes, although there has been some increase in the number of jurisdictions that do so in recent years. In 2014, Cadmus found that only California had a process for attributing savings to appliance standards; since then four additional jurisdictions have conducted formal attribution analyses or are likely to initiate formal attribution processes. The following sections detail how each state is claiming savings for their standard adoption support or compliance enhancement programs.

California

In California, the IOUs have received energy savings credit for appliance standards supported through their C&S program based on an approach essentially the same as that described earlier for building codes. In addition to savings credit for California standards, the IOUs can get credit for adoption of federal standards they have supported. In most cases, federal standards are adopted through the U.S. Department of Energy's procedures, but some federal standards are adopted legislatively. The attribution process for federal standards has been tailored to account for the unique features of the federal adoption process.

To date, the IOUs have not claimed savings for efforts to improve compliance with appliance standards. Their most recent program includes efforts to increase compliance with standards, so it is likely they will want to claim savings credit for increased compliance at some point, and this will trigger development of a method to assess attribution.

Pacific Northwest (Idaho, Montana, Oregon, Washington)

Just since 2012, NEEA and other Pacific Northwest parties have been involved significantly in the adoption of 20 federal appliance standards (State of Oregon 2018). According to recent estimates from NEEA's quarterly performance report, appliance standards contribute 28% of regional electricity savings, more than any other regional energy efficiency investment (NEEA 2018).

NEEA has supported recent studies to assess the effectiveness of NEEA's standard advocacy efforts and the influence of NEEA and other organizations on energy savings from adoption of various standards. NEEA has not specified a standardized methodology for calculating attribution, but the basic approach starts with data collection through a literature review and interviews with knowledgeable stakeholders. The evaluators then assess NEEA's effectiveness in the adoption process by identifying how well it accomplished each step in its standard development logic model. Calculation of attribution to the efforts of energy efficiency advocates then follows an approach like that used for the evaluation of California IOUs' C&S program described earlier. It relies on estimating the relative significance of barriers to standard adoption and the relative influence of different stakeholders in overcoming those barriers (Cadmus June 2016; Cadmus 2018). The attribution assessment has been done in evaluations so far by either an expert panel or the evaluator.

Massachusetts and Rhode Island

Although PAs have not implemented appliance standard support programs yet in either Massachusetts or Rhode Island, we anticipate that they will in the near future. ASAP has been working with stakeholders in both states for almost 10 years, and both have adopted state standards over that period (Cadmus September 18, 2018). PAs in Massachusetts have put forth preliminary specifications for an appliance standard advocacy program, which are being considered in the policy making process. National Grid is a leader of these efforts in Massachusetts and, as the only IOU in Rhode Island, we anticipate it will make a similar push there because appliance standards development and advocacy are one step in its overall C&S initiative.

Given that the programs are undefined, the approach for evaluating attribution has not been developed yet in either state. However, given the precedence in the building codes area, Cadmus expects that the regulators in both states will pursue formal attribution approaches similar to the approaches applied to the building code support programs.

Arizona—SRP

SRP's Appliance and Equipment Standards program is designed to increase awareness of and advocate for more robust efficiency standards at the national, state, and local levels. SRP has claimed energy savings from its efforts influencing the statewide adoption of a minimum efficiency standard for pool pumps effective January 1, 2012. The legislated standard applies to pool pumps of one horsepower and larger and requires pumps that can operate at a minimum of two speeds. SRP takes credit for energy savings attributable to its advocacy work, contributing to Arizona's change in standards from single-speed pumps to two-speed pool pumps.

The savings credited to the standard interact with savings SRP claims for its pool pump incentive program. SRP provides incentives for variable speed pool pumps, which are more efficient than the two-speed pumps required by the standard. SRP claims 50% of the savings for a two-speed pump compared to a single-speed pump, and attributes those savings to its standards program.

SRP's initial approach was to set attribution at the 50% level. For the next program evaluation, Cadmus understands that SRP will use a process like the one used to determine attribution for the codes program to reassess the reasonableness of this attribution factor.

Deemed Attribution Approach

Arizona—IOUs

As for building codes, the Arizona IOUs have claimed savings for appliance standards under the ACC regulations. TEP's Energy Codes and Standards Enhancement Program is designed to improve compliance with current energy codes and standards and support the adoption of newer codes and standards (TEP 2017). APS' Building Codes and Appliance Standards Initiative offers compliance enhancement support to code officials, building professionals, and other market actors (APS 2017).

The regulation allows the IOUs to claim up to one-third of the savings from appliance standards as quantified through a measurement and evaluation study conducted by the utility. The regulation does not say the IOUs can claim electricity savings from appliance standards so there is some ambiguity about whether they are claiming the savings for credit toward their savings targets. The IOUs have not allocated budgets to evaluate savings either so there is uncertainty about whether or how they are claiming savings from standards.

Full Savings without Determining Attribution or Attribution Permitted without Approach Specified

Given the status of appliance standards advocacy by PAs in most states, the most common situation is that savings from standards are included in savings and load forecasts, but attribution is not estimated, or the estimation method has not been defined yet. Several jurisdictions in this situation are described briefly below.

New York

The Systems Benefit Charge program administered by NYSERDA includes the Advanced Energy Codes and Standards Program. One component of this program has been contributing to the development of appliance and equipment standards, specifically those not covered by federal standards (NYSERDA 2013). Savings from standards are accounted for, but no effort has been made to determine attribution.

In his 2018 State of State address, Governor Cuomo directed NYSERDA to propose new 2025 energy efficiency targets by Earth Day, April 22. Appliance standards were one key component of the targets, but they have not been implemented to date.

New Jersey

In 2018, New Jersey's Clean Energy Act, Bill A-3723, required utilities to establish energy efficiency and peak demand reduction programs to be approved by the BPU. The BPU is required to adopt performance indicators for each utility to establish reasonably achievable targets for energy usage reductions and peak demand reductions, taking into account appliance efficiency standards.

The act permits utilities to apply all energy savings attributable to programs available to its customers, as well as energy efficiency standards. However, there has been no information to date about how savings will be attributed to codes and standards programs.

Illinois

Illinois' FEJA requires utilities to include proposals for C&S programs and utility procurement plans must include an analysis of the impact of energy efficiency appliance standards, both current and projected, as well as opportunities to expand the programs.

In response to these requirements, Illinois utilities have joined together for a potential statewide code compliance enhancement program. However, they have not taken similar steps yet to address appliance standards and no information is available yet on how they might determine savings and attribution.

Minnesota

The Minnesota Next Generation Energy Act allows utilities to claim savings credit for appliance standards toward the annual energy savings target. No information is available yet on the process for estimating savings or attribution (State of Minnesota 2017).

Hawaii

In addition to its building codes activities, Hawaii Energy provides advocacy and outreach support for advanced standards. One role of the Department of Business, Economic Development, and Tourism's 2016 energy impact forecast was to understand opportunities for energy savings from standards activities in Hawaii, and what role the Hawaii Energy programs might play in achieving these savings. Hawaii Energy's team has since developed a logic model to guide its standards and codes activities (Mitchell-Jackson et al. 2016).

In the standards area, one strategy Hawaii Energy is implementing is requiring efficiency levels above current codes and standards (Hawaii Energy 2018). Hawaii Energy is also increasing strategic efforts advocating for minimum product standards for electric appliances brought to Hawaii. Hawaii Energy will partner with other agencies to understand the market dynamics of appliances shipped to Hawaii, their shelf life, and the impact California's appliance standards may have on Hawaii in the absence of Hawaii standards. While Hawaii has not adopted any state standards, the Standards Enhancement target for program year 2018 is the implementation of three engagements to advance legislation for Hawaii to explore and adopt state appliance efficiency standards. A bill was developed to adopt California standards, but it did not pass this year.

How savings and attribution will be addressed for appliance standards has not been determined.

Ontario

As for codes, savings from forecast appliance standards are subtracted from the gross reference load forecast. There is no information indicating LDCs engage in activities to support and standards, and no attempt is made to assess attribution.

Manitoba

As it does for building codes, Manitoba Hydro engages in activities to support appliance standards. Forecast savings are counted toward the utility's savings goals without any analysis of attribution.

No Savings: Standards Considered Non-Resource or No Program

Vermont

In 2016, Vermont passed a law (House Bill H.410) adopting 16 new state appliance standards (Granda 2018). The adopted standards are the complete set of standards recommended by ASAP. The state also adopted all existing federal standards into law to avoid the possibility of a rollback at the federal level.

Like efforts supporting building energy codes, we found no evidence that EVT or any other entity in Vermont would claim savings from the standards.

Other States

There are activities in several states supporting the adoption of appliance standards that have not involved PAs. These include the following:

- Connecticut: standards can be adopted administratively
- Oregon: an executive order has been issued for the state to develop a plan to adopt new standards
- Washington: a bill was proposed in 2018 to adopt 19 new standards, but it has not passed

Findings

This report provides a review of how various jurisdictions in North America attribute or determine the share of energy savings to credit to program administrators for their efforts supporting codes and standards. To provide a broader context, we also documented the status of PA involvement in codes and standards in jurisdictions where there is no process for crediting savings to the PAs' efforts.

Our key findings from this study are presented below:

Energy savings from building codes and appliance standards affect load forecasts and utility revenue requirements. Load forecasts based on econometric models capture the effect of existing codes and standards and can be adjusted to account for new codes and standards. Similarly, end-use load forecasts can adjust estimates of end-use loads to account for existing or new codes and standards. Load forecasts and utility revenue requirements can be adjusted to account for adopted codes and standards that have known effective dates. The savings from codes and standards are applied, along with estimated energy-efficiency program savings, to the energy forecast estimates based on underlying load growth to produce the net load growth estimate. The savings from new codes and standards can be a significant fraction of the total energy-efficiency savings.

The relationship between programs to support codes and standards and other DSM programs is complex. Most PAs and regulators recognize that adoption of more stringent building codes and appliance standards by policy makers make it more difficult for conventional DSM programs to produce energy savings. This has motivated several PAs to seek ways to explicitly support the adoption of codes and standards and enhance compliance with them, and some of these PAs have sought to claim energy savings attributable to their efforts. Some PAs have suggested that conventional DSM programs ready the market for the adoption of new codes and standards and that these DSM programs should receive indirect energy savings credit for allowing these codes and standards to be adopted sooner than they would otherwise be. This argument is similar to the logic underlying the BC DSM regulation issued in 2008. Another approach that has been considered is increasing the amount of codes and standards savings attributed to the PA because prior PA programs helped ready the market for adoption of the subsequent codes and standards. None of the jurisdictions that Cadmus investigated outside BC have instituted a policy or process for measuring and attributing such savings, possibly because of the complexities involved.

***While attribution continues to be a topic of interest among utilities, PAs in most states and jurisdictions do not claim savings for their C&S efforts*.** Some PAs that do not claim attribution for C&S savings do fund code enhancement programs or otherwise provide C&S support that result in energy savings that are reflected in their net load forecasts and revenue estimates.

No standardized attribution method exists, but most methods have some common features. Attribution approaches for C&S programs implemented by PAs range from no attribution to attribution based on a rigorous, formal analytic process. There is a trend toward formalized approaches, especially in cases where PAs are engaged in well-defined code or standard programs and they have specific energy savings goals to meet. The most common features of the formal approaches include basing attribution on a documented evidentiary record of influence and relying on the professional judgment of objective experts or evaluators to assess attribution, usually through a Delphi panel process.

The number of jurisdictions attributing energy code savings has increased. Six jurisdictions have formal processes for attributing savings to building code activities. This is a three-fold increase since 2014. PA efforts in these areas include both code adoption and code compliance support. Formal attribution processes are split about equally between code adoption and code compliance enhancement efforts. The number of jurisdictions with deemed attribution approaches has remained at three, though the jurisdictions have changed.

Number of jurisdictions attributing appliance standard savings has increased, but there are still relatively few that do. Counting the Pacific Northwest as a single jurisdiction, five jurisdictions have, or are expected to have soon, a formal or deemed process for attributing energy savings to standards activities by PAs. PA standard support activities have focused almost exclusively on adoption rather than compliance.

Standards advocacy offers opportunities for significant energy savings if barriers can be overcome. While the number of PAs advocating for appliance standards and the number of jurisdictions allowing PAs to receive energy savings credit for these efforts has been small to date, experience indicates that appliance standards may offer the potential for larger energy savings opportunities than new building codes or improved code compliance. PAs have been slower to get involved with appliance standards for several reasons including PAs are less familiar with appliance standards and the common mechanism of adopting standards legislatively is a political process in which PAs are reluctant to get involved. Identifying and overcoming these barriers could open more opportunities for PAs to support appliance standards.

Energy Studies Process Audit F2019

AUDIT TYPE	AUDIT RATING
RISK BASED AUDIT	G

Legend:

Minor issues and impacts identified

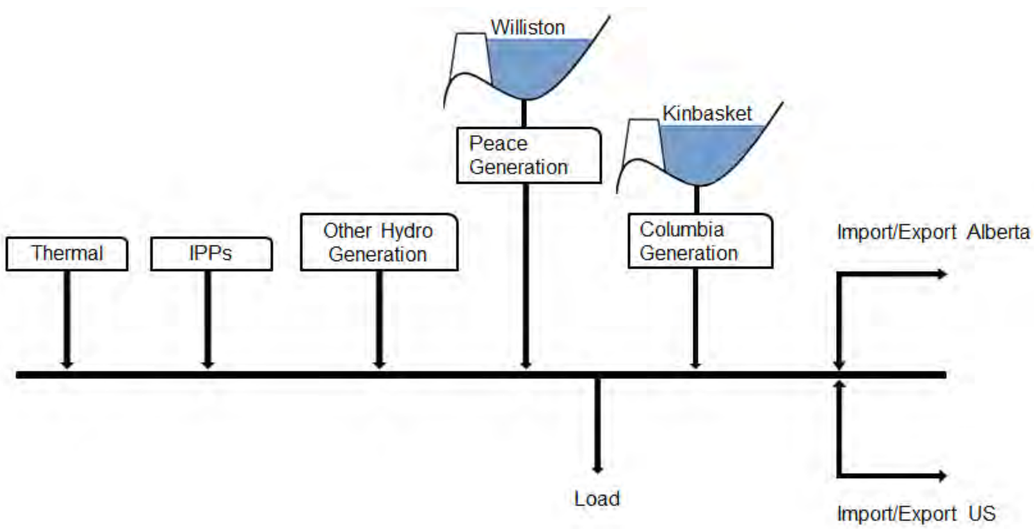
Critical issues and impacts identified

Audit Objective

- To evaluate whether the monthly Energy Studies process reliably supports operations, financial and strategic planning at BC Hydro.
- This audit was conducted in conformance with the International Standards for the Professional Practice of Internal Auditing.

Background

- BC Hydro's primary source of seasonal and multi-year operational flexibility is the Kinbasket reservoir on the Columbia River and Williston reservoir on the Peace River. Together, the total storage in these reservoirs is approximately 90% of the total storage capability in the system.
- Hydropower generation from these plants on the Peace and Columbia is coordinated with the remainder of the BC Hydro Generating Stations, generation from independent power producers, and other energy sources to meet regional demand. Exchange with neighbouring power markets in Canada and the US are taken into account in the coordination. An illustration is provided in the figure below.



- BC Hydro's objective for system coordination is to maximize risk neutral long-term net revenue from operations. Water should be valued to provide strategies for when to use and when to store water in the reservoirs. Without good strategies, non-optimal system states could occur over time where:
  - Reservoirs are full and more inflow will lead to spillage.
  - Reservoir levels are critically low, resulting in import at high prices or curtailment of demand.
- Operational strategies can be found by applying mathematical models to compute the marginal value of water for different points in the future.

Energy Studies Process Audit F2019

- If the marginal value of water is above market price at a given time, the best decision is to store water for generation at a later time. If the marginal value is below market price then the water is used for generation.
- To compute accurate water values, the long-term scheduling models should reflect both the dynamics and constraints that affect operational flexibility, and the uncertainties that impact future reservoir operation (such as inflows and market prices).

- BC Hydro produces an Energy Study every month. The primary objective is to forecast, over a five year horizon, an optimal set of reservoir and generating station operations and market transactions under current forecasts of market, inflow, and weather conditions.
- The Energy Study process consists of numerous proprietary models which are developed and maintained by a specialized team in Generation System Operations. Some key models have been reviewed externally over the last 20 years as part of continuous improvement efforts.
- Audit Services engaged SINTEF Energy Research as subject matter experts to review the Energy Studies process and selected key models. SINTEF has more than 40 years of experience in developing models for planning and operation of hydrothermal power systems.

Key Findings

Summary

- BC Hydro has a well-established Energy Studies process in place. Governance is effective with adequate level of oversight, and responsibilities are well understood across the team.
- Key models developed are appropriate and the methodologies applied are in line with leading industry practices. The Energy Study process can be further automated to reduce cycle time and free up resources.
- Energy Study reports are prepared on time; however they do not serve short-term operational planning needs.

Governance

- Effective management oversight is in place. Energy Studies results are reported monthly to key user groups at BC Hydro and Powerex, and quarterly to the Operations and Planning Committee of the Board. During the interim, weekly meetings are also held with management to review and discuss results and related variances.
- High level strategies and objectives exist to guide the group. BC Hydro has developed in-house models for long-term scheduling. These models are built to maximize risk neutral long-term net revenue. The strategy to develop custom models is appropriate due to the complexity of the Columbia River Treaty.
- Team structure, roles, and responsibilities are clearly defined. Succession planning is in place. The System Optimization team is part of the Operations Planning group within Generation System Operations. The team is comprised of four specialized engineers with backgrounds in various disciplines such as system design, hydro-technical, and water resources.
- The Energy Studies financial policy is outdated and requires updating. The policy defines approval levels for domestic buy and sell prices, but some details are outdated such as titles and positions.

Energy Studies Process Audit F2019

Energy Studies Process

Models and methodologies for long-term scheduling of hydropower-dominated systems have been widely used in the industry for the last 50 years. Countries such as Brazil, Canada, Norway, Sweden, New Zealand and Iceland all have traditions for using mathematical models for finding the long-term optimal use of water in their hydropower-dominated systems.

- Methodologies applied to optimize the two major river systems (Columbia and Peace) separately and then coordinated are appropriate and reasonable. The Energy Study cycle time could be improved as it currently takes approximately three weeks to complete. Further automation would provide more updated prices and free up labour resources.
- Key models are developed using standard development tools and programming languages. Source codes are tracked and retained in a version control system. While most key models can accommodate changes in the system, the Peace model is less flexible as it is based on legacy software codes. Management is working on a replacement solution.
  - Developer documentation for the models should be enhanced to ensure model maintenance, quality review, and knowledge transfer.
- Inputs and assumptions used in the various models are generally reasonable. Model inputs are primarily comprised of load forecast, temperature, water inflows, market prices, outages, and electricity purchase agreements. Changes in assumptions are discussed amongst the team, logged via version control, and communicated externally.
- Comprehensive process is in place to review the Energy Study results. This includes weekly discussions within Generation System Operations and with Powerex, and monthly comparisons to previous results.
- No regular backtesting is performed in the current process. Typically, calculated marginal prices would be compared with market prices to assess model performance. Given there are no market prices for the BC Hydro system, this would not be possible. However, actual reservoir operations could be compared with model simulation.

Outputs

- Monthly Energy Study Report is distributed timely to key users in Finance, Generation System Operations, Powerex, and BC Hydro.
- Although water values for the short-term horizon are computed from the Energy Study process, some users indicated the information provided does not always serve short-term operational needs.
  - The Operations Planning group often relies on a less sophisticated model to aid with short-term system planning as information provided from the Energy Studies may not represent the current state of the system due to outdated inputs.

Management Comments and Action Plans

- Management agrees with the recommendations in the audit report and will take actions to address them. Two recommendations will be completed by March 31, 2019. The remaining recommendations will be reviewed by June 30, 2019 as part of an overall Energy Study model development strategy.

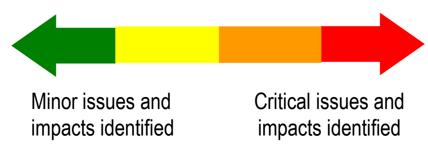
Energy Studies Process Audit F2019

CONTENTS

Legend:



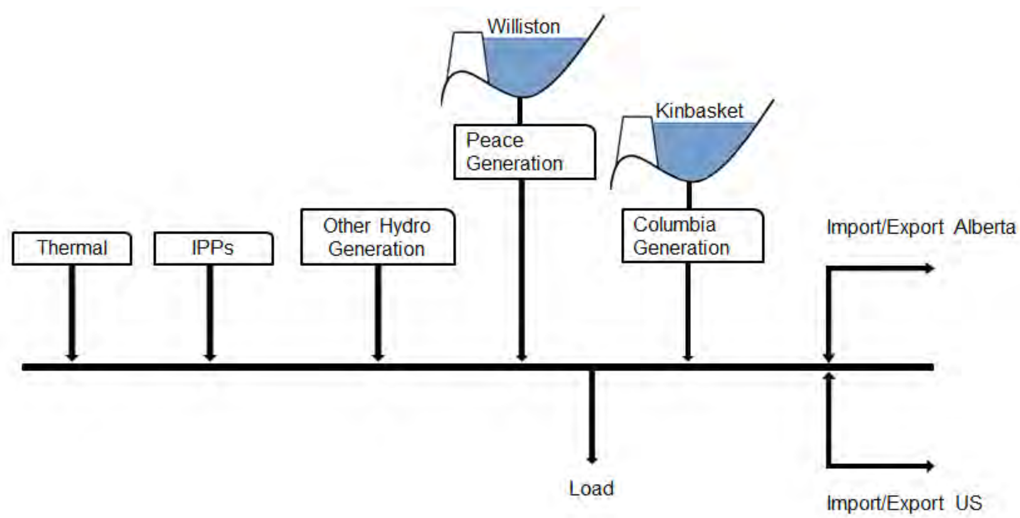
Energy Studies Process Audit F2019

1a. Executive Summary

- For each audit, Audit Services provides two separate Audit Reports. The first report is a Summary Audit Report prepared for Senior Management and the Audit & Finance Committee (AFC) of the Board. This Management Audit Report provides additional information and related audit recommendations for management purposes and will not be presented to the AFC.
- Management should also refer to the Summary Audit Report for high level conclusions and findings.

1b. Background

- BC Hydro's primary source of seasonal and multi-year operational flexibility is the Kinbasket reservoir on the Columbia River and Williston reservoir on the Peace River. Together, the total storage in these reservoirs is approximately 90% of the total storage capability in the system.
- Hydropower generation from these plants on the Peace and Columbia is coordinated with the remainder of the BC Hydro Generating Stations, generation from independent power producers, and other energy sources to meet regional demand. Exchange with neighbouring power markets in Canada and the US are taken into account in the coordination. An illustration is provided in the figure below.



- BC Hydro's objective for system coordination is to maximize risk neutral long-term net revenue from operations. Water should be valued to provide strategies for when to use and when to store water in the reservoirs. Without good strategies, non-optimal system states could occur over time where:
  - Reservoirs are full and more inflow will lead to spillage.
  - Reservoir levels are critically low resulting in import at high prices or curtailment of demand.
- Operational strategies can be found by applying mathematical models to compute the marginal value of water for different points in the future.

Energy Studies Process Audit F2019

  - If the marginal value of water is above market price at a given time, the best decision is to store water for generation at a later time. If the marginal value is below market price then the water is used for generation.
  - To compute accurate water values, the long-term scheduling models should reflect both the dynamics and constraints that affect operational flexibility, and the uncertainties that impact future reservoir operation (such as inflows and market prices).
- BC Hydro produces an Energy Study every month. The primary objective is to forecast, over a five year horizon, an optimal set of reservoir and generating station operations and market transactions under current forecasts of market, inflow and weather conditions.
- The Energy Study process consists of numerous proprietary models which are developed and maintained by a specialized team in Generation System Operations. Some key models have been reviewed externally over the last 20 years as part of continuous improvement efforts.
- Audit Services engaged SINTEF Energy Research as subject matter experts to review the Energy Studies process and selected key models. SINTEF has more than 40 years of experience in developing models for planning and operation of hydrothermal power systems.

1c. Audit Objective and Scope

Objective

- Evaluates whether the monthly Energy Studies process reliably supports operations, financial and strategic planning at BC Hydro.

Scope

- The Audit primarily focuses on the following areas:
  - **Governance** – strategies, objectives, roles and responsibilities
  - **Energy Studies process** – models, inputs, assumptions, validation, change management, data management, documentation
  - **Outputs / Reporting** – review and approval, timeliness, user expectations
- This audit was conducted in conformance with the International Standards for the Professional Practice of Internal Auditing.
- The audit team was supplemented by two subject matter experts from SINTEF:
  - Birger Mo is a senior research scientist at SINTEF since 1987, working with load forecasting, risk management, hydro scheduling and hydrothermal market modelling. He obtained his PhD in 1991 in Engineering Cybernetics from the Norwegian University of Science and Technology. He participated in previous BC Hydro reviews and consulting work related to the Peace model (1998) and Columbia modelling and coordination (1999 and 2008).
  - Arild Helseth is a research scientist at SINTEF since 2008, working with development and analyses related to hydrothermal market models and medium-term hydropower scheduling models. He obtained his PhD from the Norwegian University of Science and Technology, Department of Electric Power Engineering, in 2008.

Energy Studies Process Audit F2019

1d. Findings, Recommendations and Management Action Plans

Summary

BC Hydro has a well-established Energy Studies process in place. Governance is effective with appropriate level of oversight, and responsibilities and accountabilities are well understood across the team.

Key models developed are appropriate and the methodologies applied are in line with leading industry practices. The Energy Studies process can be further automated to reduce cycle time and free up resources.

Energy Study reports are prepared on time and contain an appropriate level of detail; however they do not serve short-term operational planning needs.

Governance

Overall Conclusion

Effective governance is in place over the Energy Studies process. High-level strategies and objectives are set up for the team. Responsibilities and accountabilities are well understood across the team.

Key Conclusions and Findings

- Adequate level of management oversight is in place. Energy Study results are reported monthly to the Executive VP, Operations, key user groups at BC Hydro and Powerex, and quarterly to the Operations and Planning Committee of the Board. Weekly meetings are also held with management to review and discuss results and related variances.
- High level strategies and objectives exist to guide the group. BC Hydro has developed in-house models for long-term hydrothermal scheduling. These models are built to maximize risk neutral long-term net revenue. Strategy to develop in house models is appropriate because of the complexity of the Columbia River Treaty.
    - An annual Generation System Operations (GSO) business plan identifies objectives, metrics, and major activities for all the groups within GSO. At the activity level, each group has a monthly action plan tracker to track monthly progress on specific action items.
- Team structure, responsibilities and accountabilities are clearly defined and well understood. The System Optimization team is part of the Operations Planning group within GSO. The team is comprised of four specialized engineers with backgrounds in various disciplines such as system design, hydro-technical, and water resources.
    - Two team members rotate each month to run the Energy Studies process, while the other two members are tasked with model development, ad-hoc enquiries and other team priorities.
- Succession planning is in place and formally documented. Most of the 85 models involved in the Energy Studies process are documented in the Model Inventory, and have been assigned a primary and a secondary owner. The secondary owner maintains the assigned model when the primary modeller is not available, and also reviews the model for any coding errors.

Energy Studies Process Audit F2019

- A secondary owner has not yet been identified for COSTA (Columbia River Treaty Simulator) and CODA (Domestic allocation optimizer). Discussions with the team indicated that this succession gap can be remediated quickly.

- The Energy Studies financial policy is outdated and requires updating. The current policy defines approval levels for domestic buy and sells prices when there is a threshold change from the last approved price. This policy however needs to be reviewed and updated as it was last edited in March 2011, and some details are outdated such as titles and positions.

	Recommendations	Management Action Plans
	Governance	
1	Continue working on the succession matrix to find a secondary owner for COSTA and CODA models.	Management will formalize the succession matrix by March 31, 2019.
2	Review and update Energy Studies financial approval policy.	Management will review and re-publish the policy by March 31, 2019.

Energy Studies Process

Overall Conclusion

The Energy Studies suite of models is appropriate and the methodologies applied are in line with leading practices. Models have been developed using standard development tools and programming languages. Continuous enhancements have been made to the key models over the last decade particularly in the optimization for the Columbia River.

Key areas for improvement include process automation, upgrading legacy software coding for the Peace River model, refining documentation, and periodically backtesting to gain more insights into model performance.

Key Conclusions and Findings

Overview

- Models and methodologies for long-term scheduling of hydropower-dominated systems have been widely used in the industry for the last 50 years. Countries such as Brazil, Canada, Norway, Sweden, New Zealand and Iceland all have rich traditions for using mathematical models for finding the long-term optimal use of water in their hydropower-dominated systems.

Methodology and Approach

- Methodologies applied to optimize the two major river systems (Columbia and Peace) separately and then coordinated are appropriate and reasonable. BC Hydro currently uses internationally recognized methodologies (SDP for Peace and SSDP for Columbia) for calculating water values.
  - SDP (Stochastic Dynamic Programming) method is the oldest and traditionally most applied. In this method the expected future profit as function of the state variables (i.e. reservoir levels, inflows) are calculated and stored for discrete values.

Energy Studies Process Audit F2019

- SSDP (Stochastic Sampling Dynamic Programming) method calculates the future profit for each specific scenario assuming that decisions are taken with respect to all possible future scenarios. SSDP is particularly well suited to deal with stochasticity (uncertainties in input parameters) represented by historical observations and scenario dependent constraints.
- SDDP (Stochastic Dual Dynamic Programming) would allow optimization of the two rivers in one unified model instead of maintaining and coordinating two models. However, there is no straightforward solution to include all Columbia (state and scenario dependent) constraints in the SDDP approach. Consequently, BC Hydro's current decoupling method seems reasonable.

- The Energy Study cycle time could be improved as it currently takes approximately three weeks to complete. Presently, there are many manual components and synchronizing points which slow down the process. Further automation would provide more frequent basin price updates and free up labour resources.

Key Models

- The Market Model methodology is appropriate for forecasting future electricity spot prices. Market Model is an econometric (regression) model that provides forecasts for future electricity spot prices for the electricity market in the US that BC Hydro can sell to or buy from as function of important drivers.
  - The Market Model was last reviewed externally in 2005. The basic methodology behind the model has been more or less unchanged for many years, but model code was rewritten as part of the Comet Improvement Project implemented in 2016. Model parameters are updated yearly based on the availability of new observations.
  - Econometric models are statistical models which in their simplest form can be a linear regression between observed gas price and electricity prices based on historical prices.
- The methodology used to schedule the Peace River system is reasonable. The Peace model was implemented over 30 years ago and has been extensively tested through years of operational use. The team has reported limited familiarity with the legacy code used in the Peace model. Management is working on a replacement solution with updated coding.
  - The current model does not incorporate a snow state variable which could result in underestimating probabilities for prolonged wet or dry periods when computing water values.
  - Peace Model is an optimization model where the Williston reservoir level and the Henry Hub gas price are treated as state variables. The model uses historical inflow sequences (from 1973) to represent uncertainty in inflow, assuming that each inflow scenario is equally likely to happen in the future.
    - Optimization is a mathematical model where the optimal decision is determined according to a defined objective function and subject to a set of constraints.
- The methodology used to schedule the Columbia River system (COSTA and MUREO) is appropriate and considered best practice. However, given the complexities of the Columbia River system and the River Treaty, more effort should be put into verifying the results of the implemented models. Verification could be done by benchmarking against a second model which the team is currently developing with a university research group.
  - COSTA is the new Columbia River Treaty simulator designed to implement the complex rules of the Columbia River Treaty. Results are used as constraints in downstream models to optimize and simulate the operation of Kinbasket and Arrow reservoirs.

Energy Studies Process Audit F2019

- A simulation is a computer based imitation of the physical operation of the system.
- MUREO is the new optimization model for the Columbia system and uses the outputs from COSTA. The main results from MUREO are an optimal strategy for operation of the major reservoirs in the Columbia system.

- SOPHOS is a rule-based system simulator and is appropriate; however the formulation could be more generalized. Parts of the simulator could be based on optimization and would make it more adaptable to changes in the BC Hydro system and applicable to other reservoirs.
  - The loading of generation plants as well as marginal prices would come as direct results of optimization.
  - SOPHOS prepares input data to the Columbia and Peace optimizers, then simulates system operation based on the water values and recommended plant discharges obtained from those optimizers.

Models Development

- Key models are developed using standard development tools and programming languages such as Java, Fortran, and AMPL. Source codes are tracked and retained in version control. While most of the key models are responsive to accommodate changes in the system, the Peace model is less flexible and based on legacy codes as discussed previously.
- User guides and developer documentation are available for most of the key models reviewed, however improvements are required. Developer documentation for the Peace model is missing and the updated developer documentation for MUREO, COSTA and SOPHOS are not self-explanatory.
  - Comprehensive and clear developer documentation is critical to ensure model maintenance, quality review, and knowledge transfer to other developers within the team.

Inputs and Assumptions

- Inputs and assumptions used in the various models are generally reasonable. Model inputs primarily comprised of load forecast, temperature, water inflows, market prices, outages, and electricity purchase agreements. Changes in assumptions are discussed amongst the team, logged via version control, and communicated externally.
  - Input data has been stored in a version control system since 2009.
  - Interviews indicated that timing of the load forecast and level of details provided could be enhanced for the purposes of improving the Energy Studies process.
- One area of improvement relates to price inputs into the Market Model. Considerations should be given to incorporate the California market prices into the Market Model to obtain better water values. Main inputs to the Market Model include forward market prices for gas at Henry Hub and forward prices for electricity at Mid-C.
  - The forecasted power prices for the different US markets such as California are a significant factor for the calculated BC Hydro marginal prices, and decisions on import/export and generation.

Validation & Backtesting

- Comprehensive process is in place to review the Energy Study results. The review process comprises of weekly discussions within GSO and with Powerex, monthly comparisons to previous results, and a simplified short-term model (Ultralight model).

Energy Studies Process Audit F2019

- No regular backtesting (or benchmarking) is performed in the current process. Typically, calculated marginal prices would be compared with market prices to assess model performance. Given there are no market prices for the BC Hydro system, this would not be possible. However, actual reservoir operation could be compared to model simulations.
  - Backtesting could be easier to perform if the process is further automated as discussed previously.

	Recommendations	Management Action Plans
	Energy Studies Process	
3	**Methodology/Approach** - Identify opportunities to further automate the manual components of the Energy Studies process.	- Management will develop an Energy Study model development strategy by June 30 2019 that will address the priority and timing of actions to be taken relating to recommendations #3 to #11. - Management will review the existing process, identify areas to automate and create an implementation plan.
4	**Key Models** - Finalize a replacement solution for the Peace Model (with code from MUREO). - Consider including a state variable for snow in the optimization methodology used for the Peace River.	- Management will review the status of the Peace optimization and decide whether to replace the existing model.
5	**Key Models** - Benchmark the Columbia River optimization models with results obtained by a second model (such as the current university research project).	- Management will review options for benchmarking the Columbia River optimization models.
6	**Key Models** - Consider generalizing the SOPHOS simulator and adding a daily optimizer.	- Management will review options for generalizing SOPHOS.
7	**Model Development** - Improve developer documentation for the key models. Documentation should be stand-alone, and contains sufficient level of details. - Provides description of each model's key properties, its underlying assumptions, and what is actually being modelled.	- Management will review current developer documentation and update documentation standards.

Energy Studies Process Audit F2019

	Recommendations	Management Action Plans
8	**Inputs and Assumptions** ❑ Consider adding California pricing to the Market Model to obtain better water values.	❑ Management will initiate a policy review of the use of California pricing in the Energy Studies.
9	❑ Continue working with the Load Forecast group on timing of the load forecast and level of details provided.	❑ Management will initiate a review of how the load forecast is operationalized.
10	**Validation & Backtesting** ❑ Investigate options for periodic benchmarking or backtesting of key model results.	❑ Management will review options for benchmarking and backtesting of key model results.

Outputs

Overall Conclusion

Energy Study Reports are prepared on time and results are communicated to Management on a regular basis; however the results do not provide sufficiently strong signals for short-term operational planning purposes as reports are only released once a month.

Key Conclusions and Findings

- Monthly Energy Study Report is distributed timely to key users with narratives to explain material variances. Board updates on Energy Studies results are also produced on a quarterly basis. The Report is widely distributed to key stakeholders in Finance, Generation System Operations, Powerex, and BC Hydro. Each monthly package contains the following:
  - Operational Risk Summary provides status of key system components and constraints risks.
  - Briefing Note provides summary and detailed analysis on key drivers, loads, system operation, market activity and outcomes of the monthly energy study report. Provides final recommendation on Domestic Threshold Buy / Sell Price based on Energy Study Report.
  - Detailed report on current month forecast, previous month forecast, and latest Board Approved forecast.
- Although water values for the short-term horizon are computed from the Energy Study (ES) process, some users indicated the information provided does not always serve short-term operational needs. The Operations Planning group often relies on a less sophisticated model ("Ultralight model") to seek basin price information for short-term system planning.
  - The results from the Ultralight model are compared against those from the ES models. Interviews revealed that the water values from the Ultralight model often deviate from those obtained by the ES models. Decisions are made through discussions with management and expert assessment.
  - Although the Ultralight model can provide water values within a day, it is not as sophisticated as the ES models.

Energy Studies Process Audit F2019

- Ultralight uses Excel which is a less flexible development environment and does not facilitate a computationally efficient solution process. As well, the implementation and working principle of this model is only known by one person who will be retiring within the year.
- The Ultralight model uses an alternative approach instead of formal optimization which is used in key models within the Energy Studies Process. This approach can speed up the problem solving process, however finding an optimal solution is not guaranteed.

- Using different models with different planning horizons in a hierarchy is common in other hydro dominated systems like Scandinavia and Brazil. However, it appears the Ultralight model is an alternative parallel model that is easier to run, rather than a model for refining the long-terms signals (i.e. water values) from the Energy Study models.

	Recommendations	Management Action Plans
	Outputs	
11	❑ Review the use of the Energy Study results for short-term operational purposes. ❑ Evaluate the Ultralight model, both in terms of its role in scheduling hierarchy, methodology and implementation. ❑ Consider building a more robust operational model for shorter term planning with more formal coupling with the Energy Studies models.	❑ Management will review the process for shorter term modelling.

Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Appendix EE

Tariff Sheets

Table of Contents

List of Tables

Section 1 of this appendix describes how the requested rate increase in this Application will be applied to the default tiered rates for BC Hydro's residential and transmission service rate classes in accordance with previously approved Commission pricing principles. The default rates for the other rate classes do not have specific approved pricing principles applicable to them and they have been determined by increasing each component of the rate by the requested rate increase.

BC Hydro's OATT rates are the subject of Chapter 9 of the Fiscal 2020 to Fiscal 2021 Revenue Requirements Application (**RRA**) and are not explained in this appendix. Appendix EE provides black-lined and clean copies of the tariff pages with the proposed rates that will be applicable on April 1, 2019.

Section 2 contains the fiscal 2020 rates which are requested to be effective April 1, 2019 on an interim and refundable basis. Table EE-1 of this appendix sets out the rates that will be applicable to each of the Rate Schedules in each rate class for fiscal 2020 and fiscal 2021 and compares them to the fiscal 2019 rates, which were on a final basis as per Commission Order No. G-47-18.

1 Application of Rate Increases

1.1 Residential Rates

1.1.1 Rate Schedules (RS) 1101, 1121 – Residential Service

Rate Schedule 1101 is the Residential Inclining Block (**RIB**) rate, which is the default Residential rate. Rate Schedule 1121 is the RIB rate for Multiple Residential Service. The RIB rate structure is a two-step inclining block rate with the first step called the Step-1 energy rate and the amount above that the Step-2 energy rate. The RIB rate was implemented on October 1, 2008.

On September 24, 2015, BC Hydro filed its 2015 Rate Design Application which requested approval of 'pricing principles' for fiscal 2017 to fiscal 2019 for the RIB rate and that would be effective April 1, 2016. The term “pricing principles” refers to how the revenue requirement rate increases, which are set by the Commission through BC Hydro’s Revenue Requirements Applications, are applied to each of the RIB rate’s pricing elements.

BC Hydro’s proposed RIB Pricing Principles for Rate Schedules 1101 and Rate Schedules 1121 for fiscal 2017 to fiscal 2019 were to uniformly increase the three pricing elements of the RIB rate by the amount of the approved rate increases. These pricing principles were approved by Directive 1 of Commission Order No. G-5-17.

On October 4, 2018, BC Hydro applied to extend these pricing principles to March 31, 2020. The Commission approved the extension of the existing RIB rate pricing principles for fiscal 2020 by Commission Order No. G-214-18.

BC Hydro uses the approved pricing principles to derive the RIB rates shown in Table EE-1 below. As the pricing principles for fiscal 2021 have not yet been determined and will be the subject of a future rate design application prior to the end of fiscal 2021, the current pricing principles have been applied to that year.

To derive fiscal 2020 RIB rates, each of the three components of the RIB rate (Step-1 energy rate, Step-2 energy rate and Basic Charge) are increased by the proposed rate increase of 6.85 per cent. The same approach has been used to derive the fiscal 2021 RIB rates, using the proposed rate increase of 0.72 per cent. The fiscal 2020 rates are requested to apply on an interim basis and if the Commission approves a different rate increase than BC Hydro is applying for in fiscal 2020, BC Hydro will reflect this in final fiscal 2020 rates.

1.2 Transmission Service Rates

1.2.1 Rate Schedule (RS) 1823 – Transmission Service – Stepped Rate

BC Hydro applied for approval of Rate Schedule 1823 Stepped Rate pricing principles for the period fiscal 2017 to fiscal 2019 in its 2015 Rate Design Application. These pricing principles were approved by Directive 9 of Commission Order No. G-5-17.

Under the pricing principles, for fiscal 2017, the Tier 2 rate is set to the lower end of BC Hydro's long run marginal cost of energy and the Tier 1 rate is set to reflect the 4.0 per cent fiscal 2017 rate increase according to the bill neutrality approach i.e., 90 per cent of the Tier 1 rate plus 10 per cent of the Tier 2 rate is equal to the flat rate (Rate Schedule 1827 energy rate or the Rate Schedule 1823 Energy Charge A). Thereafter, in fiscal 2018 and fiscal 2019, the applicable rate increases are applied equally to both Tier 1 and Tier 2 energy rates as per the Commission Order.

On February 15, 2019, BC Hydro applied to extend the current fiscal 2018 and fiscal 2019 RS 1823 Stepped Rate approved pricing principles to the end of fiscal 2021.

The fiscal 2020 Transmission Service stepped rates in Table EE-1 are based on the assumption that the Commission approves BC Hydro's application to extend the pricing principles to the end of fiscal 2021. Therefore, the proposed fiscal 2020 rate increase of 6.85 per cent is applied equally to the RS 1823 Tier 1 energy rate and the Tier 2 energy rate and the same approach has been used to derive the fiscal 2021 rates, using the proposed rate increase of 0.72 per cent.

Other pricing elements (demand charge, energy rate applicable to Rate Schedule 1823 customers that do not have a Customer Baseline Load and monthly minimum charge) will increase by the same applicable RRA rate increase.

2 Summary of Fiscal 2020 and Fiscal 2021 Rates

Table EE-1 provides the rates in each BC Hydro rate schedule for fiscal 2020 and fiscal 2021 and a comparison to the fiscal 2019 rates which are approved on a final basis as per Commission Order No. G-47-18.

Table EE-1 Fiscal 2019 and Fiscal 2020 Rates

Rate Class	Rate Schedule	Rate	F2019 Approved	F2020 Rate Increase 6.85%	F2021 Rate Increase 0.72%
Residential	1101 / 1121	Basic Charge ($/day)	0.1956	0.2090	0.2105
		Step-1 energy rate ($/kWh)	0.0884	0.0945	0.0952
		Step-2 energy rate ($/kWh)	0.1326	0.1417	0.1427
Residential	1105 (closed)[1]	Energy rate ($/kWh)	0.0636	0.0713	0.0790
Residential Zone II	1107 / 1127	Basic Charge ($/day)	0.2086	0.2229	0.2245
		Step-1 energy rate ($/kWh)	0.1059	0.1132	0.1140
		Step-2 energy rate ($/kWh)	0.1820	0.1945	0.1959
Residential	1148 (closed)	Basic Charge ($/day)	0.2086	0.2229	0.2245
		Energy rate $/kWh	0.1059	0.1132	0.1140
Residential	1151 / 1161	Basic Charge ($/day)	0.2086	0.2229	0.2245
		Energy rate $/kWh	0.1059	0.1132	0.1140

[1] For the test period, the proposed rate increases are applied according to the residential E-Plus phase-out design, as approved by BCUC Order No. G-194-17. As such, the rate increases as shown in this table do not directly reflect the applied for rate increases in this application.

Rate Class	Rate Schedule	Rate	F2019 Approved	F2020 Rate Increase 6.85%	F2021 Rate Increase 0.72%
Exempt General Service	1200 / 1201 / 1210 / 1211	Basic Charge ($/day)	0.2502	0.2673	0.2692
		Demand rate - Step-1 ($/kW)	0	0	0
		Demand rate - Step-2 ($/kW)	6.10	6.52	6.57
		Demand rate - Step-3 ($/kW)	11.69	12.49	12.58
		Energy Rate - Tier 1 ($/kWh)	0.1190	0.1272	0.1281
		Energy Rate - Tier 2 ($/kWh)	0.0572	0.0611	0.0615
General Service	1205 / 1206 / 1207 (closed)	Energy Rate - Tier 1 ($/kWh)	0.0579	0.0619	0.0623
		Energy Rate - Tier 2 ($/kWh)	0.0379	0.0405	0.0408
		Energy rate during period of interruption ($/kWh)	0.3367	0.3598	0.3624
Small General Service Zone II	1234	Basic Charge ($/day)	0.2502	0.2673	0,2692
		Energy Rate - Tier 1 ($/kWh)	0.1190	0.1272	0.1281
		Energy Rate - Tier 2 ($/kWh)	0.1981	0.2117	0.2132
Distribution Service	1253	Monthly Minimum energy charge($/month)	45.87	49.01	49.36
Large General Service Zone II	1255 / 1256 / 1265 / 1266	Basic Charge ($/day)	0.2502	0.2673	0.2692
		Energy Rate - Tier 1 ($/kWh)	0.1190	0.1272	0.1281
		Energy Rate - Tier 2 ($/kWh)	0.1981	0.2117	0.2132
Distribution Service	1268	Energy charge ($/kWh)	0.00184	0.00197	0.00198

Rate Class	Rate Schedule	Rate	F2019 Approved	F2020 Rate Increase 6.85%	F2021 Rate Increase 0.72%
Shore Power Service (Distribution)	1280	Administrative Charge ($/month)	150.00	150.00	150.00
		Energy Rate ($/kWh)	0.09836	0.10510	0.10585
Net Metering Service	1289	Energy Rate $/kWh	0.0999	0.0999	0.0999

1. RESIDENTIAL SERVICE

RATE SCHEDULES 1101, 1121 – RESIDENTIAL SERVICE

Availability	For Residential Service. Service is normally single phase, 60 hertz at the Secondary Voltage available. In BC Hydro's discretion, Service may be three phase 120/208 or 240 volts.
Applicable in	Rate Zone I.
Rate	1. Rate Schedule 1101 – Residential Service: **Basic Charge:** 20.90 ¢ per day plus **Energy Charge:** (a) For Customers billed monthly: Step 1: First 675 kWh per month@ 9.45 ¢/kWh Step 2: Additional kWh per month@ 14.17 ¢/kWh (b) For Customers billed bi-monthly: Step 1: First 1350 kWh per two months@ 9.45 ¢/kWh Step 2: Additional kWh per two months@ 14.17 ¢/kWh Note: For billing purposes, Step 1 is pro-rated on a daily basis. **Minimum Charge:** The Basic Charge

	2. Rate Schedule 1121 – Multiple Residential Service: **Basic Charge:** 20.90 ¢ per Dwelling per day plus **Energy Charge:** Per Dwelling (a) For Customers billed monthly: Step 1: First 675 kWh. per month@ 9.45 ¢/kWh Step 2: Additional kWh per month@ 14.17 ¢/kWh (b) For Customers billed bi-monthly: Step 1: First 1350 kWh per two months@ 9.45 ¢/kWh Step 2: Additional kWh per two months@ 14.17 ¢/kWh Note: For billing purposes, Step 1 is pro-rated on a daily basis. **Minimum Charge:** The Basic Charge per Dwelling
Discount for Ownership of Transformers	A discount of 25 ¢ per month per kW of Maximum Demand will be applied to amounts owing under Rate Schedule 1121 if the Customer supplies Transformation. BC Hydro will install Metering Equipment with both Demand and Energy measurement capability at the Secondary Voltage.
Special Conditions	1. The maximum capacity of all heating elements energized at any one time in all water heaters at the Premises served under these Rate Schedules must not exceed the greater of 1,500 watts and 45 watts per litre (200 watts per imperial gallon) of tank capacity, except with BC Hydro's advance written permission. 2. Rate Schedule 1121 applies if the Premises contains more than two Dwellings.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under these Rate Schedules, before taxes and levies.

1. RESIDENTIAL SERVICE

RATE SCHEDULE 1105 – RESIDENTIAL SERVICE – DUAL FUEL (CLOSED)

Availability	For residential space heating and water heating. Electricity purchased under this Rate Schedule will be separately metered. Service is single phase, 60 hertz, at 120/240 or 240 volts. This Rate Schedule is available only for Premises served under this Rate Schedule on January 15, 1990 and continuously thereafter and only in Premises where there has been no change in Customer since April 1, 2008.
Applicable in	Rate Zone I in areas where and when, in BC Hydro's opinion, BC Hydro's transmission, sub-transmission and distribution circuit feeders are or will be capable of handling the load.
Rate	**Energy Charge:** 7.13 ¢ per kWh
Special Conditions	1. Service under this Rate Schedule is not available to any Premises where Service was previously supplied and Terminated. 2. BC Hydro will upgrade an existing Service Connection supplying firm load to serve additional load in accordance with the Electric Tariff, however, no new or additional load is permitted under this Rate Schedule at any time. All unauthorized consumption of Electricity as estimated by BC Hydro will be billed at the rate for Electricity on the appropriate default Residential Service Rate Schedule. 3. The maximum capacity of all heating elements energized at any one time in all water heaters at the Premises served under this Rate Schedule must not exceed the greater of 1,500 watts and 45 watts per litre (200 watts per imperial gallon) of tank capacity, except with BC Hydro's advance written permission.

Rate Increase	Effective April 1, 2019 the rates under this Rate Schedule include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

1. RESIDENTIAL SERVICE

RATE SCHEDULES 1151, 1161 – EXEMPT RESIDENTIAL SERVICE

Availability	For Residential Service and uses exempted from Rate Schedules 1101 and 1121 (Residential Service), including: 1. Use on farms as set out in the definition of Residential Service in the Terms and Conditions; and 2. Use in Rate Zone IB. Service is normally single phase, 60 hertz at the Secondary Voltage available. In BC Hydro's discretion, Service may be three phase 120/208 or 240 volts.
Applicable in	Rate Zone I and Rate Zone IB.
Rate	1. Rate Schedule 1151 – Residential Service: **Basic Charge:** 22.29 ¢ per day plus **Energy Charge:** 11.32 ¢ per kWh **Minimum Charge:** The Basic Charge 2. Rate Schedule 1161 – Multiple Residential Service: **Basic Charge:** 22.29 ¢ per day per Dwelling per day plus **Energy Charge:** 11.32 ¢ per kWh **Minimum Charge:** The Basic Charge per Dwelling

Discount for Ownership of Transformers	A discount of 25 ¢ per month per kW of Maximum Demand will be applied to amounts owing under Rate Schedule 1161 if the Customer supplies Transformation. BC Hydro will install Metering Equipment with both Demand and Energy measurement capability at the Secondary Voltage.
Special Conditions	The maximum capacity of all heating elements energized at any one time in all water heaters at the Premises served under these Rate Schedules must not exceed the greater of 1,500 watts and 45 watts per litre (200 watts per imperial gallon) of tank capacity, except with BC Hydro's advance written permission.

2. GENERAL SERVICE

RATE SCHEDULES 1200, 1201, 1210, 1211 – EXEMPT GENERAL SERVICE (35 KW AND OVER)

Availability	For Customers who qualify for General Service where supply is 60 hertz, single or three phase at Secondary or Primary Voltage and Billing Demand is 35 kW or more. BC Hydro reserves the right to determine the voltage of the Service Connection.
Applicable in	Rate Zone IB.
Rate	**Basic Charge:** 26.73 ¢ per day plus **Demand Charge:** First 35 kW of Billing Demand per Billing Period @ $0.00 per kW Next 115 kW of Billing Demand per Billing Period @ $6.52 per kW All additional kW of Billing Demand per Billing Period @ $12.49 per kW plus **Energy Charge:** First 14800 kWh of Energy consumption in the Billing Period @ 12.72 ¢ per kWh All additional kWh of Energy consumption in the Billing Period @ 6.11 ¢ per kWh

Discounts	1. A discount of 1½% will be applied to the above charges if a Customer's supply of Electricity is metered at a Primary Voltage. 2. A discount of 25 ¢ per Billing Period per kW of Billing Demand will be applied to the above charges if a Customer supplies Transformation. 3. If a Customer is entitled to both of the above discounts, the discount for metering at a Primary Voltage will be applied first.
Monthly Minimum Charge	50% of the highest Demand Charge billed in any Billing Period wholly within an on-peak period during the immediately preceding 11 Billing Periods. For the purpose of this provision an on-peak period commences on November 1 in any year and terminates on March 31 of the following year.
Rate Schedules	1. Rate Schedule 1200: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and BC Hydro supplies Transformation. 2. Rate Schedule 1201: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and BC Hydro supplies Transformation. 3. Rate Schedule 1210: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and the Customer supplies Transformation. 4. Rate Schedule 1211: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and the Customer supplies Transformation.

