    d. Continue to defer, on an annual and ongoing basis, any variances between forecast and actual dismantling costs to the Dismantling Cost Regulatory Account, continue to apply interest to the balance of the account and recover the forecast interest charged to the account each year, and continue to recover the forecast account balance at the end of a test period over the next test period;
    e. Defer low-carbon electrification expenditures to the Demand-Side Management Regulatory Account;
    f. Remove the reference to the "Prescribed Standards" from the description of what may be deferred to the Site C Regulatory Account;
    g. Closure of the Capital Project Investigation Costs Regulatory Account at the end of fiscal 2021; and
    h. Closure of the Rate Smoothing Regulatory Account in fiscal 2020.

4. The requested depreciation rates for the Burrard synchronous condense facility, for new Water Rights, Infrastructure Rights and LED Streetlights asset classes and for three new asset classes for agreements recognized as leases under IFRS 16, *Leases* are approved on an ongoing basis.

5. The requested OATT rates for fiscal 2020 and fiscal 2021 in Table 9-8 of the Application are approved effective April 1, 2019 and April 1, 2020, respectively.

6. The requested demand side management (DSM) expenditure schedule of $207.1 million in fiscal 2020 and fiscal 2021 as set out in Table 10-1 of the Application is accepted.

7. The request for reconsideration of Directive 3 of the BCUC's Decision on BC Hydro's Fiscal 2017 to Fiscal 2019 Revenue Requirements Application which directs BC Hydro to file a certificate of public convenience and necessity (CPCN) application for the Northwest Substation Upgrade project is allowed, and Directive 3 is varied to no longer require BC Hydro to file a CPCN for the project.

8. The requested reconsideration is allowed with respect to the following directives, which are rescinded:
   a. Directive 61 of the BCUC's Decision on BC Hydro's Fiscal 2005 to Fiscal 2006 Revenue Requirements Application which directed that a prorated amount of costs from portfolio-level initiatives be added to the cost of each DSM program to assess cost effectiveness; and
   b. Directive 57 of the BCUC's Decision on BC Hydro's Fiscal 2009 to Fiscal 2010 Revenue Requirements Application which directed that BC Hydro revenue requirement applications filed after January 1, 2011 contain financial information that follows the Uniform System of Accounts.

9. BC Hydro is directed to comply with all other directives in the Decision accompanying this order.

DATED at the City of Vancouver, in the Province of British Columbia, this (XX) day of (Month Year).

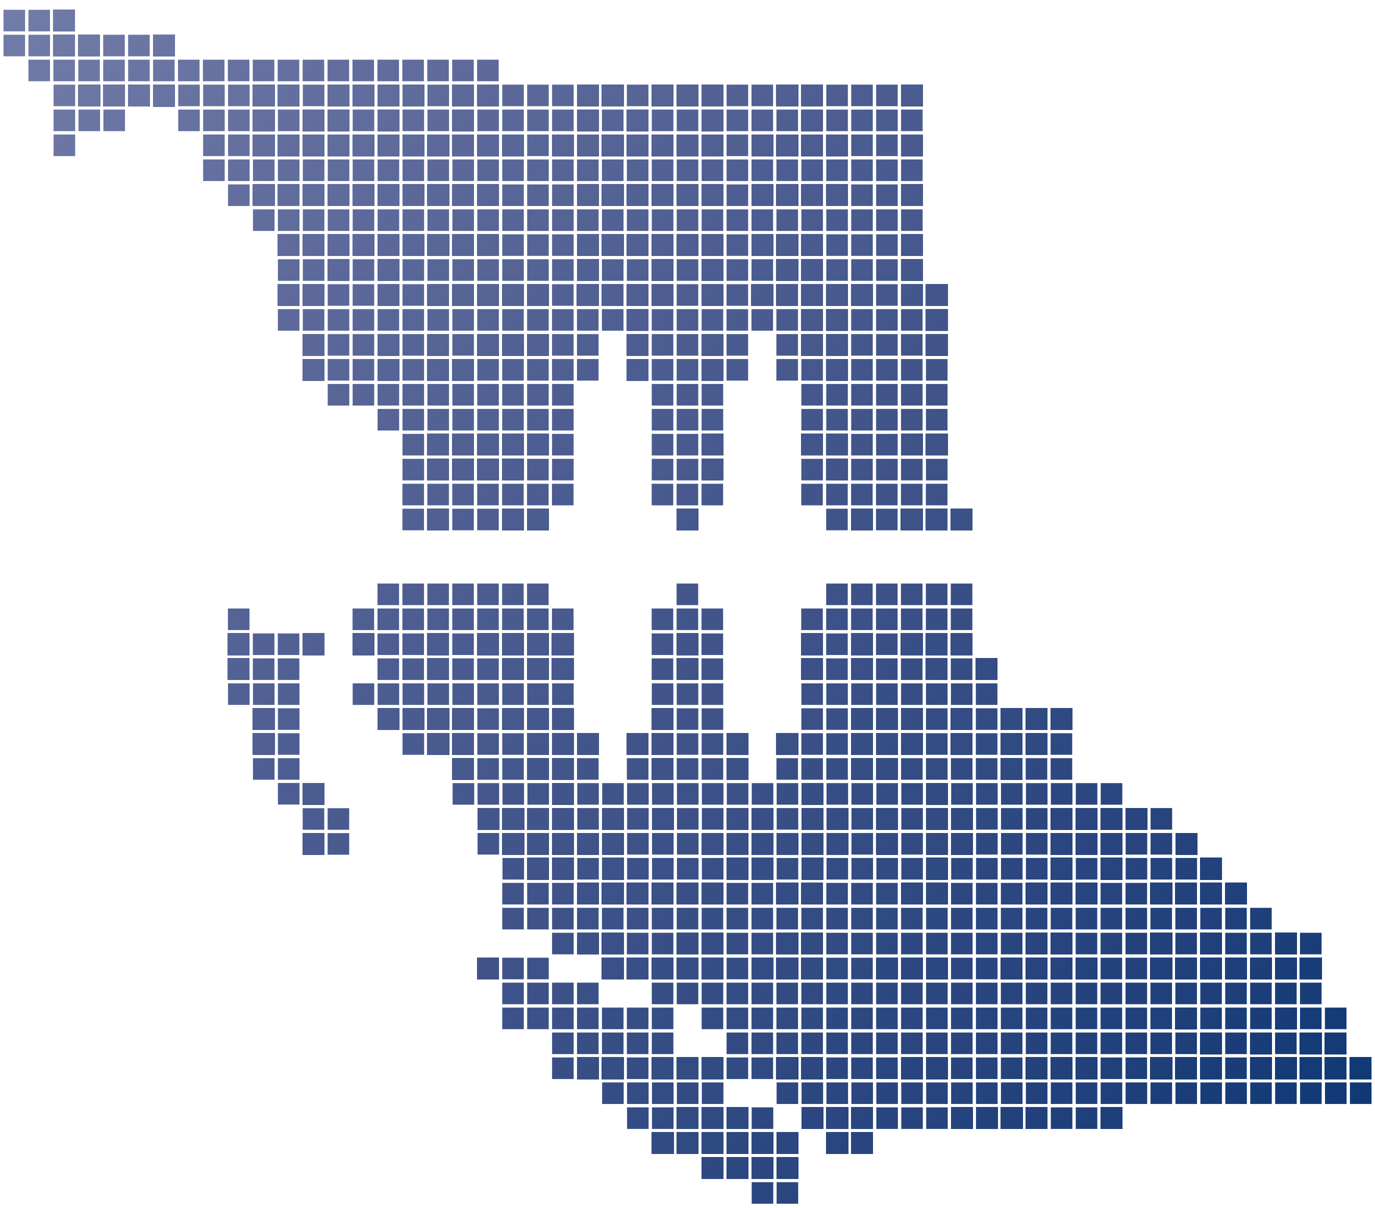
Comprehensive Review of BC Hydro

British Columbia

Ministry of Energy, Mines and Petroleum Resources

Comprehensive Review of BC Hydro: Phase 1 Final Report



Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Table of Contents

1. Executive Summary

To keep electricity rates affordable and position BC Hydro for future success, the BC government ("the government") launched a comprehensive, two-phased review (the Review) of BC Hydro, beginning in June 2018.

The Terms of Reference for Phase 1 of the Review are included as Appendix A. The first phase of the Review was conducted by the Ministry of Energy, Mines and Petroleum Resources, the Ministry of Finance and BC Hydro and is now complete, with two key outcomes:

- Enhanced regulatory oversight of BC Hydro; and
- A new five-year rates forecast that reflects cost and revenue strategies to keep rates affordable.

The purpose of this Phase 1 Final Report is to outline the work undertaken in Phase 1 and the details related to the two key outcomes above. This information will be of interest to the citizens of British Columbia and BC Hydro's customers, Indigenous Nations, communities, Independent Power Producers, as well as key stakeholders such as the Auditor General of British Columbia, the British Columbia Utilities Commission (BCUC) and other parties engaged in BC Hydro's regulatory processes. Key decisions related to Phase 1 are complete, and this Final Report explains how the outcomes are being implemented.

The Terms of Reference for Phase 2 will be finalized and made public in early 2019. Phase 2 is expected to focus on how the energy industry and markets are transforming, how to ensure BC Hydro's long-term sustainability with those transformations and BC Hydro's role in implementing electrification initiatives critical to the CleanBC plan, government's plan to reach its 2030 climate targets through reduction of greenhouse gas emissions in transportation, buildings and industry.

1.1 Enhancing Regulatory Oversight of BC Hydro

BC Hydro is in a unique position compared to other public utilities in B.C. As an electric utility, its mandate is to provide safe and reliable electricity services to its customers, under the oversight of the BCUC. As a provincial Crown corporation, it also has a role in implementing government policies. The two objectives are not always aligned, particularly in cases where implementing government policy may have costs for BC Hydro and its customers.

In recent years, the government exercised its authority under the *Utilities Commission Act* to direct BCUC decision-making and outcomes on a number of matters to achieve policy objectives, including the setting and capping of BC Hydro's rate increases for specific years covered by the 10 Year Rates Plan (April 1, 2014 to March 31, 2024) and directing certain outcomes related to BC Hydro's regulatory accounts. These measures have led to concerns from the B.C. Auditor General and others that the government's actions have unduly impacted the BCUC's role as the independent regulator of BC Hydro.

Phase 1 of the Review has resulted in a number of actions (please refer to Section 4 and Appendix D for further detail) that enhance the regulatory oversight of BC Hydro, while still enabling the government to advance its social, economic and environmental priorities:

- The government, has accepted a recommendation from the review that BC Hydro write off the entire balance forecast of BC Hydro's Rate Smoothing Regulatory Account in Fiscal 2019. BC Hydro will request the closure of the account in its F2020-F2021 Revenue Requirements Application, to be filed with the BCUC in February 2019. As part of the previous government's 2013 10 Year Rates Plan, the BCUC was directed by government to allow the account without the ability for the BCUC to provide appropriate oversight.
- The government has repealed a number of regulations that restricted the BCUC's decision-making in the past. Moving forward, this will enable the BCUC to review and make decisions on BC Hydro's costs, proposed rate increases and almost all regulatory accounts, programs and capital projects.
- The government intends to introduce legislation to restore the BCUC's authority to review and approve BC Hydro's Integrated Resource Plan (IRP). The IRP will be submitted to the BCUC by February 2021. This timing enables development of the IRP to be informed by Phase 2 of the Review and the CleanBC plan.
- The government intends to enable the BCUC to begin setting BC Hydro's allowed net income for rate-setting purposes, following a two-year transition period for Fiscal 2020[1] and Fiscal 2021, during which BC Hydro's current net income target of $712 million will remain in place.
- The government has changed the accounting rules that BC Hydro is required to follow. BC Hydro will fully adopt International Financial Reporting Standards (IFRS) for Fiscal 2019. IFRS is aligned with the Canadian Generally Accepted Accounting Principles. This change addresses a recommendation made by the Auditor General.

The changes to the regulatory framework, and other regulations required to implement the outcomes of Phase 1 of the Review, are summarized in Appendix C.

1 The fiscal years within this report start on April 1, and end on March 31 of the following year. As an example, "Fiscal 2020" refers to the fiscal year that starts April 1, 2019 and ends on March 31, 2020.

1.2 New Rates Forecast

The cumulative increase in bills for ratepayers is forecast to be 8.1% over the next five years (Fiscal 2020 through Fiscal 2024). This is approximately 40% lower than the 13.7% increase for the same period under the previous 2013 10 Year Rates Plan and more than 20% lower than the forecast rate of B.C. inflation for the period. Actual rate increases will be determined by the BCUC through future Revenue Requirements Applications.

Table 1: BC Hydro Five Year Rates Forecast

	Fiscal 2020 Apr 1, 2019 – Mar 31, 2020	Fiscal 2021 Apr 1, 2020 – Mar 31, 2021	Fiscal 2022 Apr 1, 2021 – Mar 31, 2022	Fiscal 2023 Apr 1, 2022 – Mar 31, 2023	Fiscal 2024 Apr 1, 2023 – Mar 31, 2024	Cumulative Five Years*
Current Rates Forecast – Annual Rate Increase before reducing the DARR	6.8%	0.7%	2.2%	0.0%	3.2%	n/a
Current Rates Forecast – Annual Bill Impact including reduction in DARR**	1.8%	0.7%	2.2%	0.0%	3.2%	8.1%
Previous Govt's 10 Year Rates Plan – Annual Bill Impact	2.6%	2.6%	2.6%	2.6%	2.6%	13.7%
Forecast BC Inflation	2.3%	2.0%	2.0%	2.0%	2.0%	10.7%

* *cumulative rates do not equal the sum of individual rate changes shown for each year due to the effect of compounding.*

** *after reducing the Deferral Account Rate Rider (**DARR**) from 5% to 0%, beginning in Fiscal 2020. Under the 2013 10 Year Rates Plan, the DARR was set at 5% indefinitely – it was expected to remain at 5% at least through Fiscal 2024. Going forward, the BCUC will now determine how the DARR is set and applied. This change is explained further in Section 4.1.3.*

As a result of the Review, and in order to achieve the forecast rate increases shown above, government and BC Hydro are taking a number of actions to keep rates affordable.