Definitions	Billing Demand is the Maximum Demand in the Billing Period, subject to Special Condition No. 1. Billing Period means a month between regular meter readings, provided that in cases where meter readings are not available or are delayed for any reason BC Hydro may vary the number of days in the Billing Period.
Special Conditions	1. Metering Equipment with both Demand and Energy measurement capability will normally be installed. Until such Metering Equipment is installed, or if the installed Metering Equipment does not have Demand measurement capability, Billing Demand will be as estimated by BC Hydro. 2. Migration rule: Customers taking Service under these Rate Schedules will be moved to Service under Rate Schedule 1300, 1301, 1310 or 1311 (Small General Service) if Billing Demand in each of the last 12 consecutive Billing Periods was less than 35 kW.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under these Rate Schedules, before taxes and levies.
Rate Increase	Effective April 1, 2019 the rates under these Rate Schedules include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

2. GENERAL SERVICE

RATE SCHEDULES 1205, 1206, 1207 – GENERAL SERVICE – DUAL FUEL (CLOSED)

Availability	For general space heating, water heating and industrial process heating on an interruptible basis. Electricity purchased under these Rate Schedules will be separately metered. Service is 60 hertz single or three phase at the Secondary or Primary Voltage available. BC Hydro reserves the right to determine the voltage of the Service Connection. These Rate Schedules are available only for Premises served under these Rate Schedules on January 15, 1990 and continuously thereafter, only with respect to equipment served under these Rate Schedules on January 15, 1990 and continuously thereafter, and only in Premises where there has been no change in Customer since April 1, 2008.
Applicable in	Rate Zone I in areas where, in BC Hydro's opinion, BC Hydro's transmission, sub-transmission and distribution circuit feeders are or will be capable of handling the load.
Rate	Except as stated hereunder the rate will be: **Energy Charge:** First 8000 kWh per month @ 6.19 ¢ per kWh All additional kWh per month @ 4.05 ¢ per kWh Exception: If during a Period of Interruption a Customer fails to comply with BC Hydro’s requirement to cease the use of Electricity and BC Hydro, in its sole discretion, continues to supply Electricity, the rate for such Electricity will be: **Energy Charge:** 35.98 ¢ per kWh

ACCEPTED:______________________

ORDER NO.______________________ ______________________
COMMISSION SECRETARY

Period of Interruption	A period during which a Customer is required by BC Hydro to cease the use of Electricity under these Rate Schedules.
Rate Schedules	1. Rate Schedule 1205 – Small Commercial Applications: Applies to a Customer whose interruptible heating load is mostly in support of a commercial activity and whose firm Electricity is billed on a General Service (under 35 kW) Rate Schedule. 2. Rate Schedule 1206 – Large Commercial Applications: Applies to a Customer whose interruptible heating load is mostly in support of a commercial activity and whose firm Electricity is billed on a General Service (35 kW and over) Rate Schedule. 3. Rate Schedule 1207 – Industrial Applications: Applies to a Customer whose interruptible heating load is mostly in support of an industrial activity and whose firm Electricity is billed on a General Service Rate Schedule or for farm use on a Residential Rate Schedule.
Special Conditions	1. BC Hydro may, at any time and from time to time, interrupt the supply of Electricity under these Rate Schedules whenever there is a lack of surplus hydro energy and Service cannot be provided economically from other energy sources.

ACCEPTED:____________________

ORDER NO.____________________

____
COMMISSION SECRETARY

	2. A Customer taking Service under these Rate Schedules is required to have, to BC Hydro's satisfaction, an installed permanent backup heating system using an alternative fuel, or an installed permanent independent electrical generating system, in good working order, and an adequate supply of fuel therefor, so that the Customer can continue heating operations when the supply of Electricity is interrupted. The output rating of the backup system must be of sufficient capacity to supply the heating load served under these Rate Schedules. If at any time a Customer fails to comply with the foregoing requirements, BC Hydro may immediately Terminate the supply of Electricity under these Rate Schedules to such Customer. 3. BC Hydro will interrupt the supply of Electricity by either manual or automatic means or by written notice by registered mail or hand delivery to the Customer to cease the use of Electricity under these Rate Schedules. A Customer who has been given such written notice to cease the use of Electricity under these Rate Schedules will in accordance with the requirements of the notice cease such use and will not begin to use Electricity again until so authorized by BC Hydro, by written notice. If a Customer fails to comply with these requirements, BC Hydro may in its sole discretion: (a) Continue to supply Electricity, in which case the rate will be the rate for Electricity during a Period of Interruption as stated in these Rate Schedules, or (b) Terminate the supply of Electricity under these Rate Schedules.

ACCEPTED:____________________

ORDER NO.____________________

COMMISSION SECRETARY

	4. The initial contract period for dual fuel interruptible Service under these Rate Schedules is: (a) One year where no new facility is required to be constructed or the only facility required to be constructed by BC Hydro to serve the Customer is a drop Service Connection, or (b) Two years where more than a drop Service Connection is required to be constructed by BC Hydro to serve the Customer. At the expiration of a contract period, the contract period is automatically extended from year to year unless either the Customer or BC Hydro gives written notice to the other 30 days prior to the anniversary date. Transfer of the load served under these Rate Schedules to a general firm Rate Schedule will not be permitted during a Period of Interruption. 5. These Rate Schedules are not available to Premises where Electricity under it was previously supplied and Terminated. 6. BC Hydro will upgrade an existing Service Connection supplying firm load to serve additional load under these Rate Schedules. The charge for upgrading will be the same as applicable to a new Service Connection. 7. For existing Customers adding load to take Service under these Rate Schedules, and where an overhead distribution Extension is required to accommodate such added load BC Hydro will contribute toward the estimate cost of the Extension an amount not exceeding two times the annual revenue as estimated by BC Hydro to be received by the applicant. Any excess cost will be contributed by the applicant.

ACCEPTED:______________________

ORDER NO.______________________

____
COMMISSION SECRETARY

8. No other load than that stipulated in the Availability clause is permitted under these Rate Schedules. Any unauthorized use of Electricity or any refusal by a Customer to permit access to Premises in accordance with the Terms and Conditions of BC Hydro's Electric Tariff will result in immediate Termination under the applicable Rate Schedule and all unauthorized consumption as estimated by BC Hydro will be billed at the rate for Electricity during a Period of Interruption as stated in these Rate Schedules.

9. In addition to and without restriction of any other limitations of liability of BC Hydro, BC Hydro will specifically not be liable for any loss, damage, injury or expense occasioned to or suffered by any Customer receiving Service on these Rate Schedules, or by any other Person, for or by reason of any interruption of Electricity supply whatsoever for any reason whatsoever.

10. A Customer who signs a contract with BC Hydro for the supply of Electricity to new load under these Rate Schedules during the period commencing July 1, 1988 and ending December 31, 1988 will be eligible to receive an incentive rebate on his Electricity bills provided the Customer begins taking Service under these Rate Schedules no later than 12 months following the date the contract was signed.

11. A rebate will be applied to reduce the effective rate to 1.1 ¢ per kWh. Such rebate will apply only to an accumulated maximum of $30.00 per kW of connected new load in excess of 35 kW and only up to the first two years following connection. Bills for Energy consumed will be calculated and presented at full rates with the rebate for any given period applied to the following bill. The maximum two year period of billing rebates will be extended by the equivalent of any Period of Interruption. Rebates will not be applied to reduce the rate applicable for consumption during a Period of Interruption, nor will rebates be applied to reduce Power Factor surcharges.

	12. At the conclusion of any Period of Interruption, BC Hydro may Terminate Service under these Rate Schedules to any Customer who used Electricity during a Period of Interruption, unless it can be demonstrated to BC Hydro's satisfaction that adequate standby facilities exist.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under these Rate Schedules, before taxes and levies.
Rate Increase	Effective April 1, 2019 the rates under these Rate Schedules include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

ACCEPTED:

ORDER NO.

COMMISSION SECRETARY

2. GENERAL SERVICE

RATE SCHEDULE 1234 – SMALL GENERAL SERVICE (UNDER 35 KW) – ZONE II

Availability	For all purposes where a meter with Demand measurement capability is not installed because the Customer's Demand as estimated by BC Hydro is less than 35 kW. Supply is 60 hertz, single or three phase at an available Secondary Voltage.
Applicable in	Rate Zone II.
Rate	**Basic Charge:** 26.73 ¢ per day plus **Energy Charge:** First 7000 kWh per month @ 12.72 ¢ per kWh All additional kWh per month @ 21.17 ¢ per kWh **Minimum Charge:** The Basic Charge
Special Conditions	Special Conditions for Unmetered Service: 1. BC Hydro may permit unmetered Service under this Rate Schedule if it can estimate to its satisfaction the Energy used in kilowatt hours over a period of two months based on the connected load and the hours of use. 2. The Customer, if required by BC Hydro, will provide and maintain such controls, including timing devices, as BC Hydro considers necessary, and facilities satisfactory to BC Hydro for the maintenance of such controls. 3. The hours of use per period will be as specified by the Customer or as estimated by BC Hydro, whichever is greater.

ACCEPTED:______________________________

ORDER NO.______________________________

____
COMMISSION SECRETARY

4. The Customer will supply, install and maintain all wiring, fixtures, control devices and equipment, including the controls and devices described in Special Condition No. 2, at the expense of the Customer.

5. All wiring, fixtures, control devices and equipment and the method of installing, operating and maintaining the same are subject to the approval of BC Hydro which approval may be withdrawn by BC Hydro, at any time, at BC Hydro's sole discretion.

6. The Customer will notify BC Hydro immediately of any proposed or actual change in load, load characteristics, or hours of use.

7. BC Hydro may at any time, in its sole discretion, install Metering Equipment, and thereafter bill the Customer on the appropriate Rate Schedule as a metered account.

8. For display signs and signboard lighting, where hours of use are controlled by timing devices, the following turn-on times will apply, unless BC Hydro otherwise agrees in writing:

Period	Turn-on Time
January 1 to January 15:	4:00 p.m.
January 16 to February 28:	4:30 p.m.
March 1 to April 30:	6:30 p.m.
May 1 to August 15:	8:30 p.m.
August 16 to September 30:	6:30 p.m.
October 1 to November 15:	4:30 p.m.
November 16 to December 31:	4:00 p.m.

	9. In all cases, where hours of use of display signs or signboard lighting commence at dusk and are controlled either by timing devices or by photo-electric cells, the following hours of use for a period of two months will be deemed for billing purposes: Dusk to 10 p.m.: 216 hours Dusk to 11 p.m.: 270 hours Dusk to 12 p.m.: 330 hours Dusk to 1 a.m.: 380 hours Dusk to Dawn: 666 hours (All times are Pacific Time.)
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019 the rates under this Rate Schedule include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

2. GENERAL SERVICE

RATE SCHEDULE 1253 – DISTRIBUTION SERVICE – IPP STATION SERVICE

Availability	For Customers who are Independent Power Producers (**IPPs**) served at distribution voltage, on an interruptible basis.
Applicable in	Rate Zone I excluding Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Energy Charge:** The sum, over the billing period, of the hourly Energy consumed multiplied by the entry in the Intercontinental Exchange (**ICE**) Mid Columbia (Mid-C) Peak, and Mid-C Off-Peak weighted average index price as published by the ICE in the ICE Day Ahead Power Price Report that corresponds to the time when consumption occurred, during that hour.
Monthly Minimum Charge	$49.01
Special Conditions	1. BC Hydro agrees to provide Electricity under this Rate Schedule to the extent that it has energy and capacity to do so. 2. BC Hydro may, without notice to the Customer, refuse to supply or terminate the supply of Electricity under this Rate Schedule if at any time BC Hydro does not have sufficient energy or capacity. 3. Prior to taking Electricity under this Rate Schedule, the Customer may be required to obtain approval from BC Hydro. BC Hydro will advise the Customer of the need to obtain approval prior to the taking of Electricity under this Rate Schedule. 4. Electricity taken under this Rate Schedule is to be used solely for maintenance and black-start requirements and will not displace electricity that would normally be generated by the Customer.

ACCEPTED:______________________

ORDER NO.______________________ ______________________
COMMISSION SECRETARY

Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019 the Monthly Minimum Charge under this Rate Schedule includes an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

2. GENERAL SERVICE

RATE SCHEDULES 1255, 1256, 1265, 1266 – GENERAL SERVICE (35 KW AND OVER) – ZONE II

Availability	For all purposes. Supply is 60 hertz, single or three phase at Secondary or Primary Voltage. BC Hydro reserves the right to determine the voltage of the Service Connection.
Applicable in	Rate Zone II.
Rate	**Basic Charge:** 26.73 ¢ per day plus **Energy Charge:** First 200 kWh per kW of Billing Demand per month @ 12.72 ¢ per kWh All additional kWh per month @ 21.17 ¢ per kWh
Discounts	1. A discount of 1½% will be applied to the above charges if a Customer's supply of Electricity is metered at a Primary Voltage. 2. A discount of 25 ¢ per month per kW of Billing Demand will be applied to the above rate if a Customer supplies Transformation. 3. If a Customer is entitled to both of the above discounts the discount for metering at a Primary Voltage will be applied first.
Monthly Minimum Charge	The monthly minimum charge to be paid by a Customer on Rate Schedule 1255, 1256, 1265 or 1266, as applicable, will be the charge the Customer would have been billed under Rate Schedule 1200, 1201, 1210 or 1211 (Exempt General Service – 35 kW and over), respectively.
Rate Schedules	1. Rate Schedule 1255: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and BC Hydro supplies Transformation.

	2. Rate Schedule 1256: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and BC Hydro supplies Transformation. 3. Rate Schedule 1265: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and the Customer supplies Transformation. 4. Rate Schedule 1266: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and the Customer supplies Transformation.
Special Conditions	1. Metering Equipment with both Demand and Energy measurement capability will normally be installed. Until such Metering Equipment is installed, or if the installed Metering Equipment does not have Demand measurement capability, Billing Demand will be as estimated by BC Hydro. 2. Where the Customer’s Demand is or is likely to be in excess of 45 kVA, BC Hydro may require such Customer to execute a special contract for Service, including such special conditions as BC Hydro, in its sole discretion considers necessary.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under these Rate Schedules, before taxes and levies.
Rate Increase	Effective April 1, 2019 the rates under these Rate Schedules include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. ______.

2. GENERAL SERVICE

RATE SCHEDULE 1268 – DISTRIBUTION SERVICE – IPP DISTRIBUTION TRANSPORTATION ACCESS

Availability	For Customers who have generators connected to BC Hydro's distribution system and who want to access BC Hydro's transmission system pursuant to and in accordance with BC Hydro's Open Access Transmission Tariff (OATT).
Applicable in	Rate Zone I excluding Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Distribution Transportation Charge:** 0.197 ¢ per kWh
Special Conditions	1. The Customer is required to pay the costs, including the cost of altering existing facilities, to connect the generator to BC Hydro's distribution system in accordance with BC Hydro's Connection Requirements for Utility or Non-Utility Generation, 35 kV and Below. 2. For Customers with self-generation (i.e., with a Customer Baseline Load (**CBL**) greater than zero), this Rate Schedule is only applicable to sales of Surplus Energy. It may not be used by self-generating Customers who appear to have varied their demand for power from BC Hydro based on the actual or anticipated difference between BC Hydro's rate for providing Service to them and the market price of power. 3. For the purposes of this Rate Schedule, "Surplus Energy" in any period is the energy made available from generation by the Customer calculated as the difference between the Customer's CBL and the Customer's actual consumption from BC Hydro in that period.

ACCEPTED:______________________________

ORDER NO.______________________________ ______________________________
COMMISSION SECRETARY

	4. The Customer's CBL is established, in general, by determining the Customer's Energy consumption, on a monthly basis, for the past three years; in cases where inadequate history exists, alternative methods may be used to determine a Customer's CBL. Once established, the Customer's CBL will not be automatically adjusted for changes in the Customer's net metered consumption from BC Hydro. Any subsequent changes to the CBL must be due to changes in the Customer's load and not due to changes in its generation. The Customer must provide metered output from its generator which demonstrates an increase in generation output commensurate in time and amount with the Surplus Energy transported using this Rate Schedule. Where it appears that the Customer has transported on this Rate Schedule Energy that is not Surplus Energy, BC Hydro will provide replacement energy to the Customer's load at market prices, subject to Commission approval for such sales. 5. The metering point to determine the electricity being delivered to BC Hydro's distribution system will be determined by BC Hydro. The electricity delivered to BC Hydro's distribution system will also be deemed to be delivered to BC Hydro's transmission system (that is, no distribution loss adjustment will be applied to the electricity from an independent power producer or self-generator when determining capacity and energy delivered to BC Hydro's transmission system).
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019 the rate under this Rate Schedule includes an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

2. GENERAL SERVICE

RATE SCHEDULE 1280 – SHORE POWER SERVICE (DISTRIBUTION)

Availability	For the supply of Shore Power to Port Customers who qualify for General Service for use by Eligible Vessels while docked at the Port Customer's Port Facility, on an interruptible basis. Shore Power Service is supplied at 60 Hz, three phase at Primary Voltage.
Applicable in	Rate Zone I.
Rate	**Administrative Charge:** \$150.00 per month plus **Energy Charge:** 10.510 ¢ per kWh
Special Conditions	1. BC Hydro agrees to provide Electricity under this Rate Schedule to the extent that it has energy and capacity to do so. BC Hydro may refuse or Terminate Service under this Rate Schedule in circumstances where BC Hydro does not have sufficient energy or capacity. For greater certainty, BC Hydro will not be required to construct an Extension for the purpose of increasing the capacity of BC Hydro's distribution system to provide Shore Power Service under this Rate Schedule. 2. The terms and conditions under which Shore Power Service is supplied are contained in the Shore Power Service Agreement (Electric Tariff Supplement No. 86). The Port Customer will pay to BC Hydro the charges set out in this Rate Schedule in addition to any charges set out in the Shore Power Service Agreement. 3. A Port Customer that provides Port Electricity at a Port Facility under Rate Schedules 1600, 1601, 1610, 1611 or 1823 is not eligible to take Shore Power Service under this Rate Schedule to provide Port Electricity to that Port Facility, or any Port Facility served by the same BC Hydro delivery facilities.

ACCEPTED:______________________________

ORDER NO.______________________________

____
COMMISSION SECRETARY

	4. On each occasion, if any, that BC Hydro is required to dispatch power line technicians or other workers to operate the switchgear for each connect and disconnect of Eligible Vessels docked at the Port Customer's Port Facility, BC Hydro will charge, and the Port Customer will pay, the reasonable time and labour costs for this service. The charge will be based on prevailing BC Hydro contracted labour rates and will be separately itemized on the Port Customer's monthly bill.
Definitions	For purposes of this Rate Schedule, capitalized terms have the meanings given to them in Electric Tariff Supplement No. 86.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

2. GENERAL SERVICE

RATE SCHEDULES 1300, 1301, 1310, 1311 – SMALL GENERAL SERVICE (UNDER 35 KW)

Availability	For Customers who qualify for General Service and whose Demand, metered or estimated by BC Hydro, as applicable, is less than 35 kW. Supply is 60 hertz, single or three phase at a Secondary or Primary Voltage.
Applicable in	Rate Zone I and Rate Zone IB.
Rate	**Basic Charge:** 36.45 ¢ per day plus **Energy Charge:** 12.53 ¢ per kWh **Minimum Charge:** The Basic Charge
Discounts	1. A discount of 1½% will be applied to the above charges if Customer's supply of Electricity is metered at a Primary Voltage. 2. A discount of 25 ¢ per month per kW of Demand will be applied if a Customer supplies Transformation. 3. If a Customer is entitled to both of the above discounts, the discount for metering at a Primary Voltage will be applied first.
Rate Schedules	1. Rate Schedule 1300: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and BC Hydro supplies Transformation. 2. Rate Schedule 1301: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and BC Hydro supplies Transformation.

ACCEPTED:____________________

ORDER NO.____________________

COMMISSION SECRETARY

	3. Rate Schedule 1310: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and the Customer supplies Transformation. 4. Rate Schedule 1311: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and the Customer supplies Transformation.
Special Conditions	Special Conditions for Unmetered Service: 1. BC Hydro may permit unmetered Service under these Rate Schedules if it can estimate to its satisfaction the Energy used in kilowatt hours over a period of two months based on the connected load and the hours of use. 2. The Customer, if required by BC Hydro, will provide and maintain such controls, including timing devices, as BC Hydro considers necessary, and facilities satisfactory to BC Hydro for the maintenance of such controls. 3. The hours of use per period will be as specified by the Customer, or as estimated by BC Hydro, whichever is greater. 4. The Customer will supply, install and maintain all wiring, fixtures, control devices and equipment, including the controls and devices described in Special Condition No. 2, at the expense of the Customer. 5. All wiring, fixtures, control devices and equipment and the method of installing, operating and maintaining the same are subject to the approval of BC Hydro which approval may be withdrawn by BC Hydro, at any time, at BC Hydro's sole discretion. 6. The Customer will notify BC Hydro immediately of any proposed or actual change in load, load characteristics, or hours of use.

ACCEPTED:

ORDER NO.

COMMISSION SECRETARY

7. BC Hydro may at any time, in its sole discretion, install Metering Equipment, and thereafter bill the Customer on the appropriate Rate Schedule as a metered account.

8. For display signs and signboard lighting, where hours of use are controlled by timing devices, the following turn-on times will apply, unless BC Hydro otherwise agrees in writing:

Period	Turn-on Time
January 1 to January 15:	4:00 p.m.
January 16 to February 28:	4:30 p.m.
March 1 to April 30:	6:30 p.m.
May 1 to August 15:	8:30 p.m.
August 16 to September 30:	6:30 p.m.
October 1 to November 15:	4:30 p.m.
November 16 to December 31:	4:00 p.m.

9. In all cases, where hours of use of display signs or signboard lighting commence at dusk and are controlled either by timing devices or by photo-electric cells, the following hours of use for a period of two months will be deemed for billing purposes:

Dusk to 10 p.m.:	216 hours
Dusk to 11 p.m.:	270 hours
Dusk to 12 p.m.:	330 hours
Dusk to 1 a.m.:	380 hours
Dusk to Dawn:	666 hours

(All times are Pacific Time.)

	Migration Rules: 1. Migration rules from Small General Service: Customers taking Service under these Rate Schedules will be moved to Service: (a) Under Rate Schedules 1500, 1501, 1510 or 1511 (Medium General Service) if Demand in half of the last six bi-monthly billing periods or half of the last 12 monthly billing periods (as applicable) was 35 kW or more, but less than 150 kW. (b) Under Rate Schedules 1600, 1601, 1610 or 1611 (Large General Service) if Demand in half of the last six bi-monthly billing periods or half of the last 12 monthly billing periods (as applicable) was 150 kW or more, or if total Energy consumption in any 12 consecutive month period exceeded 550,000 kWh. 2. Migration rules to Small General Service: Customers will be moved to Service under these Rate Schedules (Small General Service) from Rate Schedules 1600, 1601, 1610 or 1611 (Large General Service) or Rate Schedules 1500, 1501, 1510 or 1511 (Medium General Service) if Billing Demand in each of the last 12 billing periods was less than 35 kW.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under these Rate Schedules, before taxes and levies.
Rate Increase	Effective April 1, 2019 the rates under these Rate Schedules include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

2. GENERAL SERVICE

RATE SCHEDULES 1500, 1501, 1510, 1511 – MEDIUM GENERAL SERVICE (35 KW OR GREATER AND LESS THAN 150 KW)

Availability	For Customers who qualify for General Service and whose Billing Demand is equal to or greater than 35 kW but less than 150 kW, and whose Energy consumption in any 12-month period is equal to or less than 550,000 kWh. Supply is 60 hertz, single or three phase at Secondary or Primary Voltage. BC Hydro reserves the right to determine the voltage of the Service Connection.
Applicable in	Rate Zone I.
Rate	**Basic Charge:** 26.73 ¢ per day plus **Demand Charge:** $5.42 per kW of Billing Demand plus **Energy Charge:** 9.68 ¢ per kWh
Discounts	1. A discount of 1½% will be applied to the above charges if a Customer's supply of Electricity is metered at a Primary Voltage. 2. A discount of 25 ¢ per Billing Period per kW of Billing Demand will be applied to the above charges if a Customer supplies Transformation. 3. If a Customer is entitled to both of the above discounts, the discount for metering at a Primary Voltage will be applied first.

Monthly Minimum Charge	50% of the highest Demand Charge billed in any Billing Period wholly within an on-peak period during the immediately preceding 11 Billing Periods. For the purpose of this provision an on-peak period commences on November 1 in any year and terminates on March 31 of the following year.
Rate Schedules	1. Rate Schedule 1500: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and BC Hydro supplies Transformation. 2. Rate Schedule 1501: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and BC Hydro supplies Transformation. 3. Rate Schedule 1510: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and the Customer supplies Transformation. 4. Rate Schedule 1511: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and the Customer supplies Transformation.
Definitions	1. Billing Demand The Billing Demand will be the highest kW Demand in the Billing Period. 2. Billing Period A month between regular meter readings, provided that in cases where meter readings are not available or are delayed for any reason BC Hydro may vary the number of days in the Billing Period.

Definitions	1. Irrigation Season: In respect of each Service Connection the period commencing with a meter reading on or about March 1 in any year, having a mid-season meter reading on or about July 31, and ending with a meter reading on or about October 31 in that same year. BC Hydro may, in its discretion extend such period by postponing the termination date to any date not later than November 30, for the sole purpose of permitting a Customer to fill reservoirs necessary for the operation of the irrigation or sprinkling system. 2. Non-Irrigation Season: The period commencing at the end of one Irrigation Season and terminating at the beginning of the next Irrigation Season.
Special Conditions	1. No equipment provided with Electricity under this Rate Schedule will be served with Electricity under any other Rate Schedule while the Customer's Service Agreement under this Rate Schedule is in force. 2. Normally the Service Connection will be energized during the Non-Irrigation Season, but will be Disconnected if a Customer so requests. 3. The Minimum Charge during the Irrigation Season will commence in March for an account that has not been Terminated by the Customer, whether or not the Service Connection is energized and will be billed in two installments, at the end of July and at the end of October. 4. For the Irrigation Season, a bill will be rendered following the July and October meter readings. The first bill will be the greater of the Energy Charge and the Minimum Charge for the period March 1 to July 31. The second bill will be the greater of the Energy Charge for the season and the Minimum Charge for the season, less payment received for the first billing charges.

ACCEPTED:____________________

ORDER NO.____________________ ________________________

COMMISSION SECRETARY

	5. For the Non-Irrigation Season a bill will be rendered following the March meter reading provided that there is registered Energy consumption. 6. If a motor is rated in horsepower, the conversion factor from horsepower to kilowatts will be: 1 horsepower = 0.746 kilowatts
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019 the rates under this Rate Schedule include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

4. STREET LIGHTING SERVICE

RATE SCHEDULE 1701 – OVERHEAD STREET LIGHTING

Availability	For lighting of public highways, streets and lanes in cases where BC Hydro owns, installs and maintains the fixtures, conductors, controls and poles.
Applicable in	Any area served by suitable overhead distribution lines.
Rate	Per fixture per month as set out below: 100 watt H.P. sodium vapour unit $19.60 150 watt H.P. sodium vapour unit $23.38 200 watt H.P. sodium vapour unit $26.99 *175 watt mercury vapour unit $21.54 *250 watt mercury vapour unit $24.82 *400 watt mercury vapour unit $31.99 Wattages are lamp watts. * Note Special Condition No. 2.
Special Conditions	1. Connection Charge No charge will be made for Service Connections. 2. Mercury Vapour Mercury vapour fixtures are not available for new installations.

ACCEPTED:

ORDER NO.

COMMISSION SECRETARY

	3. Extension Policy BC Hydro will construct a distribution Extension if required by the applicant in accordance with the Terms and Conditions of the Electric Tariff as applicable. When, at the Customer's request, a new fixture replaces an existing fixture, the Customer will pay to BC Hydro the original cost of the existing fixture, less any accumulated depreciation, and the cost of removing the existing fixture. 4. Relocation and Redirection of Fixtures The Customer will pay the full cost of relocating or redirecting fixtures when the change is made at the request of the Customer. 5. Design BC Hydro will design the installation of overhead street lighting fixtures. 6. Lamps Failing to Operate BC Hydro will, without charge, replace lamps or components that fail to operate, unless breakage is the reason for such failure in which case the Customer will be charged the cost of the material required to make the fixture operate. 7. Term of Service Agreement The term of the initial Service Agreement under this Rate Schedule will be not more than five years; renewal periods will be for five years.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

Rate Increase	Effective April 1, 2019 the rates under this Rate Schedule include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

4. STREET LIGHTING SERVICE

RATE SCHEDULE 1702 – PUBLIC AREA ORNAMENTAL STREET LIGHTING

Availability	For lighting of public highways, streets and lanes and municipal pathways and for public area seasonal lighting displays, in those cases where the Customer owns, installs and maintains the standards, fixtures, conductors and controls.
Applicable in	All Rate Zones.
Rate	**Energy Charge:** For each unmetered fixture: 3.77 ¢ per watt of Billing Wattage per month For each metered fixture: 11.32 ¢ per kWh
Definitions	Billable Wattage is the sum of all wattage, on all fixtures used by the Customer. For fixtures without dimming controls, the watts per fixture will include the wattage of the lamp plus, where applicable, the wattage of the ballast. For fixtures with dimming controls, the watts per fixture will be equal to: 1. The wattage of the lamp plus, where applicable, the wattage of the ballast, multiplied by 2. The ratio of effective fixture wattage after dimming to fixture wattage before dimming.

COMMISSION SECRETARY

Special Conditions	1. Service Connection Where necessary BC Hydro will provide an overhead or underground Service Connection in accordance with the Terms and Conditions of the Electric Tariff. No Service Connection will be made to add any ornamental street lighting system which does not provide for eight or more street lighting fixtures except that, if the potential is 120/240 volts, at BC Hydro's discretion, a Service Connection may be made for a system of less than eight. Receptacle loads will be permitted for Service under this Rate Schedule provided that such receptacles are used predominantly for seasonal lighting displays, meaning that no more than 10% of the usage may be for other purposes. 2. Extension Policy BC Hydro will construct a distribution Extension if required by the applicant in accordance with the Terms and Conditions of the Electric Tariff. 3. Power Factor All installations of mercury vapour, sodium vapour or fluorescent lamps will be equipped with the necessary auxiliaries to assure that a Power Factor of not less than 90% lagging will be maintained. 4. Term of Service Agreement The term of the initial Service Agreement under this Rate Schedule will be not more than five years; renewal periods will be for five years.

	5. Fixtures with Automated Dimming Controls The following special terms and conditions apply to lighting fixtures fitted with dimming controls: (a) For purposes of this Special Condition No. 5, “dimming controls” means control units or fittings attached to, or forming part of, a street lighting fixture capable of being programmed or remotely operated so as to reduce the lumens output of the lamps during specified hours each day while the lamps are in operation. The reductions may vary according to the hours of the day, the days of the week, and the seasons of the year. (b) A Customer wishing to have fixtures with dimming controls separately rated under this Rate Schedule must submit a dimming schedule satisfactory to BC Hydro listing each light fixture fitted with dimming controls, the wattage of the fixture (including the lamp and, where applicable, the ballast), the dimming control setting or settings and the hours each day that the dimming control setting or settings will be in operation. (c) Whenever the Customer wishes to make changes in the lighting fixtures listed in the dimming schedule or in the dimming control settings or hours of operation, the Customer will submit an updated lighting fixture schedule to BC Hydro listing any changes. Changes will be permitted on a semi-annual basis (twice per year).

	6. Unmetered Service (a) BC Hydro may permit unmetered Service under this Rate Schedule if it can estimate to its satisfaction the Energy used in kilowatt hours over a period of one month based on the connected load and hours of use. (b) The Customer will notify BC Hydro immediately of any proposed or actual change in load, or load characteristics, or hours of use. (c) BC Hydro, in its discretion, may at any time install Metering Equipment and thereafter bill the Customer on the Energy consumption registered.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019 the rates under this Rate Schedule include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

4. STREET LIGHTING SERVICE

RATE SCHEDULE 1703 – STREET LIGHTING SERVICE

Availability	For lighting of public highways, streets and lanes in those cases where the Customer owns, installs and maintains the fixtures, conductors and controls on poles of BC Hydro. Available only to Customers formerly taking Service on Rate Schedule 1755, 1756, 1757, 1758, 1759 or 1767, to the City of New Westminster in respect of a portion of D.L. 172, to the Municipality of Sparwood and to the City of Vancouver.
Applicable in	The Cities of Victoria and Prince Rupert, the Municipalities of Oak Bay, Esquimalt, Saanich and Central Saanich, the Village of Sidney, the unorganized areas of Port Renfrew and Shawnigan Lake, a portion of D.L. 172 in the City of New Westminster, Natal and the City of Vancouver.
Rate	**Energy Charge:** 3.77 ¢ per watt of Billing Wattage per month plus **Contact Charge:** $1.13 per contact per month The Contact Charge is a per fixture charge for the use of pole space.
Definitions	Billable Wattage is the sum of all wattage, on all fixtures used by the Customer. For fixtures without dimming controls, the watts per fixture will include the wattage of the lamp plus, where applicable, the wattage of the ballast. For fixtures with dimming controls, the watts per fixture will be equal to: 1. The wattage of the lamp plus, where applicable, the wattage of the ballast, multiplied by 2. The ratio of effective fixture wattage after dimming to fixture wattage before dimming.

Special Conditions	1. Extension Policy No Extension will be made to provide Service to street lights under this Rate Schedule. 2. Power Factor All installations of mercury vapour, sodium vapour or fluorescent lamps will be equipped with the necessary auxiliaries to assure that a Power Factor of not less than 90% lagging will be maintained. 3. Term of Service Agreement The term of the initial Service Agreement under this Rate Schedule will be not more than five years; renewal periods will be for five years. 4. Fixtures with Automated Dimming Controls The following special terms and conditions apply to lighting fixtures fitted with dimming controls: (a) For purposes of this Special Condition No. 4, “dimming controls” means control units or fittings attached to, or forming part of, a street lighting fixture capable of being programmed or remotely operated so as to reduce the lumens output of the lamps during specified hours each day while the lamps are in operation. The reductions may vary according to the hours of the day, the days of the week, and the seasons of the year. (b) A Customer wishing to have fixtures with dimming controls separately rated under this Rate Schedule must submit a dimming schedule satisfactory to BC Hydro listing each light fixture fitted with dimming controls, the wattage of the fixture (including the lamp and, where applicable, the ballast), the dimming control setting or settings and the hours each day that the dimming control setting or settings will be in operation.

	(c) Whenever the Customer wishes to make changes in the lighting fixtures listed in the dimming schedule or in the dimming control settings or hours of operation, the Customer will submit an updated lighting fixture schedule to BC Hydro listing any changes. Changes will be permitted on a semi-annual basis (twice per year).
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019 the rates under this Rate Schedule include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

4. STREET LIGHTING SERVICE

RATE SCHEDULE 1704 – TRAFFIC CONTROL EQUIPMENT

Availability	For lighting of traffic signals, traffic signs and traffic warning devices, and other equipment for controlling or directing vehicular or pedestrian traffic on public highways in those cases where the Customer owns, installs, and maintains the standards, fixtures, controls and associated equipment.
Applicable in	All Rate Zones.
Rate	**Energy Charge:** 11.32 ¢ per kWh
Special Conditions	1. Service Connections Where necessary BC Hydro will provide an overhead or underground Service Connection in accordance with section 3 of the Terms and Conditions (Provision of Electricity). 2. Unmetered Service (a) BC Hydro may permit unmetered Service under this Rate Schedule if it can estimate to its satisfaction the Energy used in kilowatt hours over a period of one month based on the connected load and hours of use. (b) The Customer shall notify BC Hydro immediately of any proposed or actual change in load, or load characteristics, or hours of use. (c) BC Hydro, in its discretion, may at any time install a meter or meters and thereafter bill the Customer on the consumption registered.

4. STREET LIGHTING SERVICE

RATE SCHEDULE 1755 – PRIVATE OUTDOOR LIGHTING (CLOSED)

Availability	For outdoor lighting Service to illuminate property other than public streets or lanes (private property), where Service is provided from dusk to dawn and the supply is single phase, 60 hertz at the Secondary Voltage available. This Rate Schedule is available only in Premises served under this Rate Schedule on January 1, 1975 and only with respect to lights served under this Rate Schedule on January 1, 1975 and continuously thereafter, except BC Hydro may replace a mercury vapour unit with a high pressure sodium unit having approximately the same equivalent light output.
Applicable in	All Rate Zones.
Rate	**Charge per fixture per month as follows:** 1. Where a light is mounted on a pole that was installed by the Customer or by BC Hydro at the Customer's expense: 175 watt mercury vapour unit or replacement 100 watt H.P. sodium vapour unit — $18.37 400 watt mercury vapour unit or replacement 150 watt H.P. sodium vapour unit — $31.66

	2. Where a light is mounted on a pole that is on public property, or an easement, and is part of BC Hydro's distribution system: 175 watt mercury vapour unit or replacement 100 watt H.P. sodium vapour unit — $19.51 400 watt mercury vapour unit or replacement 150 watt H.P. sodium vapour unit — $32.81 3. Where a light is mounted on a pole that was installed on the Customer's property by BC Hydro, at its expense, solely for the purpose of supporting the light: 175 watt mercury vapour unit or replacement 100 watt H.P. sodium vapour unit — $24.02 400 watt mercury vapour unit or replacement 150 watt H.P. sodium vapour unit — $37.81 Except that if two or more lights are mounted at one time on the same pole the rates for the additional light or lights will be as set out under part 1 above.
Special Conditions	1. BC Hydro will provide and install: (a) An outdoor light consisting of luminaire, mast arm, ballast, lamp and photo-electric control, and (b) Not more than one span of overhead secondary conductors per light. 2. The Customer will be required to contribute the estimated cost of any plant required to make Secondary Voltage available at a point not more than one span from the light; such contribution is not subject to refund.

5. TRANSMISSION SERVICE

RATE SCHEDULE 1823 – TRANSMISSION SERVICE – STEPPED RATE

Availability	For all purposes. Supply is at 60 kV or higher. Customers supplied with Electricity under Rate Schedule 1825 (Time-of-Use) may only revert to Service under this Rate Schedule as permitted under Rate Schedule 1825.
Applicable in	Rate Zone I excluding the Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Demand Charge:** \$8.697 per kVA of Billing Demand per Billing Period plus **Energy Charge: A** For new Customers and Customers that do not have a CBL by order of the British Columbia Utilities Commission: 5.098 ¢ per kWh for all kWh per Billing Period This rate will apply until the Customer has been supplied with Electricity under this Rate Schedule for 12 Billing Periods or another period approved by the British Columbia Utilities Commission, after which the Customer will be supplied with Electricity at the rate specified in Part B below.

ACCEPTED:______________________________

ORDER NO.______________________________

____
COMMISSION SECRETARY

	Energy Charge: B For Customers with a CBL: 4.535 ¢ per kWh applied to all kWh up to and including 90% of the Customer's CBL in each Billing Year 10.160 ¢ per kWh applied to all kWh above 90% of the Customer's CBL in each Billing Year Note: Customers previously supplied with Electricity under Rate Schedule 1825 will be subject to the rates in Part B above from the time the Customer commences taking Service under this Rate Schedule. **Monthly Minimum Charge:** $8.697 per kVA of Billing Demand
Definitions	1. Billing Year The Billing Year is the 12 month billing period starting with the first day of the Billing Period which commences nearest to April 1 in each year, and ending on the last day of such 12-month Billing Period. 2. Billing Demand The Billing Demand will be: (a) The highest kVA Demand during the High Load Hours (**HLH**) in the Billing Period; or (b) 75% of the highest Billing Demand for the Customer's Plant in the immediately preceding period of November to February, both months included; or (c) 50% of the Contract Demand stated in the Electricity Supply Agreement for the Customer's Plant, whichever is the highest value, provided that for new Customers the Billing Demand for the initial two Billing Periods will be the average of the daily highest kVA Demands for the Customer's Plant.

ACCEPTED:______________________

ORDER NO.______________________

____
COMMISSION SECRETARY

	3. Customer Baseline Load (**CBL**) The Customer Baseline Load (**CBL**) is the Customer's historic annual energy consumption in kWh as approved by the British Columbia Utilities Commission. The Customer's CBL will initially be determined by BC Hydro, and be subject to revision from time to time, in accordance with the criteria and procedures set forth in BC Hydro's "Customer Baseline Load (**CBL**) Determination Guidelines" (Electric Tariff Supplement No. 74). All CBLs will be subject to final approval of the British Columbia Utilities Commission. 4. High Load Hours (**HLH**) High Load Hours (**HLH**) is the period of hours from 06:00 to 22:00 Monday to Saturday, except for Statutory Holidays (New Year's Day, Family Day, Good Friday, Victoria Day, Canada Day, B.C. Day, Labour Day, Thanksgiving Day, Remembrance Day and Christmas Day). 5. Low Load Hours (**LLH**) Low Load Hours (**LLH**) are all hours other than HLH.
Special Conditions	1. A Customer having two or more operating plants may elect to have a single aggregated CBL determined for all or any combination of its operating plants in accordance with BC Hydro's "Customer Baseline Load (**CBL**) Determination Guidelines" (Electric Tariff Supplement No. 74). Thereafter, BC Hydro will issue a single bill for all operating plants included in the aggregation, and the Energy Charge payable will be determined on the basis of the aggregated CBL. However, the Demand Charge will continue to be determined separately for each operating plant.

	2. If any initial, revised, or aggregate CBL for a Customer has not been determined by BC Hydro and approved by British Columbia Utilities Commission by the time at which the CBL would become effective, BC Hydro may determine the CBL on an interim basis and apply that CBL for the purposes of any billing periods and bills rendered to the Customer until such time as the CBL has been finally determined and approved by the British Columbia Utilities Commission, following which BC Hydro will make any necessary billing adjustments. 3. If a Customer taking Service at the rates in Part B of the Energy Charge rate section above Terminates Service under this Rate Schedule prior to the end of a Billing Year, the Customer's CBL or aggregate CBL will be prorated for the portion of the Billing Year during which the Customer was taking Service, and the prorated CBL or aggregate CBL will be used for the purposes of applying the rates in Part B to all energy consumption during the Billing Year up to the time of Termination. BC Hydro will make any necessary billing adjustments and bill the Customer for the difference (if any) owing.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Note	The terms and conditions under which Transmission Service is supplied are contained in Electric Tariff Supplement Nos. 5 and 6, or Electric Tariff Supplement Nos. 87 and 88, as applicable.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

Rate Increase	Effective April 1, 2019 the rates under this Rate Schedule include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. _____.

ACCEPTED:____________________________

ORDER NO.____________________________ ____________________________________

5. TRANSMISSION SERVICE

RATE SCHEDULE 1825 – TRANSMISSION SERVICE – TIME-OF-USE (TOU) RATE

Availability	For Customers who provide notice by February 15 of each year and who at the time of application are eligible to take Service under Rate Schedule 1823 (Stepped Rate) at the Energy Charge rates set out in Part B of the rate section of that Rate Schedule, and who have entered into a TOU (Transmission Service) Agreement by March 15 of that year. Customers will start Service under Rate Schedule 1825 in the first Billing Period after April 1.
Applicable in	Rate Zone I excluding the Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Demand Charge:** $8.697 per kVA of Billing Demand per Billing Period plus **Energy Charge:** 1. Winter HLH Period: 4.535 ¢ per kWh applied to all kWh up to and including 90% of the Customer's Winter HLH Period CBL. 11.337 ¢ per kWh applied to all kWh above 90% of the Customer's Winter HLH Period CBL. 2. Winter LLH Period: 4.535 ¢ per kWh applied to all kWh up to and including 90% of the Customer's Winter LLH Period CBL. 10.275 ¢ per kWh applied to all kWh above 90% of the Customer's Winter LLH Period CBL.

ACCEPTED:______________________

ORDER NO.______________________

COMMISSION SECRETARY

	3. Spring Period: 4.535 ¢ per kWh applied to all kWh up to and including 90% of the Customer’s Spring Period CBL. 9.151 ¢ per kWh applied to all kWh above 90% of the Customer’s Spring Period CBL. 4. Remaining Period: 4.535 ¢ per kWh applied to all kWh up to and including 90% of the Customer’s Remaining Period CBL applicable. 10.035 ¢ per kWh applied to all kWh above 90% of the Customer’s Energy CBL applicable in the Billing Period.
Definitions	1. Billing Demand The Demand for billing purposes will be: (a) The highest kVA Demand during the High Load Hours (**HLH**) in the Billing Period; or (b) 75% of the highest Billing Demand for the Customer's Plant in the immediately preceding period of November to February, both months included; or (c) 50% of the Contract Demand stated in the Electricity Supply Agreement for the Customer's Plant, whichever is the highest value.

ACCEPTED:__________________________

ORDER NO.__________________________ __________________________________

COMMISSION SECRETARY

	2. Customer Baseline Load (CBL) The Customer Baseline Load (**CBL**) is the Customer's historic consumption (in kWh) as approved by the British Columbia Utilities Commission. For the purposes of this Rate Schedule, the Customer's CBL will consist of four separate CBLs – one each for the Winter HLH Period, the Winter LLH Period, the Spring Period and the Remaining Period. The Customer's CBL will initially be determined by BC Hydro, and be subject to revision from time to time, in accordance with the criteria and procedures set forth in BC Hydro's "Customer Baseline Load (**CBL**) Determination Guidelines" (Electric Tariff Supplement No. 74). All CBLs will be subject to final approval of the British Columbia Utilities Commission. 3. High Load Hours (**HLH**) High Load Hours (**HLH**) is the period of hours from 06:00 to 22:00 Monday to Saturday, except for Statutory Holidays (New Year's Day, Family Day, Good Friday, Victoria Day, Canada Day, B.C. Day, Labour Day, Thanksgiving Day, Remembrance Day and Christmas Day). 4. Low Load Hours (**LLH**) The Low Load Hours (**LLH**) are all hours other than HLH. 5. Remaining Period The Remaining Period is all Billing Periods other than the Winter Period or the Spring Period. 6. Spring Period The Spring Period comprises the two Billing Periods starting with the first day of the Billing Period that commences nearest to May 1 each year and ending on the last day of the second Billing Period thereafter.

	7. Winter Period The Winter Period comprises four Billing Periods starting with the first day of the Billing Period that commences nearest to November 1 each year and ending on the last day of the fourth Billing Period thereafter.
Special Conditions	1. Service under this Rate Schedule will be provided only while a TOU (Transmission Service) Agreement with the Customer is in effect. 2. A Customer having two or more operating plants may elect to have a single aggregated CBL determined for all or any combination of its operating plants in accordance with BC Hydro's "Customer Baseline Load (CBL) Determination Guidelines" (Electric Tariff Supplement No. 74). Separate Energy CBL values will be determined for each plant and then aggregated. BC Hydro will issue a single bill for all operating plants included in an aggregation, and the Energy Charge payable will be determined on the basis of the aggregated Energy CBL value. The Demand Charge will continue to be determined separately for each operating plant. 3. If any initial, revised, or aggregate CBL for a Customer has not been determined by BC Hydro and approved by British Columbia Utilities Commission by the time at which the CBL would become effective, BC Hydro may determine the CBL on an interim basis and apply that CBL for the purposes of any billing periods and bills rendered to the Customer until such time as the CBL has been finally determined and approved by the British Columbia Utilities Commission, following which BC Hydro will make any necessary billing adjustments.

ACCEPTED:______________________

ORDER NO.______________________

____
COMMISSION SECRETARY

	4. In accordance with the TOU (Transmission Service) Agreement, the Customer will have a period of 30 days following approval of the Customer's initial CBL by the British Columbia Utilities Commission within which the Customer may, by written notice to BC Hydro, withdraw from taking Service under this Rate Schedule, and revert to taking Service under Rate Schedule 1823 (Stepped Rate). This right of withdrawal is available only when the Customer first subscribes to take Service under this Rate Schedule, and is applicable only in respect of the initial CBL determination. If the Customer exercises this right of withdrawal Rate Schedule 1823 will apply from the commencement of the then current Billing Year, and BC Hydro will make any necessary billing adjustments accordingly. 5. Customers taking Service under Rate Schedule 1852 (Modified Demand) may not also take Service under this Rate Schedule.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Note	The terms and conditions under which Transmission Service is supplied are contained in the Electricity Supply Agreement (Electric Tariff Supplement No. 5, or Electric Tariff Supplement No. 87, as applicable) as amended by the Electric Tariff Supplement No. 72 (TOU (Transmission Service) Agreement), and Electric Tariff Supplement No. 6, or Electric Tariff Supplement No. 88, as applicable.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019 the rates under this Rate Schedule include an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

5. TRANSMISSION SERVICE

RATE SCHEDULE 1852 – TRANSMISSION SERVICE – MODIFIED DEMAND

Availability	To a Customer supplied with Electricity at 60 kV or higher who is taking Service under Rate Schedule 1823 (Stepped Rate) at the time of application, and is a party to a Modified Demand Agreement under Electric Tariff Supplement No. 54 which is in force, and which is in a location, as determined by BC Hydro, that will allow BC Hydro to curtail load to alleviate a potential local or regional transmission constraint, or take advantage of a market opportunity. The annual subscription period for new subscribers is from September 1 to October 31.
Applicable in	Rate Zone I excluding the Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Excess Demand Charge:** $8.697 per kVA of metered kVA Demand in excess of the Maximum Demand Level during Low Load Hours
Definitions	1. Billing Demand The Billing Demand will be: (a) The highest kVA Demand during the High Load Hours (**HLH**) in the Billing Period; or (b) 75% of the highest Billing Demand for the Customer's Plant in the immediately preceding period of November to February, both months included; or (c) 50% of the Contract Demand stated in the Electricity Supply Agreement for the Customer's Plant, whichever is the highest value.

ACCEPTED:______________________

ORDER NO.______________________

COMMISSION SECRETARY

	2. High Load Hours (**HLH**) High Load Hours (**HLH**) means the period(s) in a 24-hour day and during those days of a calendar week in which Electricity usage is typically highest in a particular region, as determined by BC Hydro in its discretion based on load characteristics and transmission constraints in that region from time to time, and designated in a Modified Demand Agreement. 3. Low Load Hours (**LLH**) Low Load Hours (**LLH**) are all hours other than HLH. 4. LLH CBL Energy LLH CBL Energy means the highest monthly energy consumption during the LLH over the last 12 Billing Periods, or an estimate of consumption if insufficient data is available. 5. Maximum Demand Level Maximum Demand Level has the meaning set out in the Modified Demand Agreement. For a Customer with more than one designated period of High Load Hours, separate Maximum Demand Levels will be stated for each corresponding period of Low Load Hours. For a Customer with a single designated period of High Load Hours, a single Maximum Demand Level will be stated for all Low Load Hours. The highest Maximum Demand Level will not exceed 95% of Contract Demand stated in the Customer's Electricity Supply Agreement, and is subject to local transmission availability.

Special Conditions	1. The terms and conditions under which Transmission Service is supplied are contained in Electric Tariff Supplement Nos. 5 and 6. The provisions of Rate Schedule 1823 (Stepped Rate) and Electric Tariff Supplement Nos. 5 and 6 continue to apply to Customers receiving Service under this Rate Schedule. In the case of a conflict between this Rate Schedule or the Modified Demand Agreement and Rate Schedule 1823 or Electric Tariff Supplement Nos. 5 or 6, the provisions of this Rate Schedule and the Modified Demand Agreement will govern. 2. If for any two Billing Periods the total energy consumed under Rate Schedule 1852, during the LLH, is greater than the LLH CBL Energy by 10% or more, the highest kVA Demand in each such Billing Period during the High Load Hours will be adjusted by the ratio of the average monthly LLH Energy during such two Billing Periods over the LLH CBL Energy. The adjusted highest kVA Demand will apply for a period of 12 months after the second Billing Period included in the adjustment calculation. The LLH CBL Energy will be recalculated using the consumption history of the most recent 12 Billing Periods. 3. The Minimum Reduction under the Modified Demand Agreement will be the greater of 50% of the difference between the Maximum Demand Level and the LLH CBL Demand, and 10 MW. 4. The Maximum Number of Demand Reduction Transactions under the Modified Demand Agreement will be the greater of Maximum Duration multiplied by the Maximum Number of Demand Reduction Transactions, and 48 hours.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

5. TRANSMISSION SERVICE

RATE SCHEDULE 1853 – TRANSMISSION SERVICE – IPP STATION SERVICE

Availability	For Customers who are Independent Power Producers (**IPPs**) served at transmission voltage, on an interruptible basis.
Applicable in	Rate Zone I excluding Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Energy Charge:** The sum, over the Billing Period, of the hourly energy consumed multiplied by the entry in the Intercontinental Exchange (**ICE**) Mid-Columbia (Mid-C) Peak, and Mid-C Off-Peak weighted average index price as published by the ICE in the ICE Day Ahead Power Price Report that corresponds to the time when consumption occurred, during that hour
Monthly Minimum Charge	$49.01
Special Conditions	1. BC Hydro agrees to provide Electricity under this Rate Schedule to the extent that it has energy and capacity to do so. 2. BC Hydro may, without notice to the Customer, refuse to supply or terminate the supply of Electricity under this Rate Schedule if at any time BC Hydro does not have sufficient energy or capacity. 3. Prior to taking Electricity under this Rate Schedule, the Customer may be required to obtain approval from BC Hydro. BC Hydro will advise the Customer of the need to obtain approval prior to the taking of Electricity under this Rate Schedule. 4. Electricity taken under this Rate Schedule is to be used solely for maintenance and black-start requirements and will not displace electricity that would normally be generated by the Customer.