Write-off of Rate Smoothing Regulatory Account

The write-off of the Rate Smoothing Regulatory Account, noted in Section 1.1, will reduce BC Hydro's forecast overall regulatory account balance at the end of Fiscal 2019 by 24%, from $4.7 billion to $3.6 billion. Lowering the overall regulatory account balance means lowering the amount that would be otherwise recovered from ratepayers, thus reducing rate pressures over the next five years.

Energy Procurement

Recognizing that energy procurement is a major cost driver for BC Hydro, and that BC Hydro is currently forecast to be in energy surplus into the 2030s, Phase 1 of the Review assessed how energy procurement costs could be reduced. The primary areas where future costs can be managed are expiring biomass Electricity Purchase Agreements and the Standing

Offer Program, which is BC Hydro's only active procurement program for new Electricity Purchase Agreements.

The government and BC Hydro have worked together to develop a biomass energy strategy to address the expiry of Electricity Purchase Agreements for biomass projects in the next few years. As a result, BC Hydro intends to acquire up to 80%, in aggregate, of the historical energy deliveries received under biomass Electricity Purchase Agreements that are due to expire before March 31, 2022. The prices offered for the biomass energy will also be lower relative to current contract terms to achieve savings for ratepayers while recognizing the socio-economic importance of these forest sector facilities. Separately, the government will work with the forest sector in transitioning to the use of forest sector waste for higher value renewable fuels, consistent with the CleanBC plan.

BC Hydro stopped taking any applications under the Standing Offer Program in August 2017. The Standing Offer Program will be suspended indefinitely by BC Hydro in accordance with a regulation being issued by the government under the *Clean Energy Act*. This suspension applies to new Electricity Purchase Agreements only, with the exception of five specific projects, each of which are part of Impact Benefit Agreements with BC Hydro and/or are mature projects that have significant Indigenous Nations involvement[2].

Capital Program, Operating Costs and Revenues

BC Hydro will reduce planned capital additions by $2.7 billion, from $18.5 billion to $15.8 billion over the 10 years from Fiscal 2020 to Fiscal 2029. BC Hydro has carefully considered system impacts. Safety and reliability risks will be managed through targeted investments, with no reductions in investments to meet legal, regulatory or tariff requirements.

Despite significant cost pressures, BC Hydro expects to limit base operating cost increases below the forecast rate of provincial inflation over the Fiscal 2020 to Fiscal 2024 period through savings from initiatives, prudent cost management and other measures such as leveraging Lean principles through BC Hydro's Work Smart process improvement program.

At the same time as it implements cost saving strategies, BC Hydro will also work to increase revenues, including attraction of additional domestic demand.

2 *https://www.bchydro.com/news/press_centre/news_releases/2018/bc-hydro-to-proceed-with-five-first-nations--clean-energy-projec.html*

1.3 NEXT STEPS

Regulatory changes have been or are being made to implement most Phase 1 outcomes. Where needed, legislation to implement Phase 1 outcomes is expected to be introduced in the Spring 2019 Legislative Session. See Appendix D for further detail.

Through a separate initiative, government will engage with Indigenous Nations to discuss the impacts the indefinite suspension may have on the economic individual nations, and how these impacts may be mitigated. Further information about this engagement process is available at ***www.engage.gov.bc.ca/SOPengagement.ca***.

BC Hydro will begin negotiations with those parties holding biomass Electricity Purchase Agreements expiring before March 31, 2022 for new load offset and/or energy purchase agreement(s). The government will also begin working with the forest industry on production of clean fuels to support the long-term sustainability of the sector and help meet the CleanBC greenhouse gas emission reduction targets.

The Phase 1 Review will inform BC Hydro's next Revenue Requirements Application, to be filed with the BCUC in February 2019.

2. Strategic Context

Electricity rates in B.C. have risen by over 70% in the past 10 years. Though the most recent Hydro Quebec Rate Comparison Report[3] shows that BC Hydro has the third lowest residential rates in North America, government's overarching policy commitments include making life affordable for British Columbians and building a strong, sustainable, innovative economy. In line with these objectives, the government's mandate letters to BC Hydro and the Minister of Energy, Mines and Petroleum Resources include commitments to conduct the Review.

In addition to the foregoing context on rates, over a number of years, BC Hydro has secured energy through power acquisitions from Independent Power Producers, the addition of Site C, and, to a lesser extent, through upgrades to its existing facilities. While electrification to support the CleanBC Plan will consume some of this surplus energy, growth in demand from existing electricity use is slowing, which means BC Hydro expects to remain in surplus into the 2030s.

BC Hydro operates in an evolving environment. For example, more stringent environmental and safety standards add valuable protections for the environment and enhance safety of workers and the public, while also adding cost and complexity to BC Hydro's work.

The first phase of the Review was designed to identify cost savings, efficiencies, new revenue streams and other changes to keep electricity rates affordable and predictable over the long-term, while ensuring BC Hydro has the resources it needs to continue providing clean, safe and reliable electricity.

Equally important, this phase also focused on helping to ensure sound financial and regulatory oversight of BC Hydro.

The outcomes from this first phase are assisting BC Hydro in preparing its next Revenue Requirements Application, to be filed with the BCUC in February 2019. During the BCUC's review of that application, stakeholders and the public will have a further opportunity to see and comment on how the outcomes of the first phase of the Review have influenced BC Hydro's financial/operational plan and electricity rates.

Phase 2 of the Review will focus on transformational aspects to changing energy markets. It will be informed by new government strategies, including the CleanBC plan. While Phase 1 focused on the next five years, Phase 2 will take a longer-term view and focus on recommendations to ensure BC Hydro is well positioned to maximize opportunities flowing from shifts taking place in the global and regional energy sectors, technological changes and climate objectives. Terms of Reference for Phase 2 of the Review will be finalized and made public in early 2019.

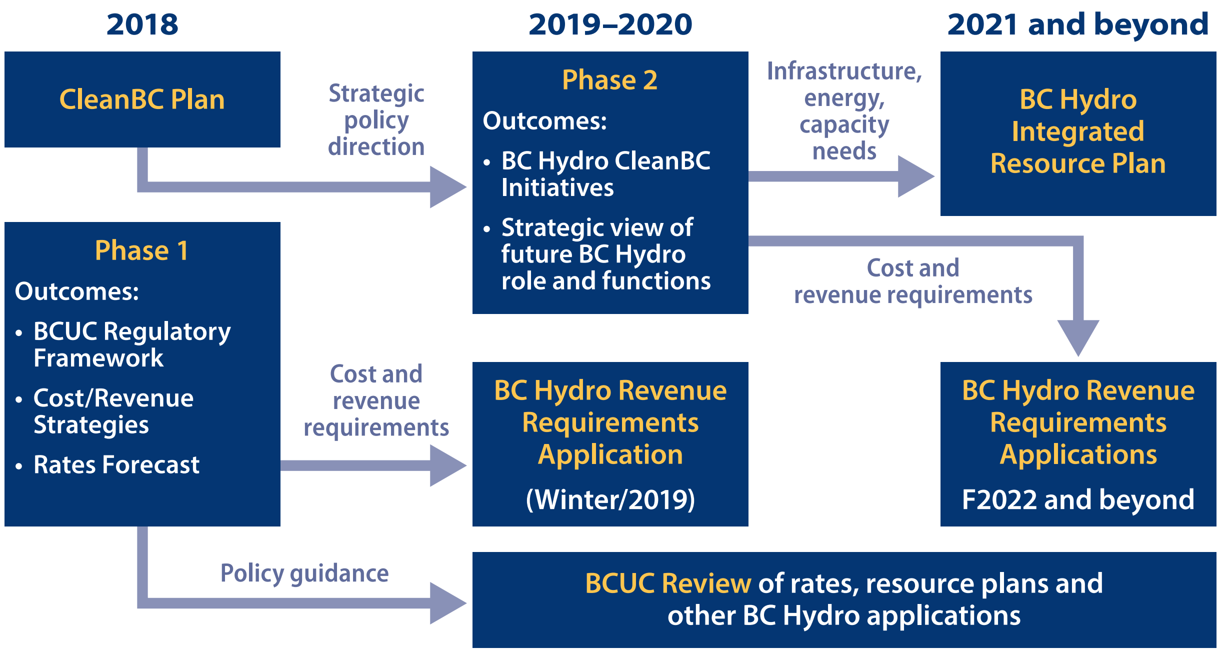
The figure below shows the interrelated nature of these various policy activities:

Figure 1: Policy Activities



2.1 PREVIOUS REVIEWS OF BC HYDRO

In 2011, a provincial government Deputy Ministers' Committee conducted a review of BC Hydro, focusing on cost reductions, efficiency and several policy issues. As a result, BC Hydro reduced its operating costs by $390 million over a three-year period, reprioritized capital expenditures and reached cost-effective agreements with service providers. In addition, BC Hydro and the government worked together to review the growth of regulatory accounts, with a report completed in March 2014.

In addition to reductions stemming from previous reviews, in 2013 the government and BC Hydro again worked together to reduce pressure on rates and the result was the 2013 10 Year Rates Plan. Government and BC Hydro continued to work together and took further actions after the 10 Year Rates Plan was released to ensure that its targets would be met. The 10 Year Rates Plan covering Fiscal 2015 to Fiscal 2024 had three main components: BC Hydro actions to reduce costs; government actions; and the creation of a Rate Smoothing Regulatory Account. BC Hydro actions related to the 10 Year Rates Plan included finding operating savings to limit cost growth, reducing capital expenditures and selling surplus properties. Government actions included the elimination of the third tier of the provincial water rental rate, reducing and then freezing BC Hydro's allowed net income for rate-setting purposes, and reducing and ultimately eliminating dividend payments to the government. Government issued directions to the BCUC and made other regulations to implement the 10 Year Rates Plan.

The Rate Smoothing Regulatory Account, established in 2014 as a result of government direction, was used to smooth the higher annual rate increases that would have been required to cover BC Hydro's costs in the early years of the 10 Year Rates Plan by enabling BC Hydro to defer collection of revenues from ratepayers to the later years of the Plan.

As of March 31, 2018, the Rate Smoothing Regulatory Account had reached a balance of $815 million. BC Hydro was scheduled to further defer another $325 million in revenues into the Rate Smoothing Regulatory Account in Fiscal 2019 (April 1, 2018 to March 31, 2019), which would bring the total balance to approximately $1.14 billion by March 31, 2019. The balance in the account was to be recovered from ratepayers by the end of the plan in Fiscal 2024 (April 1, 2023 to March 31, 2024).

2.2 BCUC Oversight of BC Hydro

BC Hydro's primary role is to provide safe, reliable and affordable power to its customers. BC Hydro is regulated by the BCUC, which is an independent agency of the government that is responsible for regulating B.C.'s energy utilities. The BCUC works to ensure that British Columbians get value from their utilities with safe, reliable energy services, while also ensuring the owners of the entities it regulates are able to earn a fair return on their invested capital. BC Hydro submits applications to the BCUC every few years to obtain approval of its proposed rate increases. The BCUC then holds a regulatory process to determine if these rate increases are in the best interests of BC Hydro's ratepayers, while also ensuring the long-term sustainability of BC Hydro.

At the same time, as a Crown corporation and agent of government, BC Hydro is also an important instrument of public policy. As such, government may require BC Hydro to undertake projects that benefit the public good, such as projects that support the achievement of the government's legislated greenhouse gas emissions reduction targets or those that promote reconciliation with First Nations and Indigenous peoples of B.C. This dual role can, and has, created conflict between BCUC decisions and government's desire to advance policy priorities through its Crown corporation.

Under the *Utilities Commission Act*, the government has the authority to provide legal direction to the BCUC to guide or define the outcomes of the BCUC's decision-making. The previous government used this authority when implementing the 2007 Energy Plan and the 2013 10 Year Rates Plan. Of note, government directed the BCUC to set or cap BC Hydro's rate increases at specific levels in the first five years of the 10 Year Rates Plan. Government also directed the BCUC to:

- establish BC Hydro's Rate Smoothing Regulatory Account;
- set BC Hydro's allowed net income for rate-setting purposes, which forms part of the government's overall revenue projections within its annual Fiscal Plan;
- approve the scope and amortization periods of some of BC Hydro regulatory accounts; and,
- allow BC Hydro to implement a number of policy decisions, such as the Smart Metering Infrastructure Program and the decommissioning of the Burrard Thermal Generating Station.

The following table outlines the rate increases in the first five years of the 2013 10 Year Rates Plan:

Table 2: Rate Increases in the 2013 10 Year Rates Plan for Fiscal 2015 to Fiscal 2019

2013 10 Year Rates Plan	Fiscal 2015	Fiscal 2016	Fiscal 2017	Fiscal 2018	Fiscal 2019
Rate Increases	9% Rate increase set by Direction	6% Rate increase set by Direction	4.0% Rate cap set by Direction	3.5% Rate cap set by Direction	3.0% Rate cap set by Direction

In the final five years of the 10 Year Rates Plan, the rate increases were to be set by the BCUC, with a target of 2.6% annual rate increases in each of those years.

2.3 Concerns from the Auditor General

The Auditor General is an independent Officer of the Legislature, and, under a fixed term of office in legislation, has a mandate to conduct audits and performance reviews of government entities, including ministries, Crown corporations and other organizations controlled by, or accountable to, the provincial government. These audits and reviews are intended to report on how well government is managing its responsibilities and resources. The Office of the Auditor General will be taking over as BC Hydro's external auditor starting April 1, 2019.

Past and current Auditors General have expressed an opinion that the government has inappropriately fettered the BCUC's oversight of BC Hydro (including with respect to setting rates and directing other outcomes) and that BC Hydro may not be fully operating as a cost of service utility, where rates are set to ensure a utility is able to recover its costs and provide a reasonable return to its shareholder. Because of these concerns, the current Auditor General qualified the government's Fiscal 2017 and Fiscal 2018 Public Accounts.

In providing a qualified opinion on government's Fiscal 2018 Public Accounts, the Auditor General noted that the government, when consolidating BC Hydro, did not meet accepted accounting standards for rate-regulated accounting because government direction has largely pre-determined BC Hydro's allowable costs, net income, rate increases and regulatory accounts, leading to rate increases that have not been designed to fully recover the cost of service.

In response to the Auditor General's qualification of the government's Fiscal 2017 Public Accounts, government made a $950 million summary-level adjustment in its financial statements in August 2018. The Auditor General's opinion recognized government's negative adjustment of $950 million and noted that government's Crown corporation earnings and year-end surplus would have been $4.505 billion lower if government had made a full negative adjustment of $5.455 billion, representing the total balance of BC Hydro's regulatory accounts as of March 31, 2018. Though the Auditor General acknowledged the adjustment and its purpose, she noted that there was more work to be done to restore the BCUC's independent oversight of BC Hydro and to avoid future qualifications.