Availability	For Customers supplied with Electricity under Rate Schedule 1823 (Stepped Rate), 1825 (TOU Rate), 1827 (Rate for Exempt Customers) or 1852 (Modified Demand), on an interruptible basis.
Applicable in	Rate Zone I excluding the Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Administrative Charge:** $150.00 per Period of Use plus **Energy Charge:** During the Period of Use, 10.160 ¢ per kWh of metered Rate Schedule 1880 energy consumption, determined as set out below
Definitions	1. HLH Reference Demand HLH Reference Demand is the highest kVA Demand in the HLH for the current Billing Period prior to the Period of Use, but excluding any prior Period of Use. If the Period of Use extends over an entire Billing Period, the highest kVA Demand in the HLH from the prior Billing Period will be used in determining the HLH Reference Demand, excluding any Period of Use in the prior Billing Period. For the purpose of determining HLH Reference Demand, the HLH periods are as defined in Rate Schedule 1823, 1825, 1827 or 1852, whichever is applicable. 2. Period of Use A period of consecutive hours during which Electricity is taken under this Rate Schedule. The Period of Use is as defined by the Customer when requesting Service from BC Hydro under this Rate Schedule 1880 and may extend into subsequent Billing Periods.

Rate Schedule 1880 Energy Determination	During HLH periods, the kWh consumption on an hourly basis which exceeds the HLH high kWh per hour within the Period of Use or portion thereof where HLH high kWh per hour is the product of HLH Reference Demand multiplied by the Power Factor for the half hour when the HLH Reference Demand occurred. For the purpose of the Rate Schedule 1880 Energy Determination, the HLH periods are as defined in Rate Schedule 1823, 1825, 1827 or 1852, whichever is applicable.
Special Conditions	1. BC Hydro agrees to provide Electricity under this Rate Schedule to the extent that it has energy and capacity to do so. 2. BC Hydro may, without notice to the Customer, refuse to supply or terminate the supply of Electricity under this Rate Schedule if at any time during the Period of Use BC Hydro does not have sufficient energy or capacity.

ACCEPTED:____________________

ORDER NO.____________________

COMMISSION SECRETARY

3. This Rate Schedule is only for the following purposes:

   To provide Electricity the Customer would otherwise generate during periods when all or part of the Customer's electrical generating plant is curtailed.

   Electricity used for this purpose may be taken on an instantaneous basis when the impact of the instantaneous pickup of loads normally provided by the Customer's electrical generation units does not occur after BC Hydro has advised the Customer that a period of system constraint or potential system constraint exists.

   During periods of potential system constraints, BC Hydro will require Customers to arm load shedding relays to ensure that the loss of electricity production from a Customer's electrical generation unit will not result in a demand greater than the Customer's Maximum kVA Demand on BC Hydro's system. BC Hydro may require the Customer to provide it with control of these load shedding relays. During periods of potential system constraints, upon a Customer's request, BC Hydro will endeavour to provide Electricity normally provided by the Customer's electrical generation unit.

   The Customer is required to advise BC Hydro within 30 minutes of taking Electricity under this Rate Schedule for this purpose. If the Customer fails to advise BC Hydro within 30 minutes, measured Demand and Energy consumption will be billed under Rate Schedule 1823, 1825, 1827 or 1852, whichever is applicable.

4. Electricity taken under this Rate Schedule will not displace Electricity otherwise to be taken by the Customer under Rate Schedule 1823, 1825, 1827 or 1852.

   Electricity taken under this Rate Schedule will not displace electricity that would normally be generated by the Customer for the purpose of re-sale.

	5. In addition to the charges specifically set out in this Rate Schedule, the Customer will pay for any additional facilities required to deliver Electricity under this Rate Schedule provided that BC Hydro obtains the prior consent of the Customer for construction of the additional facilities. 6. A Customer may be required to allow BC Hydro to install metering and communication equipment to measure the electricity output of the Customer's self-generation unit. 7. BC Hydro will bill for Electricity taken under Rate Schedule 1880 at the same time it bills for Electricity taken under Rate Schedule 1823, 1825, 1827 or 1852, whichever is applicable.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Note	The terms and conditions under which Transmission Service is supplied are contained in Electric Tariff Supplement Nos. 5 and 6, or Electric Tariff Supplement Nos. 87 and 88, as applicable.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019 the Energy Charge under this Rate Schedule includes an interim rate increase of 6.85% before rounding, approved by BCUC Order No. .

5. TRANSMISSION SERVICE

RATE SCHEDULE 1891 – TRANSMISSION SERVICE – SHORE POWER SERVICE

Availability	For the supply of Shore Power to Port Customers for use by Eligible Vessels while docked at the Port Customer's Port Facility, on an interruptible basis. Supply is at 60 kV or higher.
Applicable in	Rate Zone I.
Rate	**Administrative Charge:** $150.00 per month plus **Energy Charge:** 10.160 ¢ per kWh for all kWh in a billing period
Definitions	For purposes of this Rate Schedule, capitalized terms have the meanings given to them in the Shore Power Service Agreement (Electric Tariff Supplement No. 86).
Special Conditions	1. BC Hydro agrees to provide Electricity under this Rate Schedule to the extent that it has energy and capacity to do so. BC Hydro may refuse Service under this Rate Schedule in circumstances where BC Hydro does not have sufficient energy or capacity. For greater certainty, BC Hydro will not be required to construct a System Reinforcement under Electric Tariff Supplement No. 6 to provide Shore Power Service under this Rate Schedule. 2. The terms and conditions under which Shore Power Service is supplied are contained in the Shore Power Service Agreement (Electric Tariff Supplement No. 86). The Port Customer will pay to BC Hydro the charges set out in this Rate Schedule in addition to any charges set out in the Shore Power Service Agreement.

	3. A Port Customer that provides Port Electricity at a Port Facility under Rate Schedules 1600, 1601, 1610, 1611 (Large General Service) or 1823 (Stepped Rate) is not eligible to take Shore Power Service under this Rate Schedule to provide Port Electricity to that Port Facility, or a Port Facility served by the same BC Hydro delivery facilities. 4. On each occasion, if any, that BC Hydro is required to dispatch power line technicians or other workers to operate the switchgear for each connect and disconnect of Eligible Vessels docked at the Port Customer's Port Facility, BC Hydro will charge, and the Port Customer will pay, the reasonable time and labour costs for this service. The charge will be based on prevailing BC Hydro contracted labour rates and will be separately itemized on the Port Customer's monthly bill.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

5. TRANSMISSION SERVICE

RATE SCHEDULE 3808 – TRANSMISSION SERVICE – FORTISBC INC.

Availability	This Rate Schedule is available to FortisBC Inc. (FortisBC) in accordance with the terms and conditions of the Agreement between BC Hydro and FortisBC entered into and deemed effective July 1, 2014 (Power Purchase Agreement). Contract Demand must not exceed 200 MW in any hour.
Applicable in	For Electricity delivered to FortisBC at each Point of Delivery as defined in the Power Purchase Agreement.
Rate	**Demand Charge:** \$8.697 per kW of Billing Demand per Billing Month plus **Energy Charge:** Tranche 1 Energy Price: 5.098 ¢ per kWh Tranche 2 Energy Price: 9.509 ¢ per kWh

ACCEPTED:____________________

ORDER NO.____________________

COMMISSION SECRETARY

Definitions	1. Billing Demand The Billing Demand in any Billing Month will be the greatest of: (a) The maximum amount of Electricity (in kW) scheduled under the Power Purchase Agreement, for any hour of the Billing Month; (b) 75% of the maximum amount of Electricity (in kW) scheduled under the Power Purchase Agreement in any hour in the 11 months of the Term immediately prior to the Billing Month (or less than 11 months, if the Effective Date is less than 11 months prior to the month); and (c) 50% of the Contract Demand (in kW) for the Billing Month. If FortisBC has reduced the Contract Demand in accordance with the Power Purchase Agreement, the amount of Electricity specified in item (b) above may not exceed an amount equal to 100% of the Contract Demand. 2. Maximum Tranche 1 Amount The Maximum Tranche 1 Amount for each Contract Year is 1,041 GWh. 3. Scheduled Energy Less Than or Equal to Annual Energy Nomination In any Contract Year, for the amount of the Scheduled Energy taken or deemed to be taken that is less than or equal to the Annual Energy Nomination, FortisBC will pay: (a) The Tranche 1 Energy Price for each kWh of such Scheduled Energy taken or deemed taken that is less than or equal to the Maximum Tranche 1 Amount; and (b) The Tranche 2 Energy Price for each kWh of such Scheduled Energy taken that exceeds the Maximum Tranche 1 Amount.

	4. Scheduled Energy Exceeding the Annual Energy Nomination In any Contract Year, for the amount of the Scheduled Energy taken or deemed to be taken that exceeds the Annual Energy Nomination, FortisBC will pay: (a) 150% of the Tranche 1 Energy Price, for each kWh of such Scheduled Energy taken or deemed taken that that exceeds the Annual Energy Nomination, but is less than or equal to the Maximum Tranche 1 Amount; and (b) 115% of the Tranche 2 Energy Price, for each kWh of such Scheduled Energy taken that exceeds the Annual Energy Nomination and also exceeds the Maximum Tranche 1 Amount. 5. Annual Minimum Take In any Contract Year, FortisBC will schedule and take an amount of Electricity equal to at least 75% of the Annual Energy Nomination, and will be responsible for any Annual Shortfall.
Note	The terms and conditions under which Service is supplied to FortisBC are contained in the Power Purchase Agreement.
Taxes	The rates and charges set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

Schedule 01

Point-To-Point Transmission Service

Availability	For transmission of electricity on a firm and non-firm basis from one or more Point(s) of Receipt (POR) to one or more Point(s) of Delivery (POD).
Rate for Long-Term Firm Service	The Reserved Capacity Charge for the Long-Term Firm Service Rate will be up to a maximum price as set out below except where the POD is a point of interconnection between the Transmission System and the transmission system of FortisBC Inc., in which case the rate shall be zero ($0.00). The Maximum Reserved Capacity Charge is $78,433/MW of reserved capacity per year to be invoiced monthly. Reserved Capacity Billing Demand The Reserved Capacity Billing Demand is determined for each POR(s), POD(s) pair. The Reserved Capacity for each pair of POR(s) and POD(s) will be the maximum non-coincident sum of the designated POR(s) and POD(s) included in the pair.

ACCEPTED:______________________

ORDER NO.______________________ ______________________
COMMISSION SECRETARY

Schedule 01 – Point-To-Point Transmission Service (continued)

Rate for Short-Term Firm and Non-Firm Service	The posted prices for Short-Term Firm and Non-Firm Service will be less than or equal to a maximum price ($/MWh) as set out below, except where the POD is a point of interconnection between the Transmission System and the transmission system of FortisBC Inc., in which case the rate shall be zero ($0.00). Maximum Price for: 1. Monthly delivery: $6,536.12/MW of Reserved Capacity per month. 2. Weekly delivery: $1,508.34/MW of Reserved Capacity per week. 3. Daily delivery: $214.89/MW of Reserved Capacity per day. 4. Hourly delivery: $8.95/MW of Reserved Capacity per hour. Discount Rate: For discounted paths posted on the Transmission Provider's OASIS, the Transmission Customer shall pay each month for Reserved Capacity Billing Demand the greater of the rates set forth below and the rate offered by the Transmission Customer and accepted by the Transmission Provider up to the maximum rate for Short-Term Firm and Non-Firm Service: 1. Hourly delivery: $3/MW of Reserved Capacity per hour in the Heavy Load Hour period (06:00-22:00, Monday - Saturday, excluding NERC holidays) and $1/MW of Reserved Capacity per hour for the Light Load Hour period (remaining hours and days). 2. Daily delivery: sum of the hourly delivery charge in the 24 hour period in the day.
Reserved Capacity for Short-Term Firm and Non-Firm Services	The Reserved Capacity shall be the maximum of the sum of non-coincident POD(s) Capacity Reservations or sum of non-coincident POR(s) Capacity Reservations.

Schedule 01 – Point-To-Point Transmission Service (continued)

Penalty Charge	In addition to the applicable rate for service and associated charges for Ancillary Services, a penalty charge will be applied to all unauthorized usage at a rate of 125 percent of the maximum hourly delivery charge.
Special Conditions	Discounts: The following conditions apply to discounts for transmission service: 1. any offer of a discount made by BC Hydro must be announced to all Eligible Customers solely by posting on the OASIS, 2 any customer-initiated requests for discounts (including requests for use by one's wholesale merchant or an affiliate's use) must occur solely by posting on the OASIS, 3. once a discount is negotiated, details must be immediately posted on the OASIS, and 4. for any discount agreed upon for service on a path, from POR(s) POD(s), BC Hydro must offer the same discounted transmission service rate for the same time period to all Eligible Customers on all unconstrained transmission paths that go to the same POD(s) on the Transmission System.
Taxes	The Rate and Charges contained herein are exclusive of applicable taxes.
Resales	The rates and rules governing charges and discounts stated above shall not apply to resales of transmission service, compensation for which shall be governed by section 23.1 of the Tariff
Note	The terms and conditions under which Transmission Service is supplied are contained in BC hydro's Open Access Transmission Tariff. Capitalized terms appearing in this Rate Schedule, unless otherwise noted, shall have the meaning ascribed to them therein.

Effective April 1, 2019, this rate schedule is approved on an interim basis as per BCUC Order No. ____.

Schedule 03

Scheduling, System Control, and Dispatch Service

Preamble	This service is required to schedule the movement of power through, out of, within, or into a Control Area. This service can be provided only by the operator of the Control Area in which the transmission facilities used for transmission service are located. Scheduling, System Control and Dispatch Service is to be provided directly by BC Hydro. The Transmission Customer must purchase this service from BC Hydro. The charges for Scheduling, System Control and Dispatch Service are to be based on the rates set forth below.
Availability	In support of Network Integration Transmission Service, Long and Short-Term Firm Point-to-Point Transmission Service, and Non-Firm Point-to-Point Transmission Service.
Rate	$0.133 per MW of Reserved Capacity per hour.
Taxes	The Rate and Charges contained herein are exclusive of applicable taxes.
Note	A description of the methodology for discounting Scheduling, System Control and Dispatch Services provided under this Schedule is contained in Section 3 of the BC Hydro OATT.

Effective April 1, 2019, this rate schedule is approved on an interim basis as per BCUC Order No. ______.

ORDER NO.____________________ ____________________

COMMISSION SECRETARY

Discounts	1. A discount of 1½% will be applied to the above charges if a Customer's supply of Electricity is metered at a Primary Voltage. 2. A discount of 25 ¢ per Billing Period per kW of Billing Demand will be applied to the above charges if a Customer supplies Transformation. 3. If a Customer is entitled to both of the above discounts, the discount for metering at a Primary Voltage will be applied first.
Monthly Minimum Charge	50% of the highest Demand Charge billed in any Billing Period wholly within an on-peak period during the immediately preceding 11 Billing Periods. For the purpose of this provision an on-peak period commences on November 1 in any year and terminates on March 31 of the following year.
Rate Schedules	1. Rate Schedule 1200: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and BC Hydro supplies Transformation. 2. Rate Schedule 1201: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and BC Hydro supplies Transformation. 3. Rate Schedule 1210: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and the Customer supplies Transformation. 4. Rate Schedule 1211: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and the Customer supplies Transformation.

Definitions	Billing Demand is the Maximum Demand in the Billing Period, subject to Special Condition No. 1. Billing Period means a month between regular meter readings, provided that in cases where meter readings are not available or are delayed for any reason BC Hydro may vary the number of days in the Billing Period.
Special Conditions	1. Metering Equipment with both Demand and Energy measurement capability will normally be installed. Until such Metering Equipment is installed, or if the installed Metering Equipment does not have Demand measurement capability, Billing Demand will be as estimated by BC Hydro. 2. Migration rule: Customers taking Service under these Rate Schedules will be moved to Service under Rate Schedule 1300, 1301, 1310 or 1311 (Small General Service) if Billing Demand in each of the last 12 consecutive Billing Periods was less than 35 kW.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under these Rate Schedules, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the rates under these Rate Schedules included~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.
	~~Effective April 1, 2018 the rates under these Rate Schedules include an increase of 3.0% before rounding, approved by BCUC Order No. G-47-18.~~

2. GENERAL SERVICE

RATE SCHEDULES 1205, 1206, 1207 – GENERAL SERVICE – DUAL FUEL (CLOSED)

Availability	For general space heating, water heating and industrial process heating on an interruptible basis. Electricity purchased under these Rate Schedules will be separately metered. Service is 60 hertz single or three phase at the Secondary or Primary Voltage available. BC Hydro reserves the right to determine the voltage of the Service Connection. These Rate Schedules are available only for Premises served under these Rate Schedules on January 15, 1990 and continuously thereafter, only with respect to equipment served under these Rate Schedules on January 15, 1990 and continuously thereafter, and only in Premises where there has been no change in Customer since April 1, 2008.
Applicable in	Rate Zone I in areas where, in BC Hydro's opinion, BC Hydro's transmission, sub-transmission and distribution circuit feeders are or will be capable of handling the load.
Rate	Except as stated hereunder the rate will be: **Energy Charge:** First 8000 kWh per month @ 6.19~~5.79~~ ¢ per kWh All additional kWh per month @ 4.05~~3.79~~ ¢ per kWh Exception: If during a Period of Interruption a Customer fails to comply with BC Hydro's requirement to cease the use of Electricity and BC Hydro, in its sole discretion, continues to supply Electricity, the rate for such Electricity will be: **Energy Charge:** 35.98~~33.67~~ ¢ per kWh

ACCEPTED:____________________________

ORDER NO.____________________________

COMMISSION SECRETARY

Period of Interruption	A period during which a Customer is required by BC Hydro to cease the use of Electricity under these Rate Schedules.
Rate Schedules	1. Rate Schedule 1205 – Small Commercial Applications: Applies to a Customer whose interruptible heating load is mostly in support of a commercial activity and whose firm Electricity is billed on a General Service (under 35 kW) Rate Schedule. 2. Rate Schedule 1206 – Large Commercial Applications: Applies to a Customer whose interruptible heating load is mostly in support of a commercial activity and whose firm Electricity is billed on a General Service (35 kW and over) Rate Schedule. 3. Rate Schedule 1207 – Industrial Applications: Applies to a Customer whose interruptible heating load is mostly in support of an industrial activity and whose firm Electricity is billed on a General Service Rate Schedule or for farm use on a Residential Rate Schedule.
Special Conditions	1. BC Hydro may, at any time and from time to time, interrupt the supply of Electricity under these Rate Schedules whenever there is a lack of surplus hydro energy and Service cannot be provided economically from other energy sources.

ACCEPTED:______________________________

ORDER NO.______________________________

____
COMMISSION SECRETARY

	2. A Customer taking Service under these Rate Schedules is required to have, to BC Hydro's satisfaction, an installed permanent backup heating system using an alternative fuel, or an installed permanent independent electrical generating system, in good working order, and an adequate supply of fuel therefor, so that the Customer can continue heating operations when the supply of Electricity is interrupted. The output rating of the backup system must be of sufficient capacity to supply the heating load served under these Rate Schedules. If at any time a Customer fails to comply with the foregoing requirements, BC Hydro may immediately Terminate the supply of Electricity under these Rate Schedules to such Customer. 3. BC Hydro will interrupt the supply of Electricity by either manual or automatic means or by written notice by registered mail or hand delivery to the Customer to cease the use of Electricity under these Rate Schedules. A Customer who has been given such written notice to cease the use of Electricity under these Rate Schedules will in accordance with the requirements of the notice cease such use and will not begin to use Electricity again until so authorized by BC Hydro, by written notice. If a Customer fails to comply with these requirements, BC Hydro may in its sole discretion: (a) Continue to supply Electricity, in which case the rate will be the rate for Electricity during a Period of Interruption as stated in these Rate Schedules, or (b) Terminate the supply of Electricity under these Rate Schedules.

ACCEPTED:____________________

ORDER NO.____________________ ____________________

COMMISSION SECRETARY

	4. The initial contract period for dual fuel interruptible Service under these Rate Schedules is: (a) One year where no new facility is required to be constructed or the only facility required to be constructed by BC Hydro to serve the Customer is a drop Service Connection, or (b) Two years where more than a drop Service Connection is required to be constructed by BC Hydro to serve the Customer. At the expiration of a contract period, the contract period is automatically extended from year to year unless either the Customer or BC Hydro gives written notice to the other 30 days prior to the anniversary date. Transfer of the load served under these Rate Schedules to a general firm Rate Schedule will not be permitted during a Period of Interruption. 5. These Rate Schedules are not available to Premises where Electricity under it was previously supplied and Terminated. 6. BC Hydro will upgrade an existing Service Connection supplying firm load to serve additional load under these Rate Schedules. The charge for upgrading will be the same as applicable to a new Service Connection. 7. For existing Customers adding load to take Service under these Rate Schedules, and where an overhead distribution Extension is required to accommodate such added load BC Hydro will contribute toward the estimate cost of the Extension an amount not exceeding two times the annual revenue as estimated by BC Hydro to be received by the applicant. Any excess cost will be contributed by the applicant.

	8. No other load than that stipulated in the Availability clause is permitted under these Rate Schedules. Any unauthorized use of Electricity or any refusal by a Customer to permit access to Premises in accordance with the Terms and Conditions of BC Hydro's Electric Tariff will result in immediate Termination under the applicable Rate Schedule and all unauthorized consumption as estimated by BC Hydro will be billed at the rate for Electricity during a Period of Interruption as stated in these Rate Schedules.
	9. In addition to and without restriction of any other limitations of liability of BC Hydro, BC Hydro will specifically not be liable for any loss, damage, injury or expense occasioned to or suffered by any Customer receiving Service on these Rate Schedules, or by any other Person, for or by reason of any interruption of Electricity supply whatsoever for any reason whatsoever.
	10. A Customer who signs a contract with BC Hydro for the supply of Electricity to new load under these Rate Schedules during the period commencing July 1, 1988 and ending December 31, 1988 will be eligible to receive an incentive rebate on his Electricity bills provided the Customer begins taking Service under these Rate Schedules no later than 12 months following the date the contract was signed.
	11. A rebate will be applied to reduce the effective rate to 1.1 ¢ per kWh. Such rebate will apply only to an accumulated maximum of $30.00 per kW of connected new load in excess of 35 kW and only up to the first two years following connection. Bills for Energy consumed will be calculated and presented at full rates with the rebate for any given period applied to the following bill. The maximum two year period of billing rebates will be extended by the equivalent of any Period of Interruption. Rebates will not be applied to reduce the rate applicable for consumption during a Period of Interruption, nor will rebates be applied to reduce Power Factor surcharges.

	12. At the conclusion of any Period of Interruption, BC Hydro may Terminate Service under these Rate Schedules to any Customer who used Electricity during a Period of Interruption, unless it can be demonstrated to BC Hydro's satisfaction that adequate standby facilities exist.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under these Rate Schedules, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the rates under these Rate Schedules include~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.
	~~Effective April 1, 2018 the rates under these Rate Schedules include an increase of 3.0% before rounding, approved by BCUC Order No. G-47-18.~~

ORDER NO.____________________

COMMISSION SECRETARY

2. GENERAL SERVICE

RATE SCHEDULE 1234 – SMALL GENERAL SERVICE (UNDER 35 KW) – ZONE II

Availability	For all purposes where a meter with Demand measurement capability is not installed because the Customer's Demand as estimated by BC Hydro is less than 35 kW. Supply is 60 hertz, single or three phase at an available Secondary Voltage.
Applicable in	Rate Zone II.
Rate	**Basic Charge:** 26.73~~25.02~~ ¢ per day plus **Energy Charge:** First 7000 kWh per month @ 12.72~~11.90~~ ¢ per kWh All additional kWh per month @ 21.17~~19.81~~ ¢ per kWh **Minimum Charge:** The Basic Charge
Special Conditions	Special Conditions for Unmetered Service: 1. BC Hydro may permit unmetered Service under this Rate Schedule if it can estimate to its satisfaction the Energy used in kilowatt hours over a period of two months based on the connected load and the hours of use. 2. The Customer, if required by BC Hydro, will provide and maintain such controls, including timing devices, as BC Hydro considers necessary, and facilities satisfactory to BC Hydro for the maintenance of such controls. 3. The hours of use per period will be as specified by the Customer or as estimated by BC Hydro, whichever is greater.

ACCEPTED:______________________________

ORDER NO.______________________________

____
COMMISSION SECRETARY

4. The Customer will supply, install and maintain all wiring, fixtures, control devices and equipment, including the controls and devices described in Special Condition No. 2, at the expense of the Customer.

5. All wiring, fixtures, control devices and equipment and the method of installing, operating and maintaining the same are subject to the approval of BC Hydro which approval may be withdrawn by BC Hydro, at any time, at BC Hydro's sole discretion.

6. The Customer will notify BC Hydro immediately of any proposed or actual change in load, load characteristics, or hours of use.

7. BC Hydro may at any time, in its sole discretion, install Metering Equipment, and thereafter bill the Customer on the appropriate Rate Schedule as a metered account.

8. For display signs and signboard lighting, where hours of use are controlled by timing devices, the following turn-on times will apply, unless BC Hydro otherwise agrees in writing:

Period	Turn-on Time
January 1 to January 15:	4:00 p.m.
January 16 to February 28:	4:30 p.m.
March 1 to April 30:	6:30 p.m.
May 1 to August 15:	8:30 p.m.
August 16 to September 30:	6:30 p.m.
October 1 to November 15:	4:30 p.m.
November 16 to December 31:	4:00 p.m.

ACCEPTED:______________________

ORDER NO.______________________

____
COMMISSION SECRETARY

	9. In all cases, where hours of use of display signs or signboard lighting commence at dusk and are controlled either by timing devices or by photo-electric cells, the following hours of use for a period of two months will be deemed for billing purposes: Dusk to 10 p.m.: 216 hours Dusk to 11 p.m.: 270 hours Dusk to 12 p.m.: 330 hours Dusk to 1 a.m.: 380 hours Dusk to Dawn: 666 hours (All times are Pacific Time.)
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the rates under this Rate Schedule include~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.
	~~Effective April 1, 2018 the rates under this Rate Schedule include an increase of 3.0% before rounding, approved by BCUC Order No. G-47-18.~~

2. GENERAL SERVICE

RATE SCHEDULE 1253 – DISTRIBUTION SERVICE – IPP STATION SERVICE

Availability	For Customers who are Independent Power Producers (**IPPs**) served at distribution voltage, on an interruptible basis.
Applicable in	Rate Zone I excluding Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Energy Charge:** The sum, over the billing period, of the hourly Energy consumed multiplied by the entry in the Intercontinental Exchange (**ICE**) Mid Columbia (Mid-C) Peak, and Mid-C Off-Peak weighted average index price as published by the ICE in the ICE Day Ahead Power Price Report that corresponds to the time when consumption occurred, during that hour.
Monthly Minimum Charge	$49.01~~45.87~~
Special Conditions	1. BC Hydro agrees to provide Electricity under this Rate Schedule to the extent that it has energy and capacity to do so. 2. BC Hydro may, without notice to the Customer, refuse to supply or terminate the supply of Electricity under this Rate Schedule if at any time BC Hydro does not have sufficient energy or capacity. 3. Prior to taking Electricity under this Rate Schedule, the Customer may be required to obtain approval from BC Hydro. BC Hydro will advise the Customer of the need to obtain approval prior to the taking of Electricity under this Rate Schedule. 4. Electricity taken under this Rate Schedule is to be used solely for maintenance and black-start requirements and will not displace electricity that would normally be generated by the Customer.

Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the Monthly Minimum Charge under this Rate Schedule includes~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.
	~~Effective April 1, 2018 the Monthly Minimum Charge under this Rate Schedule includes an increase of 3.0% before rounding, approved by BCUC Order No. G-47-18.~~

ORDER NO.____________________________ ______________________________

COMMISSION SECRETARY

2. GENERAL SERVICE

RATE SCHEDULES 1255, 1256, 1265, 1266 – GENERAL SERVICE (35 KW AND OVER) – ZONE II

Availability	For all purposes. Supply is 60 hertz, single or three phase at Secondary or Primary Voltage. BC Hydro reserves the right to determine the voltage of the Service Connection.
Applicable in	Rate Zone II.
Rate	**Basic Charge:** 26.73~~25.02~~ ¢ per day plus **Energy Charge:** First 200 kWh per kW of Billing Demand per month @ 12.72~~11.90~~ ¢ per kWh All additional kWh per month @ 21.17~~19.81~~ ¢ per kWh
Discounts	1. A discount of 1½% will be applied to the above charges if a Customer's supply of Electricity is metered at a Primary Voltage. 2. A discount of 25 ¢ per month per kW of Billing Demand will be applied to the above rate if a Customer supplies Transformation. 3. If a Customer is entitled to both of the above discounts the discount for metering at a Primary Voltage will be applied first.
Monthly Minimum Charge	The monthly minimum charge to be paid by a Customer on Rate Schedule 1255, 1256, 1265 or 1266, as applicable, will be the charge the Customer would have been billed under Rate Schedule 1200, 1201, 1210 or 1211 (Exempt General Service – 35 kW and over), respectively.
Rate Schedules	1. Rate Schedule 1255: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and BC Hydro supplies Transformation.

ACCEPTED:________________________

ORDER NO.________________________

COMMISSION SECRETARY

	2. Rate Schedule 1256: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and BC Hydro supplies Transformation. 3. Rate Schedule 1265: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and the Customer supplies Transformation. 4. Rate Schedule 1266: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and the Customer supplies Transformation.
Special Conditions	1. Metering Equipment with both Demand and Energy measurement capability will normally be installed. Until such Metering Equipment is installed, or if the installed Metering Equipment does not have Demand measurement capability, Billing Demand will be as estimated by BC Hydro. 2. Where the Customer’s Demand is or is likely to be in excess of 45 kVA, BC Hydro may require such Customer to execute a special contract for Service, including such special conditions as BC Hydro, in its sole discretion considers necessary.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under these Rate Schedules, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the rates under these Rate Schedules include~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.

ORDER NO.________________________

____
COMMISSION SECRETARY

2. GENERAL SERVICE

RATE SCHEDULE 1268 – DISTRIBUTION SERVICE – IPP DISTRIBUTION TRANSPORTATION ACCESS

Availability	For Customers who have generators connected to BC Hydro's distribution system and who want to access BC Hydro's transmission system pursuant to and in accordance with BC Hydro's Open Access Transmission Tariff (OATT).
Applicable in	Rate Zone I excluding Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Distribution Transportation Charge:** 0.197~~0.184~~ ¢ per kWh
Special Conditions	1. The Customer is required to pay the costs, including the cost of altering existing facilities, to connect the generator to BC Hydro's distribution system in accordance with BC Hydro's Connection Requirements for Utility or Non-Utility Generation, 35 kV and Below. 2. For Customers with self-generation (i.e., with a Customer Baseline Load (**CBL**) greater than zero), this Rate Schedule is only applicable to sales of Surplus Energy. It may not be used by self-generating Customers who appear to have varied their demand for power from BC Hydro based on the actual or anticipated difference between BC Hydro's rate for providing Service to them and the market price of power. 3. For the purposes of this Rate Schedule, "Surplus Energy" in any period is the energy made available from generation by the Customer calculated as the difference between the Customer's CBL and the Customer's actual consumption from BC Hydro in that period.

ACCEPTED:____________________

ORDER NO.____________________

____
COMMISSION SECRETARY

	4. The Customer's CBL is established, in general, by determining the Customer's Energy consumption, on a monthly basis, for the past three years; in cases where inadequate history exists, alternative methods may be used to determine a Customer's CBL. Once established, the Customer's CBL will not be automatically adjusted for changes in the Customer's net metered consumption from BC Hydro. Any subsequent changes to the CBL must be due to changes in the Customer's load and not due to changes in its generation. The Customer must provide metered output from its generator which demonstrates an increase in generation output commensurate in time and amount with the Surplus Energy transported using this Rate Schedule. Where it appears that the Customer has transported on this Rate Schedule Energy that is not Surplus Energy, BC Hydro will provide replacement energy to the Customer's load at market prices, subject to Commission approval for such sales. 5. The metering point to determine the electricity being delivered to BC Hydro's distribution system will be determined by BC Hydro. The electricity delivered to BC Hydro's distribution system will also be deemed to be delivered to BC Hydro's transmission system (that is, no distribution loss adjustment will be applied to the electricity from an independent power producer or self-generator when determining capacity and energy delivered to BC Hydro's transmission system).
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the rate under this Rate Schedule include~~d~~s an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.

	~~Effective April 1, 2018 the rate under this Rate Schedule includes an increase of 3.0% before rounding, approved by BCUC Order No. G-47-18.~~

2. GENERAL SERVICE

RATE SCHEDULE 1280 – SHORE POWER SERVICE (DISTRIBUTION)

Availability	For the supply of Shore Power to Port Customers who qualify for General Service for use by Eligible Vessels while docked at the Port Customer's Port Facility, on an interruptible basis. Shore Power Service is supplied at 60 Hz, three phase at Primary Voltage.
Applicable in	Rate Zone I.
Rate	**Administrative Charge:** $150.00 per month plus **Energy Charge:** 10.510~~9.836~~ ¢ per kWh
Special Conditions	1. BC Hydro agrees to provide Electricity under this Rate Schedule to the extent that it has energy and capacity to do so. BC Hydro may refuse or Terminate Service under this Rate Schedule in circumstances where BC Hydro does not have sufficient energy or capacity. For greater certainty, BC Hydro will not be required to construct an Extension for the purpose of increasing the capacity of BC Hydro's distribution system to provide Shore Power Service under this Rate Schedule. 2. The terms and conditions under which Shore Power Service is supplied are contained in the Shore Power Service Agreement (Electric Tariff Supplement No. 86). The Port Customer will pay to BC Hydro the charges set out in this Rate Schedule in addition to any charges set out in the Shore Power Service Agreement. 3. A Port Customer that provides Port Electricity at a Port Facility under Rate Schedules 1600, 1601, 1610, 1611 or 1823 is not eligible to take Shore Power Service under this Rate Schedule to provide Port Electricity to that Port Facility, or any Port Facility served by the same BC Hydro delivery facilities.

ACCEPTED:____________________

ORDER NO.____________________ ____________________

COMMISSION SECRETARY

	4. On each occasion, if any, that BC Hydro is required to dispatch power line technicians or other workers to operate the switchgear for each connect and disconnect of Eligible Vessels docked at the Port Customer's Port Facility, BC Hydro will charge, and the Port Customer will pay, the reasonable time and labour costs for this service. The charge will be based on prevailing BC Hydro contracted labour rates and will be separately itemized on the Port Customer's monthly bill.
Definitions	For purposes of this Rate Schedule, capitalized terms have the meanings given to them in Electric Tariff Supplement No. 86.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

2. GENERAL SERVICE

RATE SCHEDULES 1300, 1301, 1310, 1311 – SMALL GENERAL SERVICE (UNDER 35 KW)

Availability	For Customers who qualify for General Service and whose Demand, metered or estimated by BC Hydro, as applicable, is less than 35 kW. Supply is 60 hertz, single or three phase at a Secondary or Primary Voltage.
Applicable in	Rate Zone I and Rate Zone IB.
Rate	**Basic Charge:** 36.45~~34.11~~ ¢ per day plus **Energy Charge:** 12.53~~11.73~~ ¢ per kWh **Minimum Charge:** The Basic Charge
Discounts	1. A discount of 1½% will be applied to the above charges if Customer's supply of Electricity is metered at a Primary Voltage. 2. A discount of 25 ¢ per month per kW of Demand will be applied if a Customer supplies Transformation. 3. If a Customer is entitled to both of the above discounts, the discount for metering at a Primary Voltage will be applied first.
Rate Schedules	1. Rate Schedule 1300: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and BC Hydro supplies Transformation. 2. Rate Schedule 1301: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and BC Hydro supplies Transformation.

ACCEPTED:______________________________

ORDER NO.______________________________

____
COMMISSION SECRETARY

	3. Rate Schedule 1310: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and the Customer supplies Transformation. 4. Rate Schedule 1311: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and the Customer supplies Transformation.
Special Conditions	Special Conditions for Unmetered Service: 1. BC Hydro may permit unmetered Service under these Rate Schedules if it can estimate to its satisfaction the Energy used in kilowatt hours over a period of two months based on the connected load and the hours of use. 2. The Customer, if required by BC Hydro, will provide and maintain such controls, including timing devices, as BC Hydro considers necessary, and facilities satisfactory to BC Hydro for the maintenance of such controls. 3. The hours of use per period will be as specified by the Customer, or as estimated by BC Hydro, whichever is greater. 4. The Customer will supply, install and maintain all wiring, fixtures, control devices and equipment, including the controls and devices described in Special Condition No. 2, at the expense of the Customer. 5. All wiring, fixtures, control devices and equipment and the method of installing, operating and maintaining the same are subject to the approval of BC Hydro which approval may be withdrawn by BC Hydro, at any time, at BC Hydro's sole discretion. 6. The Customer will notify BC Hydro immediately of any proposed or actual change in load, load characteristics, or hours of use.

7. BC Hydro may at any time, in its sole discretion, install Metering Equipment, and thereafter bill the Customer on the appropriate Rate Schedule as a metered account.

8. For display signs and signboard lighting, where hours of use are controlled by timing devices, the following turn-on times will apply, unless BC Hydro otherwise agrees in writing:

Period	Turn-on Time
January 1 to January 15:	4:00 p.m.
January 16 to February 28:	4:30 p.m.
March 1 to April 30:	6:30 p.m.
May 1 to August 15:	8:30 p.m.
August 16 to September 30:	6:30 p.m.
October 1 to November 15:	4:30 p.m.
November 16 to December 31:	4:00 p.m.

9. In all cases, where hours of use of display signs or signboard lighting commence at dusk and are controlled either by timing devices or by photo-electric cells, the following hours of use for a period of two months will be deemed for billing purposes:

Dusk to 10 p.m.:	216 hours
Dusk to 11 p.m.:	270 hours
Dusk to 12 p.m.:	330 hours
Dusk to 1 a.m.:	380 hours
Dusk to Dawn:	666 hours

(All times are Pacific Time.)

2. GENERAL SERVICE

RATE SCHEDULES 1500, 1501, 1510, 1511 – MEDIUM GENERAL SERVICE (35 KW OR GREATER AND LESS THAN 150 KW)

Availability	For Customers who qualify for General Service and whose Billing Demand is equal to or greater than 35 kW but less than 150 kW, and whose Energy consumption in any 12-month period is equal to or less than 550,000 kWh. Supply is 60 hertz, single or three phase at Secondary or Primary Voltage. BC Hydro reserves the right to determine the voltage of the Service Connection.
Applicable in	Rate Zone I.
Rate	**Basic Charge:** 26.73~~25.02~~ ¢ per day plus **Demand Charge:** $5.42~~5.07~~ per kW of Billing Demand plus **Energy Charge:** 9.68~~9.06~~ ¢ per kWh
Discounts	1. A discount of 1½% will be applied to the above charges if a Customer's supply of Electricity is metered at a Primary Voltage. 2. A discount of 25 ¢ per Billing Period per kW of Billing Demand will be applied to the above charges if a Customer supplies Transformation. 3. If a Customer is entitled to both of the above discounts, the discount for metering at a Primary Voltage will be applied first.

Monthly Minimum Charge	50% of the highest Demand Charge billed in any Billing Period wholly within an on-peak period during the immediately preceding 11 Billing Periods. For the purpose of this provision an on-peak period commences on November 1 in any year and terminates on March 31 of the following year.
Rate Schedules	1. Rate Schedule 1500: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and BC Hydro supplies Transformation. 2. Rate Schedule 1501: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and BC Hydro supplies Transformation. 3. Rate Schedule 1510: Applies if a Customer's supply of Electricity is metered at a Secondary Voltage and the Customer supplies Transformation. 4. Rate Schedule 1511: Applies if a Customer's supply of Electricity is metered at a Primary Voltage and the Customer supplies Transformation.
Definitions	1. Billing Demand The Billing Demand will be the highest kW Demand in the Billing Period. 2. Billing Period A month between regular meter readings, provided that in cases where meter readings are not available or are delayed for any reason BC Hydro may vary the number of days in the Billing Period.

3. IRRIGATION SERVICE

RATE SCHEDULE 1401 – IRRIGATION SERVICE

Availability	For motor loads of 746 watts or more used for irrigation and outdoor sprinkling where Electricity will be used principally during the Irrigation Season as defined below. Supply is 60 hertz, single or three phase at the Secondary or Primary Voltage available. BC Hydro reserves the right to determine the voltage of the Service Connection.
Applicable in	Rate Zone I and Rate Zone IB.
Rate	1. During the Irrigation Season: **Energy Charge:** 6.12~~5.73~~ ¢ per kWh **Minimum Charge:** $6.12~~5.73~~ per kilowatt of connected load per month for a period of eight months commencing in March in any year whether Energy consumption is registered or not. 2. During the Non-Irrigation Season: **Energy Charge:** First 150 kWh @ 6.12~~5.73~~ ¢ per kWh All additional kWh @ 48.52~~45.41~~ ¢ per kWh **Minimum Charge:** Where Energy consumption is 500 kWh or less, Nil. Where Energy consumption is more than 500 kWh, $48.94~~45.80~~ per kilowatt of connected load.
Discount for Ownership of Transformers	A discount of 25 ¢ per month per kW of connected load will be applied to the above charges if a Customer supplies the Transformation.

Definitions	1. Irrigation Season: In respect of each Service Connection the period commencing with a meter reading on or about March 1 in any year, having a mid-season meter reading on or about July 31, and ending with a meter reading on or about October 31 in that same year. BC Hydro may, in its discretion extend such period by postponing the termination date to any date not later than November 30, for the sole purpose of permitting a Customer to fill reservoirs necessary for the operation of the irrigation or sprinkling system. 2. Non-Irrigation Season: The period commencing at the end of one Irrigation Season and terminating at the beginning of the next Irrigation Season.
Special Conditions	1. No equipment provided with Electricity under this Rate Schedule will be served with Electricity under any other Rate Schedule while the Customer's Service Agreement under this Rate Schedule is in force. 2. Normally the Service Connection will be energized during the Non-Irrigation Season, but will be Disconnected if a Customer so requests. 3. The Minimum Charge during the Irrigation Season will commence in March for an account that has not been Terminated by the Customer, whether or not the Service Connection is energized and will be billed in two installments, at the end of July and at the end of October. 4. For the Irrigation Season, a bill will be rendered following the July and October meter readings. The first bill will be the greater of the Energy Charge and the Minimum Charge for the period March 1 to July 31. The second bill will be the greater of the Energy Charge for the season and the Minimum Charge for the season, less payment received for the first billing charges.

4. STREET LIGHTING SERVICE

RATE SCHEDULE 1701 – OVERHEAD STREET LIGHTING

Availability	For lighting of public highways, streets and lanes in cases where BC Hydro owns, installs and maintains the fixtures, conductors, controls and poles.
Applicable in	Any area served by suitable overhead distribution lines.
Rate	Per fixture per month as set out below: 100 watt H.P. sodium vapour unit $19.60~~18.34~~ 150 watt H.P. sodium vapour unit $23.38~~21.88~~ 200 watt H.P. sodium vapour unit $26.99~~25.26~~ *175 watt mercury vapour unit $21.54~~20.16~~ *250 watt mercury vapour unit $24.82~~23.23~~ *400 watt mercury vapour unit $31.99~~29.94~~ Wattages are lamp watts. * Note Special Condition No. 2.
Special Conditions	1. Connection Charge No charge will be made for Service Connections. 2. Mercury Vapour Mercury vapour fixtures are not available for new installations.

ACCEPTED:______________________

ORDER NO.______________________ ______________________

COMMISSION SECRETARY

	3. Extension Policy BC Hydro will construct a distribution Extension if required by the applicant in accordance with the Terms and Conditions of the Electric Tariff as applicable. When, at the Customer's request, a new fixture replaces an existing fixture, the Customer will pay to BC Hydro the original cost of the existing fixture, less any accumulated depreciation, and the cost of removing the existing fixture. 4. Relocation and Redirection of Fixtures The Customer will pay the full cost of relocating or redirecting fixtures when the change is made at the request of the Customer. 5. Design BC Hydro will design the installation of overhead street lighting fixtures. 6. Lamps Failing to Operate BC Hydro will, without charge, replace lamps or components that fail to operate, unless breakage is the reason for such failure in which case the Customer will be charged the cost of the material required to make the fixture operate. 7. Term of Service Agreement The term of the initial Service Agreement under this Rate Schedule will be not more than five years; renewal periods will be for five years.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

4. STREET LIGHTING SERVICE

RATE SCHEDULE 1702 – PUBLIC AREA ORNAMENTAL STREET LIGHTING

Availability	For lighting of public highways, streets and lanes and municipal pathways and for public area seasonal lighting displays, in those cases where the Customer owns, installs and maintains the standards, fixtures, conductors and controls.
Applicable in	All Rate Zones.
Rate	**Energy Charge:** For each unmetered fixture: 3.77~~3.53~~ ¢ per watt of Billing Wattage per month For each metered fixture: 11.32~~10.59~~ ¢ per kWh
Definitions	Billable Wattage is the sum of all wattage, on all fixtures used by the Customer. For fixtures without dimming controls, the watts per fixture will include the wattage of the lamp plus, where applicable, the wattage of the ballast. For fixtures with dimming controls, the watts per fixture will be equal to: 1. The wattage of the lamp plus, where applicable, the wattage of the ballast, multiplied by 2. The ratio of effective fixture wattage after dimming to fixture wattage before dimming.

Special Conditions	1. Service Connection Where necessary BC Hydro will provide an overhead or underground Service Connection in accordance with the Terms and Conditions of the Electric Tariff. No Service Connection will be made to add any ornamental street lighting system which does not provide for eight or more street lighting fixtures except that, if the potential is 120/240 volts, at BC Hydro's discretion, a Service Connection may be made for a system of less than eight. Receptacle loads will be permitted for Service under this Rate Schedule provided that such receptacles are used predominantly for seasonal lighting displays, meaning that no more than 10% of the usage may be for other purposes. 2. Extension Policy BC Hydro will construct a distribution Extension if required by the applicant in accordance with the Terms and Conditions of the Electric Tariff. 3. Power Factor All installations of mercury vapour, sodium vapour or fluorescent lamps will be equipped with the necessary auxiliaries to assure that a Power Factor of not less than 90% lagging will be maintained. 4. Term of Service Agreement The term of the initial Service Agreement under this Rate Schedule will be not more than five years; renewal periods will be for five years.

	5. Fixtures with Automated Dimming Controls The following special terms and conditions apply to lighting fixtures fitted with dimming controls: (a) For purposes of this Special Condition No. 5, “dimming controls” means control units or fittings attached to, or forming part of, a street lighting fixture capable of being programmed or remotely operated so as to reduce the lumens output of the lamps during specified hours each day while the lamps are in operation. The reductions may vary according to the hours of the day, the days of the week, and the seasons of the year. (b) A Customer wishing to have fixtures with dimming controls separately rated under this Rate Schedule must submit a dimming schedule satisfactory to BC Hydro listing each light fixture fitted with dimming controls, the wattage of the fixture (including the lamp and, where applicable, the ballast), the dimming control setting or settings and the hours each day that the dimming control setting or settings will be in operation. (c) Whenever the Customer wishes to make changes in the lighting fixtures listed in the dimming schedule or in the dimming control settings or hours of operation, the Customer will submit an updated lighting fixture schedule to BC Hydro listing any changes. Changes will be permitted on a semi-annual basis (twice per year).

	6. Unmetered Service (a) BC Hydro may permit unmetered Service under this Rate Schedule if it can estimate to its satisfaction the Energy used in kilowatt hours over a period of one month based on the connected load and hours of use. (b) The Customer will notify BC Hydro immediately of any proposed or actual change in load, or load characteristics, or hours of use. (c) BC Hydro, in its discretion, may at any time install Metering Equipment and thereafter bill the Customer on the Energy consumption registered.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the rates under this Rate Schedule include~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.

4. STREET LIGHTING SERVICE

RATE SCHEDULE 1703 – STREET LIGHTING SERVICE

Availability	For lighting of public highways, streets and lanes in those cases where the Customer owns, installs and maintains the fixtures, conductors and controls on poles of BC Hydro. Available only to Customers formerly taking Service on Rate Schedule 1755, 1756, 1757, 1758, 1759 or 1767, to the City of New Westminster in respect of a portion of D.L. 172, to the Municipality of Sparwood and to the City of Vancouver.
Applicable in	The Cities of Victoria and Prince Rupert, the Municipalities of Oak Bay, Esquimalt, Saanich and Central Saanich, the Village of Sidney, the unorganized areas of Port Renfrew and Shawnigan Lake, a portion of D.L. 172 in the City of New Westminster, Natal and the City of Vancouver.
Rate	**Energy Charge:** 3.77~~3.53~~ ¢ per watt of Billing Wattage per month plus **Contact Charge:** $1.13~~1.06~~ per contact per month The Contact Charge is a per fixture charge for the use of pole space.
Definitions	Billable Wattage is the sum of all wattage, on all fixtures used by the Customer. For fixtures without dimming controls, the watts per fixture will include the wattage of the lamp plus, where applicable, the wattage of the ballast. For fixtures with dimming controls, the watts per fixture will be equal to: 1. The wattage of the lamp plus, where applicable, the wattage of the ballast, multiplied by 2. The ratio of effective fixture wattage after dimming to fixture wattage before dimming.

4. STREET LIGHTING SERVICE

RATE SCHEDULE 1755 – PRIVATE OUTDOOR LIGHTING (CLOSED)

Availability	For outdoor lighting Service to illuminate property other than public streets or lanes (private property), where Service is provided from dusk to dawn and the supply is single phase, 60 hertz at the Secondary Voltage available. This Rate Schedule is available only in Premises served under this Rate Schedule on January 1, 1975 and only with respect to lights served under this Rate Schedule on January 1, 1975 and continuously thereafter, except BC Hydro may replace a mercury vapour unit with a high pressure sodium unit having approximately the same equivalent light output.
Applicable in	All Rate Zones.
Rate	**Charge per fixture per month as follows:** 1. Where a light is mounted on a pole that was installed by the Customer or by BC Hydro at the Customer's expense: 175 watt mercury vapour unit or replacement 100 watt H.P. sodium vapour unit — $18.37~~17.19~~ 400 watt mercury vapour unit or replacement 150 watt H.P. sodium vapour unit — $31.66~~29.63~~

COMMISSION SECRETARY

	2. Where a light is mounted on a pole that is on public property, or an easement, and is part of BC Hydro's distribution system: 175 watt mercury vapour unit or replacement 100 watt H.P. sodium vapour unit — $19.51~~18.26~~ 400 watt mercury vapour unit or replacement 150 watt H.P. sodium vapour unit — $32.81~~30.71~~ 3. Where a light is mounted on a pole that was installed on the Customer's property by BC Hydro, at its expense, solely for the purpose of supporting the light: 175 watt mercury vapour unit or replacement 100 watt H.P. sodium vapour unit — $24.02~~22.48~~ 400 watt mercury vapour unit or replacement 150 watt H.P. sodium vapour unit — $37.81~~35.39~~ Except that if two or more lights are mounted at one time on the same pole the rates for the additional light or lights will be as set out under part 1 above.
Special Conditions	1. BC Hydro will provide and install: (a) An outdoor light consisting of luminaire, mast arm, ballast, lamp and photo-electric control, and (b) Not more than one span of overhead secondary conductors per light. 2. The Customer will be required to contribute the estimated cost of any plant required to make Secondary Voltage available at a point not more than one span from the light; such contribution is not subject to refund.

	3. BC Hydro reserves the sole right to determine whether or not a light will be installed on a pole that is part of BC Hydro's distribution system. 4. The prior approval of BC Hydro is required if a Customer intends to install its own poles, and such poles will be maintained to BC Hydro's satisfaction at the Customer's expense. 5. BC Hydro will maintain all equipment owned by BC Hydro and will replace lamps which have failed. Any breakage will be repaired by BC Hydro at the Customer's expense.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the rates under this Rate Schedule include~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.

COMMISSION SECRETARY

	Energy Charge: B For Customers with a CBL: 4.535~~4.244~~ ¢ per kWh applied to all kWh up to and including 90% of the Customer's CBL in each Billing Year 10.160~~9.509~~ ¢ per kWh applied to all kWh above 90% of the Customer's CBL in each Billing Year Note: Customers previously supplied with Electricity under Rate Schedule 1825 will be subject to the rates in Part B above from the time the Customer commences taking Service under this Rate Schedule. **Monthly Minimum Charge:** $8.697~~8.139~~ per kVA of Billing Demand
Definitions	1. Billing Year The Billing Year is the 12 month billing period starting with the first day of the Billing Period which commences nearest to April 1 in each year, and ending on the last day of such 12-month Billing Period. 2. Billing Demand The Billing Demand will be: (a) The highest kVA Demand during the High Load Hours (**HLH**) in the Billing Period; or (b) 75% of the highest Billing Demand for the Customer's Plant in the immediately preceding period of November to February, both months included; or (c) 50% of the Contract Demand stated in the Electricity Supply Agreement for the Customer's Plant, whichever is the highest value, provided that for new Customers the Billing Demand for the initial two Billing Periods will be the average of the daily highest kVA Demands for the Customer's Plant.

	3. Customer Baseline Load (**CBL**) The Customer Baseline Load (**CBL**) is the Customer's historic annual energy consumption in kWh as approved by the British Columbia Utilities Commission. The Customer’s CBL will initially be determined by BC Hydro, and be subject to revision from time to time, in accordance with the criteria and procedures set forth in BC Hydro's "Customer Baseline Load (**CBL**) Determination Guidelines" (Electric Tariff Supplement No. 74). All CBLs will be subject to final approval of the British Columbia Utilities Commission. 4. High Load Hours (**HLH**) High Load Hours (**HLH**) is the period of hours from 06:00 to 22:00 Monday to Saturday, except for Statutory Holidays (New Year’s Day, Family Day, Good Friday, Victoria Day, Canada Day, B.C. Day, Labour Day, Thanksgiving Day, Remembrance Day and Christmas Day). 5. Low Load Hours (**LLH**) Low Load Hours (**LLH**) are all hours other than HLH.
Special Conditions	1. A Customer having two or more operating plants may elect to have a single aggregated CBL determined for all or any combination of its operating plants in accordance with BC Hydro’s “Customer Baseline Load (**CBL**) Determination Guidelines” (Electric Tariff Supplement No. 74). Thereafter, BC Hydro will issue a single bill for all operating plants included in the aggregation, and the Energy Charge payable will be determined on the basis of the aggregated CBL. However, the Demand Charge will continue to be determined separately for each operating plant.

	2. If any initial, revised, or aggregate CBL for a Customer has not been determined by BC Hydro and approved by British Columbia Utilities Commission by the time at which the CBL would become effective, BC Hydro may determine the CBL on an interim basis and apply that CBL for the purposes of any billing periods and bills rendered to the Customer until such time as the CBL has been finally determined and approved by the British Columbia Utilities Commission, following which BC Hydro will make any necessary billing adjustments. 3. If a Customer taking Service at the rates in Part B of the Energy Charge rate section above Terminates Service under this Rate Schedule prior to the end of a Billing Year, the Customer's CBL or aggregate CBL will be prorated for the portion of the Billing Year during which the Customer was taking Service, and the prorated CBL or aggregate CBL will be used for the purposes of applying the rates in Part B to all energy consumption during the Billing Year up to the time of Termination. BC Hydro will make any necessary billing adjustments and bill the Customer for the difference (if any) owing.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Note	The terms and conditions under which Transmission Service is supplied are contained in Electric Tariff Supplement Nos. 5 and 6, or Electric Tariff Supplement Nos. 87 and 88, as applicable.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

5. TRANSMISSION SERVICE

RATE SCHEDULE 1825 – TRANSMISSION SERVICE – TIME-OF-USE (TOU) RATE

Availability	For Customers who provide notice by February 15 of each year and who at the time of application are eligible to take Service under Rate Schedule 1823 (Stepped Rate) at the Energy Charge rates set out in Part B of the rate section of that Rate Schedule, and who have entered into a TOU (Transmission Service) Agreement by March 15 of that year. Customers will start Service under Rate Schedule 1825 in the first Billing Period after April 1.
Applicable in	Rate Zone I excluding the Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Demand Charge:** $8.697~~8.139~~ per kVA of Billing Demand per Billing Period plus **Energy Charge:** 1. Winter HLH Period: 4.535~~4.244~~ ¢ per kWh applied to all kWh up to and including 90% of the Customer's Winter HLH Period CBL. 11.337~~10.611~~ ¢ per kWh applied to all kWh above 90% of the Customer's Winter HLH Period CBL. 2. Winter LLH Period: 4.535~~4.244~~ ¢ per kWh applied to all kWh up to and including 90% of the Customer's Winter LLH Period CBL. 10.275~~9.616~~ ¢ per kWh applied to all kWh above 90% of the Customer's Winter LLH Period CBL.

ACCEPTED:_____________________________

ORDER NO._____________________________ ___________________________________

	3. Spring Period: 4.535~~4.244~~ ¢ per kWh applied to all kWh up to and including 90% of the Customer's Spring Period CBL. 9.151~~8.565~~ ¢ per kWh applied to all kWh above 90% of the Customer's Spring Period CBL. 4. Remaining Period: 4.535~~4.244~~ ¢ per kWh applied to all kWh up to and including 90% of the Customer's Remaining Period CBL applicable. 10.035~~9.392~~ ¢ per kWh applied to all kWh above 90% of the Customer's Energy CBL applicable in the Billing Period.
Definitions	1. Billing Demand The Demand for billing purposes will be: (a) The highest kVA Demand during the High Load Hours (**HLH**) in the Billing Period; or (b) 75% of the highest Billing Demand for the Customer's Plant in the immediately preceding period of November to February, both months included; or (c) 50% of the Contract Demand stated in the Electricity Supply Agreement for the Customer's Plant, whichever is the highest value.

ACCEPTED:________________________

ORDER NO.________________________

____
COMMISSION SECRETARY

	2. Customer Baseline Load (CBL) The Customer Baseline Load (**CBL**) is the Customer's historic consumption (in kWh) as approved by the British Columbia Utilities Commission. For the purposes of this Rate Schedule, the Customer's CBL will consist of four separate CBLs – one each for the Winter HLH Period, the Winter LLH Period, the Spring Period and the Remaining Period. The Customer's CBL will initially be determined by BC Hydro, and be subject to revision from time to time, in accordance with the criteria and procedures set forth in BC Hydro's "Customer Baseline Load (**CBL**) Determination Guidelines" (Electric Tariff Supplement No. 74). All CBLs will be subject to final approval of the British Columbia Utilities Commission. 3. High Load Hours (**HLH**) High Load Hours (**HLH**) is the period of hours from 06:00 to 22:00 Monday to Saturday, except for Statutory Holidays (New Year's Day, Family Day, Good Friday, Victoria Day, Canada Day, B.C. Day, Labour Day, Thanksgiving Day, Remembrance Day and Christmas Day). 4. Low Load Hours (**LLH**) The Low Load Hours (**LLH**) are all hours other than HLH. 5. Remaining Period The Remaining Period is all Billing Periods other than the Winter Period or the Spring Period. 6. Spring Period The Spring Period comprises the two Billing Periods starting with the first day of the Billing Period that commences nearest to May 1 each year and ending on the last day of the second Billing Period thereafter.

	7. Winter Period The Winter Period comprises four Billing Periods starting with the first day of the Billing Period that commences nearest to November 1 each year and ending on the last day of the fourth Billing Period thereafter.
Special Conditions	1. Service under this Rate Schedule will be provided only while a TOU (Transmission Service) Agreement with the Customer is in effect. 2. A Customer having two or more operating plants may elect to have a single aggregated CBL determined for all or any combination of its operating plants in accordance with BC Hydro's "Customer Baseline Load (CBL) Determination Guidelines" (Electric Tariff Supplement No. 74). Separate Energy CBL values will be determined for each plant and then aggregated. BC Hydro will issue a single bill for all operating plants included in an aggregation, and the Energy Charge payable will be determined on the basis of the aggregated Energy CBL value. The Demand Charge will continue to be determined separately for each operating plant. 3. If any initial, revised, or aggregate CBL for a Customer has not been determined by BC Hydro and approved by British Columbia Utilities Commission by the time at which the CBL would become effective, BC Hydro may determine the CBL on an interim basis and apply that CBL for the purposes of any billing periods and bills rendered to the Customer until such time as the CBL has been finally determined and approved by the British Columbia Utilities Commission, following which BC Hydro will make any necessary billing adjustments.

ACCEPTED:____________________

ORDER NO.____________________

____
COMMISSION SECRETARY

	4. In accordance with the TOU (Transmission Service) Agreement, the Customer will have a period of 30 days following approval of the Customer's initial CBL by the British Columbia Utilities Commission within which the Customer may, by written notice to BC Hydro, withdraw from taking Service under this Rate Schedule, and revert to taking Service under Rate Schedule 1823 (Stepped Rate). This right of withdrawal is available only when the Customer first subscribes to take Service under this Rate Schedule, and is applicable only in respect of the initial CBL determination. If the Customer exercises this right of withdrawal Rate Schedule 1823 will apply from the commencement of the then current Billing Year, and BC Hydro will make any necessary billing adjustments accordingly. 5. Customers taking Service under Rate Schedule 1852 (Modified Demand) may not also take Service under this Rate Schedule.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Note	The terms and conditions under which Transmission Service is supplied are contained in the Electricity Supply Agreement (Electric Tariff Supplement No. 5, or Electric Tariff Supplement No. 87, as applicable) as amended by the Electric Tariff Supplement No. 72 (TOU (Transmission Service) Agreement), and Electric Tariff Supplement No. 6, or Electric Tariff Supplement No. 88, as applicable.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the rates under this Rate Schedule include~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.
	~~Effective April 1, 2018 the rates under this Rate Schedule include an increase of 3.0% before rounding, approved by BCUC Order No. G-47-18.~~

5. TRANSMISSION SERVICE

RATE SCHEDULE 1827 – TRANSMISSION SERVICE – RATE FOR EXEMPT CUSTOMERS

Availability	For all purposes. Supply is at 60 kV or higher. Only for City of New Westminster and University of British Columbia and other Customers exempted from Rate Schedule 1823 (Stepped Rate) by the British Columbia Utilities Commission.
Applicable in	Rate Zone I excluding the Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Demand Charge:** $8.697~~8.139~~ per kVA of Billing Demand per Billing Period plus **Energy Charge:** 5.098~~4.771~~ ¢ per kWh for all kWh in a Billing Period **Monthly Minimum Charge:** $8.697~~8.139~~ per kVA of Billing Demand
Definitions	1. Billing Demand The Billing Demand will be: (a) The highest kVA Demand during the High Load Hours (**HLH**) in the Billing Period; or (b) 75% of the highest Billing Demand for the Customer's Plant in the immediately preceding period of November to February, both months included; or (c) 50% of the Contract Demand stated in the Electricity Supply Agreement for the Customer's Plant, whichever is the highest value.

	2. High Load Hours (**HLH**) High Load Hours (**HLH**) is the period of hours from 06:00 to 22:00 Monday to Saturday, except for Statutory Holidays (New Year's Day, Family Day, Good Friday, Victoria Day, Canada Day, B.C. Day, Labour Day, Thanksgiving Day, Remembrance Day and Christmas Day). 3. Low Load Hours (**LLH**) Low Load Hours (**LLH**) are all hours other than HLH.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Note	The terms and conditions under which Transmission Service is supplied are contained in Electric Tariff Supplement Nos. 5 and 6, or Electric Tariff Supplements Nos. 87 and 88, as applicable.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the rates under this Rate Schedule include~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.
	~~Effective April 1, 2018 the rates under this Rate Schedule include an increase of 3.0% before rounding, approved by BCUC Order No. G-47-18.~~

5. TRANSMISSION SERVICE

RATE SCHEDULE 1852 – TRANSMISSION SERVICE – MODIFIED DEMAND

Availability	To a Customer supplied with Electricity at 60 kV or higher who is taking Service under Rate Schedule 1823 (Stepped Rate) at the time of application, and is a party to a Modified Demand Agreement under Electric Tariff Supplement No. 54 which is in force, and which is in a location, as determined by BC Hydro, that will allow BC Hydro to curtail load to alleviate a potential local or regional transmission constraint, or take advantage of a market opportunity. The annual subscription period for new subscribers is from September 1 to October 31.
Applicable in	Rate Zone I excluding the Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Excess Demand Charge:** $8.697~~8.139~~ per kVA of metered kVA Demand in excess of the Maximum Demand Level during Low Load Hours
Definitions	1. Billing Demand The Billing Demand will be: (a) The highest kVA Demand during the High Load Hours (**HLH**) in the Billing Period; or (b) 75% of the highest Billing Demand for the Customer's Plant in the immediately preceding period of November to February, both months included; or (c) 50% of the Contract Demand stated in the Electricity Supply Agreement for the Customer's Plant, whichever is the highest value.

	2. High Load Hours (**HLH**) High Load Hours (**HLH**) means the period(s) in a 24-hour day and during those days of a calendar week in which Electricity usage is typically highest in a particular region, as determined by BC Hydro in its discretion based on load characteristics and transmission constraints in that region from time to time, and designated in a Modified Demand Agreement. 3. Low Load Hours (**LLH**) Low Load Hours (**LLH**) are all hours other than HLH. 4. LLH CBL Energy LLH CBL Energy means the highest monthly energy consumption during the LLH over the last 12 Billing Periods, or an estimate of consumption if insufficient data is available. 5. Maximum Demand Level Maximum Demand Level has the meaning set out in the Modified Demand Agreement. For a Customer with more than one designated period of High Load Hours, separate Maximum Demand Levels will be stated for each corresponding period of Low Load Hours. For a Customer with a single designated period of High Load Hours, a single Maximum Demand Level will be stated for all Low Load Hours. The highest Maximum Demand Level will not exceed 95% of Contract Demand stated in the Customer's Electricity Supply Agreement, and is subject to local transmission availability.

ACCEPTED:______________________________

ORDER NO.______________________________ ____

COMMISSION SECRETARY

Special Conditions	1. The terms and conditions under which Transmission Service is supplied are contained in Electric Tariff Supplement Nos. 5 and 6. The provisions of Rate Schedule 1823 (Stepped Rate) and Electric Tariff Supplement Nos. 5 and 6 continue to apply to Customers receiving Service under this Rate Schedule. In the case of a conflict between this Rate Schedule or the Modified Demand Agreement and Rate Schedule 1823 or Electric Tariff Supplement Nos. 5 or 6, the provisions of this Rate Schedule and the Modified Demand Agreement will govern. 2. If for any two Billing Periods the total energy consumed under Rate Schedule 1852, during the LLH, is greater than the LLH CBL Energy by 10% or more, the highest kVA Demand in each such Billing Period during the High Load Hours will be adjusted by the ratio of the average monthly LLH Energy during such two Billing Periods over the LLH CBL Energy. The adjusted highest kVA Demand will apply for a period of 12 months after the second Billing Period included in the adjustment calculation. The LLH CBL Energy will be recalculated using the consumption history of the most recent 12 Billing Periods. 3. The Minimum Reduction under the Modified Demand Agreement will be the greater of 50% of the difference between the Maximum Demand Level and the LLH CBL Demand, and 10 MW. 4. The Maximum Number of Demand Reduction Transactions under the Modified Demand Agreement will be the greater of Maximum Duration multiplied by the Maximum Number of Demand Reduction Transactions, and 48 hours.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the rate under this Rate Schedule includes~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.
	~~Effective April 1, 2018 the rate under this Rate Schedule includes an increase of 3.0% before rounding, approved by BCUC Order No. G-47-18.~~

5. TRANSMISSION SERVICE

RATE SCHEDULE 1853 – TRANSMISSION SERVICE – IPP STATION SERVICE

Availability	For Customers who are Independent Power Producers (**IPPs**) served at transmission voltage, on an interruptible basis.
Applicable in	Rate Zone I excluding Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Energy Charge:** The sum, over the Billing Period, of the hourly energy consumed multiplied by the entry in the Intercontinental Exchange (**ICE**) Mid-Columbia (Mid-C) Peak, and Mid-C Off-Peak weighted average index price as published by the ICE in the ICE Day Ahead Power Price Report that corresponds to the time when consumption occurred, during that hour
Monthly Minimum Charge	$49.01~~45.87~~
Special Conditions	1. BC Hydro agrees to provide Electricity under this Rate Schedule to the extent that it has energy and capacity to do so. 2. BC Hydro may, without notice to the Customer, refuse to supply or terminate the supply of Electricity under this Rate Schedule if at any time BC Hydro does not have sufficient energy or capacity. 3. Prior to taking Electricity under this Rate Schedule, the Customer may be required to obtain approval from BC Hydro. BC Hydro will advise the Customer of the need to obtain approval prior to the taking of Electricity under this Rate Schedule. 4. Electricity taken under this Rate Schedule is to be used solely for maintenance and black-start requirements and will not displace electricity that would normally be generated by the Customer.

ACCEPTED:________________

ORDER NO.________________

COMMISSION SECRETARY

Taxes	The rates and Monthly Minimum Charge set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the Monthly Minimum Charge under this Rate Schedule includes~~d~~ an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.
	~~Effective April 1, 2018 the Monthly Minimum Charge under this Rate Schedule includes an increase of 3.0% before rounding, approved by BCUC Order No. G-47-18.~~

5. TRANSMISSION SERVICE

RATE SCHEDULE 1880 – TRANSMISSION SERVICE – STANDBY AND MAINTENANCE SUPPLY

Availability	For Customers supplied with Electricity under Rate Schedule 1823 (Stepped Rate), 1825 (TOU Rate), 1827 (Rate for Exempt Customers) or 1852 (Modified Demand), on an interruptible basis.
Applicable in	Rate Zone I excluding the Districts of Kingsgate-Yahk and Lardeau-Shutty Bench.
Rate	**Administrative Charge:** \$150.00 per Period of Use plus **Energy Charge:** During the Period of Use, 10.160~~9.509~~ ¢ per kWh of metered Rate Schedule 1880 energy consumption, determined as set out below
Definitions	1. HLH Reference Demand HLH Reference Demand is the highest kVA Demand in the HLH for the current Billing Period prior to the Period of Use, but excluding any prior Period of Use. If the Period of Use extends over an entire Billing Period, the highest kVA Demand in the HLH from the prior Billing Period will be used in determining the HLH Reference Demand, excluding any Period of Use in the prior Billing Period. For the purpose of determining HLH Reference Demand, the HLH periods are as defined in Rate Schedule 1823, 1825, 1827 or 1852, whichever is applicable.

ACCEPTED:______________________________

ORDER NO.______________________________

COMMISSION SECRETARY

	2. Period of Use A period of consecutive hours during which Electricity is taken under this Rate Schedule. The Period of Use is as defined by the Customer when requesting Service from BC Hydro under this Rate Schedule 1880 and may extend into subsequent Billing Periods.
Rate Schedule 1880 Energy Determination	During HLH periods, the kWh consumption on an hourly basis which exceeds the HLH high kWh per hour within the Period of Use or portion thereof where HLH high kWh per hour is the product of HLH Reference Demand multiplied by the Power Factor for the half hour when the HLH Reference Demand occurred. For the purpose of the Rate Schedule 1880 Energy Determination, the HLH periods are as defined in Rate Schedule 1823, 1825, 1827 or 1852, whichever is applicable.
Special Conditions	1. BC Hydro agrees to provide Electricity under this Rate Schedule to the extent that it has energy and capacity to do so. 2. BC Hydro may, without notice to the Customer, refuse to supply or terminate the supply of Electricity under this Rate Schedule if at any time during the Period of Use BC Hydro does not have sufficient energy or capacity.

	3. This Rate Schedule is only for the following purposes: To provide Electricity the Customer would otherwise generate during periods when all or part of the Customer's electrical generating plant is curtailed. Electricity used for this purpose may be taken on an instantaneous basis when the impact of the instantaneous pickup of loads normally provided by the Customer's electrical generation units does not occur after BC Hydro has advised the Customer that a period of system constraint or potential system constraint exists. During periods of potential system constraints, BC Hydro will require Customers to arm load shedding relays to ensure that the loss of electricity production from a Customer's electrical generation unit will not result in a demand greater than the Customer's Maximum kVA Demand on BC Hydro's system. BC Hydro may require the Customer to provide it with control of these load shedding relays. During periods of potential system constraints, upon a Customer's request, BC Hydro will endeavour to provide Electricity normally provided by the Customer's electrical generation unit. The Customer is required to advise BC Hydro within 30 minutes of taking Electricity under this Rate Schedule for this purpose. If the Customer fails to advise BC Hydro within 30 minutes, measured Demand and Energy consumption will be billed under Rate Schedule 1823, 1825, 1827 or 1852, whichever is applicable. 4. Electricity taken under this Rate Schedule will not displace Electricity otherwise to be taken by the Customer under Rate Schedule 1823, 1825, 1827 or 1852. Electricity taken under this Rate Schedule will not displace electricity that would normally be generated by the Customer for the purpose of re-sale.

ACCEPTED:____________________

ORDER NO.____________________ ____________________

COMMISSION SECRETARY

	5. In addition to the charges specifically set out in this Rate Schedule, the Customer will pay for any additional facilities required to deliver Electricity under this Rate Schedule provided that BC Hydro obtains the prior consent of the Customer for construction of the additional facilities. 6. A Customer may be required to allow BC Hydro to install metering and communication equipment to measure the electricity output of the Customer's self-generation unit. 7. BC Hydro will bill for Electricity taken under Rate Schedule 1880 at the same time it bills for Electricity taken under Rate Schedule 1823, 1825, 1827 or 1852, whichever is applicable.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Note	The terms and conditions under which Transmission Service is supplied are contained in Electric Tariff Supplement Nos. 5 and 6, or Electric Tariff Supplement Nos. 87 and 88, as applicable.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.
Rate Increase	Effective April 1, 2019~~2016 and April 1, 2017~~ the Energy Charge under this Rate Schedule include~~d~~s an interim rate increase~~s~~ of 6.85%~~4.0% and 3.5%, respectively,~~ before rounding, ~~both~~ approved by BCUC Order No. ~~G-47-18~~.
	~~Effective April 1, 2018 the Energy Charge under this Rate Schedule includes an increase of 3.0% before rounding, approved by BCUC Order No. G-47-18.~~

ACCEPTED:____________________________

ORDER NO.____________________________ ____________________________
COMMISSION SECRETARY

5. TRANSMISSION SERVICE

RATE SCHEDULE 1891 – TRANSMISSION SERVICE – SHORE POWER SERVICE

Availability	For the supply of Shore Power to Port Customers for use by Eligible Vessels while docked at the Port Customer's Port Facility, on an interruptible basis. Supply is at 60 kV or higher.
Applicable in	Rate Zone I.
Rate	**Administrative Charge:** $150.00 per month plus **Energy Charge:** 10.160~~9.509~~ ¢ per kWh for all kWh in a billing period
Definitions	For purposes of this Rate Schedule, capitalized terms have the meanings given to them in the Shore Power Service Agreement (Electric Tariff Supplement No. 86).
Special Conditions	1. BC Hydro agrees to provide Electricity under this Rate Schedule to the extent that it has energy and capacity to do so. BC Hydro may refuse Service under this Rate Schedule in circumstances where BC Hydro does not have sufficient energy or capacity. For greater certainty, BC Hydro will not be required to construct a System Reinforcement under Electric Tariff Supplement No. 6 to provide Shore Power Service under this Rate Schedule. 2. The terms and conditions under which Shore Power Service is supplied are contained in the Shore Power Service Agreement (Electric Tariff Supplement No. 86). The Port Customer will pay to BC Hydro the charges set out in this Rate Schedule in addition to any charges set out in the Shore Power Service Agreement.

ACCEPTED:____________________________

ORDER NO.____________________________ ______________________________
COMMISSION SECRETARY

	3. A Port Customer that provides Port Electricity at a Port Facility under Rate Schedules 1600, 1601, 1610, 1611 (Large General Service) or 1823 (Stepped Rate) is not eligible to take Shore Power Service under this Rate Schedule to provide Port Electricity to that Port Facility, or a Port Facility served by the same BC Hydro delivery facilities. 4. On each occasion, if any, that BC Hydro is required to dispatch power line technicians or other workers to operate the switchgear for each connect and disconnect of Eligible Vessels docked at the Port Customer's Port Facility, BC Hydro will charge, and the Port Customer will pay, the reasonable time and labour costs for this service. The charge will be based on prevailing BC Hydro contracted labour rates and will be separately itemized on the Port Customer's monthly bill.
Taxes	The rates set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

Definitions	1. Billing Demand The Billing Demand in any Billing Month will be the greatest of: (a) The maximum amount of Electricity (in kW) scheduled under the Power Purchase Agreement, for any hour of the Billing Month; (b) 75% of the maximum amount of Electricity (in kW) scheduled under the Power Purchase Agreement in any hour in the 11 months of the Term immediately prior to the Billing Month (or less than 11 months, if the Effective Date is less than 11 months prior to the month); and (c) 50% of the Contract Demand (in kW) for the Billing Month. If FortisBC has reduced the Contract Demand in accordance with the Power Purchase Agreement, the amount of Electricity specified in item (b) above may not exceed an amount equal to 100% of the Contract Demand. 2. Maximum Tranche 1 Amount The Maximum Tranche 1 Amount for each Contract Year is 1,041 GWh. 3. Scheduled Energy Less Than or Equal to Annual Energy Nomination In any Contract Year, for the amount of the Scheduled Energy taken or deemed to be taken that is less than or equal to the Annual Energy Nomination, FortisBC will pay: (a) The Tranche 1 Energy Price for each kWh of such Scheduled Energy taken or deemed taken that is less than or equal to the Maximum Tranche 1 Amount; and (b) The Tranche 2 Energy Price for each kWh of such Scheduled Energy taken that exceeds the Maximum Tranche 1 Amount.

	4. Scheduled Energy Exceeding the Annual Energy Nomination In any Contract Year, for the amount of the Scheduled Energy taken or deemed to be taken that exceeds the Annual Energy Nomination, FortisBC will pay: (a) 150% of the Tranche 1 Energy Price, for each kWh of such Scheduled Energy taken or deemed taken that that exceeds the Annual Energy Nomination, but is less than or equal to the Maximum Tranche 1 Amount; and (b) 115% of the Tranche 2 Energy Price, for each kWh of such Scheduled Energy taken that exceeds the Annual Energy Nomination and also exceeds the Maximum Tranche 1 Amount. 5. Annual Minimum Take In any Contract Year, FortisBC will schedule and take an amount of Electricity equal to at least 75% of the Annual Energy Nomination, and will be responsible for any Annual Shortfall.
Note	The terms and conditions under which Service is supplied to FortisBC are contained in the Power Purchase Agreement.
Taxes	The rates and charges set out in this Rate Schedule are exclusive of goods and services and provincial sales taxes.
Rate Rider	The Deferral Account Rate Rider as set out in Rate Schedule 1901 applies to all charges payable under this Rate Schedule, before taxes and levies.

Report on the Theory and Practice of Performance-Based Regulation

A REPORT ON THE THEORY AND PRACTICE OF PERFORMANCE-BASED REGULATION

By

Dennis L. Weisman Ph.D.*

December 12, 2018

EXECUTIVE SUMMARY

This report is designed to be a self-contained introduction to performance-based regulation (PBR) with an emphasis on the energy sector in North America. The main topics include: key differences between PBR and traditional cost-of-service regulation (COSR), the various forms of PBR and their efficiency properties, common misconceptions about PBR, the economic and public policy principles that should inform the design and implementation of PBR, the mechanics of PBR, the advantages and disadvantages of earnings sharing mechanisms, the importance of regulatory commitment and the role of benchmarking in PBR regimes.

Whereas COSR is frequently treated in the literature as a discrete alternative to PBR, these two types of regulatory regimes are best understood in terms of lying along a continuum based on the strengths of the incentives for efficient performance. The textbook model of COSR with no regulatory lag contemplates instantaneous rate reductions that serve to normalize excess returns. This regulatory regime lies at the far left on this continuum indicating extremely weak (low-powered) incentives. In contrast, long-term PBR with no earnings sharing or rebasing lies at the far right on this continuum indicating extremely strong (high-powered) incentives. Notably, COSR with a long regulatory lag may reside on this continuum to the right of a short-term PBR regime that incorporates a narrow deadband, pronounced earnings sharing and a full rebasing of rates at the end of the PBR term. In this special case, COSR exhibits more high-powered incentives than PBR. The key point is that PBR is not necessarily superior to COSR in all cases.

An important consideration concerns the unique challenges that arise in applying PBR to crown corporations and how these challenges may be overcome. The expected gains from adopting PBR may be subject to greater uncertainty in the case of crown corporations because they are *de facto* subject to two different regulatory authorities—the regulatory commission and the government owner. Nonetheless, PBR plans have been successfully applied to public enterprises.

Finally, if the PBR regime is not developed in accordance with sound economic principles, or there is not a strong commitment to the fundamental tenets of PBR on the part of either the regulator or the government, the significant resources required to design and implement a PBR regime would be difficult to justify. The adoption of PBR may simply fail the cost-benefit test under these conditions.

TABLE OF CONTENTS

LIST OF FIGURES AND TABLES

1. Introduction

This report examines the theory and practice of performance-based regulation (PBR) with an emphasis on the energy sector, including electricity and natural gas, in North America. In certain cases, references are made to the telecommunications industry to compare and contrast the experience with incentive regulation in that sector with that of the energy sector.

Whereas traditional cost-of-service regulation (COSR) is frequently treated in the literature as a discrete alternative to PBR, these two types of regulatory regimes are best understood in terms of lying along a continuum based on the strengths of the incentives for efficient performance as illustrated in Figure 1. The textbook model of COSR with no regulatory lag contemplates instantaneous rate reductions that serve to normalize excess returns. This regulatory regime lies at the far left on this continuum indicating extremely weak (low-powered) incentives. In contrast, long-term PBR (price/revenue caps) with no earnings sharing or rebasing lies at the far right on this continuum indicating extremely strong (high-powered) incentives. Notably, COSR with a long regulatory lag may reside on this continuum to the right of a short-term PBR regime that incorporates a narrow deadband, pronounced earnings sharing and a full rebasing of rates at the end of the PBR term. In this special case, COSR exhibits more high-powered incentives than PBR.

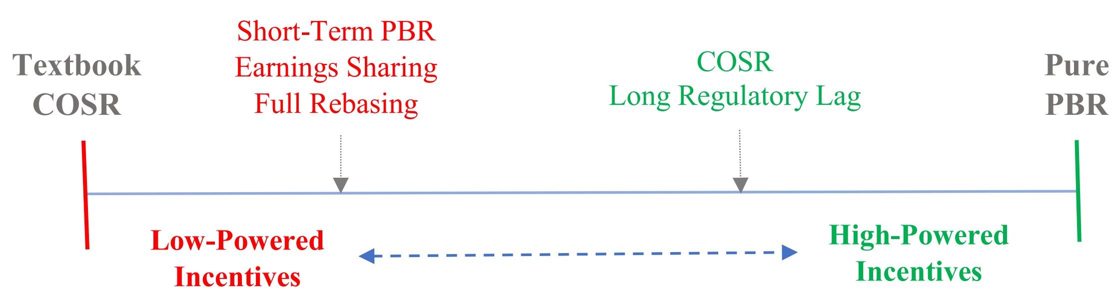

Figure 1. Continuum of Regulatory Regimes

In addition to reviewing the basic elements of PBR, this report addresses a number of important questions related to the design and implementation of PBR. These questions include but are not limited to the following.

- How is PBR defined and how does it differ from COSR?
- What are the most common forms of PBR?
- What are the efficiency properties of PBR and how do they differ from COSR?
- What are the most common misconceptions about PBR?
- What economic and public policy principles should guide the design of a PBR regime?
- How can PBR be designed to address conservation objectives?
- Is PBR superior to COSR in all settings?
- What are the advantages and disadvantages of earnings sharing mechanisms?
- What is the role of benchmarking in PBR regimes?
- What complexities arise in applying PBR to crown corporations?

While the economics literature typically compares the textbook models of COSR and PBR in extolling the superiority of the latter, the real world in which "the devil is in the details" is not nearly as straightforward. In addition, while numerous published econometric studies and literature surveys have concluded that incentive regulation in the North American telecommunications sector has conferred net gains on all key stakeholder groups (consumers, regulated firms, competitors and regulators), there is no comparable literature in the energy sector that permits such broad conclusions to be drawn at this point in time. In addition, while Canada appears to have firmly embraced PBR as a superior alternative to COSR, the experience with PBR in the United States is mixed and is perhaps best characterized as a series of fits and starts. What precisely explains this disparate experience with PBR in moving north and south of the border remains an outstanding question.

The outline for the remainder of this report is as follows. Section 2 provides a comprehensive overview of COSR and PBR and their respective incentive properties. This discussion includes common observations and misperceptions about PBR, a set of general PBR principles, the PBR alphabet as well as earnings sharing and efficiency carryover mechanisms. The implications of regulatory commitment for the performance of PBR is the subject of Section 3. Section 4 discusses the role of benchmarking in PBR regimes. The myriad issues that arise in applying PBR to crown corporations are examined in Section 5. Section 6 provides a summary and conclusion.

2. OVERVIEW OF COSR AND PBR

2.1 The Different Properties of Regulatory Regimes

There is a consensus in the literature that economic regulation should be limited to essential services that are not subject to the discipline of competitive market forces.[1, 2] Essential services are typically defined as services of such importance to the economic and social welfare of the citizenry that universal access to such services at affordable rates remains a key element of public policy. Traditional infrastructure industries in which economic regulation is applied include electric power, natural gas, telecommunications and water.[3]

1 See Alfred E. Kahn, THE ECONOMICS OF REGULATION: PRINCIPLES AND INSTITUTIONS, New York. Volume I, John Wiley and Sons, 1970, pp. 11-12.

2 Professor David Sappington observes that "It is generally preferable to replace regulatory control with the discipline of competition when competition provides adequate protection for consumers." David E. M. Sappington, "Price Regulation," HANDBOOK OF TELECOMMUNICATIONS ECONOMICS, Martin Cave, Sumit Majumdar, and Ingo Vogelsang, eds., Amsterdam: North-Holland, 2002, Chapter 7, p. 265, note 58.

3 Economic regulation has also been applied to varying degrees in the transportation sector (commercial aviation, trucking and railroads).

Economic regulation can at best serve as an imperfect substitute for competition. This is the case because regulators do not have the requisite information to replicate a competitive market outcome.[4] Incentives play a critical role in a market economy *vis-à-vis* a centrally planned, command economy in allocating scarce resources to their highest-valued use and in encouraging the most efficient means of producing society's goods and services. In similar fashion, PBR seeks to put in place stronger incentives for efficiency relative to traditional COSR.[5]

It is instructive to commence by defining precisely what is meant by the term PBR (or what is commonly referred to as "$I - X$" regulation).[6] Incentive regulation or PBR "can be defined as the design and implementation of rules that encourage a regulated firm to achieve desired goals by

---

4 Indeed, as Professor Alfred Kahn has observed:

> Manifestly, the operating expenses and capital outlays of public utility companies are by far the most important component of their rate levels, on the one hand, and the efficiency with which they make use of society's resources on the other. Therefore, in terms of their quantitative importance, it would be reasonable to expect regulatory commissions to give these costs the major part of their attention. But in fact they have not done so; they have given their principal attention instead to the limitation of profits.
>
> The reasons for this perverse distribution of effort illustrate once again the inherent limitations of regulation as an institution of effective social control of industry. Effective regulation of operating expenses and capital outlays would require a detailed, day-by-day, transaction-by-transaction, and decision-by-decision review of every aspect of the company's operation. Commissions could do so only if they were prepared completely to duplicate the role of management itself. This society has never been willing to have commissions fill the role of management and doubtless with good reason: it is difficult to see how any company could function under two separate, coequal managements, each with an equally pervasive role in its operations.

Alfred E. Kahn, THE ECONOMICS OF REGULATION: PRINCIPLES AND INSTITUTIONS, Volume I, New York: John Wiley and Sons, 1970, pp. 29-30.

5 The terms PBR and incentive regulation are used interchangeably. In common parlance, PBR typically refers to incentive regulation in the electric power and natural gas industries. The term incentive regulation is more commonly used in the telecommunications industry.

6 I represents a measure of inflation and X is a productivity factor. The X factor determines the trajectory of prices/revenues over the course of the PBR term after controlling for inflation (i.e., real prices/revenues). Hence, a positive (negative) X factor allows prices/revenues to increase slower (faster) than the rate of inflation, abstracting from the other components of the PBR plan discussed below.

granting some, but not complete, discretion to the firm."[7] In the preponderance of cases, PBR has been applied to private enterprises rather than public enterprises. The firm is granted some discretion under a PBR plan to induce it to employ its superior information (e.g., detailed knowledge of its cost structure and consumer demand) to further social goals. The firm's discretion is limited, however, because its goals are generally not congruent with social goals. The regulated (private) firm is obliged to act in the best interests of its shareholders (e.g., maximizing financial returns), while social goals generally involve more broadly defined interests (e.g., efficiency).

Regulators recognized the potential economic benefits that could be realized from (partially) decentralizing control to the regulated firm. The early economics literature on price cap regulation emphasizes two distinct yet related themes. First, the regulator is not omniscient and hence the regulated firm may have superior information with respect to its own costs and demands. Second, efficiency is the result of a discovery process and the regulated firm must be provided with the requisite incentives to invest in the (unobservable) effort required for such discovery.

> The interest in price caps also reflects a growing understanding that governmental regulation is limited in what it can accomplish. The firms that are the object of regulation are almost always better informed than regulators about their costs and the consequences of adopting particular, detailed regulatory schemes for prices or conditions of service. Thus, rather than creating regulation based on the premise of an omniscient regulator being able to set optimal prices based on full knowledge of costs and demand, a more realistic regulatory goal is to design incentive mechanisms for the regulated firm that will lead it to maximize society's objectives (whether these are efficiency, distributive, or other objectives) while pursuing its self interest.[8]
>
> It [RPI – X] does not assume costs and demands are given or known; indeed, the problem is to provide adequate incentives for the company to discover them. The aim is to stimulate alertness to lower cost techniques and hitherto unmet demands. The

8 Jan Paul Acton and Ingo Vogelsang, "Introduction to the Symposium on Price Cap Regulation," *Rand Journal of Economics*, Volume 20(3), Autumn 1989, p. 369.

> emphasis is on productive rather than allocative efficiency (and even the $RPI - X$ price caps reflects distributional rather than allocative considerations).[9, 10]

It is useful to define a regulatory regime in terms of its underlying incentive properties, whether it provides the regulated firm with "high-powered" or "low-powered" incentives for performance. A high-powered regulatory regime is one in which the regulated firm is responsible for a large share of its actual costs. In contrast, a low-powered regulatory regime is one in which the regulated firm is typically able to affect a high degree of pass through of cost changes in the form of rate changes.[11] Hence, in a high (low)-powered regulatory regime the regulated firm retains a large (small) share of each additional dollar in earnings. Traditional, COSR is typically considered a relatively low-powered regulatory regime.[12] In contrast, pure price (revenue) cap regulation is typically considered a relatively-high powered regulatory regime.[13]

Regulatory regimes may be partitioned into two basic types: (1) earnings-based regulatory regimes and (2) price or revenue-based regulatory regimes.[14] In addition, regulators may opt for a

---

9 Michael E. Beesley and Stephen C. Littlechild, "The Regulation of Privatized Monopolies in the United Kingdom," *Rand Journal of Economics*, Volume 20(3), Autumn 1989, p. 467.

10 In addition, Professor Littlechild's latest reflections upon the intellectual foundations for price caps in the UK reveal that the focus of price cap regulation was not cast in traditional negative terms, the "prevention of excess profits" but rather on improving efficiency and expanding the range of profitable opportunities through innovation and discovery. Stephen Littlechild, "The Birth of RPI-X and Other Observations," in THE UK MODEL OF UTILITY REGULATION, Ian Bartle, ed., London: CRI, September 2003, pp. 31-49.

11 See, for example, Jean-Jacques Laffont and Jean Tirole, A THEORY OF INCENTIVES IN PROCUREMENT AND REGULATION, Cambridge MA: The MIT Press, 1993, p. 11.

12 It should be noted, however, that even under COSR the power of the regime can be ratcheted up considerably if there is a relatively long regulatory lag (i.e., the period over which the regulated firm is not subject to an earnings review and a recalibration of rates to achieve a target rate of return). For a discussion of the benefits of regulatory lag in strengthening incentives, see Alfred E. Kahn, THE ECONOMICS OF REGULATION, Volume II, New York: John Wiley and Sons, 1971, pp. 48-9.

13 The adjective "pure" in this context refers to PBR regimes (price/revenue caps) in which there is no *ex post* sharing of earnings.

14 The earnings-based regulatory regime can be expressed in terms of the constraint $\Pi \leq \overline{\Pi}$, where Π is the actual earnings of the regulated firm and $\overline{\Pi}$ is the earnings cap or maximum earnings allowed. Similarly, the price-based (revenue-based) regulatory regime can be expressed in terms of the constraint

mixed PBR regime in which price (revenue) cap regulation incorporates a safeguard in the form of earnings sharing to ensure that financial returns do not diverge too far from acceptable levels.[15] Earnings that are too high may prompt ratepayers to question whether regulation has been effective in protecting them against excessive rates. Conversely, earnings that are too low may impede the regulated firm's ability to raise capital and thereby threaten its financial viability. In general, as discussed in greater detail below, incorporating earnings sharing into the PBR regime tends to weaken the power of the regime.

Traditional COSR is an example of an earnings-based regulatory regime that seeks to instill competitive discipline by limiting the regulated firm's financial returns. Pure price (revenue) cap regulation is an example of a price-based regulatory regime that seeks to instill competitive discipline by capping the prices (revenues) of the regulated firm. A central question in the literature on the economics of regulation concerns whether earnings-based regimes, price-based regimes, or some combination of the two types of regulation are the best means to replicate the discipline of competitive markets.[16]

$P \leq \bar{P}$ or $R \leq \bar{R}$, where P is an index of average prices, R is revenues, $\bar{P}$ is the regulator-determined price cap and $\bar{R}$ is the regulator-determined revenue cap. Notably, price (revenue) caps have similar efficiency properties, but dissimilar pricing properties. See Michael Crew and Paul Kleindorfer, "Price Caps and Revenue Caps: Incentives and Disincentives for Efficiency," in PRICING AND REGULATORY INNOVATIONS UNDER INCREASING COMPETITION, Michael A Crew, ed., Boston: Kluwer Academic Press, 1996, pp. 21-38.

15 The various arguments both for and against earnings sharing in PBR regimes are reviewed in Section 2.6 *infra*.

16 Paul L. Joskow, "Incentive Regulation in Theory and Practice: Electricity Distribution and Transmission Networks," in ECONOMIC REGULATION AND ITS REFORM: WHAT HAVE WE LEARNED?, Nancy L. Rose, ed., Chicago: The University of Chicago Press, 2014, pp. 291-344.

Broad-based, indexed PBR plans take a number of different forms,[17] including price caps, revenue caps, and revenue-per-customer caps.[18] The superior incentive properties of price cap regulation derive from breaking the link between allowed revenues and costs. This feature of price cap regulation renders the regulated firm the residual claimant for its efficiency gains. This means that the regulated firm retains a full dollar for each additional dollar of cost savings until rebasing occurs at the end price cap regime.[19] This contrasts with COSR in which efficiency gains are typically not retained by the firm for a prolonged period of time but rather passed along to consumers in the form of price reductions, or a slower rate of price growth.

> As a rough characterization, under rate-of-return regulation reviews are infrequent, and the regulatory lag is endogenous because either side can request a review, whereas under price caps the lag is relatively long, and the date of the next review is fixed in advance. The difference is one of degree rather than kind.[20]

The Ontario Energy Board (OEB) offers the following perspective on the differences between a long-term PBR regime and COSR.

---

17 A broad-based PBR plan is one that permits substantial variation in the earnings of the regulated firm and does not link the variation explicitly to specific performance dimensions (e.g., service quality, reliability or cost-containment for specific capital projects). Indexed PBR plans directly link the maximum-permissible prices or revenues (i.e., the price cap or revenue cap) to an external price index. Hence, in the transition from COSR to PBR, the standard for consumer protection changes from prevention against excessive profits to prevention against excessive prices. See Jordan Jay Hillman and Ronald Braeutigam, PRICE LEVEL REGULATION FOR DIVERSIFIED PUBLIC UTILITIES, Boston: Kluwer Academic Publishers, 1989, pp. 80-81.

18 The latter two are more common in the electric power industry because they do not encourage demand growth and therefore are viewed as more compatible with conservation measures. In contrast, price cap regulation is the standard approach in the telecommunications industry in both Canada and the United States. Price cap regulation is also used in the current PBR plan in Alberta for electric distribution companies (as they have yet to experience negative demand growth).

19 Regulatory commitment is key to the superior performance of price cap regulation. The regulated firm must credibly believe that the regulator will not simply appropriate the cost savings it was encouraged to discover. See Dennis L. Weisman, "Is There 'Hope' for Price Cap Regulation?" *Information Economics and Policy*, Volume 14(3), 2002, pp. 349–370. Please refer to Section 3 for additional discussion of this important issue.

20 Mark Armstrong, Simon Cowan, and John Vickers, REGULATORY REFORM, Cambridge MA: The MIT Press, 1994, p. 172.

> By way of commentary, the Board observes that PBR is not just light-handed cost of service regulation. For the electricity distribution utilities in Ontario, PBR represents a fundamental shift from the historical cost of service regulation. It provides the utilities with incentive for behaviour which more closely resembles that of competitive, cost-minimizing, profit-maximizing companies. Customers and shareholders alike can gain from efficiency enhancing and cost-minimizing strategies that will ultimately yield lower rates with appropriate safeguards for service quality. Under PBR the regulated utility will be responsible for making its investments based on business conditions and the objectives of its shareholder within the constraints of the price cap, and subject to service quality standards set by the Board.[21]

Under COSR, successful efforts at discovery and innovation are typically "rewarded" with mandated reductions in service rates should earnings be deemed excessive. Unsuccessful efforts at innovation and discovery run the risk of cost disallowances. Hence, from the perspective of the regulated firm, COSR can devolve into a "game" of *heads you win and tails I lose*. Consequently, the expected returns to a utility from innovation under COSR may be extremely limited if they exist at all.[22] Conversely, under PBR the utilities are permitted to retain the fruits of their successful efforts (and also bear the costs of their unsuccessful efforts) *pro tempore* which underscores their willingness to bear the risks associated with investment in innovation.[23]

Relative to traditional COSR, the theoretical literature finds that delinking revenues and costs under pure price (revenue) cap regulation, which renders the firm the residual claimant for its efficiency gains,[24] provides the regulated firm with incentives to (1) operate with the least-cost

---

21 Ontario Energy Board, RP-1999-0034 Decision with Reasons, January 18, 2000, Paragraph 2.0.14.

22 This discussion refers to the stylized, textbook model of COSR. In practice, regulatory lag can strengthen the incentives of a regulated firm under COSR because it does not instantaneously appropriate efficiency gains and pass them on to consumers in the form of lower rates.

23 It should be noted that intellectual property laws, including copyrights, patents and trademarks are designed to operate in a similar fashion. These laws are structured to reward the successful innovator with temporary monopolies to provide the requisite incentive for innovation. Specifically, they permit the successful innovator to enjoy the fruits of the innovation for a specific period of time before allowing other firms to use the innovation which concomitantly reduces market prices. See Susan Scotchmer, INNOVATION AND INCENTIVES, Cambridge MA: The MIT Press, 2004, chapter 3.

24 In this context, the term *residual claimant* means that the regulated firm has claim to the entirety of the difference (residual) between its revenues and costs just like any other firm operating in a competitive

technology; (2) operate with no waste; (3) diversify efficiently into new markets; (4) undertake efficient levels of cost-reducing innovation; (5) accurately report its costs;[25] and (6) eliminate regulatory abuse.[26]

These superior incentives for efficiency derive from the fact that pure price cap regulation operates much like a *fixed-price contract*. This property benefits consumers because the prices they pay do not vary directly with the reported costs of the firm. As a result, consumers bear little or no risk for the duration of the price cap regime. Conversely, traditional COSR (and some forms of price cap regulation with earnings sharing) operate much like a *cost-plus contract*. This means that the prices that consumers pay under COSR tend to vary directly with the reported costs of the firm and therefore may exhibit greater volatility. In other words, consumers bear more risk.

2.2 Preliminary Observations about PBR

This subsection discusses some preliminary observations and misconceptions about PBR as a precursor to the development of a set of general PBR principles in the following subsection.

---

market. One key difference is that the regulated firm's prices are "capped" by regulation, whereas the forces of supply and demand interact to determine the market price that competitive firms treat as exogenous (i.e., beyond their control). In other words, just as the market price is exogenous to the behavior of any one firm in the market, changes in the price cap should be exogenous to the behavior of the regulated firm.

25 Ronald Braeutigam and John C. Panzar, "Diversification Incentives Under 'Price-Based' and 'Cost-Based' Regulation," *Rand Journal of Economics*, Volume 20(3), 1989, pp. 373-391.

26 In this context, abuse refers to resources consumed by the regulated firm for which the realized costs exceed the benefits. In other words, abuse represents expenditures on resources that the regulated firm would not undertake if it had to bear their full cost. See Glenn Blackmon, INCENTIVE REGULATION AND THE REGULATION OF INCENTIVES, Boston: Kluwer Academic Publishers, 1994. It is instructive to elaborate further upon the problem of abuse that can arise under earnings sharing. Suppose the regulated firm is operating in a region of financial returns where the "earnings tax" is 50 percent. This means that each additional dollar of expenditures only costs the regulated firm 50 cents. This asymmetry provides the regulated firm with incentives to incur a dollar's worth of costs when the benefits it derives are less than one dollar (but no lower than 50 cents). In contrast, under pure price cap regulation, an extra dollar of expenditures costs the firm precisely one dollar. Hence, the regulated firm, similar to a competitive firm, would incur expenditures only when the benefits are at least as great as the costs.

Preliminary PBR Observations	
Observation 1.	The Regulated Firm Under PBR Bears Greater Risk in Exchange for the Prospect of Greater Reward.
Observation 2.	PBR is Not a One-Size-Fits All Proposition.
Observation 3.	The Adoption of PBR is Not a Zero-Sum Game.
Observation 4.	Broad-based PBR is Generally Superior to Targeted PBR.
Observation 5.	PBR in North America Has Not Realized the Same Traction in Electricity as Incentive Regulation in Telecommunications.
Observation 6.	PBR May Not Be Preferable to COSR in All Settings.

2.2.1 Observation 1 Explained (Risk-Return Tradeoffs)

The greater risk that the firm bears under PBR must be coupled with the distinct possibility, though not a guarantee of greater reward. The prospect of greater reward is the impetus for the regulated firm's investment in cost-reducing effort.

> Absent credible rewards for superior performance and/or credible penalties for poor performance, the regulated firm will have little incentive to incur the effort costs that increase the likelihood of good performance.[27]

As discussed in greater detail in Section 3 below, the risk-return tradeoff under PBR is critical to a strong regulatory commitment and, in turn, the performance of PBR. A PBR regime that appropriates "excess earnings" during prosperous times and questions the regulated firm's diligence in cost control during less prosperous times cannot be expected to improve upon traditional COSR.

2.2.2 Observation 2 Explained (PBR Plans are Heterogeneous)

[27] David E. M. Sappington, "Designing Incentive Regulation," *Review of Industrial Organization*, Volume 9, 1994, pp. 262-263.

A PBR plan that is implemented for a particular company should reflect both the type of behavior the regulator wishes to encourage (which can vary across companies) and the unique characteristics of the regulated industry and the regulated company. As Professor Guthrie concludes from his survey of the economic literature on the relationship between regulation and infrastructure investment:

> The two most important lessons to be drawn from the literature surveyed here are that there is no single combination of regulatory settings that is best in all situations and that the various components of a regulatory scheme are interrelated. The most appropriate regulatory scheme for a given situation will depend on the characteristics of the firm and industry being regulated, as well as the institutional environment.[28]

2.2.3 Observation 3 Explained (PBR is Not Zero-Sum)

If PBR were to be a zero-sum game, the gains to regulated firms would be perfectly offset by the losses to consumers. A carefully designed PBR plan need not result in this outcome. In fact, the empirical evidence from the U.S. telecommunications industry suggests that incentive regulation was a *win-win proposition* for all key stakeholders (consumers, firms, regulators and competitors).[29, 30] What is more, as a general proposition the efficiency gains that arise under PBR should not be construed to suggest that the regulated firm was deliberately inefficient under COSR.

> In spite of the fact that incentive regulation can be a “win-win” proposition, some parties view incentive regulation as a little more than a “scheme” used by utilities to increase their profits and earn windfall gains. These added profits may even be viewed as “bribes” to get utilities to do what they should be doing already. A common refrain is that because utilities have a “statutory obligation” to be efficient, any additional rewards for achieving efficient behavior through incentive regulation are

28 Graeme Guthrie, “Regulating Infrastructure: The Impact on Risk and Investment,” *Journal of Economic Literature*, Volume 44(4), December 2006, p. 966.

29 See, for example, Jaison R. Abel, “The Performance of The State Telecommunications Industry Under Price-Cap Regulation: An Assessment of The Empirical Evidence,” NRRI 00-14, The National Regulatory Research Institute, September 2000.

30 A common litmus test for PBR performance concerns whether consumers realized lower rates or a slower rate of price escalation under PBR than they would have experienced under traditional COSR.

> unnecessary—and serve only to foster an inequitable distribution of efficiency gains between regulated firms and consumers. This line of argument would seem to suggest that any efficiencies realized by the regulated firm following the adoption of incentive regulation must imply that, under cost-of-service regulation, regulated entities either deliberately engaged in inefficient behavior or were able to "conceal" more efficient operating practices from regulators through their superior knowledge of operating conditions.[31]
>
> While the possibility of such behavior cannot be ruled out *a priori*, this claim is incorrect as a general proposition. This is because the achievement of performance gains is first and foremost a "discovery process" in which more efficient operating practices and superior use of technology are learned over time. It is the recognition of this discovery process that leads to the conclusion that the efficiency gains realized under incentive regulation need not imply that the firm was knowingly inefficient under cost-of-service regulation. To the contrary, it is quite plausible that the firm under COSR was as efficient as it knew how to be.[32]

2.2.4 Observation 4 Explained (Merits of Broad-Based PBR)

If a PBR plan targets financial incentives too specifically on a single dimension of the firm's performance, the firm will be inclined to devote excessive attention to this one dimension and neglect other important dimensions.[33] Suppose, for example, that a regulator's primary goal is to implement the lowest possible prices for electric power. In addition, however, the regulator is concerned about the level of service quality. If the regulator rewards the firm solely on the basis of average prices, the firm may have incentives to allow service quality to deteriorate. Therefore, even though the regulator's primary goal is to elicit low prices for electricity, it would be ill-advised to ignore critical dimensions of service quality in designing a PBR plan. Instead, the

---

[31] Dennis L. Weisman and Johannes P. Pfeifenberger, "Efficiency as a Discovery Process: Why Enhanced Incentives Outperform Regulatory Mandates," *The Electricity Journal*, Volume 16(1), January/February 2003, p. 59 (footnote omitted).

[32] *Id*., footnote omitted.

[33] This discussion is based, in part, on David E. M. Sappington and Dennis L. Weisman, "Seven Myths About Incentive Regulation," in PRICING AND REGULATORY INNOVATIONS UNDER INCREASING COMPETITION AND OTHER ESSAYS, Michael A. Crew, ed., Boston: Kluwer Academic Publishers, 1996, pp. 5-8.

regulator should couple financial incentives to lower electricity prices with supplementary financial incentives to maintain or improve service quality.[34]

More generally, while PBR plans should be more broad-based rather than overly targeted, this does not mean that such incentive plans should force the firm to bear financial responsibility for all possible dimensions of its performance. To the contrary, a well-designed PBR plan should hold the firm financially responsible for dimensions of its performance over which it exercises significant control, and relieve the firm of financial responsibility for performance dimensions over which it has little or no control.