3. Approach, Scope & Governance of Phase 1

In the first phase of the Review, an Advisory Group consisting of staff from the Ministry of Energy, Mines and Petroleum Resources, the Ministry of Finance, and BC Hydro reviewed issues and opportunities that were raised by staff working groups. The Advisory Group was co-chaired by the Assistant Deputy Minister, Electricity and Alternative Energy Division of the Ministry of Energy, Mines and Petroleum Resources and the Chief Accounting Officer of BC Hydro.

The Review was conducted internally to leverage the knowledge of staff in both Ministries and at BC Hydro, especially regarding the regulatory system in B.C. and BC Hydro's business.

The Advisory Group reported monthly to the Steering Committee, which provided feedback and advice on recommendations to responsible Ministers. The Steering Committee was comprised of:

- Deputy Minister, Ministry of Energy, Mines and Petroleum Resources
- Deputy Minister, Ministry of Finance
- President and Chief Operating Officer, BC Hydro
- Executive Chair, BC Hydro
- Executive Vice-President, Finance, Technology, Supply Chain & Chief Financial Officer, BC Hydro[4]

The Terms of Reference for Phase 1 of the Review are included as Appendix A.

4 This member joined the Steering Committee in August 2018.

4. Phase 1 Outcomes

Decisions resulting from Phase 1 of the Review focus on ensuring sound financial and regulatory oversight of BC Hydro and measures to keep rates affordable.

4.1 Ensuring Sound Financial and Regulatory Oversight of BC Hydro

To help ensure sound financial and regulatory oversight of BC Hydro, the government has made changes to the accounting standards BC Hydro must follow and is taking steps to enhance the BCUC's oversight of BC Hydro. This is being done in a way that recognizes impacts to the government's overall Fiscal Plan, while advancing government's social, economic and environmental priorities. These changes also aim to address previous concerns that have been raised by the Auditor General and transition toward increased independent regulatory oversight.

4.1.1 Write-off of the Rate Smoothing Regulatory Account

The balance of the Rate Smoothing Regulatory Account on BC Hydro's financial statements as of March 31, 2018 was $815 million. Based on the previous government's 10 Year Rates Plan, BC Hydro was scheduled to further defer about $325 million in revenues into the Rate Smoothing Regulatory Account in Fiscal 2019, which would have brought the total Rate Smoothing Regulatory Account balance to approximately $1.14 billion. The balance in the account was to be recovered from ratepayers by the end of the plan in Fiscal 2024.

Rate smoothing can be an appropriate goal and an appropriate reason to have a regulatory account, but in this case, the BCUC was directed by government to allow the account without the ability to provide appropriate review and oversight.

As an outcome of the review, government has accepted the recommendation that BC Hydro cease using the Rate Smoothing Regulatory account and write off the entire balance in Fiscal 2019, which will significantly reduce BC Hydro's regulatory account balances. This means that the balance in the account will not be recovered from ratepayers. BC Hydro will request closure of the account in its Fiscal 2020 to Fiscal 2021 Revenue Requirements Application, for be filed with the BCUC in February 2019.

As the cost of the write-off will be borne by BC Hydro and the government, there will be an approximate $190 million negative net impact to the Province's Fiscal Plan in Fiscal 2019. This figure represents the amount over and above the $950 million summary-level adjustment the government made to its Fiscal 2018 financial statements. The impact on BC Hydro's financial statements is an expected net loss of approximately $425 million for Fiscal 2019. Ongoing debt servicing costs (estimated at $45 million annually) related to the Rate Smoothing Regulatory Account will continue to be recovered from ratepayers.

The table below summarizes these changes and other expected reductions in Fiscal 2019 that are further described in section 4.1.3 as a result of other forecast changes (e.g., positive trading results and the continued collection of most regulatory accounts in rates).

Table 3: Total BC Hydro Regulatory Account Balance

Total BC Hydro Regulatory Account Balance ($ billions)	Province of BC Public Accounts	BC Hydro Financial Statements
Ending Balance Fiscal 2018	$4.505[A]	$5.455[A]
Rate Smoothing Write-off	-0.186[A]	-1.136[A, B]
Other Forecast Changes in Fiscal 2019	-0.696	-0.696
Forecast Ending Balance Fiscal 2019	$3.623	$3.623

A *There are differences between the Public Accounts and BC Hydro's financial statements because the government already made a $950M summary-level adjustment to its financial statements at the end of Fiscal 2018 to reduce BC Hydro's net regulatory asset balance.*

B *BC Hydro has written off the balance of the Rate Smoothing Regulatory Account in its third quarter financial statements, for the period ending December 31, 2018. The balance at the time was $1.04 billion. The remaining amounts that would have been deferred to the account for the remainder of the fiscal year would have brought the total to $1.136 billion. These remaining amounts will impact BC Hydro's net income instead of being deferred and hence the total write-off impact is $1.136 billion in Fiscal 2019.*

4.1.2 Changes in Accounting Rules

The accounting rules that BC Hydro was required to follow under the *Budget Transparency and Accountability Act* included an exemption from the requirement that rates be set by an independent, third party regulator. The Auditor General has been critical of this exemption, which is unique to BC Hydro, and believes it means the rules BC Hydro was required to follow were not aligned with Generally Accepted Accounting Principles.

As an outcome of the Review, government has removed this exemption and the effect is that BC Hydro will adopt International Financial Reporting Standards (IFRS), without exception, as recommended by the Auditor General. This change is effective for BC Hydro's year-end financial statements for Fiscal 2019. IFRS rules permit the use of rate-regulated accounting, which is the practice of using regulatory accounts.

4.1.3 Enhanced BCUC Oversight of BC Hydro

The government is restoring the BCUC's authority to oversee key aspects of BC Hydro's business, including rate-setting and regulatory accounts, on a go-forward basis as discussed in the sections below.

The government has repealed Direction No. 7 under the *Utilities Commission Act*, which:

- implemented the previous government's 2013 10 Year Rates Plan by establishing set rate increases, rate caps or targets;
- required the BCUC to set the Deferral Account Rate Rider at 5% indefinitely;
- set BC Hydro's allowed annual net income for rate-setting purposes; and
- required the BCUC to approve creation of the Rate Smoothing Regulatory Account and the deferral of specified revenues into it.

Regulatory changes have been or are being made to implement most decision outcomes of Phase 1 of the Review. Legislation required to further implement Phase 1 decision outcomes is expected to be introduced in the Spring 2019 Legislative Session.