2.2.5 Observation 5 Explained (Disparate Adoption of PBR)

The pervasive adoption of incentive regulation in the telecommunications industry has not been replicated in the electric power industry. PBR in the electric power industry has generally failed to gain traction, though this trend is more evident in the U.S. than in Canada.[35] Plans were often terminated prematurely or were not renewed once they expired. While there is no consensus view explaining this disparate adoption of PBR across the two industries, the literature has identified several factors that may help to explain this phenomenon.[36]

[34] For example, the regulator may condition the degree of earnings sharing on the level of service quality provided by the regulated firm. When the regulated firm maintains or improves service quality, it may be permitted to retain a larger share of realized earnings and conversely.

[35] Even in Canada, however, the proper treatment of capital in the PBR regime has confounded regulators. The process of developing the appropriate treatment of capital within a PBR regime has proven to be an iterative one. This contrasts with the experience in the telecommunications industry in which an "equilibrium" model of incentive regulation that was remarkably uniform across companies and jurisdictions emerged relatively quickly. The electricity sector is seemingly still in search of an equilibrium model of PBR.

[36] David E. M. Sappington and Dennis L. Weisman, "The Price Cap Regulation Paradox in the Electricity Sector," *The Electricity Journal*, Volume 29, April 2016, pp. 1–5; and David E. M. Sappington and Dennis L. Weisman "The Disparate Adoption of Price Cap Regulation in the U.S. Telecommunications and Electricity Sectors," *Journal of Regulatory Economics*, Volume 49(2), April 2016, pp. 250–264.

Industry Competition

One of the desirable properties of price (revenue) cap regulation is that it (i) provides the regulated firm with greater pricing flexibility necessary to respond to increasing competition; and (ii) protects competitors by precluding the regulated firm from offsetting competitive losses by increasing rates for monopoly services. Competition has been less pronounced in the electric power industry than in the telecommunication industry. As a result, the impetus for adopting PBR in the electric power sector may be somewhat less. This may change, however, with public policies designed to increase competition and distributed generation. Vertically-integrated utilities are particularly likely to require pricing flexibility to retain large users on their systems. This closely parallels the experience of telecommunications providers that were especially vulnerable to large users bypassing their networks.

Differential Productivity Growth Rates

The telecommunications industry, driven in part by Moore's law,[37] has experienced rapid productivity growth. Conversely, productivity growth has slowed in the electric power industry.[38,]

---

[37] Moore's Law describes the rapid decline in the cost of computing power, which translates directly into reduced costs of supplying switched telecommunications services. Moore's Law roughly states that "the cost of a given amount of computing power halves every 18 months." Jonathan Nuechterlein and Philip Weiser, DIGITAL CROSSROADS, Cambridge MA: MIT Press, Second Edition, 2013, p. 149.

[38] Productivity is defined as the ratio of outputs to inputs, whereas productivity growth is defined as the percentage change in outputs less the percentage change in inputs. The average annual total factor productivity growth rate for the 72 U.S. electricity and gas distribution firms examined in a recent study was 0.85 between 1973 and 2009. The corresponding average annual growth rate between 2000 and 2009 was -1.08. Jeff Makholm, Agustin Ros, and Meredith Case, "Total Factor Productivity and Performance-Based Ratemaking for Electricity and Gas Distribution," Presented at the 31st Annual Eastern Conference of the Center for Research in Regulated Industries, May 2012. Regulators have also recognized this trend. For example, the Alberta Utilities Commission adopted a combined *X* and stretch factor of 1.16 in 2012, but recently reduced that value to 0.3 in its latest order. This reflects a 74 percent reduction in just 4 years. Alberta Utilities Commission, Decision 2012-237, Rate Regulation Initiative Distribution Performance-Based Regulation September 12, 2012. Alberta Utilities Commission, Decision 20414-D01-2016 (errata), 2018-2022 Performance-Based Regulation Plans for Alberta Electric and Gas Distribution Utilities, February 6, 2017. The Massachusetts Commission recently adopted a negative *X* factor in its PBR plan for Eversource. This marks the first time that a

[39] This suggests that PBR may be a harder sell in electric power than it is in telecommunications. For example, regulators in the telecommunications industry could promise consumers real price reductions over time. In contrast, in the electric power industry regulators may only be able to promise consumers a slower rate of price growth. Furthermore, when productivity growth is declining over time, a backward-looking *X* factor (one based on historical data) is likely to overestimate the industry's capabilities going forward. This may well explain why PBR plans were not renewed or prematurely terminated in the electric power industry. In contrast, incentive regulation plans in the telecommunications industry have demonstrated remarkable staying power.

Moreover, the issue of supplemental capital provisions in the PBR plans in the electricity sector has no direct counterpart in incentive regulation plans in the telecommunications sector.[40,]

regulatory commission in North America has adopted a negative *X* factor in a PBR plan for distribution. See Department of Public Utilities, D.P.U. 17-05, Order Establishing Eversource's Revenue Requirement, November 30, 2017. For a discussion of the implications of a negative *X* factor in PBR plans, see Mark E. Meitzen, Phillip E. Schoech and Dennis L. Weisman, "Debunking the Mythology of PBR in Electric Power," *The Electricity Journal*, Volume 31(3), April 2018, pp. 39-46.

39 The fact that industry TFP growth has turned negative more recently is not dispositive of the industry becoming less efficient because the conditions under which service is provided have become more challenging. For example, providing security in today's environment means protecting against cyber threats and drone attacks. This contrasts sharply with yesteryear's security that may have required only a night watchman and a chain-link fence. Distributed generation requires costly infrastructure investments to allow wind/solar generators to interconnect with the distribution system. All these activities require more intensive use of inputs without necessarily generating any corresponding increase in billable outputs for the electric utilities. Finally, increased competition is likely to result in reduced output growth without a proportional reduction in input growth, especially if the utilities bear the obligation to serve as carriers of last resort. See Dennis L. Weisman, "Are the Electric Utilities Aboard the 'Train to Ithaca'?" *The Electricity Journal*, Volume 30(5), June 2017, pp. 6–9.

40 Supplemental capital refers specifically to the deficiency between capital requirements and the level of capital that is funded under the "$I - X$" PBR plan. The differences in the treatment of capital in PBR plans across the two industries can largely be explained by some of the institutional differences between the industries. Specifically, strong demand growth and falling costs that resulted in higher productivity growth allowed the telecommunications industry to fund its capital requirements under the $I - X$ cap. In addition, telecommunications firms may have been concerned that requesting supplemental capital funding would increase the likelihood that regulatory oversight would attach to services that are not presently regulated, including broadband, long-distance and video entertainment.

[41] One possible explanation for this phenomenon is that price caps based on backward-looking *X* factors allowed for increasing price-cost margins over time in telecommunications that were sufficient to fund capital requirements. In contrast, backward-looking *X* factors in the electricity sector may well result in decreasing price-cost margins over time that would render it more difficult to fund capital requirements absent special provisions in the PBR plan. This may occur because unit costs are growing at a faster rate than prices. These observations may explain why in telecommunications incentive regulation was largely driven by the regulated firms, whereas PBR in electricity and natural gas is more often spearheaded by regulators.

Conservation Concerns

Price cap regulation encourages the regulated firm to increase demand when price-cost margins are positive. While this increased demand is viewed favorably in the telecommunications industry, it is viewed less favorably in the electric power sector wherein there are conscious efforts to curtail consumption due to environmental concerns. This is one of the reasons why revenue caps and revenue-per-customer caps (along with revenue decoupling) are common forms of PBR in the electric distribution industry.[42] The latter two PBR regimes are more common in the electric power

---

41 Notably, it was common in the telecommunications industry for regulators to extract upfront "entry fees" from the regulated firms under their purview for the right to operate under price cap regulation rather than traditional rate-of-return regulation. These entry fees took many different forms, including network infrastructure/modernization commitments, rate freezes, bill credits and refunds. See David E. M. Sappington and Dennis L. Weisman, DESIGNING INCENTIVE REGULATION FOR THE TELECOMMUNICATIONS INDUSTRY, Cambridge MA: The MIT Press, 1996, chapter 3. The rationality axiom suggests that these firms would not have "purchased" the property right for price cap regulation unless they had a reasonable expectation of increased profitability.

42 Nonetheless, conservation objectives can be addressed under price cap regulation. The regulator could implement PBR in combination with rate design changes that increase the fixed component of the customer's monthly charge while simultaneously reducing the volumetric charge toward incremental cost. By reducing or eliminating the price-cost margin on usage, the regulator can discourage the utility from expanding output. A potential drawback to this approach is that a lower usage change may (depending on the price elasticity of demand) encourage greater consumption which may conflict with conservation goals. This drawback can be addressed by allowing for a positive price-cost margin but using the margin to fund conservation/educations programs rather than allowing it to flow through to

industry because they do not encourage demand growth and therefore are viewed as more compatible with conservation measures.

Reliability Concerns

The stronger incentives for cost control that accompany PBR can cause utilities to cut back on service quality and reliability.[43] This may be somewhat less of a concern in the telecommunications sector given the multitude of network platforms and service providers, including wireless and cable television.

Regulatory Bargains

In the telecommunications industry, regulated firms are multi-product providers, including basic telephone service, long-distance, vertical services (caller-ID, call-waiting etc.), broadband, and video entertainment. This allows the regulator to strike bargains with telecommunications firms in which the prices of politically-sensitive basic service rates are capped as the *quid pro quo* for limited regulation or no regulation for high-margin, discretionary services. In contrast, electric

---

the utility in the form of higher returns. Alternatively, as a side condition to the PBR plan the utility may face a constraint that limits the growth in average usage per customer. The utility can then be rewarded or penalized based on its performance in complying with this constraint. A utility that satisfies the conservation performance metric can be rewarded by being permitted to retain a larger share of its realized returns or a faster rate of growth in its prices/revenues. Conversely, a utility that fails to meet this conservation performance metric may be penalized by being permitted to retain a smaller share of its realized returns or a slower rate of growth in its prices/revenues. It is noteworthy that similar approaches have long been employed to ensure that utilities comply with reliability and quality-of-service metrics.

[43] One study finds that although service outages do not occur more frequently under PBR, the outages that do arise tend to persist for longer durations. This study also finds that reductions in service quality can be avoided with explicit financial penalties for sub-standard levels of service quality. Anna Ter-Martiroysyan and John Kwoka, "Incentive Regulation, Service Quality, and Standards in U.S. Electricity Distribution," *Journal of Regulatory Economics*, Volume 38(3), December 2010, pp. 258–273. For further discussion of the complexities inherent in designing reward/penalty schemes for efficient provisioning of service quality, see David E. M. Sappington, "Regulating Service Quality: A Survey," *Journal of Regulatory Economics*, Volume 27(2), 2005, pp. 123-154.

utilities tend not to be multi-product providers and hence the opportunity to strike such regulatory bargains is significantly reduced.

The California Meltdown

California experienced a meltdown of unprecedented proportion in its electricity sector in 2000.[44] A number of utilities in California were operating under a form of PBR when a combination of spiking wholesale electricity prices and frozen retail prices caused the firms to experience severe financial hardship. These events may have led some to attribute the firms' financial troubles to PBR, even though these difficulties were not limited to utilities that operated under PBR, and a host of factors other than PBR contributed to the meltdown (e.g., drought, siting issues, forced spot-market purchases, etc.). This misconception may have slowed the adoption of PBR nationwide.

2.2.6 Observation 6 Explained (PBR Not Always Superior to COSR)

Whereas high-powered regulatory regimes are generally superior to low-powered regulatory regimes, the expected gains from PBR over COSR may be small in certain settings. For example, when there are no informational asymmetries between the regulator and the regulated firm, there may be no efficiency gains from PBR. In this highly stylized setting, there is no reason to permit the firm to realize high earnings in order to elicit efficient behavior. The "command and control" regulator could simply direct the firm to operate efficiently in accordance with the competitive market standard. Second, the uncertainty over capital outlays may be so pronounced that efficient risk-bearing favors COSR over PBR. Third, earnings sharing can significantly reduce the power

---

44 Severin Borenstein, "The Trouble with Electricity Markets: Understanding California's Restructuring Disaster," *Journal of Economic Perspectives*, Volume 16(1), Winter 2002, pp. 191–211; and John Jurewitz, "California's Electricity Debacle: A Guided Tour," *The Electricity Journal*, Volume 15(4), May 2002, pp. 10–29.

of the regulatory regime. Hence, if the effective "earnings tax" (the share of each additional dollar in cost savings that is forfeited) imposed on the regulated firm is high the expected incremental gains from adopting PBR may be small because PBR lies closer to COSR on the continuum of regulatory regimes.[45] Finally, when the regulator's commitment to the basic tenets of the PBR regime is sufficiently weak (i.e., it cannot be expected to deliver what it promises), there may be no credible claim that PBR will perform better than COSR.[46] These concerns may be compounded in the case of crown corporations that do not operate exclusively with a profit motive.

2.3 PBR Principles

The Alberta Utilities Commission (AUC) recognized at the outset of its journey to explore alternatives to COSR that PBR can be a *win-win proposition* for all key industry stakeholders. It also understood that reaching an industry consensus on the design/objectives of the PBR plan can be so challenging that it risks derailing efforts to implement PBR altogether. To overcome this obstacle, the AUC forged an industry consensus on a set of principles to inform the design of PBR plans.[47]

---

[45] The range of returns over which the regulated firm retains a full dollar for each additional dollar in earnings is referred to as the deadband. For earnings above this range, earnings may be "taxed" in the sense that the regulated firm retains only a portion of each additional dollar in earnings. When this "tax" is high, the regulated firm's incentives to invest in cost-reducing effort are low. This is the case because the regulated firm bears the full cost of cost-reducing effort but retains only a fraction of the benefits. This also explains why economists favor lump-sum taxes on efficiency grounds; the amount of the tax is invariant to the level of earnings or performance and therefore does not negatively affect incentives.

[46] The choice between COSR and PBR is discussed in greater detail in Section 2.9 *infra*.

[47] Alberta Utilities Commission, Regulated Rate Initiative - PBR Principles, Bulletin 2010-20, July 15, 2010.

With a similar purpose in mind, I have provided a set of PBR principles herein that are very similar to those adopted by the AUC.[48] Strict adherence to these principles should serve to inform the design of a sound PBR regime that benefits all key stakeholders. The BC Commission will ultimately determine the precise weight that should be attached to each principle. The PBR principles are listed below followed by a discussion of the rationale for each principle.

PBR Principles

Principle 1.	A PBR plan should create the same efficiency incentives as those experienced in a competitive market while satisfying stipulated service quality and conservation metrics.
Principle 2.	A PBR plan should provide the regulated company with a reasonable opportunity to recover its prudently incurred costs including a fair rate of return.
Principle 3.	A PBR plan should be easy to understand, implement and administer and should result in a streamlined regulatory process.
Principle 4.	The design of the PBR plan should recognize the unique circumstances of each regulated company.
Principle 5.	Customers and the regulated companies should share the benefits of a PBR plan.
Principle 6.	The regulated company should bear limited financial responsibility for events outside of its control.

2.3.1 Principle 1 Rationale (Emulating Competitive Market Incentives)

The first policy statement in PBR Principle 1 recognizes that in serving as a substitute for competition PBR should put in place the same incentives as a competitive market. The regulatory economics literature recognizes that a primary objective of economic regulation is to emulate a competitive market standard. To this end, Professor Alfred Kahn observes that "the single most widely accepted rule for the governance of the regulated industries is regulate them in such a way

48 Principle 6 does not have a counterpart in the AUC's PBR principles but may be subsumed as a corollary to Principle 1. This principle is important and therefore included here because the distinction between exogenous and endogenous events has figured prominently in the design of PBR regimes.

as to produce the same results as would be produced by effective competition, if it were feasible."[49] In similar fashion, Professor James Bonbright observes that "Regulation, then, as I conceive it, is indeed a substitute for competition; and it is even a partly imitative substitute."[50]

An important question concerns precisely what it is that economic regulation seeks to emulate in adopting a competition standard. In the following passage, Professor Bonbright discusses the various attributes of the competition standard and the primacy of dynamic efficiency over static efficiency.

> Under unregulated competition, the price system is supposed to function in two ways with respect to the relationship between the price of the product and the cost of production. In the first place, the rate of output of any commodity will so adjust itself to the demand that the market price will tend to come into accord with production costs. But in the second place, competition will impel rival producers to strive to reduce their own production costs in order to maximize profits and even in order to survive in the struggle for markets. This latter, dynamic effect of competition has been regarded by modern economists as far more important and far more beneficent than any tendency of "atomistic" forms of competition to bring costs and prices into close alignment at any given point of time.[51, 52]

With reference to the design of a PBR regime, this passage underscores the importance of putting in place incentives for firms to invest in product and process innovation rather than focus

50 James C. Bonbright, PRINCIPLES OF PUBLIC UTILITY RATES, New York: Columbia University Press, 1961, p. 107.

51 *Id.,* p. 53.

52 Static efficiency refers to both consumption efficiency and productive efficiency at a given point in time. Consumption (allocative) efficiency is realized when the last (marginal) unit of output consumed is equal to the resource cost incurred by society in producing it. This is the familiar marginal benefit equals marginal cost condition for optimality. Productive (technical) efficiency is concerned with production at the lowest possible cost. Dynamic efficiency is concerned with the optimal investment over time in capital formation, cost-reducing innovation and product innovation. Dynamic efficiency is particularly critical in infrastructure industries that serve as key drivers of economic growth.

exclusively on the optimal alignment of prices with underlying costs at each point in time.[53] This observation has important implications for the design of a PBR regime.

The second policy statement in Principle 1 recognizes that there is a price and quality dimension to consumer welfare. To wit, consumers are unequivocally better off as a result of the lower prices they pay under PBR relative to COSR when service quality is non-decreasing, *ceteris paribus*. Whereas the regulated firm has strong incentives to reduce costs under PBR, the regulator may harbor concerns that the incentives to reduce costs may result in lower levels of service quality. This explains why most, if not all, incentive regulation plans incorporate some type of service quality benchmarks. In similar fashion, policymakers may have conservation objectives that must be compatible with the PBR regime (e.g., demand-side management).

2.3.2 Principle 2 Rationale (Reasonable Opportunity to Earn a Fair Return)

Principle 2 recognizes that whereas the regulated firm agrees to bear greater risk under PBR, this does not empower the regulator to deny the firm a reasonable opportunity to recover its costs, including a fair return. My understanding is that the legislative framework for implementing PBR in British Columbia provides that electric utilities *must* be given a reasonable opportunity to

---

[53] As Professor Joseph Schumpeter has observed,

> A system—any system, economic or other—that at *every* given point of time fully utilizes its possibilities to the best advantage may yet in the long run be inferior to a system that does so at *no* given point of time, because the latter's failure to do so may be a condition for the level or speed of long-run performance (p. 83).
>
> The introduction of new methods of production and new commodities is hardly conceivable with perfect—and perfectly prompt—competition from the start. And this means that the bulk of what we call economic progress is incompatible with it. As a matter of fact, perfect competition is and always has been temporarily suspended whenever anything new is being introduced—automatically or by measures devised for the purpose—even in otherwise perfectly competitive conditions (p. 105).

Joseph A. Schumpeter, CAPITALISM, SOCIALISM AND DEMOCRACY, New York: Harper Torchbooks, 1975 (first published in 1942).

recover their prudent costs and expenses, including a fair return. As a general proposition, the regulator should neither guarantee nor actively preclude the regulated firm from recovering its costs and earning a fair rate of return. The average returns may be comparable across COSR and PBR regimes, but we would expect the variance of returns to be larger in the latter.

2.3.3 Principle 3 Rationale (Administrative Simplicity and Regulatory Efficiency)

Principle 3 recognizes the importance of rules for PBR, including the incentives and reward structure, that are clear, objective and unambiguous. Specifically, it is critical that PBR "promise only what can be delivered and deliver whatever is promised."[54] Paying due deference to these objectives in the design and implementation of PBR should result in reducing the costs of regulation for all key stakeholders, including the regulated firm, consumers and the Commission itself. In addition, rules that are "clear, objective and unambiguous" reduce uncertainty and bolster the credibility of the PBR regime. This is paramount as a lack of credibility in administering the rewards and penalties associated with the PBR regime can undermine its performance.

2.3.4 Principle 4 Rationale (Recognize Unique Circumstances of Regulated Firm)

Principle 4 duly recognizes that regulated firms are likely to be heterogenous and therefore it is incorrect to reflexively presume that PBR is a "one-size-fits-all" proposition (See related discussion in Observation 2 *supra*).[55] This suggests that regulated firms should have some flexibility to position themselves along the PBR continuum in a manner that duly recognizes their unique circumstances. Regulated firms may differ across a number of dimensions, including

55 See David E. M. Sappington and Dennis L. Weisman, "Seven Myths About Incentive Regulation," in PRICING AND REGULATORY INNOVATIONS UNDER INCREASING COMPETITION AND OTHER ESSAYS, Michael A. Crew, ed., Boston: Kluwer Academic Publishers, 1996, pp. 4-5.

ownership structures, operating environment, customer characteristics, policy priorities and the dynamics of their capital investments. A PBR plan that is carefully calibrated to recognize these differences increases the likelihood that all stakeholder groups can be rendered better off under PBR, consistent with Principle 5.

2.3.5 Principle 5 Rationale (All Stakeholders Should Benefit from PBR)

Principle 5 recognizes that the adoption of PBR represents a change from one "political equilibrium" to another amidst a growing consensus that improvements upon traditional COSR are possible given the experience with incentive regulation across different jurisdictions and industries over time.[56] Principle 3 and Principle 5 taken together recognize that PBR should be designed and implemented with the expectation that all key stakeholder groups, including consumers, the regulated firms and the regulator, are rendered "better off" over the long run relative to COSR. In other words, the adoption of PBR should be a *win-win proposition*.[57]

2.3.6 Principle 6 Rationale (Endogenous vs. Exogenous Events)

The complex and often contentious issue of what is endogenous to the regulated firm (within its control) and what is exogenous to the regulated firm (outside of its control) has figured prominently in the design and structure of PBR plans. Principle 6 recognizes that the regulated

---

56 As Thomas Kuhn observed in his classic treatise:

> Political revolutions are inaugurated by a growing sense, often restricted to a segment of the political community, that existing institutions have ceased adequately to meet the problems posed by an environment that they have in part created. . .. Their success therefore necessitates the relinquishment of one set of institutions in favor of another . . .

Thomas Kuhn, *The Structure of Scientific Revolutions*, Chicago: University of Chicago Press, 1962, pp. 92-93.

57 David E. M. Sappington and Dennis L. Weisman, "Seven Myths About Incentive Regulation," In Michael A. Crew, ed., PRICING AND REGULATORY INNOVATIONS UNDER INCREASING COMPETITION AND OTHER ESSAYS, Boston: Kluwer Academic Publishers, 1996, pp. 10-11.

company should not unduly benefit nor be unduly penalized for events outside of its control.[58] Precisely where that line of demarcation should be drawn is not always clear.

Consider, for example, a regulated company that is statutorily required to provide service to all consumers that request it at tariffed rates and subject to minimum quality of service standards. These exogenous constraints on the regulated company may suggest that the company may have limited control of the infrastructure requirements necessary to provide service and yet somewhat more control over how the service is actually provided. Does this imply that there should be a bifurcation in the treatment of CAPEX and OPEX under the PBR plan? Indeed, some PBR plans have treated CAPEX and OPEX differently.[59] A concern, however, is that such disparate treatment can lead to inefficient capital/labor substitution in the firm's production processes.[60] As the OEB observed,

> The Board continues to support a comprehensive approach to rate-setting, recognizing the interrelationship between capital expenditures and OM&A expenditures. Rate-setting that is comprehensive creates stronger and more balanced incentives and is more compatible with the Board's implementation of an outcome-based framework.[61]

---

[58] David E. M. Sappington "Designing Incentive Regulation," *Review of Industrial Organization*, Volume 9(3), June 1994, p. 269 (A sound PBR regime should "limit the firm's financial responsibility for factors beyond its control.")

[59] See, for example, John J. Kwoka, "Investment Adequacy Under Incentive Regulation," Northeastern University Working Paper, 2009. A concern with this approach is that it can facilitate inefficient CAPEX-OPEX substitution. Indeed, this is one of the reasons why the Alberta Utilities Commission opted to change the way in which supplemental capital was treated in its second-generation PBR regime. See Alberta Utilities Commission; Decision 21981-D01-2016 (Errata), February 6, 2017, Section 6.

[60] It is noteworthy that the newly adopted approach to PBR in Britain combines the previously separate CAPEX and OPEX indexes into a single index for precisely this reason. See Peter Fox-Penner, Dan Harris and Serena Hesmondhalgh, "A Trip to RIIO in your Future? Great Britain's Latest Innovation in Grid Regulation," *Public Utilities Fortnightly*, Volume 151(10), 2013, pp. 60–65. In addition, both the Alberta Utilities Commission and the Ontario Energy Board have rejected PBR proposals that bifurcate CAPEX and OPEX. See Alberta Utilities Commission, Decision 2012-237, September 12, 2012, Sections 2.3 and 7.3.2.3; and Ontario Energy Board, Report of the Board, Renewed Regulatory Framework for Electricity Distributors: A Performance-Based Approach, October 18, 2012, pp. 7-9.

[61] Ontario Energy Board, Report of the Board, Renewed Regulatory Framework for Electricity Distributors: A Performance-Based Approach, October 18, 2012, p. 9.

2.4 Types of PBR Regimes

2.4.1 Overview

There are three basic types of indexed PBR plans that have been employed in the electric power and natural gas sectors. These are (1) price caps; (2) revenue caps and (3) revenue-per-customer caps (which the AUC applies to the natural gas utilities). The trajectory of rates or revenues under these approaches are determined by the previous year's rates/revenues and a formula (equation of motion) that is applied to these rates/revenues. This formula accounts for inflation (*I*-Factor) and an efficiency factor (*X*-factor) along with other factors to account for growth, exogenous events and pass-through provisions. (See the related discussion in Section 2.5 *infra*.) The growth factor in the PBR formula recognizes that output changes, both the number of customers and volumes, is exogenous to the regulated firm.

All three approaches to indexed PBR plans can be expected to put in place more high-powered incentives relative to traditional COSR. A notable difference between revenue caps and revenue-per-customer caps is that a revenue cap may not allow revenue to change with customer growth. This implies that under a revenue cap the regulated company may bear the financial risk associated with customer growth.

The BC Commission adopted a revenue cap PBR regime for Fortis BC with a term of 6 years. The plan employs an input (wholesale) measure of inflation and includes an earnings sharing mechanism. The Commission referred to this PBR plan as a "building blocks" approach because separate revenue caps are employed for growth capital, sustainment and other capital and O&M.[62]

[62] See British Columbia Utilities Commission, In the Matter of FortisBC Energy Inc., Multi-Year Performance Based Ratemaking Plan for 2014 Through 2018, Decision, September 15, 2014, p. 21.

The Commission adopted *X* factors (inclusive of the stretch factors) of 1.03 and 1.10 for FBC and FEI, respectively.[63]

In its second-generation PBR regime, Alberta retained price caps for the electricity distribution utilities but continued to allow the natural gas utilities to operate under a revenue-per-customer cap. This disparate treatment is explained by the fact that the electricity providers have yet to report the negative growth that the natural gas providers have experienced. In addition, at least to date, conservation initiatives would not appear to have the same urgency in Alberta as they do in some other jurisdictions.[64] All of the electricity utilities in Alberta are subject to the same general price cap formula (e.g., *X* factor and stretch factor), but supplemental capital is treated separately for each utility.

Ontario is in its fourth-generation PBR regime. Unlike the AUC, the OEB has adopted the so-called menu approach to PBR in that the distribution utilities may choose between three different regulatory regimes.[65] The OEB has adopted a price cap approach to PBR for electricity distributors and a revenue cap approach for transmission providers.[66] Unlike the AUC, the OEB has made more extensive use of statistical benchmarking. This approach essentially ratchets upward

---

63 *Id*., p. 91.

64 There is some evidence to suggest that this may change going forward. On March 29, 2017, the lieutenant-governor for the province of Alberta issued Order in Council 120/2017 ordering the Alberta Utilities Commission to inquire into, and report to, the Minister of Energy on matters relating to alternative and renewable Electric Distribution System-Connected Generation. See the following URL. http://www.qp.alberta.ca/documents/orders/Orders_in_Council/2017/317/2017_120.pdf. On March 31, 2017, the AUC initiated Proceeding 22534 to respond to this Order.

65 The large number of electricity distributors (77) in Ontario that perform under different operating conditions likely explains the menu approach. Ontario Energy Board, Report of the Board, Renewed Regulatory Framework for Electricity Distributors: A Performance-Based Approach, October 18, 2012, p. 1. Also, whereas the menu ("options") approach has some desirable efficiency properties in theory, it has encountered some implementation difficulties. See, for example, David E. M. Sappington, "Designing Incentive Regulation," *Review of Industrial Organization*, Volume 9(3), June 1994, pp. 245-272.

66 Ontario Energy Board, Handbook for Utility Rate Applications, October 13, 2016, Section 6.

(downward) the trajectory of prices/revenues based on the measured efficiency of the individual utility relative to its peer group. More efficient utilities are rewarded with a faster rate of growth in prices/revenues, whereas less efficient utilities are penalized with a slower rate of growth in prices/revenues. The benchmarking issue is examined further in Section 4 below.

A jurisdiction-by-jurisdiction survey of PBR in North America is beyond the scope of this report. Nonetheless, a review of the literature reveals that both price cap and revenue cap approaches to PBR are most common. The PBR plans vary across a number of different dimensions, including (1) the *X* factor, (2) length of the plan; (3) provisions for supplemental capital, (4) offramps/reopeners, and (5) earnings sharing mechanisms.

2.4.2 PBR for Vertically-Integrated Utilities

The production of electricity can be partitioned into three basic components: generation, transmission and distribution.[67] In some jurisdictions these components are unbundled, whereas in others the utility provides only a bundled retail service offering. Each production component can be regulated via PBR, COSR or competition. Consider, for example, the case of EPCOR in Alberta. The company provides distribution, which is subject to PBR, and transmission that remains under traditional COSR. The distribution and transmission function are structurally separated. The electric utilities in Alberta are statutorily prohibited from participating in the competitive generation market. The combination of regulatory regimes and competition for the various elements of production in the case of EPCOR in Alberta is illustrated in Table 1.

[67] Retailing/Billing is sometimes included as a separate component of production, but we abstract from that complexity here in the interest of economy of presentation.

Regulatory Regime / Production Element	COSR	PBR	Competition
Generation			√
Transmission	√		
Distribution		√	
Bundled Retail Service	n.a.	n.a	n.a

Table 1. EPCOR Combination of Regulatory Regimes and Production Elements

EPCOR may well propose that transmission, like distribution, be subject to PBR rather than COSR, or the AUC may mandate such an outcome as it did in the case of distribution. The specific attributes of each element of production may give rise to either a different form of PBR (price caps versus revenue caps) or specific design attributes for the PBR regime. For example, generation is typically characterized by more "lumpy" capital investments and this may require special provisions for capital within the PBR regime (e.g., capital trackers).[68] Conversely, the generally smoother investment profiles commonly associated with transmission and distribution elements may allow for a more limited scope of special provisions for capital in the PBR regime.

It is instructive to briefly consider the case where the individual elements of production are not unbundled, and the utility sells only a bundled retail service offering. In principle, the mechanics of PBR are no different than in the unbundled case. The primary difference that would

68 This observation notwithstanding, more efficient, interconnected power markets combined with the emergence of new technologies for producing power and distributed generation may have a mitigating effect on the scope of these special provisions. For a discussion of the role of distributed energy resources in reducing utility investments, see Mason Willrich, MODERNIZING AMERICA'S ELECTRICITY INFRASTRUCTURE, Cambridge MA: The MIT Press, 2017, chapters 9–11; and Steven W. Blume, ELECTRIC POWER SYSTEM BASICS FOR THE NONELECTRICAL PROFESSIONAL, Second Edition, Hoboken, NJ: John Wiley and Sons. 2017, pp. 196-99.

arise would be in the specific asset classes that are combined for the PBR regime and the associated productivity factors (discussed below) that should apply in calibrating the trajectory of prices over the course of the PBR regime.

2.5 The PBR Alphabet[69]

Price cap regulation is commonly referred to as "*I* – *X*" regulation because the maximum annual increase in the regulated firm's average prices is capped by an inflation index (*I*) less a productivity offset (*X*).[70, 71] The "*I* – *X*" price adjustment formula follows from the basic idea that in a competitive market (which economic regulation seeks to emulate), average productivity gains are passed on to consumers in the prices that they pay for service after controlling for inflation.[72] In order to preserve ideal incentives for efficiency it is necessary for the regulated firm to perceive that the *X* factor does not vary with its own performance so there is no ratchet effect.[73] This is

---

69 The analysis in this section applies to revenue cap regulation as well price cap regulation.

70 See Jeffrey Bernstein and David Sappington, "Setting the X Factor in Price Cap Regulation Plans," *Journal of Regulatory Economics*, Volume 16(1), July 1999, pp. 5-25.

71 In Canada and the United States, the *X* factor is typically set to reflect expected industry productivity growth. Whereas, in Europe, the *X* factor tends to be more of a "negotiated value." See Stephen Littlechild, REGULATION OF BRITISH TELECOMMUNICATIONS' PROFITABILITY, Department of Industry: Report to the Secretary of State, 1983; and Michael Crew and Paul Kleindorfer, "Incentive Regulation in the United Kingdom and the United States: Some Lessons," *Journal of Regulatory Economics,* Volume 9(3), 1996, pp. 211-225.

72 *X* is not independent of *I*. Specifically, *I* in the PBR formula can be an economy-wide or industry-specific measure of inflation. When *I* is an industry-specific measure of inflation, *X* is equal to an appropriate measure of industry productivity growth. When *I* is an economy-wide measure of inflation, *X* is comprised of two separate components. The first component is the difference between industry productivity growth and economy-wide productivity growth. The second component is the difference between economy-wide input price growth and industry-specific input price growth. For further discussion, see Mark E. Meitzen, Phillip E. Schoech and Dennis L. Weisman, "The Alphabet of PBR in Electric Power: Why X Does Not Tell the Whole Story," *The Electricity Journal*, Volume 30(8), October 2017, pp. 30-37.

73 This suggests that data on the firm's own performance can be used in the development of the *X* factor provided that (i) these data are not used repeatedly over time; and (ii) the endpoint of the data series employed in the analysis predates the announcement that the data would be used for such purposes. See generally Andrei Schleifer, "A Theory of Yardstick Competition," *Rand Journal of Economics*, Volume 16(3), 1985, pp. 319-327.

sometimes referred to as the *immutability condition*. Moreover, provided that the X factor is developed on the basis of sound economic principles and does not undermine the financial viability of the enterprise, the incentives for efficiency are invariant to both the sign and magnitude of the X factor.[74]

PBR formulae also typically incorporate Z factors, which allow the rate adjustment formulae to reflect one-time, exogenous events beyond the regulated firm's control that are not fully reflected in the other parameters of the rate adjustment formula (e.g., changes in tax/environmental policy). In addition, it is common in PBR plans to include a stretch factor (S) in the rate adjustment formula to reflect the increased productivity growth that is expected from the change from traditional COSR to PBR.[75] This stretch factor is sometimes referred to as a consumer productivity dividend because it is an *ex ante* productivity growth increment that confers upon consumers greater real price reductions or a slower rate of price growth. Hence, the annual rate adjustment formula can be expressed by

(1) $\%\Delta P = I - X - S + Z,$

where $\%\Delta P$ is the annual (maximum) percentage change in price.[76]

---

[74] Luis M.B. Cabral and Michael H. Riordan, "Incentives for Cost Reduction Under Price Cap Regulation," *Journal of Regulatory Economics*, Volume 1, 1989, pp. 93-102. The basic idea is that a regulated firm subject to an unachievable X factor will come to the realization that no amount of effort can render it financially viable. Under these conditions, the regulated firm essentially gives up which triggers a PBR reopener or the filing of a traditional rate case. This observation underscores the important point that consumers are not necessarily rendered better off with a high X factor.

[75] Stretch factors were typically not retained for second-generation incentive regulation plans in telecommunications, but the same cannot be said for PBR plans in electric distribution. The difference is likely explained by (i) more limited competition; and (ii) supplemental capital mechanisms that may retain elements of COSR in electricity distribution.

[76] In the case of revenue (R) caps, $\%\Delta R$ would replace $\%\Delta P$ on the left-hand side of (1).

The above formula is typical of that applied in the telecommunications industry. In the electric power industry, however, capital expenditures have tended to be a challenge for utilities in that the standard price cap formula, premised on a non-negative *X* factor and declining real rates, may not generate sufficient revenues to adequately fund required infrastructure improvements. Hence, it is increasingly common in the electric power industry to include a supplemental capital factor (*K*) in the PBR formula.[77] The PBR formula may also include a Y factor to account for recurring expenditures over which the utility has no control (e.g., transmission charges) and therefore the utility is allowed a full pass-through. The revised rate adjustment formula is given by

(2) $\%\Delta P = I - X - S + Z + K + Y.$

One additional parameter is the term of the PBR plan or the number of years prior to rebasing (i.e., the true-up of rates to a target rate-of-return at the end of the PBR regime).[78] While there is considerable variability in the terms of the PBR plans, 4-6 years is common, with an average of approximately 5 years. It is generally recognized that the longer the term of the PBR plan, the stronger the incentives for efficiency, *ceteris paribus*.[79]

---

77 A survey of the various methods by which capital has been addressed in PBR regimes is provided in the following. David E. M. Sappington and Dennis L. Weisman, ASSESSING THE TREATMENT OF CAPITAL EXPENDITURES IN PERFORMANCE-BASED REGULATION PLANS, Attachment 2 to the direct evidence of Dennis L. Weisman (Appendix A) on behalf of EPCOR Distribution & Transmission, Inc. Proceeding 201414, Next Generation PBR Proceeding, Alberta Utilities Commission, March 23, 2016.

78 In contrast to COSR, rebasing under PBR occurs at discrete intervals. As a result, PBR can result in "rate shock" when rebasing occurs at the end of the PBR term. Consumers are likely to react more negatively to a one-time significant rate change relative to a series of small rate changes even if the terminal rate levels are the same. Hence, the absence of rate smoothing under PBR is a potential concern. See R. Mark Isaac, "A Case Study of Some Pitfalls of Implementation," *Journal of Regulatory Economics*, Volume 3(2), 1991, pp. 193-210.

79 For a discussion of the relevant tradeoffs in setting the length of the price cap plan, see David E. M. Sappington, "Price Regulation" in HANDBOOK OF TELECOMMUNICATIONS ECONOMICS, Martin Cave, Sumit Majumdar, and Ingo Vogelsang, eds., Amsterdam: North-Holland, 2002, Chapter 7, pp. 251-252.

Two other mechanisms may accompany PBR—earnings sharing mechanisms and efficiency carryover mechanisms. These two mechanisms are discussed in the following two subsections, respectively.

2.6 Earnings Sharing Mechanisms

Regulators may have concerns that under a PBR plan the financial returns of the utility may exceed or fall short of target levels. As a result, PBR plans may include earnings sharing mechanisms (ESMs) that ensure that the utility's returns remain within "acceptable bounds." The use of ESMs has tended to vary across industries, jurisdictions and time. ESMs were common in the first-generation of indexed incentive regulation plans in the telecommunications industry in the United States, but the CRTC (Canadian Radio-television and Telecommunications Commission) never adopted ESMs for Canadian telecommunications carriers.[80] ESMs have tended to have greater longevity with PBR plans in the electricity and natural gas sectors. One possible explanation for this phenomenon is that retail competition has been slower to develop in these sectors relative to telecommunications and regulators believed that retaining ESMs was necessary to provide the proper safeguards.

A hypothetical ESM with a deadband set around the target rate of return of 10% is illustrated in Figure 2. This figure illustrates the relationship between the company's unadjusted earnings (which are the company's earnings if prices remain at the levels established at the start of the PBR

[80] See David E. M. Sappington and Dennis L. Weisman, "Price Cap Regulation: What Have We Learned from Twenty-Five Years of Experience in the Telecommunications Industry?" *Journal of Regulatory Economics*, Volume 38(3), December 2010, pp. 227–257; and David Sappington, Johannes Pfeifenberger, Phillip Hanser, and Gregory Basheda, "Status and Trends of Performance-Based Regulation in the U.S. Electric Utility Industry," *The Electricity Journal*, Volume 14(8), October 2001, pp. 71–79.

plan) and the company's authorized earnings (which are its earnings after any price adjustments that are undertaken to implement the specified sharing of earnings).

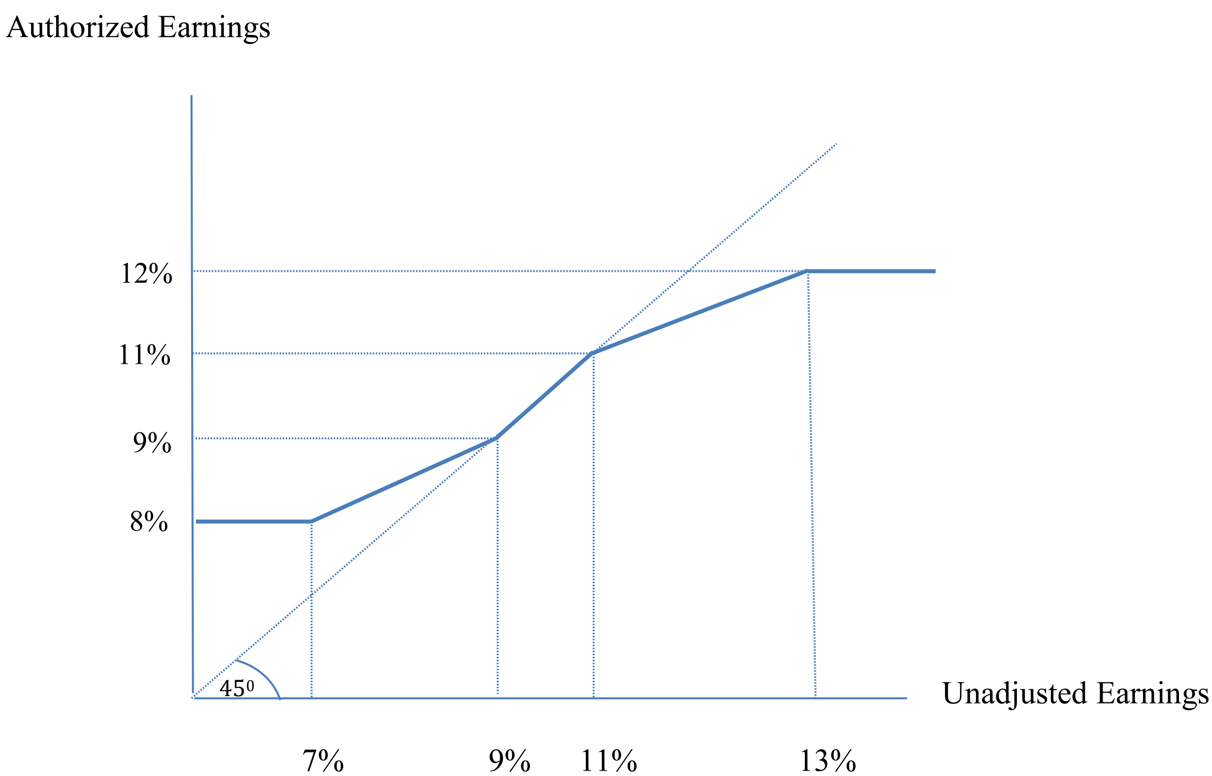

Figure 2. Earnings Sharing Mechanism

Under the hypothetical ESM illustrated in Figure 2, the company's authorized earnings coincide with its unadjusted earnings when these earnings are between 9% and 11%.[81] As unadjusted earnings increase between 11% and 13%, the company and its customers each receive

[81] Figure 2 reflects this coincidence of earnings with the solid line segment that has a slope of 1 for unadjusted earnings between 9% and 11%, the so-called deadband.

one half of the incremental earnings.[82, 83] The company is not permitted to earn more than a 12% return on investment. As unadjusted earnings decline below a 9% return on investment toward a 7% return on investment, prices are increased sufficiently to ensure the company and its customers share the incremental decline in earnings equally.[84] Prices are further increased, as necessary, to ensure the company's earnings never fall below an 8% return on investment in this example.

There are valid arguments both for and against including ESMs in PBR plans. The advantages are three-fold in nature. First, ESMs may ensure that earnings remain within "acceptable bounds." Second, ESMs may be structured to ensure that service rates do not diverge too far from efficient levels. Third, ESMs can serve as a type of "safety valve" that mitigates the political pressure on the regulator to recontract, perhaps even terminate the PBR plan, when the earnings of the regulated firm approach levels that consumers deem unacceptable. ESMs align the interests of consumers with those of the regulated firm because they return a share of any excess earnings to consumers. As a result, consumers are less likely to view the regulated firm's excess earnings as a signal that their rates are too high. ESMs serve to preserve the stability of the PBR regime precisely because they reduce the likelihood of regulatory recontracting.

> Political support for a policy can be garnered when consumers benefit financially in direct, visible ways precisely when the regulated firm benefits, as is the case under earnings-sharing plans. Widespread political support for a policy can ensure its long-

---

82 Note that the sold line segment that appears above adjusted earnings between 11% and 13% in Figure 2 has a slope between 0 and 1. The slope captures the explicit sharing of incremental earnings by the company and its customers. The larger is this slope, the larger is the fraction of incremental earnings that is awarded to the company (i.e., the lower is the "earnings tax").

83 The relevant portion of incremental earnings can be awarded to consumers in different ways. For instance, the prices charged to customers might be reduced. Alternatively a bill credit might be awarded to all customers at the end of the year. The incremental earnings might also be employed to create or expand a program aimed at particular policy objectives (e.g., rate relief for low-income customers).

84 The fraction of incremental earnings awarded to the company can be explicitly linked to the level of service quality the company delivers or its compliance with conservation metrics. Such linkages can help to ensure that the company does not increase its earnings by allowing service quality to deteriorate or by failing to comply with conservation metrics.

> term survival and thus a continued flow of benefits to all parties. A sustained flow of moderate gains can often serve all parties better than can a short-lived spurt of particularly large gains.[85]

Whereas the rationale for incorporating ESMs into PBR plan may appear sound, significant problems have arisen with ESMs in practice. As a result, there can be no guarantee that consumers are necessarily better off with PBR plans that incorporate ESMs. The expected benefits of ESMs (e.g., consumer safeguards) must be objectively weighed against their expected costs (e.g., reduced incentives and strategic behavior).

First, an ESM can blunt incentives for efficiency. To see this, recognize that a rational, profit-maximizing utility will invest in cost-reducing effort up to the point where the marginal benefit of cost-reducing effort is equal to the marginal cost of cost-reducing effort. This means that a utility that retains only 50 cents of each additional dollar of cost-savings will invest less in cost-reducing effort than a utility that retains a full dollar of each additional dollar of cost-savings, *ceteris paribus*.[86]

This characteristic of ESMs has two adverse consequences. First, the cost-savings that are passed on to consumers at the end of the PBR regime at the time of re-basing will typically be less than if there were no ESMs. Second, as a theoretical matter, a utility operating under a PBR plan with an ESM should face a lower X factor than a utility operating under a PBR plan without an

---

[85] David E. M. Sappington and Dennis L. Weisman, DESIGNING INCENTIVE REGULATION FOR THE TELECOMMUNICATIONS INDUSTRY, Cambridge MA: The MIT Press, 1996, p. 334.

[86] This distortionary effect would not arise if the profits shared were independent of the regulated company's actual performance (i.e., a lump sum tax). This observation has important implications for the discussion of PBR for crown corporations in Section 5.

ESM.[87] This implies that the rate trajectory will typically be higher under a PBR plan with an ESM relative to a PBR plan without an ESM.

Second, ESMs can give rise to incentives for "gaming" on the part of both regulators and utilities. Suppose that the ESM enables the utility to retain each additional dollar of cost-savings for returns between 9% and 11%. However, the utility retains only 50 cents of each additional dollar of cost savings for returns greater than 11%. The regulator may have an incentive to micromanage the utility's operations or strategically disallow costs to move the utility's returns into the sharing range.[88] The regulator would have no such incentive if there were no ESM (i.e., pure price (revenue) cap regulation). Similarly, the utility may have incentives to strategically defer investments or the timing of when it books specific costs to avoid the "earnings tax" and the sharing of excess returns with consumers. Hence, ESMs can elicit strategic behavior on the part of both regulators and utilities that reduce the expected benefits of PBR.

Third, formal empirical analyses of the performance of incentive regulation in the U.S. telecommunications industry when ESMs were still prominent revealed relatively modest gains

---

[87] The Federal Communications Commission explicitly recognized this tradeoff in the design of the price cap plans for the Regional Bell Operating Companies. See Federal Communications Commission, CC Docket No. 91-41, LEC Price Cap Performance Review, April 7, 1995.

[88] A possible example of this phenomenon occurred in the aftermath of epic floods that plagued the Midwest in the summer of 1993. After scrutinizing how Southwestern Bell allocated its resources in responding to this natural disaster, the Missouri Public Service Commission ordered cost disallowances that had the effect of moving the company's financial returns from the non-sharing range to the sharing range. These events prompted Southwestern Bell to move expeditiously across its five states with initiatives to eliminate earnings sharing from its price cap regulation plans.

relative to traditional COSR.[89] This is not surprising given that earnings sharing retains many of the same features as traditional COSR.[90, 91]

Fourth, a key observation is that ESMs keep the regulator in the business of evaluating the prudence of the regulated firm's decision-making. This is problematic because the informational asymmetries between the regulator and the regulated firm increase concomitantly with the complexities of the industry going forward.[92]

Evaluating the various economic arguments both for and against earnings sharing, the weight of the evidence does not support including a traditional ESM in a PBR plan. The net economic gains from replacing COSR with PBR that includes earnings sharing are likely to be small.[93] Whereas regulators, consumer groups and sometimes even regulated firms may be comforted by

---

89 To date, there have been no peer-reviewed, published, comprehensive econometric analyses of the relative performance of PBR and COSR in the electricity or natural gas industries.

90 See Donald J. Kridel, David E. M. Sappington, and Dennis L. Weisman, "The Effects of Incentive Regulation in the Telecommunications Industry: A Survey," *Journal of Regulatory Economics,* Volume 9(3), 1996, pp. 269–306; and Jaison R. Abel, "The Performance of The State Telecommunications Industry Under Price-Cap Regulation: An Assessment of The Empirical Evidence," NRRI 00-14, The National Regulatory Research Institute, September 2000.

91 The theoretical economics literature indicates that earnings sharing may [actually] provide for enhanced levels of economic welfare relative to pure price cap regulation in the presence of limited information on the part of the regulator. See Mark Armstrong and David Sappington, "Recent Developments in the Theory of Regulation," in THE HANDBOOK OF INDUSTRIAL ORGANIZATION, M. Armstrong & R. Porter eds., Amsterdam: North-Holland, Volume 3, 2007, pp. 1557-1700; Thomas Lyon, "A Model of Sliding Scale Regulation," *Journal of Regulatory Economics*, Volume 9(3), May 1996, pp. 227-247; and Richard Schmalensee, "Good Regulatory Regimes," *Rand Journal of Economics*, Volume 20(3), Autumn, 1989, pp. 417-436. Notably, these studies do not account for the myriad strategic problems with earnings sharing in practice (e.g., cost-shifting, cost-misreporting, abuse, etc.), nor do they account for the "costs of regulation" associated with administering ESMs which may be comparable to COSR.

92 See Professor Kahn's prescient discussion of this matter at note 4 *supra*.

93 This conclusion is based, in part, on the empirical analysis of price cap regulation with earnings sharing in the U.S. telecommunications industry. See notes 90 and 91 *supra*. Moreover, it can be shown that many of the desirable efficiency properties of pure price cap regulation break down under earnings sharing. See, for example, Dennis L. Weisman, "Superior Regulatory Regimes in Theory and Practice," *Journal of Regulatory Economics*, Volume 5(4) 1993, pp. 355-366.

the "safety net" that earnings sharing provides,[94] it is the very presence of that "safety net" that undercuts the performance of PBR.

Furthermore, this so-called "safety net" may prove illusory for the regulated firm. To see this, recognize that the regulator may have incentives to strategically disallow costs in order to move earnings (i) into the sharing range (and secure rate decreases) when unadjusted earnings are near the upper end of the deadband and (ii) into the deadband (and avoid rate increases) when unadjusted earnings are outside the lower end of the deadband.[95] The net effect would be to increase the risk borne by the regulated firm because the probability of high returns is decreased while the probability of low returns is increased.

The significant resources required to design and implement a PBR regime with earnings sharing would be difficult to justify when the expected benefits in terms of improved efficiency and innovation are so limited. The following quotation from a former chairman of the Massachusetts Commission is instructive.

> The [Massachusetts regulatory] commission decided that earnings sharing was not appropriate because it introduces many of the cost-of-service disincentives for efficiency that price cap regulation is designed to eliminate. The commission also did not want to have to rule on the prudence of investments in an increasingly risky and speculative industry, which would have been required for an earnings calculation.

[94] See note 88 *supra*. This parallels a related problem with COSR (capping returns on successful investments while disallowing costs on unsuccessful investments). See Lawrence A. Kolbe and William B. Tye, "The Duquesne Opinion: How Much 'Hope' is There for Investors in Regulated Firms?" *Yale Journal on Regulation*, Volume 8(1), Winter 1991, pp. 113-157.