Regulatory Accounts

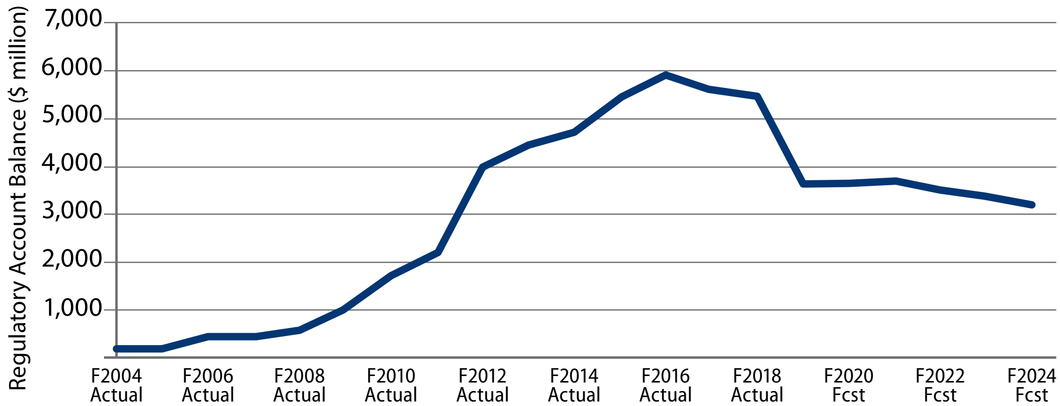
Regulatory accounts are commonly used by electric utilities in North America, are allowed under IFRS accounting rules and can be a useful tool with appropriate regulatory oversight. BC Hydro currently has 29 regulatory accounts, including the Rate Smoothing Regulatory Account. Over the last two years, BC Hydro's regulatory account balances have decreased, and BC Hydro is forecasting another decrease in Fiscal 2019 as a result of positive trading results and the continued collection of most accounts in rates.

Considering the write-off of the Rate Smoothing Regulatory Account, BC Hydro expects that the total regulatory account balance at the end of Fiscal 2019 will be $3.6 billion (as shown in Table 3), which is approximately 40% lower than the peak of nearly $6 billion at the end of Fiscal 2016 . In addition to the write-off of the Rate Smoothing Regulatory Account, BC Hydro forecasts a decrease in other accounts of approximately $700 million in Fiscal 2019 alone, due to positive operating results, positive results for Powerex (its marketing subsidiary) and a change related to accounting standards.

After the write-off of the Rate Smoothing Regulatory Account, BC Hydro has regulatory mechanisms in place to recover the balances of 25 of its 28 regulatory accounts over various periods of time, which represents approximately 86% of the net regulatory account balance forecast ending Fiscal 2019 net regulatory account balance.

Figure 2 shows BC Hydro's actual and forecast total year-end regulatory account balances from Fiscal 2004 through Fiscal 2024. This includes the impact of writing off the balance in the Rate Smoothing Regulatory Account in Fiscal 2019.

Figure 2: BC Hydro's Total Regulatory Account Balances (Actual and Forecast) for Fiscal 2004 to Fiscal 2024



Note: Fiscal 2019 – Fiscal 2024 forecast per Fiscal 2019 Quarter 3 Forecast

Figure 2 shows that BC Hydro's forecast total regulatory account balance of $3.2 billion at the end of Fiscal 2024 is over 45% lower than the peak in Fiscal 2016. Approximately 98% of the forecast balance at the end of Fiscal 2024 is related to balances in accounts that are long-term in nature (for example, accounts that provide longer-term benefits to customers such as the Demand-Side Management and Site C Regulatory Accounts) and that are thus collected from ratepayers over longer periods.

Previous government directions directed the establishment of some of the accounts, directed the deferral of certain costs into those accounts and directed the amortization period (recovery from ratepayers) of some of the accounts.

As a result of Phase 1 of the Review, the BCUC will be able to review the scope and amortization periods for all of BC Hydro's regulatory accounts on a go-forward basis. Select accounts will continue to be subject to government direction, as they directly relate to specific past and currently-confirmed government policy decisions. These accounts include the Mining Customer Payment Plan Regulatory Account and certain costs related to the Demand-Side Management Regulatory Account.

As a result of the Review, government is also directing the BCUC to allow BC Hydro to recover the March 31, 2019 balances of all of its regulatory accounts in rates over time, with the exception of the Rate Smoothing Regulatory Account. The write-off of this account will further reduce BC Hydro's total overall forecast regulatory account balance as shown in Figure 2. This helps ensure that BC Hydro is able to recover the costs it has incurred as a result of past policy decisions. The government has made the regulatory changes necessary to implement these Review outcomes.

Deferral Account Rate Rider (DARR)

The Deferral Account Rate Rider (DARR) is a surcharge (currently 5%) that applies to all charges on customer bills, excluding taxes and levies. Funds collected under the DARR were intended to be used to pay down BC Hydro's three energy deferral account balances (the

Heritage Deferral Account; the Non-Heritage Deferral Account; and the Trade Income Deferral Account). These energy deferral accounts capture variances between forecast conditions when rates are set (such as reservoir inflows, market prices and customer demand) and what actually occurs in a given year.

As part of the 2013 10 Year Rates Plan, government required the BCUC to set the DARR at 5% indefinitely, regardless of the balances in the applicable regulatory accounts. BC Hydro has used some of the over $200 million per year in revenue from the DARR to offset other costs. It was expected that the DARR would remain at 5% at least through the end of the 2013 10 Year Rates Plan in Fiscal 2024.

Following the Review, the government has repealed Direction No. 7 to the BCUC. Going forward, the BCUC will have the ability to determine how the DARR is set and applied. In its upcoming Revenue Requirements Application, BC Hydro will be proposing to lower the DARR from 5% to 0%, based on forecast March 31, 2019 balances in BC Hydro's three energy deferral account balances. This reduction in the DARR is reflected in the table of bill impacts shown on page 34.

Integrated Resource Plan (IRP)

The Integrated Resource Plan (IRP) contains BC Hydro's 20-year projection of electricity demand in B.C. and its comprehensive plan to meet this demand, including through existing facilities, demand-side management (conservation and efficiency efforts), construction or extension of new facilities and new or renewed Electricity Purchase Agreements with independent power producers.

The *Clean Energy Act* required BC Hydro to submit its IRP to government for approval by November 2018. The legislation has significantly limited the BCUC's oversight of BC Hydro's long-term plan, which hampers the BCUC's decision making on various BC Hydro activities, including its applications on capital projects.

The government has amended the deadline for the submission of the next Integrated Resource Plan to February 2021 to allow time for the IRP to be informed by the second phase of the Review and the actions required to support the CleanBC plan.

The government intends to introduce legislation in Spring 2019 to restore the BCUC's oversight authority to review and approve BC Hydro's IRP. Government's policy objectives will continue to inform BC Hydro's development of the IRP under this process moving forward.

Dividends and Net Income

BC Hydro's dividend payments provide cash flow to the government and allow the government to reduce its borrowing requirements. Dividend payments do not directly impact the surplus/deficit in government's Fiscal Plan. In accordance with government regulations, BC Hydro's dividends payable to government are reduced by $100 million per year as compared to the dividend paid in the preceding year. This will continue until the dividend payable reaches zero in Fiscal 2020, at which point dividends would not be payable again until BC Hydro reaches a debt to equity ratio of 60:40 under current policy.

A debt to equity ratio of 60:40 is comparable to other utilities in Canada. The regulation regarding dividends was put in place to support BC Hydro in paying down its debt, to improve its debt to equity ratio and to help BC Hydro finance its upcoming capital investment needs. As a result, BC Hydro's Fiscal 2019 dividend will be $59 million and $0 for the foreseeable future thereafter.

Net income is the return that BC Hydro is allowed to earn in a given fiscal year. BC Hydro's net income forms part of the government's revenue for government budget purposes. Net income is also a key source of cash resources for BC Hydro that helps finance capital and reduce borrowing.