[95] There is some evidence to indicate that regulators adopt more liberal ("pro-competitor") entry policies under pure price cap regulation *vis-à-vis* earnings-based regulatory regimes. Without earnings sharing, the regulator has no vested interest in the earnings of the regulated firm and therefore tends to view competitive entry more favorably (i.e., regulatory moral hazard). Conversely, under COSR or price cap regulation with earnings sharing, competitive entry can place upward pressure on politically sensitive service rates. See Dale E. Lehman and Dennis L. Weisman, "The Political Economy of Price Cap Regulation," *Review of Industrial Organization*. Volume 16, 2000, pp. 343-356.

> Also, earnings sharing would require an annual review of earnings, which the Commission thought would be a significant administrative burden.[96, 97]

The above observations notwithstanding, it is conceivable that some of these concerns may be mitigated if PBR with earnings sharing is merely a transitional regulatory regime that represents an intermediate step along a dynamic path toward pure PBR. This was the case with incentive regulation in the U.S. telecommunications industry.[98] The outstanding question is whether such an intermediate step is warranted in light of the decisions of other Canadian regulatory commissions to forego earnings sharing for both electric power and telecommunications companies.

Finally, it is noteworthy that the AUC explicitly rejected earnings sharing in both its first-generation and second generation PBR plans for the electric power and natural gas industry.[99] As an alternative, the AUC adopted a reopener in the PBR regime that is triggered when returns deviate from target levels by +/- 300 basis points in two consecutive years or by +/- 500 basis points in any one year.[100] The OEB has adopted a similar approach.[101] When the utility perceives that the probability of triggering these reopeners is negligible, which it will be with a sufficiently wide deadband, it will have virtually the same incentives for superior performance as if it were

---

96 Paul Vasington, "Incentive Regulation in Practice: A Massachusetts Case Study," *Review of Network Economics,* Volume 2(4), 2003, p. 459.

97 It is also important to recognize that earnings sharing in a PBR regime may prove difficult to reconcile with PBR Principles 1 and 3.

98 See David E. M. Sappington and Dennis L. Weisman, "Price Cap Regulation: What Have We Learned from Twenty-Five Years of Experience in the Telecommunications Industry?" *Journal of Regulatory Economics*, Volume 38(3), December 2010, pp. 227–257.

operating under a pure PBR regime. Nonetheless, sufficient earnings safeguards remain in place should returns diverge too far from target levels.

2.7 Efficiency Carryover Mechanisms

It is standard practice for a PBR plan to be reviewed after some stipulated period of time. This review may be limited to a reexamination of the parameters of the price (revenue) cap formula, such as the *X* factor, or entail a recalibration of the regulated firm's rates to achieve a target rate of return. In an important sense, recalibrating rates to achieve a target rate of return gives rise to efficiency distortions and possibly strategic behavior, including cost-shifting, not unlike those associated with ESMs. The regulated firm will have less than ideal incentives to innovate and discover efficiencies if it believes that the regulator will simply claw back these efficiency gains at the end of the PBR regime and pass them on to consumers in the form of lower rates. These adverse incentives are particularly pronounced toward the end of the PBR regime.

The efficiency carryover mechanism (ECM) is the construct designed to address this issue. An ECM allows the regulated firm to carry over a portion of its efficiency gains (losses) into the next PBR regime. With an ECM there is not a full true-up of rates to achieve a stipulated target rate of return at the end of the PBR term. There are countervailing incentives that should be considered. A full true-up of rates to a target rate-of-return provides weaker incentives for cost reduction, but also decreases the period of time over which prices may diverge (sub-optimally) from incremental cost. A partial true-up of rates to a target rate-of-return provides stronger incentive for cost-reduction, but also increases the period of time over which prices may diverge (sub-optimally) from incremental cost. Hence, the less complete the true-up of earnings at the end of the PBR regime, the more high-powered the regulatory regime and the stronger the firm's incentives to invest in cost-reducing innovation.

Suppose, for example, that the target rate of return (T-ROR) is 10% and the average rate of return (A-ROR) is 12% as measured over the course of the PBR regime. The ECM may be recalibrated at the beginning of the next PBR regime to achieve a T-ROR of 11% = 10% + ½ × (12% – 10%), where ½ or 50% is the adjustment percentage. Hence, the ECM enables the regulated firm to carryover a portion of its realized efficiency gains into the next PBR regime. The efficiency carryover may be limited to a stipulated number of years into the next PBR regime. Whether the ECM should be symmetric with respect to the sharing of excess or deficient returns would depend, in part, on how the other parameters of the PBR regime are calibrated and their particular risk-bearing properties.

It is instructive to examine the specific properties of this type of ECM. First, in the case of a 100% adjustment, there is a full true-up of rates to a target rate of return at the end of the PBR regime. Conversely, when the adjustment is less than 100% there is not a full true-up of rates at the end of the PBR regime. This means that when the regulated firm is successful in its pursuit of efficiencies, the ECM ensures that it will not be required to surrender all of those efficiency gains at the end of the PBR regime. Conversely, if the regulated firm is less than successful in its quest for efficiencies, the ECM ensures that it will not be made "whole" at the end of the PBR regime. In this manner, the ECM enlists both "carrots" and "sticks" to provide strong incentives for superior performance.

Second, in terms of the various efficiency tradeoffs, an adjustment closer to 100% places proportionately greater weight on static efficiency, properly aligning prices with underlying economic costs, and proportionately less weight on dynamic efficiency. Conversely, an adjustment closer to 0% places proportionately greater weight on dynamic efficiency, encouraging investment in product and process innovation, and proportionately less weight on static efficiency.

Third, incorporating an ECM into the PBR framework is consistent with PBR Principle 1 in that, depending on the value of the adjustment percentage, it can serve to "create the same efficiency incentives as those experienced in a competitive market . . ." That is to say, an ECM with an adjustment of less than 100% strengthens incentives for dynamic efficiency because the regulated firm would not be forced to surrender the entirety of its efficiency gains at the end of PBR regime. An ECM is also consistent with PBR Principle 5 in that "Customers and the regulated companies should share the benefits of a PBR plan." The sharing with an ECM occurs on an *ex post* or retrospective basis, whereas the sharing associated with the *X* factor and the stretch factor occurs on an *ex ante* or prospective basis.

2.8 Offramps and Reopeners

Offramps and reopeners are typically included in PBR plans as a safeguard against unexpected results that may render the continued operation of the PBR plan untenable.[102] The difference between an offramp and a reopener relates to the scope of the inquiry.

A reopener may be included in a PBR plan to address specific problems with the design or operation of a PBR plan that may arise over the course of the PBR plan. These specific problems may have a material impact on either the company or its customers that cannot be addressed through the various elements of the plan (*Z* factors, *Y* factors, etc.).

An off-ramp is similarly intended to serve as a safeguard against unexpected results in the operation of the PBR plan. Off-ramps differ from re-openers in that once triggered the entirety of the PBR plan is examined and possibly terminated. In contrast, a re-opener is generally intended to provide an opportunity to investigate and modify a specific component in the operation or design of the PBR

[102] See, for example, Alberta Utilities Commission, Rate Regulation Initiative Distribution Performance-Based Regulation September 12, 2012 Decision 2012-237, Section 8.

plan. Candidates for reopeners include (i) deficient/excess financial returns; (ii) material deterioration in service quality; and (iii) change in size of service territory.

2.9 The Choice Between COSR and PBR

As discussed above, a central question in the economics of regulation literature concerns whether earnings-based regulatory regimes, price-based regulatory regimes, or a combination of regulatory regimes are the best means to replicate the discipline of competitive markets. Professors Armstrong and Sappington offer the following perspective on the tradeoffs between the two principal types of regulatory regimes.

> Regulatory policy can affect infrastructure investment differently than it affects innovative effort and investment designed to reduce operating costs. To illustrate this point, first consider rate of return regulation, which promises a fair return on prudently incurred investment. When expropriation can be avoided, such a promise can deliver strong incentives for infrastructure investment. In contrast, because it requires revenues to track costs closely, rate of return regulation (like other forms of "cost-plus" regulation) typically provides limited incentive for innovation and cost reduction.
>
> Now consider price cap regulation, which typically permits revenues to diverge from realized costs for a specified period of time (e.g., four years) but does not promise specific long-term returns on investment. Although such a policy can provide substantial incentive for short-term innovation and cost reduction, it may provide limited incentive for long-term infrastructure investment. Therefore, the choice between rate of return regulation and price cap regulation will depend in part on the type of investment that is most important to secure. In settings where the top priority is to induce the regulated firm to employ its existing infrastructure more efficiently, price cap regulation may be preferable. In contrast, in settings where it is important to reverse a history of chronic underinvestment in key infrastructure, rate of return regulation may be preferable (footnotes omitted).[103]

To foreshadow the discussion in the next section, when regulatory commitment to the basic tenets of PBR is weak COSR may be expected to perform better than PBR.

> The appropriate choice between rate of return regulation and price cap regulation also is influenced by industry volatility and regulatory commitment powers. As costs and

[103] Mark Armstrong, and David E. M. Sappington, "Regulation, Competition and Liberalization," *Journal of Economic Literature*, Volume 44, June 2006, pp. 340-41 (footnotes omitted).

> demands change over an extended time period, prices and costs will invariably diverge under price cap regulation, possibly leading either to financial distress or to particularly large profit for the regulated firm. Neither of these outcomes is likely to be credibly sustained in settings where the country's institutions are weak. Therefore, in such settings, rate of return regulation may be preferable to price cap regulation in the presence of considerable industry volatility, particularly if infrastructure investment is desirable. The cost-plus nature of rate of return regulation, which ensures profits are neither excessive nor insufficient, can render its implicit commitment to set prices that track costs closely more credible than the price commitments encompassed in a price cap plan.[104]

The above passages may be construed to suggest that a bifurcated PBR plan is optimal, one that administers CAPEX under COSR and OPEX under price (revenue) caps. In fact, there have been proposals for just such an approach to PBR.[105] The problem with this silo-approach, however, is that it may foster inefficient capital-labor substitution that risks undermining the superior efficiency properties of PBR. This is one of the primary reasons that the AUC significantly modified the way supplemental capital is treated in its second-generation PBR regime.[106] Similar objectives underlie the changes to PBR in the United Kingdom.[107]

The treatment of capital in the design of PBR plans in the electricity sector has confounded regulators in North America. The AUC, the OEB and the BC Commission have all struggled with

---

[104] *Id.,* p. 341 (footnotes omitted).

[105] See, for example, John J. Kwoka, "Investment Adequacy Under Incentive Regulation," Northeastern University Working Paper, 2009.

[106] There was protracted debate among the parties in that proceeding as to whether the capital tracker approach that the AUC had adopted for supplemental capital in the first-generation PBR regime had led to overcapitalization along the lines of the familiar Averch-Johnson effect typically associated with COSR. Harvey Averch and Leland L. Johnson, "Behavior of the Firm Under Regulatory Constraint," *American Economic Review*, Volume 52(5), September 1962, pp. 1052-1069. Despite the theoretical prediction of an overcapitalization bias, the empirical support for the Averch-Johnson effect is relatively weak. See, for example, Paul L. Joskow, "Regulation and Deregulation After 25 Years: Lessons for Research in Industrial Organization," *Review of Industrial Organization*, 2005, Volume 26, pp. 169-193. See also Paul L. Joskow and Nancy L. Rose, "The Effects of Economic Regulation," in HANDBOOK OF INDUSTRIAL ORGANIZATION, Chapter 25, R. Schmalensee and R.D. Willig eds., Amsterdam: North-Holland, 1989, Volume 2, pp. 1477-1482.

[107] See the related discussion in Section 2.3.6.

this issue in the search for the optimal design of a PBR plan. This is evident in the continuing modifications that the AUC and the OEB have made to the treatment of supplemental capital in successive-generation PBR regimes.[108] Whereas it may be premature to declare victory in the search for the optimal PBR design, the industry may be somewhat closer to discerning the broad outlines of an optimal design insofar as capital is concerned and it has the following properties.

- The PBR plan should include as much capital as feasible under the price (revenue) cap subject to the guidelines provided by the PBR principles. When the "carve out" for supplemental capital within the PBR regime becomes unduly large, the merits of adopting PBR may be called into question.
- The quantum of supplemental capital is directly related to the regulator's willingness to recognize the negative trends in productivity growth and duly reflect these trends in the X factor for the PBR plan.[109]
- A key issue for regulators concerns the partition of supplemental capital into two disjoint categories: (i) supplemental capital for which it is efficient for the regulated company to bear the risk; and (ii) supplemental capital for which it is not efficient for the regulated company to bear the risk.
- The PBR plan should minimize the frequency with which the PBR plan is "reopened" to address matters of revenue adequacy while ensuring that the regulated companies do not bear excessive risk.
- Whereas past capital expenditures may have limited informational value in forecasting future capital requirements,[110] past expenditures may nonetheless provide the regulator with a useful validation check on such forecasts.

---

108 Recall that supplemental capital refers specifically to the deficiency between capital requirements and the level of capital that is funded under the "$I - X$" PBR plan.

109 The debate over negative productivity growth is concerned less with whether recent trends exhibit negative growth and more with whether this negative trend is transitory. See notes 38 and 39 *supra*. A possible solution is to allow for updating of the X factor over the course of the PBR term.

110 Future capital requirement must take into account (i) the digitalization of the electricity sector (i.e., smart grid); (ii) increased competition and interconnection requirements; (iii) enhanced security,

3. REGULATORY COMMITMENT

The conclusion that price (revenue) cap regulation is superior to COSR (in the sense that it provides more high-powered incentives for efficiency) must be qualified accordingly. Specifically, price (revenue) cap regulation closely approximates the incentive structure of a competitive market when the regulator's commitment to the basic tenets of the PBR plan is a credible one.[111] This means that the regulated firm must have confidence that changes in the level of the price (revenue) cap, as determined by the *X* factor, are independent of its own performance. In other words, the risk of expropriation by the regulator is minimal.

As discussed above, the *X* factor in a price (revenue) cap plan determines the maximum rate at which the inflation-adjusted prices (revenues) of the firm's regulated services can increase, on average, each year until the price cap plan is reviewed. For example, if the rate of inflation is 4.5% and the *X* factor is 2%, the formula would permit the regulated firm to raise prices (revenues) on average a maximum of 2.5% (4.5% – 2%) per year. When changes in the *X* factor are conditional on the regulated firm's own performance, the regulatory regime is said to incorporate a "ratchet effect" and the firm's incentives for superior performance are adversely affected as a result.[112]

To illustrate the incentive problem associated with a "ratchet effect," suppose the *X* factor is initially set at 2% and the regulated firm works diligently to discover opportunities to innovate and

---

including cybersecurity; (iv) electric automobiles and charging stations and (v) increased use of renewables. The widespread implications of increased reliance on renewables for traditional utilities are discussed in "Renewable Energy: A World Turned Upside Down," *The Economist*, February 25, 2017. http://www.economist.com/news/briefing/21717365-wind-and-solar-energy-are-disrupting-century-old-model-providing-electricity-what-will

[111] See David E. M. Sappington and Dennis L. Weisman, DESIGNING INCENTIVE REGULATION FOR THE TELECOMMUNICATIONS INDUSTRY, Cambridge MA.: MIT Press and Washington D.C.: AEI Press, 1996, Chapter 7; and Jean-Jacques Laffont and Jean Tirole, COMPETITION IN TELECOMMUNICATIONS, Cambridge MA.: MIT Press, 2000.

[112] This practice is sometimes referred to as "moving the goal posts."

improve operating efficiency. As a result of these efforts, the regulated firm is able to realize efficiency gains of 3% per year. The regulator, having observed that the firm is able to achieve efficiency gains that exceed the *X* factor, decides that the *X* factor can safely be ratcheted upward. Over time, the regulated firm learns that its greater effort to secure efficiency gains will simply be appropriated by the regulator in the form of lower rates to consumers.[113] This type of strategic behavior undermines the regulated firm's incentives to discover and implement efficiency improvements.

> Under PCR [Price Cap Regulation], the firm's earnings may be "higher than normal" because (i) the initial prices are set too high; (ii) the X-factor in the price cap plan is set too low; or (iii) the regulated firm exercised its superior business acumen and managerial prowess to outperform the industry-wide X-factor. The key point, however, is that higher than normal earnings no longer (necessarily) imply rates that are not "just and reasonable." These higher than normal earnings may simply reflect the stronger incentives for efficient performance under price cap *vis a vis* earnings regulation. Should this be the case, these additional earnings would not exist but for the regulator's commitment to allow the regulated firm to be the residual claimant for its realized efficiency gains. In other words, the ability on the part of the regulator to appropriate these earnings may exist only because the firm believed the regulator would not take unfair advantage of this opportunity. It follows that because PCR breaks the link between prices and costs, it must also break the link between higher than normal profits and excessive rates, which is essentially the *Hope* standard (footnotes omitted).[114]

[113] At least in the United States, the change from COSR to PBR has not been accompanied by a corresponding change in the underlying case law. Regulators in the U.S. have considerable discretion to adopt policies, such as entry accommodation, that reduce the regulated firm's earnings provided that they do not impede the regulated firm's ability to raise capital and remain a financially viable enterprise. See Dennis L. Weisman, "Is There 'Hope' for Price Cap Regulation?," *Information Economics and Policy*, Volume 14(3), 2002, pp. 349-370; and Ronald R. Braeutigam and John C. Panzar, "Effects of the Change from Rate-of-Return to Price-Cap Regulation," *The American Economic Review*, Papers and Proceedings, Volume 83(2), May 1993, pp.191-198. To understand the nature of the problem, recognize that the regulator can effectively breach the price cap commitment, not by directly lowering the price cap but by adopting liberal competitive entry policies that render it unprofitable for the regulated company to sustain a price at the level of the price cap. To draw an analogy, this is akin to a basketball game in which the regulator commits not to raise the height of the basket but retains the discretion to lower the floor.

[114] Dennis L. Weisman, "Is There 'Hope' for Price Cap Regulation?," *Information Economics and Policy*, Volume 14(3), 2002, pp. 63-64.

Under pure price (revenue) cap regulation *vis-à-vis* price (revenue) cap regulation with earnings sharing, the regulatory authority agrees not to adjust the prices (revenues) of the regulated firm's services on the basis of its actual earnings or costs for the duration of the PBR regime. To do so, of course, would represent a form of earnings regulation and re-establish the very link between allowed earnings and costs that price (revenue) cap regulation seeks to break. A strong regulatory commitment is therefore critical to the superior performance of the PBR regime.

It follows that if the firm is uncertain as to whether regulatory commitments will be honored, there may be little practical difference between PBR and COSR. In this manner, a weak regulatory commitment undermines the superior incentive properties of PBR. Under such conditions, the regulated firm would not operate as if it faced competitive market conditions and PBR Principle 1 is not satisfied. The problems associated with an uncertain regulatory commitment are well documented in the literature.

> …Can the regulator credibly pre-commit to a system of price cap regulation? Stated differently, can today's regulatory commission bind its successor? A regulatory agency is likely to be subjected to considerable political pressure to change the price cap or price cap formula over time. If a firm regulated by price caps begins to earn large profits, consumers will no doubt petition the regulator to lower the price in the core market.[115]
>
> This issue of recontracting and the efficiency distortions resulting therefrom is arguably one of the more serious problems with PC [Price Cap] regulation in practice. A key premise underlying PC regulation is that increased profits for the firm will be viewed by regulators and their constituency as something other than failure of regulation itself. If this premise is false, then regulators will be under constant political pressure to recontract when the firm reports higher profits. In equilibrium, the firm learns that this is how the game is played and the efficiency gains from PC regulation in theory may fail to materialize in practice.[116]

4. BENCHMARKING

A seminal theme in this discussion is the basic concept that economic regulation should seek to emulate competitive market outcomes. This concept is significantly easier to state in the abstract than it is to apply in practice. This observation underscores the role of benchmarking in PBR regimes.[117]

4.1 The Theory

Suppose that there is a utility A that is subject to economic regulation. In addition, there is a utility B that is a clone of utility A in terms of exogenous operating characteristics (i.e., size of service territory, topography, climate, number of customers, etc.). The only differentiating characteristic between the two utilities is their respective investments in (unobserved) cost-reducing effort (e). What this means is that the regulator can observe the accounting costs of the two utilities, but s/he cannot observe the amount of effort invested to obtain these costs. How might the regulator go about regulating utility A if the objective is to emulate a competitive market outcome and induce efficient investment in cost-reducing effort?

The regulator would go about creating a tournament of sorts so that utility A would act as if it faced competition from utility B even though it does not. We might refer to this tournament as pseudo competition. Let P^A and P^B denote the respective prices that utility A and utility B are permitted to charge for their services. Similarly, let $c^A(e)$ and $c^B(e)$ denote, respectively, the constant unit costs for utility A and utility B. As is standard in the literature, investment in cost-reducing effort (e) is assumed to reduce unit costs at a decreasing rate. The cost to the utility for

[117] See Andrei Schleifer, "A Theory of Yardstick Competition," *Rand Journal of Economics*, Volume 16(3), 1985, pp. 319-327.

cost-reducing effort is assumed to be increasing in effort at an increasing rate. There are assumed to be no fixed costs of production in this simplified analysis.

What pricing rule should the regulator adopt for utility A (respectively utility B)? The regulator would set $P^A = c^B(e)$ and $P^B = c^A(e)$. In other words, the price for utility A would be equal to the unit cost of utility B and *vice versa*. This pricing rule is efficient and consistent with the regulator's objective to emulate competition (in the absence of competition). To see this, let Q^A denote the number of units of output that utility A sells. Utility A's accounting profits may then be expressed by $\Pi^A = Q^A \times (P^A - c^A(e)) = Q^A \times (c^B(e) - c^A(e))$. Utility A's accounting profits are therefore equal to the product of its output and the price-cost margin on each unit of output that it sells.

There are three key observations about utility A's profit. First, utility A generates positive profits only if it is more efficient than its pseudo rival, utility B, or $c^A(e) < c^B(e)$. Otherwise, utility A realizes a loss. As a result, each utility "competes" to have the lowest cost. Second, utility A would have ideal (first-best) incentives to invest in cost reducing effort under this pricing rule. Specifically, utility A will invest in cost-reducing effort up to the point where the marginal benefit of cost-reducing effort is equal to it marginal cost. Because $P^A = c^B(e)$, utility A will choose the efficient level of cost-reducing effort since increased effort does not reduce the price that it is permitted to charge for its services (i.e., the utility is the residual claimant for its efficiency gains). The utility is not penalized for reducing its costs because its price is invariant to its actual costs. This pricing rule avoids the "ratchet effect" that is responsible for the low-powered incentives of COSR.

4.2 From Theory to Practice

The theory outlined in the previous subsection is an elegant solution to a complex problem, but the steps from theory to practice are lined with myriad obstacles. First, in the real-world there is no perfect clone for the utility. Second, utilities are heterogeneous rather than homogenous. Consequently, it can be very difficult if not impossible to reach a consensus as to the appropriate peer group of utilities to facilitate a meaningful comparison. Third, in theory, any exogenous differences between the utilities must be duly accounted for in order to adjust the compensation scheme accordingly. Failure to do so can result in either over-compensation or under-compensation for the utility. Properly accounting for these exogenous differences necessitates complex statistical analysis that can contribute to highly contentious regulatory proceedings.

There are two prospective applications of benchmarking in the context of the rate adjustment formula discussed in Section 2.5: the productivity offset (*X*) and the stretch factor (*S*). An important consideration concerns whether the benchmarking analysis applies to levels or changes in levels. This distinction is important because heterogeneity across firms is likely to be a more serious problem when benchmarking levels than when benchmarking changes in levels.

For example, some utilities are vertically-integrated, while others participate only in distribution. Scope economies (efficiencies attributable to multi-element production) may result in lower cost levels for vertically-integrated utilities in comparison with utilities engaged in distribution only. Nonetheless, the technological progress of these firms (the rate at which they can reduce their costs over time) may be quite similar. What this suggests is that a peer group of firms that is inappropriate for benchmarking levels may be entirely appropriate for benchmarking changes in levels.

4.2.1 The Productivity Offset (X)

Recall that productivity is defined as the ratio of outputs to inputs, whereas productivity growth is defined as the percentage change in outputs less the percentage change in inputs. In North American PBR plans, it is common practice to inform the development of an *X* factor on the basis of productivity growth for a representative peer group of firms that constitutes the industry. In the case where the heterogeneity across firms largely vanishes when the metric is technological progress (i.e., productivity growth as opposed to productivity), it may be advisable to employ the largest possible sample of firms. Conversely, if there is reason to believe that heterogeneity across firms persists even when the metric is technological progress, it may be advisable to restrict the sample to promote a greater degree of homogeneity.

In this latter case, it is important that (i) great care be taken in limiting the sample so that all feasible sources of heterogeneity are accounted for in the analysis; and (ii) the sample restriction does not focus too narrowly on a subset of exogenous operating characteristics to the exclusion of others. For example, suppose mean average temperature is an exogenous characteristic over which firms reasonably differ. It would not be appropriate to draw a sample based solely on this metric if there is reason to believe that the number of customers and topography are also important exogenous factors that explain differences in technological progress across firms. Hence, when it is not possible to control for all important exogenous factors that explain differences across firms there can be no reasonable guarantee that truncating the sample of firms to reflect a proper subset of exogenous characteristics produces a more representative peer group.[118]

4.2.2 The Stretch Factor (S)

[118] There is also a potential tradeoff regarding sample size. Specifically, a smaller, more homogeneous sample is likely to be less precise (e.g., greater standard deviation) and more sensitive to the results of outlier firms.

Unlike the *X* factor, there is no consensus in regulatory practice that the stretch factor (*S*) in a PBR plan can be developed in a scientifically rigorous manner on the basis of benchmarking across firms. Recall from the discussion in subsection 2.5 that *S* is designed to account for the increase in productivity growth associated with the change from COSR to PBR (i.e., from low-powered to high-powered incentives).[119] The predominant view among regulators is that the value of *S* is a judgement call. The AUC's views on this issue are seemingly representative.

> [T]he determination of the size of a stretch factor is, to a large degree, based on a regulator's judgement and regulatory precedent and does not have a "definitive analytical source" like the TFP study represents.[120, 121]

In its first-generation PBR regime, the AUC set the stretch factor at 0.2 percent for all the utilities under its jurisdiction.[122] This approach differs from that of the OEB in two important respects. First, the OEB chooses a range of stretch factors for 5 different cohorts of firms, {0.0. 0.15, 0.30, 0.45, 0.60}, that vary across companies based on their relative efficiency.[123] Second,

---

119 As the AUC observed:

> The purpose of a stretch factor is to share between the companies and customers the immediate expected increase in productivity growth as companies transition from cost of service regulation to a PBR regime.

Alberta Utilities Commission, Decision 2012-237, September 12, 2012, paragraph 479. In addition, formal benchmarking analysis was not used to develop stretch factors for telecommunications firms in North America.

120 *Id.,* paragraph 497.

121 The BC Commission stated that "We agree with Fortis that a stretch factor is judgment based and will use our judgment to determine one that is appropriate" (p. 40). The commission subsequently ordered a benchmarking study be conducted to inform its judgement (p. 82). British Columbia Utilities Commission, In the Matter of FortisBC Energy Inc., Multi-Year Performance Based Ratemaking Plan for 2014 Through 2018, Decision, September 15, 2014.

122 Alberta Utilities Commission, Decision 2012-237, September 12, 2012, paragraph 499.

123 Ontario Energy Board, EB-2010-0379, Report of the Board, Performance Measurement for Electricity Distributors: A Scorecard Approach December 4, 2013. https://www.oeb.ca/oeb/_Documents/EB-2010-0379/Report_of_the_Board_Scorecard_20140305.pdf In its third-generation PBR regime, the OEB had previously partitioned electricity distributors into three different cohorts with a range of stretch factors of {0.2, 0.4, 0.6}.

the OEB relied upon statistical benchmarking to determine the relative efficiency of each of the utilities. It is important to recall that there are 70+ regulated firms under the OEB's jurisdiction that vary significantly in terms of scale of operations.

The problem in selecting a stretch factor based on the regulated firm's relative efficiency is that it involves comparing levels of efficiency (e.g., productivity) rather than changes in efficiency (e.g., productivity growth) and thereby introduces the familiar heterogeneity problem discussed above. Specifically, is it reasonable to believe that all of the important exogenous factors that explain the differences in relative efficiency across regulated firms have been properly accounted for in the analysis?

Without addressing the relative merits of determining the stretch factor based on informed judgement *vis-à-vis* formal statistical benchmarking,[124] there is a sound policy rationale for allowing the stretch factor to (potentially) vary across firms. Consider, for example, two utilities, utility 1 and utility 2. Under COSR regulation, utility 1 behaves as if it faces high-powered incentives by implementing diligent cost-control measures and undertaking significant investment in innovation. In contrast, under COSR regulation, utility 2 behaves as if it faces the low-powered incentives that it does by implementing only modest cost control measures and undertaking only limited investment in innovation relative to utility 1. As a result, utility 1 enters PBR as a relatively efficient firm, whereas utility 2 enters PBR as relatively inefficient firm.

Suppose now that the regulator adopts the same stretch factor for both utilities. Utility 1 will have to work considerably harder than utility 2 to realize the incremental productivity gains

[124] Nonetheless, with specific reference to the statistical benchmarking approach to setting the stretch factor, the AUC stated that "the Commission does not wish to engage in this type of analysis for the purposes of PBR in Alberta because of the practical and theoretical problems associated with comparing efficiency levels among companies." Alberta Utilities Commission, Decision 2012-237, September 12, 2012, paragraph 481.

reflected in the common stretch factor because it will have already picked the “low-hanging fruit.” Conversely, utility 2 will not have to work as hard as utility 1 because the easy to pick “low-hanging fruit” has yet to be picked. Hence, in a very real sense, utility 1 has been penalized for its diligence in cost-control under COSR, while utility 2 benefits from its lack of diligence in cost-control under COSR. From utility 1’s perspective, “no good deed goes unpunished.” What this suggests is that, at least in theory, there is a credible argument for recognizing the possibility that stretch factors differ across firms. Administrative complexities, inclusive of the myriad issues associated with Principle 3, may well explain why this approach is not standard regulatory practice in North America.

5. PBR and Crown Corporations

As Observation 1 makes clear, a key tenet of PBR is that the regulated company bears greater risk in exchange for the prospect of greater reward. In the case of private enterprise, the reward metric is earnings or financial returns. Public enterprises or crown corporations are typically not profit-maximizing entities. Therefore, an important question concerns whether PBR works (or can be made to work) in the case of crown corporations?

In the case of a crown corporation, the government may have a strong interest in the “earnings” that flow from the company to the government, but profit-maximization is not its sole focus given that the higher rates that may accompany higher profits are not necessarily aligned with the interests of the citizenry. A similar issue confronted Edmonton Distribution and Transmission Incorporated (EDTI), wholly owned by EPCOR Utilities Inc. (EUI), which in turn is wholly owned by the City of Edmonton. Notably, EDTI is currently under its second-generation PBR regime administered by the AUC.[125]

It is noteworthy that postal systems throughout the world are government owned. Nonetheless, PBR has been successfully applied to postal systems to strengthen incentives for superior performance. The following quotations are helpful in framing the relevant issues.

> Rate ceilings are not merely a tool to deliver greater management flexibility. They are a powerful incentive for achieving what is largely lacking at the Postal Service today: the alignment of the interests of postal managers and employees with the interests of ratepayers. Specifically, rate ceilings allow prices to be adjusted upward within limits established by a regulator based on an "escalator" that incorporates factors for both inflation and productivity.[126]
>
> It should be noted that some doubt exists as to whether a public-sector institution (without, for example, employee stock options) can successfully use these tools. Leading experts, however, believe that a combination of *negative* incentives (such as holding managers accountable for performance) and *positive* incentives (such as performance bonuses) can take full advantage of this innovative mechanism to the ultimate benefit of ratepayers.[127]

With respect to the application of PBR to crown corporations, there are two seminal questions. First, can the PBR regime be structured so that the maximum permissible rate changes emulate a competitive market standard as per PBR Principle 1? Second, is it possible to provide management in a crown corporation with the same high-powered incentives for efficiency and innovation as managers in a private enterprise? As the discussion below makes clear both questions can be answered in the affirmative.

5.1. Competitive Rate Changes in PBR Regimes

---

[125] EPCOR Water Services Inc. (EWSI), which serves the City of Edmonton, is also regulated under a PBR framework that is approved by the City of Edmonton.

[126] EMBRACING THE FUTURE – MAKING THE TOUGH CHOICES TO PRESERVE UNIVERSAL MAIL SERVICE, Report of the President's Commission on the United States Postal Service, Washington D.C., July 31, 2003, p. 59.

[127] *Id.,* footnote omitted.

Provided that the *X* factor is developed in accordance with sound economic principles, regulators can be assured that the maximum-permissible rate changes are consistent with the competitive market standard that is called for in PBR Principle 1. Hence, the fact that the PBR regime is being applied to a crown corporation *vis-à-vis* a profit-maximizing enterprise does not present any insurmountable difficulties insofar as permissible rate changes that emulate a competitive market standard are concerned.

5.2. High-Powered Incentives for Efficiency and Innovation

The fact that profit-maximization is not the sole focus of the public enterprise can potentially weaken incentives for efficiency and innovation.[128] This observation poses a prospective problem for the application of PBR to crown corporations. Specifically, absent strong incentives for efficiency and innovation under the PBR regime managers may not be expected to invest optimally in efficiency and innovation. As a result, the rates set in the course of the rebasing process may be "too high."

This problem can be overcome, however, if the managers in a crown corporation are incented to behave as if profit-maximization were the objective of the corporation even though it is not. To see this, suppose that the government requires the corporation to surrender the entirety of its earnings on an annual basis. Under these conditions, the PBR regime would have no stronger incentives for efficiency than the textbook model of COSR. The gains from additional managerial effort are not retained by management, but simply increase the earnings that are surrendered to the government on a dollar-for-dollar basis. As a result, management sees no benefit from increasing efficiency and innovation—the benefits from additional effort are non-existent while effort and

[128] This observation notwithstanding, there are notable examples of publicly owned utilities that are incredibly innovative and efficient. See Mason Willrich, MODERNIZING AMERICA'S ELECTRICITY INFRASTRUCTURE, Cambridge MA: The MIT Press, 2017, chapter 5 and pp. 211-212.

innovation are privately costly (less effort is preferred to more). This can be thought of in terms of the government levying a 100% marginal tax rate on the earnings of the crown corporation.

Now suppose that the government no longer requires the crown corporation to surrender the entirety of its earnings. As an alternative, the government permits management to retain the difference between its current earnings and a fixed level of earnings that may be indexed over time.[129] Management would recognize that under this new compensation scheme it is the residual claimant for its efficiency gains. The amount of earnings surrendered to the government is invariant to management's behavior (just as the price/revenue cap is invariant to the firm's behavior).[130] The marginal tax rate on earnings under this compensation scheme is now 0% rather than 100%.[131] Management now has ideal incentives to improve efficiency and innovate since it retains the entirety of any surplus (net of the fixed earnings payment to the government).

---

[129] A case in point is Jacksonville Electric Authority. In 2015, this publicly owned utility had 450,000 electricity customers and contributed \$114 million to the city of Jacksonville. This contribution is scheduled to escalate at 1% per year. See Mason Willrich, MODERNIZING AMERICA'S ELECTRICITY INFRASTRUCTURE, Cambridge MA: The MIT Press, 2017, pp. 51-52.

[130] Heuristically, this incentive structure can be conceived of in terms of the government "selling" the company to management in exchange for a guaranteed stream of earnings over time. An example from the Chinese agricultural sector is instructive. Under the earlier commune system, peasants were organized into production teams. Each team member was assigned work points that attempted to measure how many hours and how effectively the member had worked. The work points were not directly related to work effort because this could not be directly observed. In addition, there was a tendency to spread the commune's earnings across the commune members in a manner that resulted in larger families receiving more earnings. China subsequently changed to a responsibility system. Each peasant family was given a long-term lease on a plot of land. The family was required to deliver a certain quota of produce to the government and was allowed to keep any surplus over and above the government quota. As a result of the adoption of the responsibility system, which provided a direct link between effort and reward, productivity soared in the agricultural system. This occurred because the family was now the residual claimant for its efforts in producing agricultural output in excess of the government quota. See John McMillan, GAMES, STRATEGIES AND MANAGERS, New York: Oxford University Press, 1992, pp. 96-98. It is estimated that 78 percent of the increase in agricultural productivity in China between 1978 and 1984 can be attributed to the incentive effects of the new responsibility system. John McMillan, John Whalley and Lijing Zhu, "The Impact of China's Economic Reforms on Agricultural Productivity Growth, *Journal of Political Economy*, Volume 97(4), August 1989, pp. 781-807.

[131] Alternatively, suppose that the government agrees to allow management to retain 50% of the difference between its actual earnings and the indexed level of earnings. This management compensation scheme

It is noteworthy that EUI in Alberta is subject to a similar compensation structure. Specifically, the EUI's shareholder has an expectation of annual dividend increases that are independent of EUI's actual performance. Management effectively retains any surplus that remains after the payment of the dividend.[132] In other words, management is the residual claimant for any gains from efficiency and innovation that remain after the dividend is paid. This compensation structure provides management with a profit motive for superior performance even though the corporation itself is not a profit-maximizing enterprise.

In similar fashion to the regulatory commitment problem discussed in Section 3, management must perceive a strong commitment on the part of the government to adhere the terms and conditions of the management compensation scheme. If the government's commitment is perceived to be weak, management may have little or no incentive to invest in the cost-reducing innovation necessary to realize positive returns.

By way of conclusion, PBR can be effectively applied to a crown corporation. In order to realize the myriad benefits expected of PBR it will be necessary for the government to adopt a management compensation structure with incentive properties similar to those discussed above. Absent such an incentive-based compensation structure for management, the crown corporation

---

would have efficiency properties similar to earnings sharing mechanisms discussed in section 2.6. The 50% marginal tax rate would tend to weaken incentives for efficiency but is nonetheless superior to the 100% marginal tax rate associated with a dollar-for-dollar pass-through. It should be noted, however, that the crown corporation could potentially be subject to two different ESMs, the first imposed by the regulator and the second imposed by the government. The strength of management's incentive to innovate will depend on the composite marginal tax rate associated with both ESMs. Suppose, for example, that the regulator implements an ESM with a marginal tax rate of t and the government further taxes earnings at a marginal tax rate of t. The composite marginal tax rate facing the crown corporation is given by $t^{comp} = t + t \times (1 - t) = 2t - t^2$. Hence, if $t = 50\%$, $t^{comp} = 75\%$. This means that the crown corporation retains only 25 cents or $(1 - t^{comp})$ of each additional dollar in cost savings, which equates to relatively low-powered incentives. This example abstracts from government-levied corporate taxes.

132 The EDTI managers further indicated that the city of Edmonton is not involved in the managerial oversight of EDTI. As a result, management has freedom to innovate in the pursuit of efficiency gains.

may have incentives for efficiency and innovation that are no stronger than those under textbook COSR regardless of the PBR regime adopted by the BC Commission. Should this be the case, the expected net benefits from adopting PBR are *de minimis*.

6. SUMMARY AND CONCLUSIONS

This report examines the fundamental properties of PBR, including design and implementation issues. The prospective benefits of adopting PBR are compared with traditional COSR. It is instructive to conceive of PBR and COSR as lying along a continuum of regulatory regimes wherein the differentiating characteristic is the strength of the incentives for efficient performance (i.e., high-powered or low-powered incentives). Depending on the design of the PBR regime, including the term of the regime, the strength of the regulatory commitment and whether it includes earnings sharing, the distance between PBR and COSR on this continuum may be great or small. In other words, a poorly designed PBR regime may not represent a significant improvement over COSR.

The experience with incentive regulation in the telecommunications industry closely tracks the predictions of the theoretical regulatory economics literature in terms of expected efficiency gains, innovation and the benefits to key stakeholder groups. The experience with PBR in the energy sector, while certainly demonstrating promise, is not as universally positive. As explained in this report, there are numerous possible explanations for these differences, including conservation objectives, differential rates of productivity growth, and the myriad complexities associated with the need for supplemental capital. In addition, it is possible that at least some of the benefits attributed to incentive regulation in the telecommunications industry were actually due to the emergence of rivalrous competition in that sector.

Policymakers should recognize that the expected gains from adopting PBR may be subject to greater uncertainty in the case of crown corporations. In many respects, these public enterprises are *de facto* subject to two different regulatory authorities—the regulatory commission of jurisdiction and its government owners. Nonetheless, PBR plans have been successfully applied to public enterprises.

Finally, if the PBR regime is not developed in accordance with sound economic principles, or there is not a strong commitment to the fundamental tenets of PBR on the part of either the regulator or the government, the significant resources required to design and implement a PBR regime would be difficult to justify. The adoption of PBR may simply fail the cost-benefit test under these conditions.

ABOUT THE AUTHOR

Dr. Weisman is Professor of Economics *Emeritus* at Kansas State University and a former Director of Strategic Marketing for SBC Communications, Inc. (now AT&T). He has testified in numerous regulatory proceedings to the economic and social impacts of regulatory policies and has advised Fortune 100 Companies and regulatory commissions on economic pricing principles, incentive (performance-based) regulation and competition policy. His primary research interests are in strategic behavior, economic regulation and antitrust. He is the author or coauthor of more than 120 articles, books and book chapters, including DESIGNING INCENTIVE REGULATION FOR THE TELECOMMUNICATIONS INDUSTRY (The MIT Press, 1996). Dr. Weisman's research has been cited by the U.S. Supreme Court, the U.S. Court of Appeals for the D.C. Circuit and numerous regulatory commissions. He currently serves on the editorial boards for the *Journal of Regulatory Economics* and *Information Economics and Policy* and previously served as an editor for *The Review of Network Economics*. He received his Ph.D. in economics from the University of Florida.

EDUCATION:

1993	Ph.D.	Economics, University of Florida
1981	M.A.	Economics, University of Colorado
1979	B.A.	Economics and Mathematics, University of Colorado

PROFESSIONAL EXPERIENCE:

1993 - Present Kansas State University, Department of Economics:

Professor *Emeritus* (2014 - Present)
Professor (2000 - 2014)
Associate Professor (1996 - 2000)
Assistant Professor (1993 - 1996)

1992 - Present Weisman Associates, LLC: Founder and President

1989 - 1993 SBC Communications Inc. (now AT&T):

Director - Strategic Marketing
Director - Special Project with Florida Public Service Commission

1982 - 1989 Southwestern Bell Telephone Company – Demand Analysis:

District Manager
Staff Manager
Staff Specialist
Assistant Staff Manager

OTHER POSITIONS HELD:

2008 - Present Board of Academic Advisors, The Free State Foundation.

2007 – 2008 Co-Guest Editor, Symposium Commemorating the Economic and Public Policy Contributions of Professor Alfred E. Kahn on the Occasion of His 90th Birthday, *The Review of Network Economics*, 2008.

OTHER POSITIONS HELD (CONTINUED):

2007 - 2008	Program Committee Member, International Telecommunications Society.
2005 - 2006	Regulatory Framework Working Group, Digital Age Communications Act (DACA) Project, Progress and Freedom Foundation.
2004 - 2005	Chairperson, Site Council, Frank V. Bergman Elementary School.
2003 - 2006	Advisory Board, The Institute for Regulatory Law and Economics.
2002 - 2003	Guest Editor, Symposium on Incentive Regulation, *The Review of Network Economics*, Vol. 2(4), December 2003.
2000 - 2003	Dean's Advisory Council On Tenure and Promotion in Arts and Sciences.
1998 - 2005	Associated Faculty Member, Center For Research In Regulated Industries, Rutgers University.
1990 - 1992	Research Fellow, Public Utility Research Center, University of Florida.

Assessing the Treatment of Capital Expenditures in PBR Plans

ASSESSING THE TREATMENT OF CAPITAL EXPENDITURES IN PERFORMANCE-BASED REGULATION PLANS

by

David E. M. Sappington and Dennis L. Weisman*

September 1, 2015

EXECUTIVE SUMMARY

This report was commissioned by EPCOR to identify and objectively evaluate the merits of potential alternative approaches to the treatment of capital expenditures (CAPEX) in performance-based regulation (PBR) regimes. This pro-active approach to the analysis may help to resolve critical issues regarding the treatment of capital in PBR regimes outside the adversarial environment of a formal regulatory proceeding.

The report analyzes both earnings-based and price-based PBR plans. A total of eleven difference approaches are evaluated (three earnings-based plans and eight price-based plans). The advantages and disadvantages of each plan are assessed, and references are provided to the relevant economics literature to facilitate further analysis. In addition, where appropriate, the PBR principles set forth by the Alberta Utilities Commission (AUC) in its 2012 PBR proceeding are linked to the various advantages and disadvantages of each approach.

Our preliminary recommendation regarding appropriate approaches reflects four main criteria. First, the AUC is unlikely to adopt any approach containing elements of traditional rate of return regulation. Second, the AUC places a large premium on simplicity, transparency and reducing the regulatory burden for all parties. Third, the preferred approaches should address the issue of capital sufficiency in a comprehensive and principled manner. Fourth, the preferred approaches must provide strong incentives for efficiency, comparable to incentives that arise in competitive markets.

Our preliminary recommendation is that the AUC adopt a pure price cap approach that incorporates an economically principled mechanism that can address all three of the capital tracker categories that EPCOR identified in the 2013 Capital Tracker proceeding. Three of the eleven approaches evaluated in the report (those analyzed in Sections III.C, III.E, and III.F) appear to satisfy these requirements. We believe that each of these approaches satisfactorily addresses both company and Commission concerns while preserving to the extent possible the desirable efficiency incentives of competitive markets.

* Eminent Scholar in Economics, University of Florida and Professor of Economics *Emeritus*, Kansas State University, respectively. The funding for this study was provided by EPCOR, but the views expressed herein are exclusively those of the authors.

List of Figures and Tables

I. INTRODUCTION.

A. Background and Purpose of this Report.

In 2012, Application No. 1606029, Proceeding ID No. 566, the Alberta Utilities Commission ("AUC") launched its first industry-wide performance-based regulation ("PBR") initiative for the electric power and natural gas industries.[1] The initiative reflected in part the largely favorable experience with PBR in the telecommunications industry.[2,3] However, it became clear early on in the process that important differences between the energy and telecommunications sectors would require a form of PBR in the Alberta energy sector that differed from common forms of PBR in the telecommunications sector.[4] In particular, the relatively simple $I - X$ price cap plans often implemented in the telecommunications sector were deemed to be inappropriate for Alberta's utilities.[5]

Alberta's utilities believed it was important to have the opportunity to formally reassess their anticipated capital requirements and adjust allowed prices accordingly during the course of the PBR regime. Such a "re-opening" mechanism typically is not present in PBR plans in the telecommunications industry. This may be the case in part because the ongoing decline in the cost of computing enables telecommunications firms to count on increasing profit margins over the course of a PBR regime.[6] Corresponding systematic cost-reducing forces are not present to the same degree in the electric power and natural gas industries. Consequently, absent an opportunity

---

1 In AUC 2009-035, the Commission issued its order for the PBR plan for ENMAX. Notably, this PBR plan was initiated at the request of ENMAX rather than the AUC. The AUC's March 25, 2010 Rate Regulation Initiative Roundtable recognized that traditional rate of return regulation was no longer the appropriate regulatory regime for the Alberta utilities, and explored alternative regulatory regimes with superior incentive properties.

2 See Abel (2000) and Lowry and Kaufman (2002), for example.

3 Two key members of the AUC, Chairman Willie Grieve and Vice-Chair Mark Kolesar, joined the Commission after long careers in the Canadian telecommunications industry. Both served on the AUC panel for the PBR initiative.

4 EPCOR (June 13, 2012, ¶¶ 121-127).

5 The $I - X$ index limits annual price changes for the regulated firm to an economy-wide inflation measure (I), less an offset (X). To illustrate, if I is 3% and X is 2%, the regulated firm is permitted to increase its prices by 1% (= 3% $-$ 2%) annually, on average. X measures the extent to which productivity in the regulated industry is expected to increase more rapidly and industry input prices are expected to increase less rapidly than in the economy as a whole. See Bernstein and Sappington (1999).

6 See Jorgenson (2001), for example.

to revisit the terms of a lengthy PBR regime, regulated firms may experience unduly low returns and face substantial earnings uncertainty.

These concerns may help to explain why, even though PBR was adopted relatively rapidly in the telecommunications sector (often at the initiative of the companies themselves), the implementation of PBR has experienced fits and starts in the electric power and natural gas industries.[7] The differential patterns of technological advance in the telecommunications and energy sectors likely has led the companies in the former sector to embrace the opportunities for enhanced earnings presented by price cap regulation and the companies in the latter sector to prefer the earnings stability afforded by traditional rate of return regulation.

By the end of the PBR hearings in the late spring of 2012, the AUC concluded that: (i) capital expenditures ("CAPEX") likely required some special treatment in the design of PBR plans; and (ii) it would be appropriate to consider the unique circumstances of each company when determining the treatment of its CAPEX under PBR.[8] In particular, the AUC recognized the need for a mechanism that would permit reconsideration of the terms of the PBR plan as the need for unforeseen capital expenditures arose. The Commission's focus then turned to designing a PBR plan that addressed the concerns of the companies regarding capital requirements over the course of the PBR regime while preserving to the greatest extent possible the incentives for efficiency that prevail in competitive markets.[9]

In its 2012 PBR decision, the AUC adopted a capital tracker approach (and associated *K* factor adjustment) as the mechanism through which the companies would be allowed to re-open the PBR plan in order to address unforeseen capital expenditures. The AUC specified three conditions that a capital project must satisfy in order to qualify as a capital tracker, and thereby receive explicit consideration by the Commission:[10]

---

[7] This issue was discussed at length at the PBR hearings and summarized in EPCOR's Final Argument in that proceeding. See EPCOR (June 13, 2012, ¶¶ 121-127).

[8] Alberta Utilities Commission (AUC), Rate Regulation Initiative, Application No. 1606029, Proceeding ID No. 566, Proceedings, Volume 10, April 27, 2012, pp. 1962-3.

[9] Makholm et al. (2012) survey PBR plans in the U.S. and Canada and discuss how regulators might incorporate "trackers" into PBR plans to address cost items not traditionally covered by PBR plans. (Dr. Jeffrey Makholm was retained by the AUC to provide economic testimony in the AUC's 2012 PBR proceeding.)

[10] AUC Decision 2012-237, ¶ 592.

(1) The project must be outside of the normal course of the company's ongoing operations.[11]

(2) Ordinarily the project must be for replacement of existing capital assets, or undertaking the project must be required by an external party.

(3) The project must have a material effect on the company's finances.

The total dollar amount of all capital projects approved by the Commission as capital trackers are included as a K factor in the price cap formula and operates in a manner similar to the exogenous factor or Z factor common to most price cap plans.[12] The Commission adopted the capital tracker approach and rejected other approaches with similar objectives. The Commission did so because it believed this approach would limit the extent to which the strong incentives of competitive markets would be diluted. Specifically, the Commission rejected other approaches suggested by the companies that the Commission believed would reintroduce elements of traditional rate of return regulation and its poor incentive properties.[13]

In the 2013 Capital Tracker proceeding, EPCOR identified three categories of capital trackers. These categories are reviewed here to provide context for the ensuing analysis. Category 1 capital trackers consist of life cycle replacement projects and/or projects that EPCOR is obligated to undertake at the request of a third party, where, in both cases, the $I - X$ component of the PBR formula does not provide any funding for CAPEX. Category 3 trackers are Category 1 type trackers that were completed and added to the rate base in 2012. Category 2 trackers consist of trackers that are intended to permit EPCOR to recover project-by-project capital funding shortfalls that it would otherwise incur when the $I - X$ component of the PBR formula includes funding for CAPEX. An outstanding issue of demonstrated interest to the Commission is whether there is an efficiency rationale for treating Category 1 and Category 3 trackers differently from Category 2 trackers.

---

11 In AUC Decision 2013-435, the Commission interpreted the phrase "outside of the normal course of the company's ongoing operations" somewhat more broadly. Specifically, the Commission allowed for capital trackers in the case of extraordinary projects as well as project-specific expenditures incurred in the course of ongoing operations that were deemed to be funded inadequately under the $I - X$. See AUC Decision 2013-435, § 3.1.3.

12 In particular, the regulated company is permitted to raise its prices annually at the rate of $I - X + K$, where I is the prevailing rate of inflation in the economy, X is a productivity factor, and K reflects costs associated with the types of unanticipated investment projects described above.

13 AUC Decision 2012-237, § 7.3. These poor incentive properties are discussed in Section II.A below.

B. AUC PBR Principles.

The Commission determined that a well-designed PBR plan should reflect the following principles:

The AUC's PBR Principles

Principle 1. A PBR plan should, to the greatest extent possible, create the same efficiency incentives as those experienced in a competitive market while maintaining service quality.

Principle 2. A PBR plan must provide the company with a reasonable opportunity to recover its prudently incurred costs including a fair rate of return.

Principle 3. A PBR plan should be easy to understand, implement and administer and should reduce the regulatory burden over time.

Principle 4. A PBR plan should recognize the unique circumstances of each regulated company that are relevant to a PBR design.

Principle 5. Customers and the regulated companies should share the benefits of a PBR plan.

The present report was commissioned by EPCOR to identify and objectively evaluate the merits of potential alternative approaches to the treatment of capital in PBR regimes. This pro-active approach to the analysis may help to resolve critical issues regarding the treatment of capital in PBR regimes outside the adversarial environment of a formal regulatory proceeding.

C. The Purpose and the Forms of PBR.

The economics literature advises that economic regulation should seek to emulate competitive market outcomes. As Professor Alfred Kahn observes:

> the single most widely accepted rule for the governance of the regulated industries is regulate them in such a way as to produce the same results as would be produced by effective competition, if it were feasible. (Kahn, 1970, p. 17)

Similarly, Professor James Bonbright observes:

> Regulation, then, as I conceive it, is indeed a substitute for competition; and it is even a partly imitative substitute. (Bonbright, 1961, p. 107)

Once the central goal of economic regulation is identified, the best means to achieve this goal must be determined. In particular, it is important to identify the form of PBR plan that will best replicate the incentives that prevail in competitive markets. Competitive market forces constrain the prices firms can charge, limiting them to only a normal return on their investments.

Consequently, a regulator might seek to emulate competitive market outcomes either by adopting an earnings-based regulating regime (which constrains a company's earnings) or by adopting a price-based regime (which constrains the prices the company can charge for the services it supplies to customers).

Traditional rate of return regulation is an example of an earnings-based regulatory regime that seeks to instill competitive discipline by limiting the regulated firm's financial returns. Pure price cap regulation is an example of a price-based regulatory regime that seeks to instill competitive discipline by capping the prices of the regulated firm. A central question in the literature on the economics of regulation is whether earnings-based regulatory regimes, price-based regulatory regimes, or some combination of the two types of regulation are the best means to replicate the discipline of competitive markets (Joskow, 2014).

Professors Armstrong and Sappington offer the following perspective on the tradeoffs between the two types of regulatory regimes.

> Now consider price cap regulation, which typically permits revenues to diverge from realized costs for a specified period of time (e.g., four years) but does not promise specific long-term returns on investment. Although such a policy can provide substantial incentive for short-term innovation and cost reduction, it may provide limited incentive for long-term infrastructure investment. Therefore, the choice between rate of return regulation and price cap regulation will depend in part on the type of investment that is most important to secure. In settings where the top priority is to induce the regulated firm to employ its existing infrastructure more efficiently, price cap regulation may be preferable. In contrast, in settings where it is important to reverse a history of chronic underinvestment in key infrastructure, rate of return regulation may be preferable (footnotes omitted).[14]

This observation highlights a central theme in the literature on the economics of regulation, namely that a one-size-fits-all approach to the design of PBR plans is not appropriate. To the contrary, a PBR plan that is implemented for a particular company should reflect both the type of behavior the regulator wishes to encourage the company to undertake (which can vary across companies) and the unique characteristics of the regulated industry and the regulated company. As Professor Guthrie concludes from his survey of the economic literature that examines the relationship between regulation and infrastructure investment:

> The two most important lessons to be drawn from the literature surveyed here are that there is no single combination of regulatory settings that is best in all situations and

[14] Armstrong and Sappington (2006, pp. 340-41).

> that the various components of a regulatory scheme are interrelated. The most appropriate regulatory scheme for a given situation will depend on the characteristics of the firm and industry being regulated, as well as the institutional environment.[15]

D. The Outline of this Report.

This report will assess several possible approaches to the treatment of capital in PBR regimes by identifying the central advantages and disadvantages of each approach. Sections II and III of the report consider earnings-based PBR plans and price-based PBR plans, respectively. Section IV provides a brief summary and a preliminary recommendation as to the preferred approach (or approaches) to the treatment of capital in PBR regimes.

II. EARNINGS-BASED PBR PLANS.

There are several different types of PBR plans that focus on limiting the earnings of the regulated company. We review here the two most common forms of such earnings-based PBR plans: banded rate of return regulation and earnings sharing regulation. First, though, we review the central features of rate of return regulation.

A. Rate of Return Regulation.

PBR plans often are viewed as alternatives to rate of return regulation ("RORR"). Therefore, to fully understand the rationale for PBR plans and their potential merits, it is helpful to review the purpose and the key features of RORR.

RORR is designed primarily to ensure that the regulated firm ("the company") can continually attract the capital it requires to deliver high quality, reliable service to customers. RORR typically pursues this goal through substantial regulatory oversight of the company's operations.

Under RORR, the company often is required to secure explicit regulatory approval for each major capital investment it undertakes. The regulator sets prices for the company's services to provide the company a reasonable opportunity to recover its prudently incurred operating expenses and earn a "fair return" on prudently incurred capital investment (AUC PBR Principle 2). The company typically is precluded from earning substantially more than the authorized return under RORR, no matter how exceptional the company's performance might be. Provided the company's

[15] Guthrie (2006, p. 966).

investments are ultimately judged to have been prudent, RORR typically protects the company against financial returns that are substantially less than the authorized return.[16]

In addition to holding hearings to assess the prudency of particular investments, RORR typically schedules general rate hearings fairly frequently to re-set the company's prices to ensure that the company's actual earnings do not diverge substantially from its authorized earnings. The company's earnings usually are monitored on an ongoing basis, and the regulator can initiate additional hearings if preliminary evidence suggests that the company's earnings have diverged substantially from authorized levels.

RORR entails both advantages and disadvantages relative to other policies. The primary potential advantages of RORR include the following four. First, by providing a relatively predictable return on investment, RORR can help the company attract capital and reduce the company's cost of capital.[17] Second, even as it encourages prudent investment, RORR can limit excessive capital investment. It can do so by requiring *ex ante* regulatory approval for major investment projects and by undertaking *ex post* reviews of the prudency of these projects after observing the extent to which the investments have proved to be used and useful in delivering high quality service to customers.

Third, RORR can avoid complaints from customers that they are being required to finance "excessive" returns for the company. Fourth, by providing returns that are sufficient to attract needed capital, RORR can limit the likelihood that customers will experience extended service interruptions or inadequate service quality (AUC PBR Principles 1 and 2).[18]

RORR also entails at least five disadvantages relative to other regulatory plans. First, RORR typically provides the company with limited incentive to minimize operating costs or otherwise realize exceptional performance. This is the case because prices are set under RORR to provide the company with (only) a fair return on investment regardless of the extent to which the company has reduced its operating costs or has otherwise exhibited exemplary performance.

Second, because the minimum rate of return required to attract investment capital can be difficult to determine precisely, RORR can provide excessive or insufficient incentive for capital

---

16 The prudence of an investment is appropriately judged according to what the company knew and what it could reasonably have known at the time the investment was undertaken (Kolbe and Tye, 1991).

17 See Fazzari et al. (1988), for example.

18 Indeed, to the extent that the regulator views the company's expenditures to enhance service quality as prudent, RORR can promote the delivery of high levels of service quality by ensuring that the firm is fully compensated for the associated expenditures.

investment. If the authorized return on investment exceeds the return required to attract adequate levels of investment capital, the company may have an incentive to undertake more than the cost-minimizing level of investment. In contrast, if investors do not find the authorized return to be commensurate with the returns they can secure on other investments of comparable risk, the company may be unable to attract the capital it requires to operate efficiently.

Third, RORR can provide the company with limited incentives to choose capital and non-capital inputs in cost-minimizing proportions (and so may be inconsistent with AUC PBR Principle 1). This is the case in part because the authorized compensation for capital investment may exceed or fall short of the level required to attract essential capital investment and in part because RORR offers little explicit financial reward for minimizing its overall operating costs.[19]

Fourth, the implementation of RORR typically requires considerable regulatory resources (and so may be inconsistent with AUC PBR Principle 2). The determination of a company's cost of capital and its capital investment needs can be a time consuming and resource intensive process. Detailed *ex ante* and *ex post* assessments of the prudency of individual capital investment projects also entails the expenditure of considerable regulatory resources, as does the ongoing monitoring of the company's realized earnings.

Fifth, confiscatory *ex post* prudence reviews can limit the company's incentive to pursue needed capital investment. Whether the confiscatory nature of a review is intentional (to secure lower prices for customers in the short run) or unintentional (e.g., caused by limited information about relevant industry considerations), the prospect of a review that prevents the company from securing a reasonable return on investments that appear prudent *ex ante* reduce the attraction of investment. The prospect of confiscatory prudence reviews also limits the firm's ability to attract capital, and so can limit the company's ability to deliver uninterrupted, high quality service to customers.[20]

B. Banded Rate of Return Regulation.

Banded rate of return regulation ("BRORR") is much like RORR, with one important exception. BRORR allows the company's earnings to vary with its observed performance, but typically only to a limited extent. In particular, if the company's realized earnings exceed a

---

[19] Despite substantial theoretical interest in this "Averch-Johnson bias" (Averch and Johnson, 1962), empirical support for the bias is not extensive. Cicala (2015) provides some recent evidence.

[20] See Kolbe and Tye (1991), for example.

specified target level of earnings (or target rate of return on investment) by a modest amount, the prices the company charges to its customers are not reduced to eliminate the "excess" earnings. Similarly, if the company's actual earnings fall below the target level of earnings, the company's prices are not increased to eliminate the earnings "deficit." Consequently, the company receives some reward for achieving earnings above a target level and incurs a penalty if its earnings fall below the target.

The essence of BRORR is illustrated in Figure 1. The figure depicts the relationship between the company's "unadjusted earnings" and its "authorized earnings." The former are the earnings the company would secure if the prices it charges to customers remain at the levels established at the outset of the BRORR regime. The latter are the earnings the company secures after any relevant price adjustments are implemented in response to an observed divergence between the firm's unadjusted earnings and its target level of earnings (E_T).

BRORR entails the specification of a critical level of earnings (E_L) below the target and another critical level of earnings (E_H) above the target. As long as the company's unadjusted earnings are between E_L and E_H, the company's prices are not revised. If the company's unadjusted earnings rise above E_H, prices are reduced to ensure the company secures earnings E_H. If the company's unadjusted earnings fall below E_L, prices are increased to ensure the company's earnings are E_L.

This relationship between the company's unadjusted earnings and its authorized earnings are reflected in the solid line in Figure 1. Regardless of the firm's unadjusted earnings, authorized earnings never fall below E_L or rise above E_H. When unadjusted earnings are between E_L and E_H, authorized earnings coincide with unadjusted earnings.

Relative to RORR, BRORR enhances the company's incentive to reduce its operating costs when its unadjusted earnings are between E_L and E_H. When unadjusted earnings are in this range under BRORR, the company effectively: (i) keeps each extra dollar of cost savings it achieves; and (ii) forfeits a dollar for each extra dollar of cost increase it experiences.[21] Therefore, at least

[21] This is why the solid line in Figure 1 has a slope of 1 when the company's unadjusted earnings are between E_L and E_H.

within the specified range of unadjusted earnings, BRORR provides incentives for cost containment similar to those that arise in competitive markets (AUC PBR Principle 1).[22]

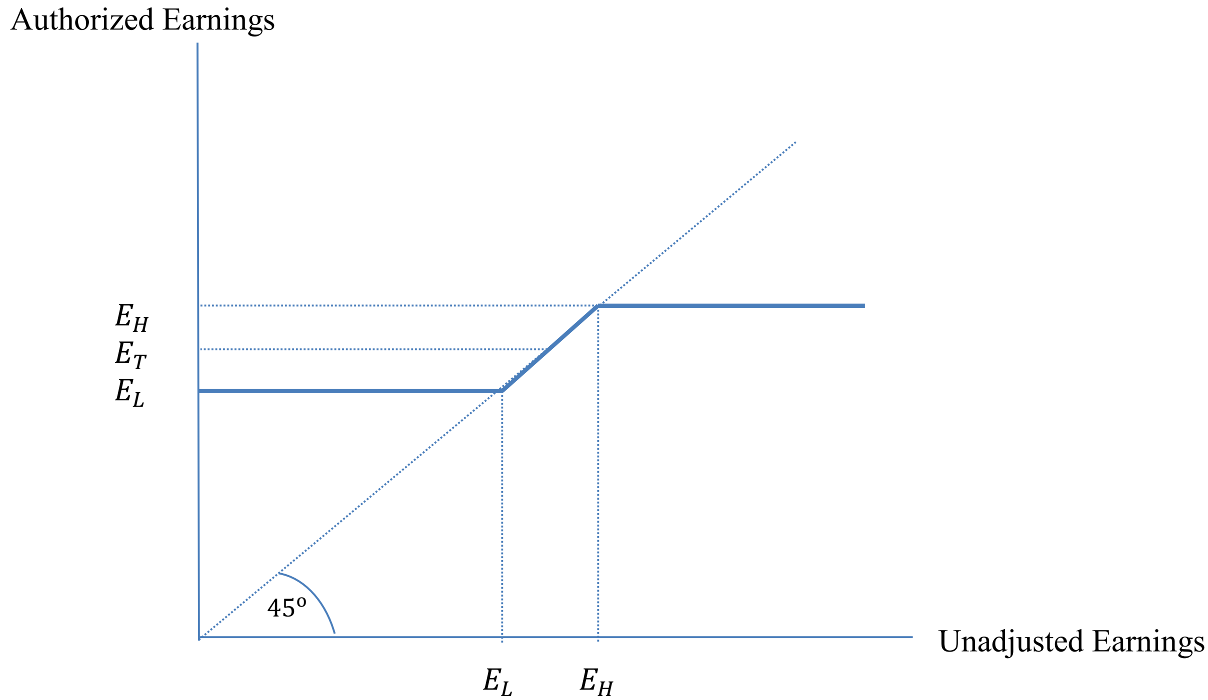

Figure 1. Banded Rate of Return Regulation

Typical values for E_L and E_H under a BRORR plan correspond to earnings that are 100 basis points below and above the target rate of return, respectively. For instance, if the target rate of return on investment is 10%, E_L would correspond to a 9% return on investment and E_H would correspond to an 11% return on investment. Consequently, whereas the company's prices might be revised whenever the company's unadjusted earnings diverged significantly from a 10% return on investment under RORR, price revisions would only occur under BRORR when the company experienced unadjusted earnings that constituted returns on investment below 9% or in excess of 11%.

The magnitude of the difference between the highest and the lowest authorized earnings (i.e., between E_H and E_L) under BRORR determines the extent to which BRORR differs from RORR.

[22] In a competitive market, a firm keeps every dollar of profit it generates (not counting taxes). Therefore, the relationship between unadjusted earnings and authorized earnings for a firm that operates in a competitive market is given by the 45° line in Figure 1.

The smaller is this magnitude, the more similar are the two regulatory policies.[23] The larger is $E_H - E_L$, the closer are the company's incentives to the incentives a firm faces in a competitive market. As $E_H - E_L$ increases, the company faces more potential earnings variation, and the range of earnings in which the firm bears the full consequences of increased or diminished unadjusted earnings expands.[24]

The increased potential variation in authorized earnings typically will enhance the company's incentive to operate efficiently because the firm: (i) has an increased opportunity to benefit financially from any cost reductions it achieves; and (ii) faces an expanded threat of financial penalties from any cost increases it experiences. The increased potential earnings variation also can increase the company's cost of capital because investors typically demand a higher level of expected compensation when they face increased downside risk. In addition, the increased potential earnings variation can conceivably invite criticism from customers that the company's earnings are too high or from the company and its shareholders that earnings are too low.

As the company's unadjusted earnings approach E_H from below, the company's incentive to undertake activities that might secure a substantial increase in unadjusted earnings becomes very limited. Most of any additional earnings the company might realize would accrue to consumers in this case because the firm's authorized earnings are capped at E_H. Similarly, as the company's unadjusted earnings approach E_L from above, the company's incentive to work diligently to avoid a decline in unadjusted earnings becomes limited. Most of any reduced earnings that might arise will effectively be borne by customers in this case because the company's authorized earnings are bounded from below at E_L. Consequently, as the company's unadjusted earnings rise toward E_H from below or decline toward E_L from above, the company's incentives can more closely resemble the incentives the company faces under RORR than the incentives it would face in a competitive market.

To help ensure that the company delivers high levels of service quality under BRORR, authorized earnings can be explicitly linked to realized levels of service quality. For example, the

---

23 RORR can be viewed as an extreme form of BRORR in which E_L, E_T, and E_H all coincide. Consequently, the range of unadjusted earnings in which RORR provides incentives similar to those that arise in competitive markets is effectively degenerate.

24 The AUC's PBR plan might be viewed as a form of BRORR because the terms of the plan can be revisited if a company experiences a variation in earnings of more than 300 basis in any two consecutive years or a variation of more than 500 basis points in any single year. See 2012 Commission Decision at ¶¶ 737-738.

BRORR plan might state that E_L and E_H will both be reduced by specific amounts if realized service quality falls below a designated level. Alternatively, or in addition, the plan might identify amounts by which E_L and E_H will be increased if realized service quality attains or exceeds a specified target.[25, 26]

C. Earnings Sharing Regulation.

Earnings sharing regulation ("ESR") is much like BRORR except that it admits greater flexibility in the manner in which earnings that diverge from a target level of earnings are shared between the company and its customers.[27] Relative to BRORR plans, ESR plans often institute sharing over a broader range of earnings and implement intermediate levels of sharing, so incremental earnings do not necessarily accrue entirely to the company or entirely to its customers (AUC PBR Principle 5).

A typical ESR plan is illustrated in Figure 2. This figure, like Figure 1, depicts the relationship between the company's unadjusted earnings (which are the company's earnings if prices remain at the levels established at the start of the ESR plan) and the company's authorized earnings (which are its earnings after any price adjustments that are undertaken to implement the specified sharing of earnings). Under the ESR plan depicted in Figure 2, the company's authorized earnings coincide with its unadjusted earnings when these earnings are between E_1 and E_2.[28] Therefore, as the company's unadjusted earnings increase between E_1 and E_2, the company is authorized to keep all of the incremental earnings (as under BRORR).

---

25 The company's authorized return under RORR might similarly be linked to the level of service quality the company delivers.

26 AUC PBR Principle 1 calls for service quality to be maintained under PBR.

27 Earnings sharing regulation is sometimes referred to as "sliding-scale regulation" (e.g., Braeutigam and Panzar, 1993; Lyon, 1996).

28 Figure 2 reflects this coincidence of earnings with the solid line segment that has a slope of 1 for unadjusted earnings between E_1 and E_2.

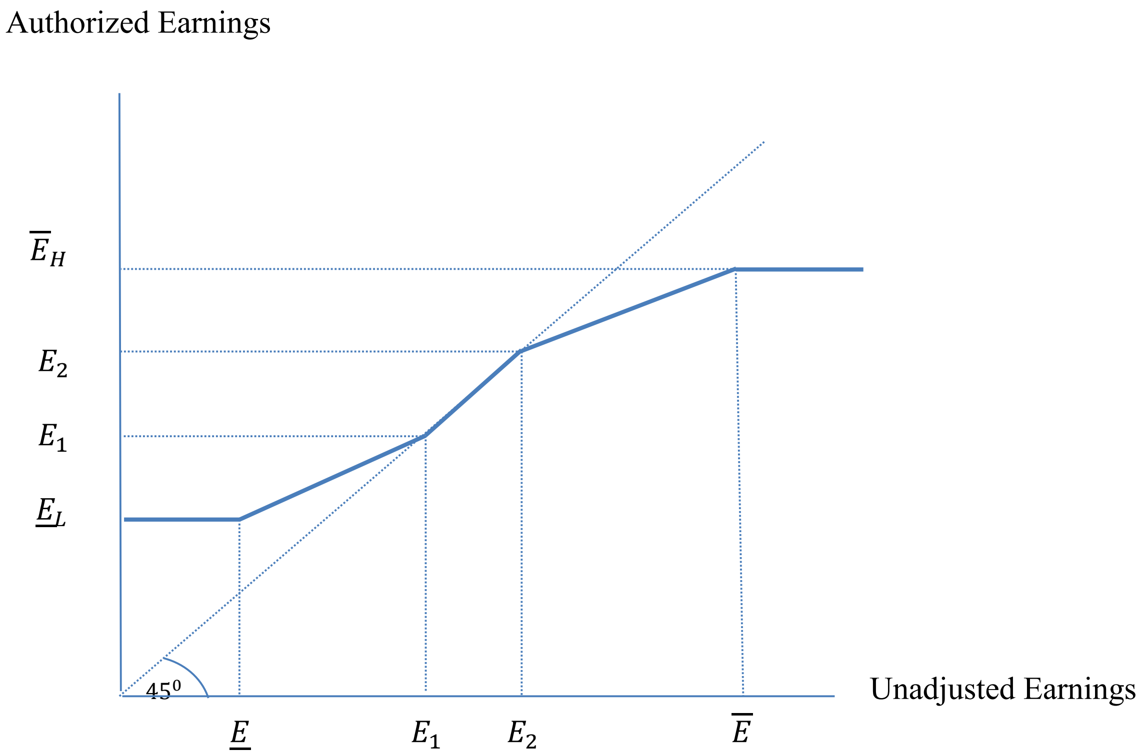

Figure 2. Earnings Sharing Regulation

As the company's unadjusted earnings increase above E_2 toward $\overline{E}$, the company is authorized to keep a fraction (e.g., one half) of the incremental earnings. The remainder of the incremental earnings is awarded to customers.[29] Thus, both the company and its customers benefit as the company's earnings increase between E_2 and $\overline{E}$ in Figure 2 (AUC PBR Principle 5).[30] Once the company's unadjusted earnings reach $\overline{E}$, though, all incremental earnings accrue to customers. Thus, the company's authorized earnings are capped at $\overline{E}_H$ in Figure 2.

[29] The relevant portion of incremental earnings can be awarded to consumers in different ways. For instance, the prices charged to customers might be reduced. Alternatively, a bill credit might be awarded to all customers at the end of each year. The incremental earnings might also be employed to create or expand a program that provides rate relief for low income customers, for example.

[30] Observe that the solid line segment that appears above the unadjusted earnings between E_2 and $\overline{E}$ in Figure 2 has a slope between 0 and 1. This slope captures the explicit sharing of incremental earnings by the company and its customers. The larger is this slope, the larger is the fraction of incremental earnings that is awarded to the company.

The ESR plan depicted in Figure 2 also places a lower bound ($\underline{E_L}$) on the company's authorized earnings and implements a sharing of the incremental "loss" the company experiences as its unadjusted earnings decline below E_1 toward $\underline{E}$. As unadjusted earnings decline in this region, prices are increased to elevate the company's earnings above the level the company would experience in the absence of any price adjustment.[31] If unadjusted earnings decline below $\underline{E}$, prices are raised commensurately to ensure that the company's earnings never decline below $\underline{E_L}$. This lower bound on authorized earnings might represent, for example, the minimum level of earnings the company can tolerate without experiencing pronounced difficulty in attracting capital, serious risk of service interruptions, and/or a substantial decline in service quality.

To provide illustrative numbers, $\underline{E}$, $\underline{E_L}$, E_1, E_2, $\overline{E_H}$, and $\overline{E}$ might be 7%, 8%, 9%, 11%, 12%, and 13%, respectively. In this case, the firm's authorized earnings coincide with its unadjusted earnings whenever these earnings constitute a return on investment between 9% and 11%. As unadjusted earnings increase between 11% and 13%, the company and its customers each receive one half of the incremental earnings. The company is not permitted to earn more than a 12% return on investment. As unadjusted earnings decline below a 9% return on investment toward a 7% return on investment, prices are increased sufficiently to ensure the company and its customers share the incremental decline in earnings equally.[32] Prices are further elevated, as necessary, to ensure the company's earnings never fall below a 7% return on investment in this example.

The primary difference between ESR and BRORR is the less abrupt changes in the allocation of incremental earnings under ESR. In particular, the company receives some, but not all, of the incremental earnings it generates as its unadjusted earnings increase above E_2 under the ESR plan in Figure 2. Consequently, although the company's incentive to generate additional earnings are diminished once its unadjusted earnings rise to E_2, the incentive is not eliminated entirely.[33]

[31] This lower level of earnings is represented in Figure 2 by the height of the 45^{o} line above unadjusted earnings between $\underline{E}$ and E_1.

[32] The fraction of incremental earnings awarded to the company can be explicitly linked to the level of service quality the company delivers. Such linkage can help to ensure that the company does not increase its earnings by reducing service quality unduly.

[33] The diminished incentive to generate additional earnings implies that the company has some incentive to engage in what Blackmon (1994) refers to as "regulatory abuse." This abuse entails expenditures on resources that the regulated firm would not undertake if it had to bear their full cost. Notice that a firm that is required to share 50 cents of each additional dollar of earnings effectively bears only 50 cents of each additional dollar of expense.

Similarly, although the company's incentive to avoid additional reductions in unadjusted earnings is diminished once these earnings fall below E_1, the incentive is not eliminated. Consequently, depending on the details of its design, an ESR plan can provide more pronounced incentives for efficient operation than a BRORR plan.[34]

The potential flexibility of ESR plans raises the possibility that a regulator might find it advantageous to implement different ESR plans for different regulated companies (AUC PBR Principle 4). To illustrate, consider the following setting. Suppose a regulator oversees the operations of two regulated firms. Company 1 is known to operate efficiently, but requires extensive investment to replace aging infrastructure. Company 2 enjoys a modern infrastructure but is believed to operate the infrastructure inefficiently. In this setting, the regulator's primary tasks are to encourage investment in company 1's infrastructure and to motivate company 2 to operate more efficiently.

The regulator might design distinct ESR plans to pursue these two distinct tasks. The regulator might implement an ESR plan for company 1 that: (i) ensures the company's authorized earnings never fall below a relatively high level; and (ii) implements a corresponding relatively modest ceiling on the maximum earnings the company can attain. This ESR plan also might award to company 1 only a modest share of the incremental unadjusted earnings it generates between the specified lower and upper bounds on earnings.

The regulator might implement a very different ESR plan for company 2. The plan might entail a relatively pronounced range in which company 2's authorized earnings can vary. Furthermore, company 2 might be awarded a relatively generous share of the incremental unadjusted earnings it generates within the specified range.

The ESR plan implemented for company 1 can help to ensure that its shareholders receive a substantial, steady return on their investment in the company. The ESR plan implemented for company 2 can provide it with strong incentives to improve its operating efficiency in order to increase its unadjusted earnings (and thus its authorized earnings). More generally, the substantial flexibility that ESR plans admit can enable a regulator to serve customers well by tailoring the ESR plan to the prevailing regulatory goals and industry conditions.

Even when an ESR plan is reasonably well tailored to the prevailing environment, though, it can still introduce many of the drawbacks that arise under RORR and BRORR, and therefore be

[34] Schmalensee (1989) and Lyon (1996), among others, discuss the potential merits of and drawbacks to ESR plans.

inconsistent with AUC PBR Principle 1. In particular, by restricting the company's earnings, ESR can limit the company's incentive to minimize operating costs and to otherwise realize exceptional performance.[35] Furthermore, because it entails ongoing monitoring of earnings, ESR can require substantial regulatory resources and therefore violate AUC PBR Principle 3. In addition, ESR plans can encourage regulators to disallow the company's expenditures on the grounds that they have been incurred imprudently. Such disallowances can increase the company's measured earnings and thereby obligate the company to deliver more "shared earnings" to customers.[36,37] The prospect of such disallowances can limit the company's incentive to pursue costly innovative activities even when the activities likely would serve customers well.[38]

---

35 ESR also can encourage strategic intertemporal cost shifting. To illustrate, a company that operates under ESR may delay costly maintenance to future years when earnings are otherwise expected to increase to levels that require the sharing of incremental earnings with customers.

36 See Sappington and Weisman (2010), for example.

37 An example of this phenomenon was presented during the AUC's 2012 PBR hearings. SBC (now AT&T), a telecommunications firm operating in the U.S., operated under an earnings sharing plan in 1993. Massive floods arose in SBC's operating territory during the summer of that year, causing pervasive service outages. The Missouri Public Service Commission questioned the manner in which SBC restored these outages and deemed that a substantial amount of costs had been incurred imprudently. The cost disallowances that followed increased the company's measured earnings into a range where the firm was required to share earnings with customers. These events prompted SBC to petition its regulators for a price cap regime without earnings sharing. See AUC (April 27, 2012, Proceedings, Volume 10, p. 1887).

38 Earnings sharing can sometimes be implemented in less transparent ways. For example, the extent to which the regulated company's prices are adjusted to reflect significant, exogenous (Z factor) events might vary with the level of the company's prevailing earnings. Alternatively, or in addition, future X factors might be ratcheted upward to extract a portion of current earnings retroactively.

III. PRICE-BASED PBR PLANS.

Unlike earnings-based PBR plans that seek to instill competitive discipline by constraining earnings, price-based PBR plans seek to instill competitive discipline by constraining prices. The recent literature on incentive regulation suggests that price-based regulatory plans often provide stronger incentives for efficient operation than do earnings-based regulatory plans.[39] The superior incentive properties of price-based regimes arise when these regimes sever the link between the regulated company's costs and the prices it is permitted to charge for its services. The following passage is instructive.

> It is possible to conclude that under a properly articulated economic rationale, consumer protection against "excessive profits", as traditionally applied under profit regulation, could not be invoked to reestablish a necessary link between prices and profits. . . . In effect, therefore, the standard of constitutional protection for consumers under a price level regime would be modified. The focus would shift from protection against "excessive profits" *per se*, as defined under profit level regulation, to protection against prices viewed as "unconscionable" and "demonstrably irrelevant" to the purposes of the price level regime. (Hillman and Braeutigam, 1989, pp. 80-81)

Pure price cap regulation can present regulated companies with incentives similar to the incentives that prevail in competitive markets.[40] In particular, price cap regulation can present companies with strong incentives to: (1) adopt the least-cost production technology; (2) operate this technology efficiently; (3) diversify efficiently into new markets; (4) undertake efficient levels of cost-reducing innovation; (5) allocate costs appropriately; and (6) report costs truthfully. These strong incentives for efficient performance reflect the fact that pure price cap regulation operates much like a *fixed-price contract*, under which payment for a service rendered does not vary with the realized cost of performing the service. Consumers benefit from a *fixed-price contract* because the prices they pay do not vary directly with the company's realized operating costs. Consequently, consumers bear little or no risk of price variation during the price cap regime. Conversely, traditional rate of return regulation (and some forms of price cap regulation with earnings sharing)

[39] See Braeutigam and Panzar (1989), Sappington (1994, 2002), and Armstrong and Sappington (2006), for example.

[40] The term "pure price cap regulation" refers to a price-based regulatory regime in which there is no earnings sharing with consumers, regardless of the level of the earnings secured by the regulated company.

operate much like a *cost-plus contract*. In particular, the prices consumers pay increase as the company's realized costs increase. Consequently, these prices can exhibit considerable volatility.

Although price cap regulation can provide strong incentives for efficient operation, it can admit very high or very low earnings. The prospect of extreme earnings can undermine regulator's commitment to the regulatory regime.[41]

> …Can the regulator credibly pre-commit to a system of price cap regulation? Stated differently, can today's regulatory commission bind its successor? A regulatory agency is likely to be subjected to considerable political pressure to change the price cap or price cap formula over time. If a firm regulated by price caps begins to earn large profits, consumers will no doubt petition the regulator to lower the price in the core market (Braeutigam and Panzar, 1989, p. 320).
>
> This issue of recontracting and the efficiency distortions resulting therefrom is arguably one of the more serious problems with PC [Price Cap] regulation in practice. A key premise underlying PC regulation is that increased profits for the firm will be viewed by regulators and their constituency as something other than failure of regulation itself. If this premise is false, then regulators will be under constant political pressure to recontract when the firm reports higher profits. In equilibrium, the firm learns that this is how the game is played and the efficiency gains from PC regulation in theory may fail to materialize in practice (Weisman, 993, pp. 364-65).

If not implemented appropriately, a severed link between prices and costs also could jeopardize service quality and reliability. When a company can secure higher earnings by reducing its operating costs, the company may be tempted to reduce its costs by allowing service quality and reliability to decline. This decline was identified as a potential problem in the early days of incentive regulation in the telecommunications industry. However, the empirical evidence generally does not support a strong causal link between incentive regulation and reduced service quality.[42] This may be the case in part because price-based PBR generally is accompanied by explicit restrictions on the level of service quality the regulated company must deliver.[43]

---

[41] See Weisman (2002) for further discussion of regulatory commitment and regulatory opportunism under price cap regulation.

[42] See Banerjee (2003) and Sappington (2003, 2005), for example.

[43] Ter-Martiroysyan and Kwoka (2010) find that although service outages do not occur more frequently under incentive regulation, the outages that do arise tend to persist for longer durations. The authors note that reductions in service quality can be avoided with explicit financial penalties for sub-standard levels of service quality. See Sappington (2005) for further discussion of the complexities inherent in designing reward/penalty schemes for efficient provisioning of service quality.

We now consider the central advantages and disadvantages of eight distinct types of price-based PBR plans. The eight plans considered here are not the only price-based PBR plans that might conceivably be implemented in Alberta. Rather, the plans are intended to reflect a representative sample of plans that have been adopted elsewhere and/or might reasonably be afforded serious consideration for possible adoption in Alberta.

A. Partial Price Caps with Bifurcation of CAPEX and OPEX and a Mid-Term CAPEX Update.

The first plan we consider contains elements of both earnings-based regulation and price-based regulation. Under this plan, CAPEX is subject to traditional rate of return regulation, whereas OPEX is subject to price cap regulation. Specifically, the company is afforded the opportunity to earn a fair return on prudently incurred capital investment. Compensation for operating expenses is governed by a price cap mechanism which limits the direct link between authorized revenues and current operating expenses. At the outset of the PBR regime, the company's aggregate revenue requirement is partitioned into a component associated with CAPEX and a component associated with OPEX. The disaggregated revenue requirement forms the basis for the rate structure implemented by the Commission. Over the course of the PBR regime, the annual adjustment to aggregate rates under the $I - X$ index is limited to the OPEX component of the revenue requirement. The price cap mechanism takes the form of pure price cap regulation because it entails no earnings sharing.

A key feature of this PBR plan is the mid-term CAPEX update. Under this plan, the company provides a CAPEX forecast at the beginning of the regime and an updated CAPEX forecast at the mid-point of the regime. This update recognizes that: (i) the company may have somewhat less control over CAPEX than OPEX;[44] and (ii) the inherent uncertainty associated with CAPEX can make it very difficult for the company to forecast CAPEX over the entire duration of the PBR regime, particularly when the length of the regime is pronounced.

The rationale for treating CAPEX and OPEX differently under the PBR plan merits additional discussion. As a public utility with: (i) a carrier-of-last resort obligation; (ii) the obligation to maintain adequate service quality and reliability; and (iii) little or no discretion regarding the markets to be served and the timeframe over which to serve them, the company's capital requirements are driven in significant part by exogenous factors, including population growth and

[44] See Kwoka (2009), for example, for a discussion of why this is likely to be the case.

consumption trends. Furthermore, the long-lived, lumpy nature of capital for public utilities implies that realized costs may diverge significantly from expected revenues. In contrast, utilities typically can fine-tune the processes and procedures they employ to control operating costs, and these costs tend to be relatively predictable.

As is the case with all PBR plans, this plan with bifurcated treatment of CAPEX and OPEX entails both advantages and disadvantage, which are now considered in turn.

The potential advantages of this bifurcated PBR plan include the following four. First, a predictable return on investment can encourage investment, help the company attract capital, and perhaps reduce the company's cost of capital (AUC PBR Principle 2). The ability to attract capital on reasonable terms can be of particular value in the rapidly-growing Alberta economy, which requires considerable infrastructure investment. Second, required *ex ante* approval for capital investment, coupled with *ex post* prudence reviews, can limit incentives for excessive capital investment. Third, high-powered incentives are focused on activities over which the company has the most control.[45] Fourth, the mid-term review recognizes the complexities inherent in forecasting CAPEX over the entire PBR regime, while eliminating administratively burdensome annual rate cases (AUC PBR Principle 3). Furthermore, if a company were forced to forecast CAPEX over the course of the entire PBR regime, it might conceivably have an incentive to overstate capital requirements in order to reduce the likelihood of reductions in service quality.

Professor John Kwoka presents evidence of under-investment in CAPEX under PBR plans that treat CAPEX and OPEX symmetrically under a simple price cap plan similar to those employed extensively in the telecommunications sector. He further points out that a number of states in the U.S. have adopted a hybrid approach to PBR in which OPEX is subject to price cap regulation, but CAPEX is subject to some variant of rate of return regulation. These observations underlie his recommendation for treating CAPEX and OPEX differently under PBR plans.

> The under-investment problem under incentive regulation is likely to be most acute under plans that cap price at a level intended to cover both capital and operating costs, leaving to the utility decisions about expenditures on each. … This understanding has prompted regulators to modify incentive plans so as to treat operating and capital costs

[45] The power of a regulatory regime refers to the fraction of realized cost savings the regulated company is permitted to retain. Pure price cap regulation is considered a high-powered regulatory regime because the regulated company is permitted to keep all of the cost savings it secures during the price cap regime. In contrast, rate of return regulation is considered a low-powered regulatory regime because the firm is typically is required to return to customers in the form of lower prices all of the cost savings that arise. See, for example, Laffont and Tirole (1993, p. 11).

> differently. The most common variant involves the use of straightforward incentive regulation for operating costs but more traditional regulation of the utility's investment. This reflects the … fact that incentive regulation seems well designed for conservation of operating costs, but less well suited to investment behavior and costs. This hybrid approach may in fact capture the comparative advantage of each mode of regulation (Kwoka, 2009, p. 15).
>
> The simplicity of incentive regulation has over time given way to recognition of the need for modifications to address quality and investment issues. Neither of these latter objectives is likely to be satisfied by a plan that simply sets price or the parameters of a pricing formula. … With respect to capital investment, there is a widespread view that some form of rate of return regulation may have a comparative advantage over incentive regulation. For this reason most alternative approaches combine incentive regulation for operating costs with some form of traditional cost-based regulation for investment decisions (Kwoka, 2009, p. 22).

Professor Kwoka's reference to the need to sacrifice some degree of simplicity in the design of PBR plans in order to address "quality and investment issues" figured prominently in the AUC's 2012 PBR proceeding. As discussed in Section I above, the Commission initially favored the simpler approach commonly employed in the telecommunications industry, whereas the companies had serious concerns that this approach could lead to capital deficiencies during the PBR regime.

The potential disadvantages of this PBR plan with a bifurcated treatment of CAPEX and OPEX include the following six. First, the company may have excessive incentive to undertake capital investment if the authorized return exceeds the company's cost of capital. Second, the company may have insufficient incentive to undertake capital investment if the authorized return falls short of the company's cost of capital. Third, the company may have limited incentive to choose capital and non-capital inputs in cost-minimizing proportions, in violation of AUC PBR Principle 1. The incentive to undertake excessive CAPEX in this framework may be even more pronounced than under traditional rate of return regulation. This is the case because the company is fully compensated for CAPEX that can serve to reduce OPEX. The reduced operating costs, in turn, can augment the company's profit under price-based regulation of OPEX if the lower costs increase the company's price-cost margins.[46] Consequently, the bifurcated treatment of CAPEX

[46] EPCOR testified in the 2012 PBR proceeding that increases in CAPEX would not generally lead to reductions in OPEX. EPCOR (August 16, 2013, ¶¶ 135-136). In specific cases (e.g., automatic meter reading), increases in CAPEX would be expected to lead to reductions in OPEX. In the telecommunications industry, the substitution of capital for labor has dramatically reduced the number of employees per access line.

and OPEX could limit the extent to which consumers share the benefits generated by PBR (AUC PBR Principle 5).

Third, the determination of a company's cost of capital and its capital investment needs can be a time-consuming, resource-intensive, and imperfect process, thereby violating AUC PBR Principle 3. Fourth, confiscatory *ex post* prudence reviews can limit incentives for capital investment. Fifth, in practice, it can be more difficult to infer from available historic data the rate at which operating costs alone are likely to change over time than to infer the rate at which all costs are likely to change. As a result, an OPEX-specific *X* factor may be difficult to estimate accurately. The AUC appeared to arrive at this conclusion when it observed "the Commission is not satisfied that there is any acceptable way to create an X factor suitable for use for non-capital-related costs only."[47]

Sixth, the impact of changes in CAPEX on appropriate OPEX-specific *X* factors may be difficult to calculate accurately. For example, the company may be able to reduce OPEX at a rate that exceeds the *X* factor only because it is authorized to increase its capital investment. As a result, it may be difficult to differentiate between endogenous reductions in OPEX that reflect superior performance by the company and exogenous reductions in OPEX that are achieved through Commission-approved CAPEX additions.

It should also be noted that the AUC summarily rejected this approach in the 2012 PBR proceeding, in part because the approach was not viewed as a significant departure from traditional rate of return regulation.[48,49] In other words, it may be difficult to reconcile this approach with AUC PBR Principle 1. In addition, to the extent that this approach retains many of the administratively burdensome aspects of traditional rate of return regulation, this approach may be inconsistent with AUC PBR Principle 3.

---

47 AUC Decision 2012-237, ¶ 58.

48 *Id.*

49 The Commission signaled at the outset of the PBR hearings in 2012 that it wished to implement a PBR regime that furthered the process of discovery and innovation that typically is not fostered by traditional rate of return regulation. To this end, the AUC distributed to all parties of record, as a potential aid to questioning by the Commission, the article by Weisman and Pfeifenberger (2003). This article explains why high-powered incentives can outperform regulatory mandates. See AUC (April 11, 2012).

B. Partial Price Caps with Bifurcation of CAPEX and OPEX and No Mid-Term CAPEX Update.

Now consider a closely related PBR plan that does not include a mid-term CAPEX update. Specifically, suppose CAPEX is subject to traditional rate of return regulation, whereas OPEX is subject to price cap regulation. In particular, the company is afforded the opportunity to earn a fair return on prudently incurred capital investment, while recovery of operating expenses is governed by a price cap index that limits the direct link between authorized revenues and current operating expenses. The plan entails no earnings sharing. The one notable difference between this approach and the one described in Section III.A is that the company provides a single CAPEX forecast at the beginning of the regime and does not update the forecast at any point during the PBR regime.

Three of the four primary advantages of this plan parallel the advantages identified in section III.A. First, a predictable return on investment can encourage investment, help the company attract capital, and perhaps reduce the company's cost of capital (AUC PBR Principle 2). Second, required *ex ante* approval for capital investment, coupled with *ex post* prudence reviews, can limit incentives for excessive capital investment. Third, high-powered incentives are focused on the (operating) activities over which the company has the most control. An additional advantage of the present plan is that the absence of a mid-term review of CAPEX reduces the frequency of administratively burdensome rate cases (AUC PBR Principle 3).

The potential disadvantages of this approach are also similar to those discussed in Section III.A, and include the following nine. First, the company may have excessive incentive to undertake capital investment if the authorized return exceeds the company's cost of capital. Second, the company may have insufficient incentive to undertake capital investment if the authorized return falls short of the company's cost of capital. Third, the company may have limited incentive to choose capital and non-capital inputs in cost-minimizing proportions (AUC PBR Principle 1). Fourth, the initial determination of a company's cost of capital and its capital investment needs can be a time-consuming, resource-intensive, and imperfect process (AUC PBR Principle 3). Fifth, confiscatory *ex post* prudence reviews can limit incentives for capital investment.

Sixth, in practice, it may be more difficult to infer from available historic data the rate at which operating costs alone are likely to change than to infer the rate at which all costs are likely to change over time. As a result, an appropriate OPEX-specific X factor can be difficult to calculate accurately. In particular, the calculation of a single X factor that pertains to both CAPEX and

OPEX simply requires the computation of an industry-wide total factor productivity growth rate. Conversely, the calculation of an OPEX-specific X factor requires the computation of a productivity factor for a subset of the inputs employed in the production process. There is no broad-based consensus on how to compute such a disaggregated productivity factor due to the inherent difficulty of identifying the unique contributions of individual factors of production.

Seventh, the impact of changes in CAPEX on appropriate OPEX-specific X factors can be difficult to calculate accurately. Specifically, if capital can be substituted for labor, then the OPEX-specific X factor should be adjusted to reflect Commission-approved CAPEX additions. Such adjustment is likely to be administratively burdensome and complex (AUC PBR Principle 3). Eighth, the absence of a mid-term review could result in actual CAPEX that departs significantly from forecast CAPEX.[50] Ninth, the absence of a mid-term review could motivate the regulator (company) to implement (propose) a regulatory regime of shorter duration, which would reduce incentives for efficiency, particularly if there is an earnings true-up prior to the start of the new PBR regime (AUC PBR Principle 1).[51]

The absence of a mid-term CAPEX forecast raises two important concerns. First, a key tenet of sound incentive regulation is to "limit the firm's financial responsibility for factors beyond its control" (Sappington, 1994, p. 269). Hence, to the extent that the company's limited ability to forecast CAPEX accurately over the entire PBR regime is largely beyond the company's control, it is generally inappropriate to hold the company financially responsible for the associated risk. Second, the company is confronted with a *Hobson's choice* of sorts. If it errs by exaggerating its CAPEX forecast at the outset of the PBR regime to hedge against uncertainty, it risks both future disallowances by the regulator on grounds of imprudence and increased regulatory scrutiny going forward. Such disallowances and increased scrutiny can impose significant costs on all parties. In contrast, if the company experiences a capital deficiency, it may be forced to choose between disappointing investors and permitting service quality to erode and incurring the associated

50 It should be noted in this regard that in the last PBR proceeding, EPCOR's position was that CAPEX forecasts beyond three years were subject to significant uncertainty and could not be deemed reliable in light of rapidly changing conditions in the Alberta economy. EPCOR (July 22, 2011, ¶ 34).

51 An earnings true-up refers to changes in retail rates that are implemented to ensure the regulated company earns its target rate of return. A true-up process can undermine a regulated company's incentives for cost minimization, particularly when true-ups occur frequently. In general, the more frequently an earnings true-up occurs under PBR, the more the plan resembles a *cost-plus contract* and the less it resembles a *fixed-price contract*.

potentially large service-quality penalties.[52] Hence, the benefits of eliminating administratively burdensome rate cases via the elimination of the mid-term review of CAPEX must be balanced carefully against the associated costs, which can be substantial.

C. Price Caps with Capital Trackers and Associated K Factors.

In its 2012 PBR decision, the AUC adopted a price cap plan with capital trackers and associated K factors. Under this plan, a single $I - X$ index governs the company's earnings, and there is no earnings sharing. The X factor reflects historic industry total factor productivity growth rates and company-specific stretch factors determined by the Commission. This index can be modified during the PBR regime by a K factor that reflects the financial consequences of specific capital investment projects as identified in the capital trackers. The projects in question, which must be outside of the normal course of the company's ongoing operations, include projects required by an external party.[53]

To be considered for a K factor adjustment, each individual capital tracker must exceed a materiality threshold.[54] There is no aggregate materiality threshold for all capital trackers combined. There is also no linkage between the magnitude of K factor adjustments and the company's prevailing earnings. The Commission adopted this PBR plan in large part to limit the dilution of the high-powered incentives that arise under pure price cap regulation and in competitive markets (AUC PBR Principle 1).[55]

The potential advantages of this PBR plan include the following five. First, the plan provides incentives for the company to limit overall production costs (both capital costs and operating costs) and to employ capital and non-capital inputs in cost-minimizing proportions (AUC PBR Principle 1). Second, by admitting K factor adjustments, the plan can afford the company a reasonable opportunity to earn a fair return on its investment even in the presence of significant changes in capital costs and capital investment needs (AUC PBR Principle 2). Third, the plan may limit a

---

[52] An increase in CAPEX without a corresponding increase in rates can be expected to lower the realized rate of return and disappoint investors.

[53] Examples include: (1) relocation of EDTI's distribution infrastructure at the request of the City of Edmonton; and (2) replacing EDTI's current Interval Meter Data Collection and Processing System ("MDCPS") with a new data collection engine that complies with Measurement Canada's requirements. See EPCOR (December 14, 2012, § 3.1.1).

[54] The materiality threshold is a minimum dollar amount that each proposed capital project must satisfy in order to be given consideration as a capital tracker.

[55] AUC (2013, ¶ 586).

company's uncertainty about its ultimate recovery of capital costs, and thereby encourage capital investment. Fourth, the plan may help to limit rate shock by allowing for rate adjustments (reflecting K factor adjustments) during the course of the PBR regime (AUC PBR Principle 5). Fifth, the plan can help to conserve regulatory resources by only considering capital trackers that exceed a specified materiality threshold (AUC Principle 3).

The potential disadvantages of this plan include the following six. First, price changes based on an X factor that reflects historic industry productivity changes may not ensure adequate compensation for the regulated company when costs are unavoidably increasing over time (AUC Principle 2).[56] Indeed, this was the issue addressed by EPCOR's Category 2 capital trackers that were proposed to address capital funding shortfalls under the $I - X$ index.[57] Specific examples include tools, equipment, and vehicle replacement that would not typically be considered outside the normal course of company operations.

Second, in practice, it can be difficult to distinguish between projects that are outside of the normal course of the company's ongoing operations and those that are not. This issue generated significant discussion in the 2012 PBR proceeding regarding the purported existence of a line of demarcation between so-called baseline CAPEX and incremental CAPEX.[58]

Third, the plan may provide the company with an incentive to identify (and possibly exaggerate) "positive" capital trackers, but overlook (or understate the impact of) "negative" capital trackers.[59] This problem may be particularly acute given the comingling of EPCOR's Category 1 and Category 3 trackers with its Category 2 trackers. Fourth, ongoing adjustments for unusual capital projects might limit incentives to minimize overall production costs (AUC PBR

---

56 An X factor that adjusts appropriately for historic industry-specific input price growth rates can provide adequate compensation for a company that operates in a steady-state environment, but potentially not in a setting where investment needs are increasing systematically over time. To the extent that the X factor only reflects historic trends, a stretch factor might be employed to account for expected changes in industry-specific productivity and input price growth rates.

57 EPCOR (December 14, 2012, pp. 67-68).

58 AUC (2012, Volume 10, pp. 1906-1920). EPCOR testified that it was difficult, if not impossible, to disentangle incremental CAPEX from baseline CAPEX. This is the case because when EPCOR undertakes an incremental CAPEX project, it is generally prudent and cost-effective to simultaneously implement other upgrades or replacements that normally would be considered baseline CAPEX.

59 It may be possible to limit this incentive with true-ups and annual *ex ante* reviews of capital tracker projects.

Principle 1).[60] Incentives can be diluted particularly severely by a full true-up of actual CAPEX associated with the capital tracker and forecast CAPEX.[61]

Fifth, despite the project-specific materiality threshold, substantial resources may be required to identify and quantify relevant capital trackers, unless the opportunity to do so is explicitly limited (AUC PBR Principle 3).[62] This is the case because it can be difficult to distinguish between projects that are outside of the normal course of the company‘s ongoing operations and projects that are within the normal course of the company’s operations. In essence, the regulator is required to second-guess the company’s operating practices, a task that is fraught with difficulty. Sixth, the company may not be able to secure adequate earnings if many unanticipated investment projects arise, each of which entails costs below the specified project-specific materiality threshold (AUC PBR Principle 2). In essence, the company may risk “death by a thousand cuts.”

A full true-up of forecast CAPEX and actual CAPEX can undermine incentives for cost containment and work at cross purposes with the high-powered incentives the Commission had sought to preserve in adopting this approach (AUC PBR Principle 1). EPCOR highlighted this concern in its final argument in the capital tracker proceeding (EPCOR, 2013, § 2.2). EPCOR proposed a full true-up of forecast CAPEX and actual CAPEX for Category 1 trackers. In light of the fact that Category 1 trackers are essentially capital-specific Z (exogenous) factors, this approach is consistent with sound incentive regulation principles.

EPCOR proposed two alternatives for strengthening the incentives for cost containment associated with its Category 2 trackers, which it referred to as Alternative 1A and Alternative 1B. Each of these alternatives and their incentives properties are discussed in turn.

Under Alternative 1A, EPCOR would be permitted to true-up its Category 2 Trackers on a prospective basis only, rather than the full, retrospective basis contemplated in the Commission’s Decision. In other words, EPCOR would not be allowed to true-up its capital trackers to actual costs for the period of time between the approval of the Category 2 Tracker and the Commission’s approval of the true-up. Instead, only a prospective true-up would be permitted, beginning at the time the true-up is approved. The prospective true-up would occur only after a stipulated period of

---

60 A requirement to demonstrate that the benefit of the proposed new capital investment could not have been achieved at lower cost through other means can help mitigate this potential problem.

61 EPCOR (2013, ¶¶ 60-66).

62 Adjustments for capital trackers might only be permitted at a limited number of times during the PBR regime.

time, ranging from the time remaining in the calendar year to the full remaining term of the PBR regime. When EPCOR effectively is held responsible for cost variances during the period of time between the approval of the Category 2 Capital Tracker and the true-up to actual costs, the company faces strong incentives to undertake only necessary, efficient capital projects.

Under Alternative 1B, EPCOR's ability to true-up its Category 2 Trackers during the PBR term would be limited to the share of the company's annual forecast capital cost for each Category 2 Tracker that is funded by the approved Capital Tracker K factor adjustment (i.e., to the portion of the company's annual forecast capital cost that is not funded by the $I - X$ mechanism). It is noteworthy that the AUC was sufficiently interested in a mechanism by which the incentives for cost containment could be strengthened that it provided the Commission's Aid to Panel Questioning (Exhibit 229) in the capital tracker proceeding.

A slightly modified form of Exhibit 229 permits a demonstration of how the true-up mechanism might work in practice. This demonstration is provided here with the aid of Table 1, which considers two distinct scenarios. Scenario 1 hypothesizes a CAPEX addition in which 50% of the required capital is funded under the $I - X$ index and 50% is funded under the capital tracker. Scenario 2 hypothesizes a CAPEX addition in which 60% of the required capital is funded under the $I - X$ index and the remaining 40% is funded under the capital tracker.

Line (L)		Scenario 1	Scenario 2
		$ Amount	$ Amount
	Forecast Stage:		
L1	Forecast CAPEX Additions	10	10
L2	Covered by $(I - X)$	5	6
L3	Capital Tracker (L1 – L2)	5	4
	True-Up Stage:		
L4	Actual CAPEX Additions	12	12
L5	Variance (L1 – L4)	2	2
L6	Variance Deemed to be Covered by $(I - X)$	1 or (50%)	1.2 or (60%)
L7	Variance Deemed to be Related to Approved Capital Tracker (L5 – L6)	1 or (50%)	0.8 or (40%)
L8	**Tracker True-Up**	**1**	**0.8**

Table 1. Capital Tracker True-Up Mechanics

First consider Scenario 1 in Table 1, where the company forecasts CAPEX Additions of 10, but only 5 are covered under the $I - X$ price cap mechanism. This leaves a residual of 5 to be financed through the capital tracker. In the true-up stage, the company's actual CAPEX Additions are assumed to be 12 rather than 10, which leaves a positive variance of 2 as shown in line L5 of Table 1. Given that 50% of the forecast CAPEX addition is not covered under the $I - X$ index, the company is only able to true-up 50% of the variance, or $0.5 \times 2 = 1$ as shown in lines L7 and L8.