Direction No. 7 to the BCUC set BC Hydro's allowed net income for rate setting purposes at a fixed amount of $712 million for Fiscal 2019 and all subsequent fiscal years. Setting allowed net income in regulation provides certainty for BC Hydro and government in developing the overall Provincial Budget and Fiscal Plan. However, this means that allowed net income is established by government rather than by the BCUC and may not reflect an appropriate return for BC Hydro's shareholder. This practice has been criticized by the Auditor General.

As an outcome of Phase 1 of the Review, the government will re-empower the BCUC to set BC Hydro's allowed net income, following a two-year transition period for Fiscal 2020 and Fiscal 2021 where BC Hydro's allowed net income of $712 million will remain in place. This transition period will allow time for the BCUC to review BC Hydro's next Revenue Requirements Application and to undertake a separate process to determine an appropriate rate of return prior to resuming the regulation of BC Hydro's allowed net income in Fiscal 2022. Government may provide policy guidance to the BCUC and/or participate in regulatory proceedings to inform this process.

Address Government Priorities

The BCUC undertakes its role so that it applies sound utility regulatory principles to its decisions, with a focus on the impact on BC Hydro's ratepayers. That means that the BCUC is not required to implement policy that does not stand on its own from a regulatory perspective. Finding #1 of the 2015 independent review of the BCUC, conducted by an expert Task Force in consultation with the BCUC and stakeholders, indicated that:

> It is the provincial government's prerogative to set provincial energy policy, to define the Commission's mandate, and to direct the Commission on specific matters…
> In the future, government should delineate policies to the Commission clearly, and in advance of Commission processes, then leave the Commission to act independently within its mandate. Where the government does wish to retain the final decision in a matter to itself, and there are complex issues within the expertise of the Commission that should be reviewed, the government should consider referring the matter to the Commission for a recommendation only.

As result of Phase 1 of the Review, if there is a priority policy item for the government to advance, government will introduce legislation or provide direction that supports it. With this approach, the BCUC will be empowered to make decisions with respect to BC Hydro in a mostly unencumbered way, in alignment with the laws and regulatory principles that are applicable to it. Where required, government may also provide policy guidance by participating in proceedings (through a letter of comment or as an intervener) or by issuing directions to the BCUC to help ensure that government's priorities are appropriately considered as part of the BCUC's decision-making processes.

There are also certain directions to the BCUC that will continue to ensure that rates remain affordable and to support the continued implementation of government policy objectives. Government will continue to direct the BCUC:

- not to calculate "expenditures for export", nor include these costs from recovery in BC Hydro's rates;
- to retain a prohibition on "retail access," unless requested by a utility;
- not to rebalance BC Hydro's rates, unless requested by a utility; and
- not to regulate Powerex.

Expenditures for Export

Among other things, the *Clean Energy Act* was intended to position B.C. to pursue opportunities for electricity export, given the anticipated high market electricity prices for clean electricity at the time. The *Clean Energy Act* set out the concept of "expenditures for export," which is unique to BC and not applicable in other Canadian jurisdictions.

To ensure the costs of pursuing such opportunities were not passed along to ratepayers, the BCUC was obliged to ensure that BC Hydro's rates would not allow BC Hydro to recover "expenditures for export" from ratepayers. Under Direction No. 7, government directed the BCUC to refrain from considering these expenditures.

In recent years, shale gas development and subsidization of renewable energy development in the United States have led to low market prices for electricity. As a result, the pursuit of large scale electricity export opportunities has lost its economic rationale and, therefore, the expenditure for export provisions are no longer required.

Government has repealed Direction No. 7 and intends to introduce legislation in Spring 2019 to amend the *Clean Energy Act* to repeal the concept of expenditures for export. In the interim, the government will continue to direct the BCUC to refrain from considering expenditures for export when determining BC Hydro's rates.

Retail Access

Retail access is the ability for customers to secure electricity from the market via a third-party provider rather than the local utility such as BC Hydro. Interest in retail access fluctuates with electricity market prices, with customers interested when open market prices are lower than local supply and not interested when market prices are higher than local supply. In a surplus situation, allowing retail access increases the amount of surplus energy that BC Hydro must export, possibly at a loss, increasing costs borne by ratepayers who do not or cannot opt for retail access.

To minimize potential costs to ratepayers, retail access for BC Hydro customers is currently prohibited, and, as a result of the Review, this prohibition will continue. The government has extended the prohibition of retail access through regulation. The prohibition will continue until or unless a public utility, in this case BC Hydro, requests otherwise.

Prohibiting retail access is not unique to BC Hydro. The prohibition of retail access can protect electricity consumers by providing price stability and reducing the duplication of costs that must be passed on consumers (for example, duplicative systems of billing, customer service etc.). In Canada, it is generally true that regions with low and stable electricity prices like Quebec, Manitoba and British Columbia do not have full retail access. In Canada, only Ontario and Alberta have full retail access for electricity rates. In these two provinces, customers can choose to have access to wholesale market prices for energy. The remaining provinces have vertically integrated utilities where customers pay regulated electricity prices.

There is evidence from the U.S. that the average retail price of electricity tends to be more volatile in regions with full retail markets.[5]

Rate Rebalancing

In addition to setting overall rates for public utilities, the BCUC may also determine how these overall costs are to be allocated between the utility's various customer classes (i.e. residential, commercial, industrial). In doing so, the BCUC strives to align, as closely as possible, the revenues received from each class with the cost the utility incurs to serve each class. If the current revenue-to-cost ratios for one or more customer classes fall above or below this range (generally +/- 5% from 100% cost recovery), the BCUC may decide to rebalance rates by increasing or decreasing rates for each customer class by a different amount until an appropriate balance is achieved.

Currently, BC Hydro's residential customers are covering 90.8% of the cost of serving them. Commercial customers are paying as much as 123.5% of their cost of service and industrial customers are just over or under 100%.[6] If the BCUC were to rebalance rates to address this imbalance, annual rate increases for residential customers for Fiscal 2020 could be up to 2.2% higher[7] than currently forecast rate increases. At the same time, rates for commercial customers would decrease and industrial rates would remain approximately the same.

The BCUC has been prohibited from rate rebalancing for the purpose of changing the revenue-to-cost ratios between BC Hydro's customer classes for each of Fiscal 2017, Fiscal 2018 and Fiscal 2019. As a result of the Review, to minimize rate increases for BC Hydro's approximately 1.8 million residential accounts, the government will continue to prohibit the BCUC from rebalancing BC Hydro's rates for Fiscal 2020 and Fiscal 2021 through regulation, since a near-

5 *https://www.nrel.gov/docs/fy18osti/68993.pdf*

6 As reported in BC Hydro's fully allocated cost of service (FACOS) report, filed with the BCUC in March 2018.

7 Equivalent to a 2% increase in the cost of service ratio for BC Hydro's residential customers for Fiscal 2020.

term rebalancing of BC Hydro's rates could conflict with government's commitment to keep life affordable for British Columbians. The decision to prohibit rate rebalancing is a matter of public policy.

The government intends to introduce legislation in Spring 2019 to amend the *Utilities Commission Act* to permanently prevent the BCUC from rebalancing rates unless otherwise requested to do so by a public utility.