Now consider Scenario 2, where 40% of the forecast CAPEX addition is not covered under the $I - X$ index. In this case, the company is only able to true-up 40% of the variance, or $0.4 \times 2 = 0.8$, as shown in lines L7 and L8. Hence, the risk the company faces, as measured by the responsibility it bears for the variance between forecast and actual CAPEX, is equal to the percentage of the CAPEX additions that are covered by the $I - X$ index.

Another way to envision the risk-bearing attributes of this true-up mechanism is to partition the cost recovery for CAPEX variance into endogenous and exogenous components. A proxy for the endogenous component (i.e., the component that is under the control of the company) is equal to the percentage of CAPEX addition governed by the $I - X$ index. A proxy for the exogenous component (i.e., the component that is beyond the control of the company) is equal to the percentage of the CAPEX addition that is not covered by the $I - X$ index. This approach, which explicitly differentiates between endogenous and exogenous components of the CAPEX variance, is consistent with the principle that a sound PBR regime should "limit the firm's financial responsibility for factors beyond its control" (Sappington, 1994, p. 269). In other words, if the company operated under an $I - X$ index with no capital trackers, it would have no opportunity to seek recourse for funding shortfalls from the regulator, because all required outlays are effectively deemed to be endogenous to the firm. In contrast, for purely exogenous events for which the $I - X$ index provides no funding, the firm would be fully compensated (just as it would be in presence of Z factors) for all prudent CAPEX outlays. Hence, it may be reasonable to limit the true-up between actual outlays and expected outlays to that portion of the expected outlay funded through the capital tracker – the exogenous component.

D. Price Caps with an Incremental Capital Module.

The price cap plan with an incremental capital module is essentially the approach the Ontario Energy Board (OEB) adopted for addressing the complexities presented by incremental CAPEX over the course of the PBR regime.[63] Under this plan, a single $I - X$ index governs the company's earnings and there is no earnings sharing. The X factor reflects historic industry total factor productivity growth rates and company-specific stretch factors determined by the Commission. This index can be modified via K factor adjustments during the course of the PBR regime to reflect specific capital investment projects. Hence, the "capital module" takes the form of an adjustment to the price cap formula to provide adequate funding for special (incremental) capital projects. These projects, which must be outside of the normal course of the company's ongoing operations, include projects required by an external party. To be considered for a K factor adjustment, the entire set of capital trackers in total must exceed a stipulated materiality threshold, but there is no materiality threshold for any individual capital tracker. Finally, the magnitude of K factor adjustments does not vary with the level of the company's prevailing earnings.

The potential advantages of this plan are similar in many respects to the advantages of the plan discussed in Section III.C above. These advantages include the following six. First, because prices are governed by a single $I - X$ index, this plan provides incentives for the company to limit overall production costs (both capital costs and operating costs) and to employ capital and non-capital inputs in cost-minimizing proportions (AUC PBR Principle 1). Second, because it includes K factor adjustments, the plan may afford the company a reasonable opportunity to earn a fair return on its investment even in the presence of significant changes in capital costs and (exogenous) capital investment needs (AUC PBR Principle 2). Third, the plan may limit a company's uncertainty about its ultimate recovery of capital costs, and thereby encourage capital investment. Fourth, the plan can help to limit rate shock by allowing for rate adjustments during the course of the PBR regime. Fifth, the plan conserves on regulatory resources to some extent by only considering capital trackers that, in total, exceed a specified materiality threshold (AUC PBR Principle 3). Six, the aggregate materiality threshold can enable the company to earn an adequate return even when the need arises for several "small" investment projects.

The potential disadvantages of this plan are also similar in many respects to the disadvantages of the plan discussed in Section III.C above. The disadvantages include the following five. First,

[63] It is noteworthy that the OEB retained the incremental capital module (ICM) for its fourth PBR regime, but modified the applicable language to allow for a somewhat broader category of CAPEX applications. Specifically, the language was revised to remove words such as "unusual" and "unanticipated" as prerequisites for an application for incremental capital, although the requirement that the proposed expenditures be non-discretionary remains (OEB, 2012, p. 18). This change may reflect the fact that a more restrictive test for CAPEX applications could increase the risk of capital insufficiency at some point during the PBR regime.

price changes that reflect historic industry productivity changes may not ensure adequate compensation in the presence of costs that increase unavoidably over time (AUC PBR Principle 2). Notably, as discussed in greater detail below, this plan addresses only one of the two predominant sources of revenue inadequacy that a company may encounter over the course of the PBR regime (i.e., exogenous CAPEX additions). Second, in practice, it can be difficult to distinguish between projects that are outside of the normal course of the company's ongoing operations and those that are not. Third, the company may have an incentive to identify (and possibly exaggerate) "positive" capital trackers, but overlook (or understate the impact of) "negative" capital trackers. Fourth, ongoing adjustments for unusual capital projects can limit incentives to minimize overall production costs (AUC PBR Principle 1). Fifth, because there is no materiality threshold on individual projects, substantial resources may be devoted to analyzing proposed capital trackers.

A key difference between this plan and the AUC's current PBR plan concerns the specific categories of capital trackers that are permitted. Under the OEB's incremental capital module approach, EPCOR's Category 1 and Category 3 capital trackers (which reflect capital projects for which the $I - X$ component of the PBR formula provides no funding) would presumably be allowed, but EPCOR's Category 2 trackers (which reflect adjustments for specific projects that are not adequately funded by the $I - X$ component of the PBR formula) would not be allowed. In this sense, the incremental capital module approach is more restrictive than the AUC's current capital tracker approach. To see why, recall that under the AUC's guidelines, if a project is to qualify as a capital tracker, then "the project must be outside of the normal course of the company's ongoing operations."[64] In AUC Decision 2013-435, the Commission adopted a relatively broad interpretation of this condition. Specifically, the Commission allowed for capital trackers in the case of extraordinary projects as well as project-specific expenditures incurred in the course of ongoing operations that were deemed to be not adequately funded under the $I – X$ index.[65] The AUC apparently felt compelled to adopt a broader view of the various sources of exogenous revenue inadequacy than the view reflected in the incremental capital module approach.[66]

---

[64] AUC Decision 2012-237, ¶ 592.

[65] AUC Decision 2013-435, § 3.1.3.

[66] It should be noted that the incremental capital module approach was placed on the record in the 2012 PBR proceeding and was addressed in the rebuttal stage of the proceeding by various parties, including EPCOR and the City of Calgary.

E. Price Caps with an *F* Factor ("*K*-Bar") Adjustment.

Under a price cap plan with an F factor adjustment, a single $I - X$ index governs the company's earnings and there is no earnings sharing. The *X* factor reflects historic industry total factor productivity growth rates and company-specific stretch factors determined by the Commission. The company identifies at the start of the PBR regime any additional "F (forward-looking) factor" adjustment that is required for (expected) revenue sufficiency. In essence, the F factor reflects the extent to which the standard $I - X$ index fails to provide the company with the opportunity to earn a fair return on its foreseeable, prudent capital investments over the course of the PBR regime (AUC PBR Principle 2).[67] During the PBR regime, the company can apply for capital trackers that are not known (and not knowable) at the start of the PBR regime. These capital trackers can reflect unique life cycle replacement projects or projects required by a third party for which the $I - X$ component of the PBR formula does not provide compensation.

The relationship between this approach and three categories of capital trackers that EPCOR identified in the capital tracker proceeding merits clarification. Under this approach, EPCOR's Category 1 and Category 3 trackers would be addressed via *K* factors, whereas EPCOR's Category 2 trackers would be addressed via the *F* factor. This bifurcation has the advantage of restricting *K* factors to those categories of capital trackers that the Commission initially envisioned in its 2012 PBR proceeding as the proper domain for *K* factor adjustments. It is further noteworthy that the AUC may have signaled some preliminary support for this approach in its 2013 Capital Tracker proceeding.[68] This approach differs from a price cap plan with an ICM by recognizing at the outset of the PBR regime that because an ICM limits capital trackers to EPCOR's category 1 and category 3 classifications, even an appropriately formulated ICM could leave the company with an exogenous revenue deficiency (i.e., a revenue deficiency through no fault of its own).

The potential advantages of a price cap plan with an F factor adjustment include the following seven. First, the plan allows the company a reasonable opportunity to earn a fair return even in the presence of significant changes in capital costs and capital investment needs (AUC PBR Principle 2). Second, the plan can encourage the company to undertake comprehensive operations planning.

---

[67] The *F* factor can change during the course of the PBR regime. However, the specific values of the *F* factor that will prevail in each year should be specified clearly at the outset of the regime to ensure that the *F* factor does not devolve into a "make-whole" safety net for the firm.

[68] Application No. 1606029, Proceeding ID No. 566, Proceedings, Transcripts, Volume 7, pp. 1335-1354, July 17, 2013.

Third, the plan provides incentives for the company to limit overall production costs (both capital costs and operating costs) and to employ capital and non-capital inputs in cost-minimizing proportions (AUC PBR Principle 1).

Fourth, a plan of this type streamlines the regulatory process after the initial forward-looking assessment of prudent capital investment (AUC PBR Principle 3). Fifth, the plan leverages familiarity with telecom style price-cap regulation (and the experience of key AUC Commissioners) while explicitly accounting for the unique characteristics of the energy sector. Sixth, to the extent that foreseeable capital expenses are pre-approved, the plan can encourage investment by reducing the financial risk the company faces.

Seventh, this plan provides for a clear line of demarcation between issues of ongoing financial solvency (EPCOR's Category 2 trackers) and the AUC's initial conception of the qualifying criteria for a capital tracker (EPCOR's Category 1 and Category 3 trackers). By limiting capital trackers to purely exogenous CAPEX, this approach may give rise to more high-powered incentives relative to those reflected in the AUC's current capital tracker approach (discussed in Section III.C above).

The potential disadvantages of a price cap plan with an F factor adjustment include the following four. First, the forward-looking approach the plan entails could provide the company with incentives to exaggerate actual capital investment needs.[69] Second, the initial forward-looking assessment of prudent capital investment requires substantial regulatory resources (AUC PBR Principle 3). Third, the line of demarcation between so-called baseline CAPEX, as reflected in the F factor, and incremental CAPEX, as reflected in the K factor, may be difficult to identify.[70] Fourth, the company may have an incentive to identify (and possibly exaggerate) "positive" capital trackers, but overlook (or understate the impact of) "negative" capital trackers.

F. Price Caps with Limited Factor Adjustments and a Midterm Review.

A price cap plan with a mid-term review but no capital trackers is similar to the price cap plan considered in Section III.E. The plan contemplates a single $I - X$ index that governs the company's

[69] These undesirable incentives can be mitigated to some extent via *ex post* prudence reviews and ongoing comparisons between projected and actual capital investments.

[70] During the 2012 PBR hearings, EPCOR argued that this approach was inherently unworkable due to the complex interrelationships between baseline capital and new capital and the lack of any systematic methodology for distinguishing between the two. See Alberta Utilities Commission (AUC), Rate Regulation Initiative, Application No. 1606029, Proceeding ID No. 566, Proceedings, Volume 10, April 27, 2012, p. 1900 and EPCOR (2012, ¶ 102).

earnings for a specified period of time (e.g., 6 years). There is no earnings sharing. The X factor reflects historic industry total factor productivity growth rates and company-specific stretch factors determined by the Commission. The company has the opportunity to identify at the start of the PBR regime any additional "F factor" adjustment that is relevant. As discussed in detail in Section III.E, the F factor reflects the extent to which the standard $I - X$ index fails to allow the company the opportunity to earn a fair return on its foreseeable prudent capital investments over the course of the PBR regime. The central difference between the plan discussed in Section III.E and the present plan is the inclusion of the option for a single, mid-term "bottom-up" review of capital requirements, with corrections for relevant capital trackers.[71] The present plan also does not permit additional capital trackers during the PBR regime.

Four key features of this review of capital requirements merit emphasis. First, the review is limited to a consideration of projects that were not known (and not knowable) at the start of the PBR regime and that are outside of the normal course of the company's ongoing operations, which include projects required by an external party.[72] Second, the mid-term review does not include a rate of return review, and is not a "top down" review of capital requirements. Third, no mid-term review is conducted if (and only if) both the Commission and the company prefer no review.[73] Fourth, other than at the mid-term review, F factor and K factor adjustments are not permitted during the PBR regime.[74]

The potential advantages of this type of plan are similar to those discussed in Section III.E, and include the following five. First, this plan provides incentives for the company to limit overall production costs (both capital costs and operating costs) (AUC PBR Principle 1). Second, the plan

---

[71] A "bottom-up" review of capital requirements evaluates a company's capital requirements on a project-by-project basis, and provides no guarantee that the sum of the capital requirements from all projects combined will permit the company to earn its target rate of return. In contrast, a "top-down" approach determines the aggregate capital requirement that is needed to ensure the company can achieve its target rate of return. In the 2013 Capital Tracker proceeding, the AUC employed the bottom-up review to determine whether the capital trackers proposed by the companies should be approved.

[72] One issue that warrants consideration is whether the regulator can penalize the company at the mid-term review for capacity that exceeds stipulated bounds (or perhaps for failure to meet service quality standards).

[73] To avoid excessive strain on limited regulatory resources during mid-term review years, the timing of reviews for different companies can be staggered appropriately.

[74] One possible variation on this design is to allow for K factor adjustments throughout the course of the PBR regime, but allow for F factor updates only at the time of the mid-term review. This has the benefit of distinguishing clearly between EPCOR's Category 1 and 3 trackers (K factor adjustments) and its Category 2 trackers (F factor update).

motivates the company to assess accurately its long-term investment needs. Third, the initial *F* factor adjustment can afford the company a reasonable opportunity to earn a fair return on its investments even in the presence of significant foreseeable changes in capital costs and capital investment needs (AUC PBR Principle 2). Fourth, plans of this type leverage familiarity with telecom style price-cap regulation (and the experience of key AUC Commissioners) while explicitly accounting for the unique characteristics of the energy sector. Fifth, this plan conserves on regulatory resources during the PBR regime, while allowing for mid-course adjustments that can be important in the energy sector (AUC PBR Principle 3).

Many of the potential disadvantages of this plan parallel those discussed in Section III.E, but some notable differences arise. The potential disadvantages of this plan include the following four. First, the potential for an *F* factor adjustment may provide the company with incentives to exaggerate actual capital investment needs. Second, by precluding capital trackers except at the mid-plan review, the plan may force the company to bear considerable risk and face the prospect of a higher cost of capital. Third, the company may have an incentive at the mid-term review to identify (and possibly exaggerate) "positive" capital trackers, but overlook (or understate the impact of) "negative" capital trackers. Fourth, the Commission may face substantial political pressure to employ the mid-term review as an earnings review, which can reduce the company's incentives to operate efficiently.[75]

Observe that the plan under consideration here allows for *K* factor adjustments at the time of the mid-term review, but does not permit annual *K* factor adjustments. In contrast, the plan discussed in Section III.E does not permit a mid-term *F* factor adjustment, but does allow for annual *K* factor adjustments. Absent further information about the environment in which the company operates, it is not possible to determine which of these plans exposes the company to greater risk. It is conceivable that an inability to seek annual *K* factor adjustments could motivate a company to seek a relatively pronounced mid-term *F* factor adjustment.

---

[75] The Massachusetts Commission explicitly declined to review Verizon's earnings when it reviewed the price cap regulation plan, noting that an earnings review could diminish the performance of the regime (Vasington, 2003). The AUC's capital tracker decision may provide support for an approach along these lines by favoring the bottom-up over the top-down approach for capital trackers. Also, the Commission recognized that if it were to review earnings when evaluating the company's capital requirements, it would effectively be employing earnings regulation. See AUC (September 12, 2012, ¶ 212).

G. Partial Price Caps with Bifurcation of CAPEX and OPEX, with a Rolling Average CAPEX Update.

We now consider another PBR plan that employs price cap regulation to limit the prices a company can charge for its regulated services. The plan entails no sharing of earnings and proceeds for a relatively long period of time (e.g., seven to ten years) before the parameters of the plan are revisited. Despite this relatively long duration, the plan does not permit capital trackers. It does, however, admit corrections for Z factor events throughout the course of the PBR regime.[76] The company's capital expenditures during the PBR regime may be subject to *ex post* prudence reviews.

In determining the price cap (i.e., the X factor) that is imposed on the company, the plan treats operating expenses and capital expenses differently. The component of the X factor that is intended to allow the company to recover its OPEX when it operates efficiently is determined in standard fashion. In particular, this component reflects the regulator's assessment of the operating expenses the company will incur annually if it works diligently to control these expenses. This component of the X factor typically does not change throughout the duration of the PBR regime.

The component of the X factor that is intended to permit the company to recover its CAPEX and earn a reasonable return on investment is determined differently. This component varies from year to year. In year t, the component reflects a N-year moving average of the company's capital expenditures, beginning L years before year t. To illustrate, suppose the PBR regime is scheduled to last for ten years, beginning in 2016. Further suppose $N = 5$ and $L = 4$. Then for each year $t =$ 2016, 2017, …, 2025, the relevant component of the X factor in year t reflects the average of the company's CAPEX in years $t - 8$, $t - 7$, $t - 6$, $t - 5$, and $t - 4$.

The choice of the parameter L in this PBR plan is particularly important. The larger is L, the more distant is the historic period that informs the estimate of the company's current capital investment requirements. Consequently, any increase in CAPEX in a given year will only increase the relevant portion of the X factor after a substantial delay.

This PBR plan entails five primary potential advantages. First, the bifurcated treatment of OPEX and CAPEX allows relatively high-powered incentives to be focused on those activities

[76] A relevant Z factor event is one: (i) that does not involve capital investment; (ii) that is unknown (and unknowable) to the company at the start of the PBR regime; (iii) that has a substantial impact on the company's earnings; and (iv) for which both the event and the financial impact of the event on the company's earnings are largely beyond the company's control.

over which the company has the most control. Second, authorized price increases designed to cover the company's capital costs are updated annually throughout the PBR regime rather than being linked solely to an initial estimate of the company's likely CAPEX needs. The annual update can link allowed revenues more closely to actual capital needs to the extent that the company's investment needs change significantly over time and the moving average of the company's historic CAPEX accurately predicts current CAPEX needs.

Third, the PBR plan conserves on regulatory resources by eliminating the use of capital trackers during the course of the PBR regime (AUC PBR Principle 3). Fourth, by linking allowed revenues directly to historic capital expenditures, the plan can limit the company's uncertainty about the ultimate recovery of capital costs, which can encourage capital investment. Fifth, coupling required *ex ante* approval for major capital investments with *ex post* prudence reviews can limit incentives for excessive capital investment.[77] A relatively long lag in relevant CAPEX (i.e., a relatively large value for L) also can help to limit incentives for excessive capital investment.

This PBR plan also entails at least five potential disadvantages, though. First, because the plan automatically increases authorized future revenue as current CAPEX increases, the plan can encourage some capital over-investment and may not provide strong incentives to reduce capital expenditures. Second, if a substantial lag (i.e., a relatively high value of L) is employed in the plan, authorized revenues will only increase to cover capital expenditures with a significant delay. Consequently, the plan could discourage the company from undertaking needed investment.[78] Third, the plan may consistently underestimate CAPEX needs if these needs are increasing systematically over time.

Fourth, identifying the best values for the N and L parameters can be difficult, in practice (AUC PBR Principle 3). For the reasons explained above, a lag that is too long can discourage investment unduly, whereas a lag that is too short could encourage over-investment (by quickly and automatically translating higher capital expenditures into higher revenues).[79] Fifth, by

[77] *Ex post* prudence reviews may not be advisable if the time lag on the moving average computation is sufficiently long. A sufficiently long lag can eliminate strategic incentives to inflate CAPEX, and so an *ex post* prudence review might serve primarily to invite regulatory opportunism.

[78] Penalties for inadequate service quality can help to enhance the company's incentive to undertake the capital expenditures required to ensure the ongoing delivery of adequate levels of service quality.

[79] Ideally, the values of N and L also should be chosen so that the moving average of historic CAPEX that is calculated each year closely approximates the company's CAPEX needs in that year. Such approximation may be possible if there are systematic cycles in required capital expenditures.

weakening the link between current capital expenditures and current authorized revenue, the plan could permit earnings well above or well below a normal rate of return in any given year. The risk associated with this earnings variation could increase the company's cost of capital.

H. Options in the Choice of Regulatory Regime.

The discussion to this point has focused on settings where the regulator designs a specific PBR for a company rather than providing the company with a choice among PBR plans. Sometimes, though, regulators can better serve customers by affording the company some choice among PBR plans.[80]

To illustrate this more general point, consider a setting where the regulator would like to implement a PBR plan that provides strong incentives for the company to operate efficiently. A price cap ("$I - X$") policy that severs the link between allowed prices and realized costs can provide such incentives. However, such a policy can permit the company to secure very high earnings (if the selected X factor is unduly low) or restrict the firm to very low earnings (if the selected X factor is unduly high). If the regulator is committed to implement a price cap policy when (s)he faces substantial uncertainty about the most appropriate value of the X factor, (s)he may set a relatively low X factor to avoid subjecting the company to financial distress. Such a policy will induce the company to operate efficiently, but may produce relatively high prices for customers (due to the low X factor) and possibly excess returns for the company.

Alternatively, the regulator might afford the company a choice between, say, a price cap ($I - X$) plan and rate of return regulation.[81] By doing so, the regulator can set a relatively high X factor (and thereby secure relatively low prices for customers under the price cap plan) without fear of subjecting the company to financial distress. When the company believes it would suffer financial distress under the challenging price cap plan, it will instead choose to operate under rate of return regulation. In contrast, when the company is confident that it can secure relatively high earnings even under the challenging price cap plan, it will choose to operate under this plan rather than under rate of return regulation. In this event, the regulator will have succeeded in implementing a

---

[80] Sappington and Weisman (1996), Sappington (2004), and Joskow (2014), among others, explain the potential benefits of allowing regulated companies to choose one regulatory plan from a carefully designed set of regulatory plans.

[81] Sappington and Weisman (1996) describe different choices that regulators have afforded companies in the telecommunications sector. Joskow (2014) describes options that have been implemented in the energy sector.

plan that provides strong incentives for efficient operation and secures for customers lower prices than they would have faced had the regulator restricted herself to necessarily implementing a price cap plan (and consequently imposing a relatively modest X factor in order to avoid financial distress).

This example illustrates the more general conclusion that when the regulated company is well informed about its capabilities and its environment but the regulator's corresponding knowledge is limited, the regulator can sometimes best serve customers by affording the company a choice among regulatory plans. Such choice can enable the regulator to design (and often secure) PBR plans that are quite favorable to customers with little risk of imposing financial distress on the company. This is the primary potential advantage of affording a company a choice among regulatory plans.

Such choice can introduce at least three potential disadvantages, though. First, the company may ultimately not choose the plan preferred by the regulator. For instance, in the example described above, the company may ultimately choose to operate under rate of return regulation rather than price cap regulation. Thus, although customers may often gain when the company is afforded a choice among regulatory plans, customers do not always gain. Second, it can be challenging both to design an appropriate set of options to offer to the company and to convince customers that they are being well served when the company is afforded a choice among regulatory plans.

Third, and relatedly, the design, implementation, and administration of optional PBR plans can be challenging and require considerable regulatory resources. Consequently, optional PBR plans may be inconsistent with AUC PBR Principle 3. Fourth, a company may secure undue profit by choosing strategically among regulatory plans over time. To illustrate, the company might initially choose to operate under rate of return regulation and later choose to operate under price cap regulation. When operating under rate of return regulation, the company might attempt to over-invest in capital-intensive technologies that reduce future operating costs. The firm might later benefit significantly from the resulting cost reductions that arise when it operates under price cap regulation.[82]

The Ontario Energy Board afforded the companies under its jurisdiction a choice among three PBR plans in 2012. The plans allows the companies to choose among: (1) an annual incentive

---

[82] Such strategic behavior can be limited by restricting the company's ability to choose freely among the prevailing options over time.

regulation index; (2) a fourth generation incentive regulation plan; and (3) custom incentive regulation.

The annual incentive regulation index is a price cap regulation plan that is intended for companies with "primarily sustainment investment needs." Therefore, the plan does not permit capital trackers. A company that chooses this plan must file a five-year investment plan. However, the required filing is less detailed than the filing required under the other plans. A company can choose this plan as long as it is not earning more than 300 basis points above its approved annual return on equity. There is no fixed term for the plan, so a company that operates under this plan can request an alternative plan at any time.

The fourth generation incentive regulation plan is a five-year price cap plan that is intended for most companies under the jurisdiction of the Ontario Energy Board. The *X* factor specified in the plan reflects historic industry average productivity growth rates, along with firm-specific stretch factors specified by the Commission. A company that selects this plan can apply for an adjustment to the *X* factor to reflect unusual anticipated capital investment needs.

The custom incentive regulation plan is a price cap plan with a duration of at least five years that is intended "for distributors with significantly large multi-year or highly variable investment commitments that exceed historical levels."[83] The plan does not include capital trackers. However, the *X* factor and the associated prices established under the plan reflect the conclusions of a comprehensive operating plan that includes anticipated capital investments. The Commission monitors the capital expenditures of each company that chooses this plan, and can terminate the plan if actual and planned expenditures differ substantially.

Options like these have the potential to tailor the PBR plan to the prevailing environment. Such tailoring can be particularly valuable when different companies face very different operating conditions. However, the design and implementation of optional PBR plans like these can require considerable regulatory resources.[84] Furthermore, it can sometimes be difficult for regulators to explain to constituents why they are permitting a regulated company to choose its preferred PBR

---

[83] Report of the Ontario Energy Board (2012, p. 19).

[84] As Sappington (1994, p. 260) observes, "Allowing for a choice among incentive plans can complicate the regulatory task, thereby sacrificing simplicity." Perhaps in part for this reason, the AUC did not appear to support the options approach in the recent PBR proceeding. See, in particular, AUC Decision 2012-237, ¶¶ 273-276.

plan rather than dictating the plan under which the company must operate. Perhaps for these reasons, optional PBR plans are not common in practice.

IV. CONCLUSION.

A. SUMMARY.

This report was commissioned by EPCOR to identify and evaluate the merits of potential alternative approaches to the treatment of capital in PBR regimes. The report analyzed three earnings-based PBR plans and eight price-based PBR plans. The advantages and disadvantages of each were assessed, and references to the relevant economics literature were provided to facilitate further analysis. The report also selectively identified the specific AUC PBR Principles that applied to the various advantages and disadvantages of each approach. This exercise was intended to assist EPCOR in evaluating the various approaches through the same lens that the AUC is likely to employ for the next PBR regime.

This report reveals at least two outstanding issues that EPCOR may wish to address prior to the termination of the current PBR regime. First, it is not apparent why an *X* factor that incorporates both productivity growth and input price differentials appropriately will fail to provide adequate compensation for a regulated company operating in a *steady-state*.[85] Second, in the 2012 PBR proceeding, EPCOR proposed a linkage between service quality performance and the efficiency-carryover mechanism. While the AUC did not adopt EPCOR's proposal, the Commission appeared to have some interest in a mechanism that linked service quality performance to the parameters of the price cap plan. The specific manner in which service quality performance should be linked to the parameters of the price cap plan is a complex question that warrants careful thought and analysis.

B. PRELIMINARY RECOMMENDATION.

Our preliminary recommendation with respect to the preferred approaches is based on four main criteria. First, the AUC is unlikely to adopt any approach containing elements of traditional rate of return regulation. Second, the AUC places a large premium on simplicity, transparency and reducing the regulatory burden for all parties. Third, the preferred approaches should address the issue of capital sufficiency in a comprehensive and principled manner. Finally, it is critical that the preferred approaches provide strong incentives for efficiency comparable to those that arise in competitive markets.

---

[85] Stated differently, it remains to specify precise conditions under which it is important to include Category 2 capital trackers in a PBR plan.

Based on the analysis set forth in the body of this report, our preliminary recommendation is that the AUC adopt a pure price cap approach that incorporates an economically principled mechanism capable of addressing all three of the capital tracker categories that EPCOR identified in the course of the 2013 Capital Tracker proceeding. We believe this approach addresses both company and Commission concerns while preserving to the extent possible the desirable incentives that arise in competitive markets. This suggests that the following three approaches merit the most serious consideration:

(1) PRICE CAPS WITH AN F FACTOR ("$\bar{K}$ -BAR") ADJUSTMENT **(III.E)**

(2) PRICE CAPS WITH LIMITED FACTOR ADJUSTMENTS AND A MIDTERM REVIEW **(III.F)**

(3) PRICE CAPS WITH CAPITAL TRACKERS AND ASSOCIATED K FACTORS (**III.C**)

In addition, we believe that the OPTIONS IN THE CHOICE OF REGULATORY REGIME (**III.H**) approach, which allows the regulated firm a limited choice among PBR plans, has considerable appeal. Recall that the Ontario Energy Board adopted this approach in its last PBR proceeding. Despite its potential merits, this approach is not included among our preliminary recommendations for two primary reasons. First, the AUC appeared to dismiss this approach out of hand in the 2012 PBR proceeding. Second, this approach entails potentially complex design issues and has encountered some difficulties in practice.

Finally, it is important to note that our preliminary recommendation does not reflect an explicit, systematic ranking of the eleven approaches from the perspective of the AUC's five PBR Principles. In subsequent analysis, EPCOR may see merit in undertaking a more formal assessment of each of the approaches from the perspective of the AUC's PBR Principles. This exercise may allow for a more refined ranking of the various approaches and better position the company to support the approach that it ultimately adopts for the next-generation PBR regime.

Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Appendix HH

Summary of BC Hydro's Internal Audits

Table of Contents

1 Listing of Internal Audits – Fiscal 2017, Fiscal 2018 and Fiscal 2019 To-Date

Audit Services performs internal audits of key areas of BC Hydro. Independent Subject Matter Experts are engaged when expertise is required on the audit subject. Since fiscal 2017, experts have assisted Audit Services from various areas of the world including Canada, United Kingdom, Switzerland, Norway, and the United States.

At the conclusion of the audit, the overall audit is ranked based on the identified issues and associated impacts. The ranking can range from a green with minor issues to red with critical issues.

	Minor issues and impacts identified
	Moderate issues and impacts identified
	Significant issues and impacts identified
	Critical issues and impacts identified

All audits are approved by the BC Hydro Audit and Finance Committee of the Board. Management is responsible for the providing Action Plans to address the recommendations from the audit. Audit Services continues to monitor management's progress to address each recommendation until completion.

2 Fiscal 2017

2.1 Independent Power Producers Contract Management

Objective: Assess whether in-service Independent Power Producers and BC Hydro adhere to Electricity Purchase Agreement terms and processes exist to effectively manage contracts.

Conclusion: Moderate issues and impacts identified. Appropriate oversight is in place. Independent Power Producers meet obligations for energy delivery. Parties are generally in compliance with the key terms and conditions. Management of agreements is sometimes reactive including resolution and reporting of invoice variances. Improvement opportunities include documentation, internal reporting and development of key performance indicators.

2.2 Demand Side Management

Objective: Assess whether effective processes and controls are in place over Demand Side Management activities and programs.

Subject Matter Expert: Engaged from GDS Canada Consulting Ltd. with over 40 years of experience including performing impact, process and market effects evaluations, and managing energy efficiency programs. The expert was also a Certified Measurement and Verification Professional.

Conclusion: Minor issues and impacts identified. Processes and controls are in place for Demand Side Management planning, program development, implementation and evaluation. Improvement opportunities include simplifying the planning process, documentation of assumptions and processes and developing a central assumptions database.

2.3 Site C Contract Procurement

Objective: Review the Site C procurement practices and assess whether contract placements follow a competitive, open and fair process.

Conclusion: Minor issues and impacts identified. Contracts were placed following a fair and competitive process. Sourcing bid documents were prepared with input from subject matter experts and rigorous evaluation processes were undertaken. Independent Fairness Advisors were involved throughout the entire procurement process to ensure fairness and transparency. Improvement opportunities include retaining approvals and implementing a formal document control process.

2.4 Generation Maintenance

Objective: Provide assurance there is an effective Generation Maintenance program to ensure assets are well maintained.

Conclusion: Minor issues and impacts identified. A strong governance framework is in place over the Program. Effective processes have been implemented to plan maintenance work and facilities are generally complying with maintenance practice requirements. A detailed reporting process has been established to monitor performance. Improvement opportunities include developing a process to review higher risk corrective and condition-based work orders, continuing to develop a data analytics program and to better integrate maintenance and capital planning and decision making.

2.5 Customer Connection Process

Objective: Review the effectiveness of the end-to-end customer connection process.

Conclusion: Moderate issues and impacts identified. The governance structure is in place to oversee the Customer Connect group. Significant progress has been made since the last audit. Work streams are well managed with reporting tools in place. Collaborative efforts among stakeholders are required to address: accuracy of estimates and cost allocations, update of drawings as built and management of material need dates. Other areas to be resolved include legacy billing issues, handling of payments and invoicing for Distribution Design and backlogs in system extension test calculations.

2.6 Disaster Preparedness

Objective: Assess BC Hydro's plans and ability to respond to, and recover from, a catastrophic disruption of business operations.

Subject Matter Expert: Engaged from PwC's business resilience practice in Western Canada with 20 years of experience in this field. Led many engagements assisting multi-national organizations to develop and implement disaster preparedness and recovery programs.

Conclusion: Moderate issues and impacts identified. Significant progress has been made in the Program since the last audit. An effective governance structure and framework has been formulated but not fully implemented. Emergency management plans, exercise and training programs are in place. Recommendations include further enhancements in enterprise-wide business impact analysis, business continuity, IT disaster recovery and corrective action plans to move the Emergency Management Program forward.

2.7 Site C Contract Management

Objective: Review contract management processes to assess whether effective controls are in place.

Conclusion: Moderate issues and impacts identified. Strong oversight is in place at both project and contract management levels with comprehensive reporting to the Board, Executive, and Project Director level. In general, invoices and change orders are reviewed in detail and approved for timely payment. Improvement opportunities include reviewing resourcing capacity, clarifying roles and responsibilities, and accelerating enhancements to the IT contract management system.

2.8 John Hart Replacement Project

Objective: Provide assurance that the John Hart Replacement Project is being appropriately executed to ensure delivery of stated objectives.

Conclusion: Minor issues and impacts identified. The Project is on track to deliver the stated objectives. Project oversight includes a strong governance structure, clear assignment of responsibilities and effective reporting. BC Hydro is monitoring and auditing work performed by the private sector partner to verify compliance with the Agreement. Contract management processes are in place to ensure invoices are reviewed, tracked and approved prior to payment and contract changes are tightly controlled.

3 Fiscal 2018

3.1 BC Hydro Business and Travel Expenses

Objective: Assess compliance with employee business and travel expense policies and procedures.

Conclusion: Minor issues and impacts identified**.** Management oversight is in place to monitor expenses. Business and travel expenses for the board of directors, executives and employees are compliant with corporate policies with some notable exceptions. Management will address spending decisions which may not fully align with the policy requirements, and review policies needing further clarity.

3.2 Load Forecasting

Objective: Review the load forecasting process to ensure timely and reliable energy and peak demand forecasts which supports operational, financial and strategic planning at BC Hydro.

Subject Matter Expert: Engaged from GDS Associates Inc. with over 30 years of load forecasting experience including preparing load forecasts for various utility clients (ranging from day-ahead to long-term horizons), and filing testimony on issues relating to load forecasting and other statistical analyses.

Conclusion: Minor issues and impacts identified. Overall, the load forecasting function at BC Hydro compares favorably to industry standards and to other large electric utilities in North America. No critical weaknesses were found. Load forecasting methodologies are consistent with best practices and load forecast outputs are provided to users and stakeholders on a timely basis. The greatest risk of load forecasting inaccuracy falls on the industrial class and is due to the uncertainty of future economic activity and the volatility of many individual customer loads. Improvement opportunities relate to making adjustments to forecast models and inputs to enhance overall forecast accuracy.

3.3 Engineering Service Provider Contracts

Objective: Review whether effective processes and controls are in place to ensure Engineering Service Providers are fulfilling their contractual obligations.

Conclusion: Minor issues and impacts identified. An established governance framework with oversight over Engineering Service Providers exists. Effective monitoring, reporting and relationship management processes are in place. Service provider invoices were verified and reviewed for accuracy and reasonableness, properly approved and paid in a timely manner. Data analytics revealed no significant overcharges or errors. Improvement opportunities relate to inefficiencies in invoice verification processes and requesting documentation from Service Providers to support expenses claims.

3.4 Horne Payne Substation Upgrade Project

Objective: Provide assurance the Horne Payne Substation Upgrade project is managed and executed to deliver stated objectives.

Conclusion: Minor issues and impacts identified. The project is appropriately managed and work is being executed to deliver the stated objectives. A governance framework is in place and the project is on track to be completed on scope, schedule and below the expected cost. The project is mostly compliant with key management plans. There are design challenges during construction potentially due to the design review processes at the time. Management of larger contracts is effective while further monitoring of smaller contracts is required.

3.5 Construction Services

Objective: Assess whether Construction Services effectively manages and delivers work to meet client needs.

Conclusion: Moderate issues and impacts identified. Overall, governance is in place and clients are highly satisfied with the quality of work. Business processes have been developed and implemented for job planning, construction and completion but these processes are not consistently followed. Reporting is in place to monitor operations however reliability of some performance metrics is impacted by data integrity issues.

3.6 Project Portfolio Management

Objective: Assess whether there is compliance with Project and Portfolio Management requirements and the effectiveness of the quality assurance function.

Conclusion: Minor issues and impacts identified. Project and Portfolio Management compliance is in place to support strong project management practices, and key tools are functioning as designed. The approach used in the quality assurance processes is appropriate, however, modifications will be required to further strengthen the methodology and ensure changes are made as issues are identified.

3.7 Indigenous Relations Agreement Management

Objective: Assess whether BC Hydro is effectively executing agreements in support of its Indigenous Relations Strategy.

Conclusion: Moderate issues and impacts identified. BC Hydro is fulfilling commitments based on audit testing. However, management practices vary depending on the type of agreement, and tracking of commitments is inconsistent. The current systems and existing processes do not fully enable the management of agreements, commitment tracking, and reporting. With the increasing volume and scope of commitments, it is essential to have standardized systems and controls that are consistently being applied. Improvement opportunities include strengthening processes and controls, addressing data integrity and reducing reliance on individual employees.

3.8 Enterprise Billing Infrastructure Project

Objective: Provide assurance during implementation that the Enterprise Billing Infrastructure Project was being effectively executed to attain project objectives.

Subject Matter Expert: Engaged from PwC with over 40 years of advising Boards and CEOs on large and complex projects and initiatives. Expert has extensive experience with business and technology solutions for corporate and public sector clients.

Conclusion: Minor issues and impacts identified. The Project was effectively executed to deliver its stated objectives. Although there were some significant risks identified by the Project Team early in the project, appropriate actions were identified and undertaken to mitigate these risks.

4 Fiscal 2019 To-Date

4.1 Dam Safety

Objective: Evaluate whether risks are identified, prioritized, and managed to ensure objectives of BC Hydro's Dam Safety Program are achieved.

Subject Matter Experts: Two experts were engaged. The first expert is the Commissioner for Dam Safety at the Swiss Federal Office of Energy. The second expert is a Professional Engineer at Health & Safety Executive (**HSE**) Major Hazards division. HSE is Great Britain's statutory regulator of occupational health and safety requirements.

Conclusion: Minor issues and impacts identified. BC Hydro has a well-established Dam Safety Program that is in line with international practices. Governance is effective with appropriate oversight, and the relationship with the regulator is strong and forthcoming. A robust risk assessment process continues to drive key dam safety activities, and operational activities are executed to monitor dams. Risk factors relating to management of the Issues Database and surveillance activities are minor on their own, but together could be an indication that elements of the Dam Safety Program may be falling behind.

4.2 Smart Meter Operations

Objective: Assess whether the Smart Meter system is fully operationalized, managed and functioning effectively.

Subject Matter Expert: Engaged from Bridge Energy Group with extensive experience in technology strategy, enterprise architecture, integration and security to utility clients. Subject matter expert also provided expertise on the fiscal 2013 Meter-to-Bill Audit.

Conclusion: Minor issues and impacts identified. The Smart Metering System is delivering intended services to the stakeholders with controls around data and application security, access and privacy. Operations are effectively governed largely due to legacy relationships from the Project and the system is well monitored.

Executive sponsorship and strategic governance need to be established to align business objectives and priorities. Improvement opportunities include testing and deployment of the technology and improved integration of meter data into the Outage Management System.

4.3 Confined Space Program

Objective: Assess whether an effective Confined Space Program is in place and being followed.

Conclusion: Moderate issues and impacts identified. Significant effort has been made to operationalize the Program across the organization including identifying and inventorying confined spaces, developing risk assessments and work procedures. Improvement opportunities include reviewing the current oversight model, implementing compliance monitoring processes and improving documentation practices to ensure worker safety and regulatory compliance.

4.4 Energy Studies Process

Objective: Evaluates whether the monthly Energy Studies process reliably supports operations, financial and strategic planning at BC Hydro.

Subject Matter Experts: Two subject matter experts engaged from SINTEF. A senior research scientist working with load forecasting, risk management, hydro scheduling and hydrothermal market modelling, and a research scientist working with development and analyses related to hydrothermal market models and medium-term hydropower scheduling models. Both scientists held Doctorates from the Norwegian University of Science and Technology.

Conclusion: Minor issues and impacts identified. BC Hydro has a well-established Energy Studies process in place. Governance is effective with appropriate level of oversight, and responsibilities and accountabilities are well understood across the team. Key models developed are appropriate and the methodologies applied are in line with leading industry practices. The Energy Study process can be further automated to reduce cycle time and free up resources. Energy Study reports are prepared on time and contain an appropriate level of detail; however they do not serve short-term operational planning needs.

4.5 Learning and Development

Objective: Assess the effectiveness of learning and development to ensure employees have the right skills at the right time.

Conclusion: Moderate issues and impacts identified. Learning opportunities are provided for employees. Processes are in place to identify required training needs, develop course curriculum, and deliver training to employees. Managers cannot effectively monitor and confirm employees have completed the required safety training for assigned work. Improvement opportunities include developing an overarching training policy for the organization and addressing limitations of the Qualification and Learning Management System.

4.6 Cheakamus Generator Replacement Project

Objective: Provide assurance that the Cheakamus Units 1 and 2 Generator Replacement Project is appropriately managed and executed to deliver stated objectives.

Conclusion: Minor issues and impacts identified. The project is on course to meet budget and schedule and is being managed and monitored appropriately. A clear governance framework is in place to support project delivery. Contracts are generally well-managed and procured in compliance with BC Hydro policies and procedures. Improvement opportunities include risk register updates, clarifying requirements around final inspections prior to signing Commissioning Notice to Operate, and periodically completing quality reviews of the transmittals and submittals log.

BC Hydro
Power smart

Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Appendix II

Abbreviations

Abbreviations

A

ABS	Accenture Business Services
AMI	Automated metering infrastructure
Application	Fiscal 2020 to Fiscal 2021 Revenue Requirements Application
AROR	Average rate of return
ASAI	Average Service Availability Index
ASC	Accounting Standards Codification
AUC	Alberta Utilities Commission

B

BC Hydro	British Columbia Hydro and Power Authority
BCEAO	British Columbia Environmental Assessment Office
BCTC	British Columbia Transmission Corporation
BCUC	British Columbia Utilities Commission
BES	Bulk electric system
BOABC	Building Officials' Association of British Columbia
BR1	Bridge River 1
BR2	Bridge River 2
BRP	Base Resource Plan
BRT	Bridge River Terminal

C

CADD	Computer-Aided Design and Drafting
CAIDI	Customer Average Interruption Duration Index
CAP	Capilano Substation
CAPEX	Capital expenditures

Capital Plan	BC Hydro's Fiscal 2020 to Fiscal 2024 Capital Plan
CBL	Customer baseline load
CBN	Clayburn Substation
CEA	*Clean Energy Act* or Canadian Electricity Association
CEA Agency	Canadian Environmental Assessment Agency
CEATI	Centre for Energy Advancement Through Technical Innovation
CGAAP	Canadian Generally Accepted Accounting Principles
CHBA	Canadian Home Builders Association
CHL	Customer hours lost
CHP	Combined heat and power
CIDC	Calgary Internet Data Centre
CIP	Critical Infrastructure Program
CKY	Cheekye Substation
CLRA	Contingent Labour Resource Augmentation Project
CO^2e	Carbon doxide equivalent
COD	Commercial operation date
Comprehensive Review	The Government of B.C.'s Comprehensive Review of BC Hydro
COO	Chief Operating Officer
COPOA	Co-Processors and Operating Agreement
COSR	Cost of service regulation
CPCN	Certificate of Public Convenience and Necessity
CPI	Consumer Price Index
CRSP	Canadian registered safety professional
CRTC	Canadian Radio-Television and Telecommunications Commission
CSA	Canadian Standards Association
CSQ	Cathedral Square Substation

D

DACS	Data and Analytics Centre
DARR	Deferral Account Rate Rider
DCAT	Dawson Creek/Chetwynd Area Transmission
D-COMS	Distribution Contract and Operations Management Services
Decision	BCUC's Decision on BC Hydro's Fiscal 2017 - Fiscal 2019 Revenue Requirements Application, released March 1, 2018
DEER	Database for energy efficiency resources
DGR	Dal Grauer Substation
DSM	Demand-side management

E

EAR	Expenditure authorization request
EARSL	Expected average remaining service life
EC&E	Energy Conservation and Efficiency Committee
ECAP	Energy Conservation Assistance Program
ECM	Efficient carryover mechanism
ECMS	Energy conservation measures
EDTI	Edmonton Distribution and Transmission Incorporated
EHR	Equipment Health Rating
EIA	Energy Information Administration (U.S.)
EIS	Environmental Impact Statement
EM&V	Evaluation, Measurement and Verification
EOC	Evaluation Oversight Committee
EOL	End-of-life
EPA	Electricity Purchase Agreement
EPCOR	Edmonton Power Corporation
ESK	Energy Savings Kit

ESM	Earnings sharing mechanisms
EVP	Energy visualization portal

F

FAAP	Financial Approval Authority Policy, (BC Hydro's employee expenditure limit policy)
FCC	Federal Communications Commission (U.S.)
FERC	Federal Energy Regulation Commission (U.S.)
First Full Funding	Baseline of a total project estimate and schedule associated with the first implementation EAR approval.
FOICO	Freedom of Information Coordinating Office
FOIPPA	*Freedom of Information and Protection of Privacy Act*
FortisBC Energy Inc.	FortisBC, gas distribution utility
FortisBC Inc.	FortisBC, integrated electricity utility serving customers in the southern interior of B.C.
FTE	Full Time Equivalent

G

GAAP	Generally Accepted Accounting Principles
GBL	Generator Baseline Load
GDP	Gross Domestic Product
GGRR	Greenhouse Gas Reduction Regulation
GHG	Greenhouse gas
GIS	Gas insulated switchgear
GJ	Gigajoule
GLD	Gold River Substation
GLT	Glouchester Substation
GMS	Gordon M. Shrum Generating Station
GOW	Goward Substation
GRTA	Generation Related Transmission Assets

GWh	Gigawatt-hour

H

HDA	Heritage Deferral Account
HLH	High load hours
HPN	Horne Payne Substation
HPS	High-pressure sodium
HPU	Hydraulic power units
HSY	Horsey Substation
HVAC	Heating, ventilation and air conditioning

I

IAS	International Accounting Standard
IBA	Impact Benefit Agreement
IBEW	International Brotherhood of Electrical Workers
ICBC	Insurance Corporation of British Columbia
IEP	Integrated Electricity Plan
IFRIC	International Financial Reporting Interpretations Committee
IFRS	International Financial Reporting Standards
IMS	Incident Management System (Safety)
INOG	Intake operating gates
IOMA	Initiative Operations, Maintenance or Administration
IPMVP	International Performance Measurement and Verification Protocol
IPP	Independent Power Producer
IRP	Integrated Resource Plan
ISD	In Service Date
ISO	International Organization for Standardization
ITA	Industry Training Authority

ITDSP	Information Technology Delivery Standard Practices

J

JOR	Jordan River Substation

K

KBU	Key Business Unit
KIDC	Kamloops Internet Data Centre
kV	Kilovolt
kW	Kilowatt
kWh	Kilowatt-hour

L

LCE	Low-carbon electrification
LDR	Ladore Generating Station
LED	Light emitting diode
LEEP	Local Energy Efficiently Partnerships
LEM	Leaders in Energy Management
LEM-C	Leaders in Energy Management - Commercial
LEM-I	Leaders in Energy Management - Industrial
LGS	Large General Service, refers to the rate class of large commercial and small industrial customers with demand greater than 150 kilowatts
LLH	Low load hours
LLO	Low Level Outlet
LMU	Line matching unit
LNG	Liquefied natural gas
Load Forecast	BC Hydro’s Fiscal 2020-2024 Load and Revenue Forecast, released in October 2018.
Load Forecast Audit	BC Hydro’s internal audit on the load forecasting function.

LRMC	Long-Run Marginal Cost
LTAP	Long Term Acquisition Plan

M

M&V	Measurement and Verification
MAIFI	Momentary Average Interruption Frequency Index
MCA	Mica Generating Station
MDE	Maximum design earthquake
MDMS	Meter Data Management System
MDN	Meridian Substation
MES	Maintenance and Emergency Stockpile of riprap
MGS	Medium General Service, refers to the rate class of commercial customers with electricity demand of greater than 35 kilowatts and less than 150 kilowatts
Mid-C	Mid-Columbia Day Ahead Price
MLE	Mount Lehman Substation
MNT	Metro North Transmission
MoveUP	Movement of United Professionals (Formally Canadian Office and Professional Employees Union)
MPLS	Multiprotocol label switching
MPT	Mount Pleasant Substation
MSA	Master Supply Agreement
MUR	Murrin Substation
MV	Mercury vapor
MW	Megawatt – one million watts or one thousand kilowatts

N

NERC	North American Electricity Reliability Corporation
NERC-CIP	North American Electricity Reliability Corporation Critical Infrastructure Program
NFOM	Non-fuel operations and maintenance expenses

NHDA	Non-Heritage Deferral Account
NIA	Non-Integrated Area
NIARG	Non-Integrated Area Ratepayers Group
NIC	Nicola Substation
NITS	Network Integration Transmission Service
NOR	Norgate Substation
NPV	Net Present Value
NTL	Natal Substation

O

O/H	Overhead
OAG	Office of the Auditor General (British Columbia)
OATT	Open Access Transmission Tariff
OEB	Ontario Energy Board
OLTC	On-load tap chargers
OMA	Operations, Maintenance or Administration
OPEX	Operating expenditures
OSH	Occupational safety and health

P

P&C	Protection and control
PAR	Progressive Aboriginal Relations
PBR	Performance based regulation
PCB	Polychlorinated biphenyl
PEM	Pemberton Substation
PIM	Performance incenting mechanism
PLC	Power Line Carrier
PMAES	Personnel, materials and external services
PMI	Project Management Institute

PPM	Project and Portfolio Management
PRES	Peace River Electricity Supply Project
Previous Application	BC Hydro's Fiscal 2017 - Fiscal 2019 Revenue Requirements Application
PSSP	Power system safety protection
PTP	Point-to-Point

R

RAS	Remedial action scheme
Resource Loaded Schedule	The project schedule with resources included, which forms the basis of the project cost estimate.
Revised Proposal	BC Hydro's submission in the BCUC's Review of the Regulatory Oversight of Capital Expenditures and Projects
RIB	Residential Inclining Block. The rate class for residential customers.
ROW	Right(s)-of-way
RRA	Revenue Requirement Application
RSRA	Rate-Smoothing Regulatory Account

S

SAE	Statistically Adjusted End-Use Model
SAIDI	System Average Interruption Duration Index
SAIFI	System Average Interruption Frequency Index
SARI	System Average Reliability Index
SBK	Southbank Substation
SCADA RTU	Supervisory control and data acquisition remote terminal unit.
SDA	Substation distribution assets
SEC	Securities and Exchange Commission (U.S.)
SEM	Strategic Energy Management

SERA	Skumatz Economic Research Associates
SFN	Stave Falls Generating Station
SGB	Shell Groundbirch Substation
SMI	Smart Metering and Infrastructure
SMW	Sumas Way Substation
SOO	Statement of objectives
SOP	Standing Offer Program
SQH	Squamish Substation
STR	Strathcona Dam

T

T&D	Transmission & Distribution
Test Period	The fiscal 2020 to fiscal 2021 period
TIDA	Trade-Income Deferral Account
TML	Teck Metals Ltd.
TMP	Thermo-Mechanical Pulping Program
TPA	Transfer Pricing Agreement
TRC	Total Resource Cost
TRR	Transmission Revenue Requirement
TSE	Truck stop electrification
TSR	Transmission Service Rate, applies to large industrial customers supplied with electricity at transmission voltage (60,000 volts or more)

U

UC	Utility Cost
UCA	*Utilities Commission Act*
UCT	Utility Cost Test
UFM	Utility Fleet Mechanic
UHF	Ultra-high frequency

UNDRIP	United Nations Declarations on the Rights of Indigenous Peoples
USMCA	United States Mexico Canada Agreement
USoA	Uniform System of Accounts

V

VAR	Volt-ampere reactive
VHF	Very high frequency
VVO	Volt var optimization

W

Waneta 2017 Transaction	BC Hydro's purchase of the remaining two-thirds interest in the Waneta Dam from Teck Metals Ltd.
WBK	Westbank Substation
WECC	Western Electricity Coordinating Council
Work Package	A document that clearly identifies a practice area's responsibilities in a project, including scope, schedule, cost and accountabilities.
WPP	Work Protection Practices
WUP	Water Use Plan

Z

Zone II	Zone II Ratepayers Group