Rate rebalancing is also prohibited through legislation in Quebec.[8]

Powerex Corp.

Powerex Corp. is a BC Hydro subsidiary and a key participant in energy markets across North America, buying and selling wholesale power, renewable and low-carbon energy and products, natural gas, ancillary services and financial energy products. Powerex's trade activities earn income which is beneficial to its shareholder (BC Hydro) and therefore to BC Hydro's ratepayers.

Powerex operates in competitive wholesale energy markets outside of B.C., where it is subject to regulation by the Federal Energy Regulatory Commission and other regulatory bodies for its wholesale activities. Falling under BCUC oversight would hamper Powerex's ability to compete and earn income in fast-moving and rapidly evolving competitive markets. For this reason, government will continue to restrict the BCUC from regulating the activities of Powerex as an outcome of the Review. It is worth noting that ICBC's optional insurance products, which also operate in a competitive environment, are not regulated by the BCUC.

4.2 Keeping Electricity Rates Affordable

For each fiscal year, BC Hydro forecasts the revenue that it needs to collect from its customers in order to cover its costs. This is known as its "revenue requirements."

BC Hydro has aging assets and an increasingly complex operating environment. It has limited ability to reduce its revenue requirements, because many of its costs are the result of past decisions, projects or contracts and are fixed. Approximately one-third of BC Hydro's Fiscal 2019 revenue requirements[9] are finance charges related to debt already incurred by BC Hydro, or capital amortization amounts resulting from previously incurred capital expenditures, while water rentals and cost of energy, including energy procurement from Independent Power Producers, make up just over one-third.

Even though BC Hydro's finance charges relate to debt that has already been incurred, BC Hydro has taken steps to minimize these costs. Through its debt management strategy, BC Hydro has used hedging to lock in low interest rates to the benefit of ratepayers and will continue to do so. This strategy, coupled with BC Hydro's strong credit rating (backed by the Province), will continue to benefit ratepayers.

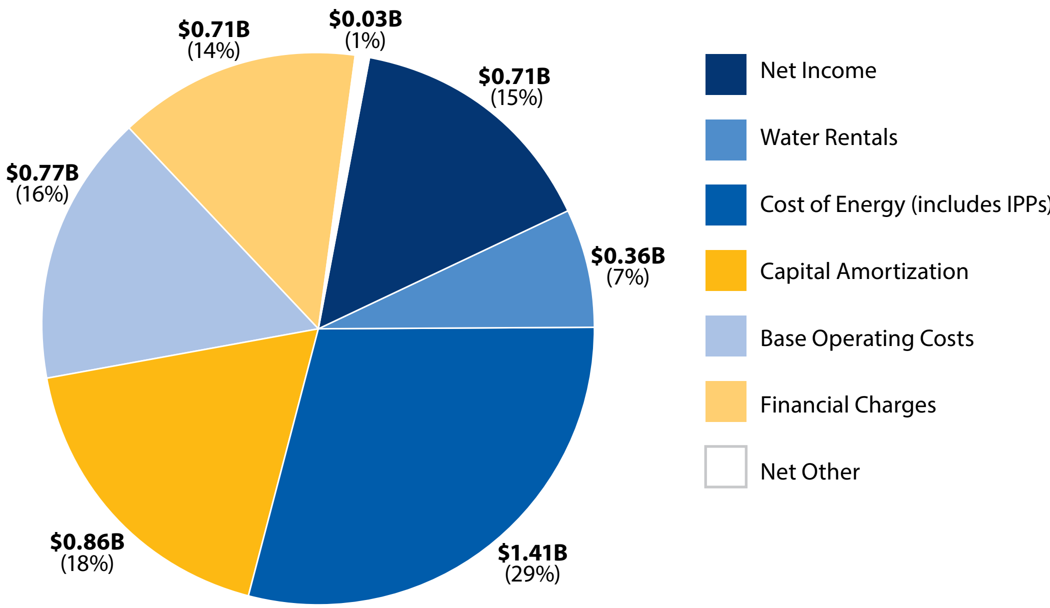
9 Before transfers to the Rate Smoothing Regulatory Account

Figure 3 below shows BC Hydro's forecast revenue requirements for Fiscal 2019.

Figure 3: BC Hydro's Total Revenue Requirement for Fiscal 2019



Despite the example of debt outlined above, because many costs are already incurred or committed, the first phase of the Review focused on BC Hydro's controllable costs drivers, revenue opportunities, and activities to keep rates affordable and support BC Hydro's continued financial sustainability. The Review identified the following strategies to enhance BC Hydro's long-term financial position:

- Write-off of the Rate Smoothing Regulatory Account
- Reduce future energy costs of purchases from Independent Power Producers
- Reduce planned capital expenditures and additions
- Tightly manage controllable operating costs
- Increase revenues

4.2.1 Write-off of the Rate Smoothing Regulatory Account

As discussed above, government has accepted the recommendation under the review that BC Hydro cease using the Rate Smoothing Regulatory Account and write off the entire balance in the account in Fiscal 2019. This means that the balance in the account will not be recovered from ratepayers. This write-off will reduce BC Hydro's total overall forecast regulatory account balance as at March 31, 2019 by roughly 24%, from $4.7 billion to $3.6 billion.

Lowering BC Hydro's overall regulatory account balance also means lowering the amount that would be otherwise recovered from ratepayers, thus reducing rate pressures over the next five years. BC Hydro continues to collect almost all of its remaining regulatory account balances in rates already and will continue to do so over recovery periods determined by the BCUC.

Through government direction, the ongoing debt servicing costs related to the Rate Smoothing Regulatory Account (estimated at $45 million annually) will continue to be recovered from ratepayers.

BC Hydro's debt has been rising as a result of its significant Capital Plan expenditures (further discussed in Section 4.2.3). In addition to affecting ongoing debt servicing costs, the write-off of the Rate Smoothing Regulatory Account reduces BC Hydro's accumulated equity balance. The impact on BC Hydro's debt:equity ratio, a key ratio in assessing BC Hydro's financial position, will exceed 80:20 at the end of Fiscal 2019. A debt:equity ratio at or below 80:20 is desirable and, with no dividends expected to be payable for the foreseeable future, BC Hydro forecasts that its debt:equity ratio will return to 80:20 by the end of Fiscal 2020), and that the ratio will continue to decline in the years that follow. BC Hydro forecasts a ratio of 76:24 at the end of Fiscal 2024.

4.2.2 Reduce Future Energy Costs from Independent Power Producers

BC Hydro has been purchasing electricity from Independent Power Producers since the 1980s. The 2002 Energy Plan relied on the private sector for new power generation and prohibited BC Hydro from developing new generation resources other than Site C and additions to certain heritage hydroelectric facilities. As a result, BC Hydro began procuring significant amounts of energy from Independent Power Producers under long-term Electricity Purchase Agreements, typically with contract terms of 20-40 years. BC Hydro currently holds over 130 contracts with Independent Power Producers, which represent over $51 billion in future financial commitments as of April 2018. Additional context can be found in the separate review by independent consultant Ken Davidson.

The cost of energy procured from Independent Power Producers is now one of BC Hydro's biggest cost drivers and these costs will be recovered from ratepayers. Though BC Hydro has not conducted competitive calls for power since 2011, it is projected to have an energy surplus into the 2030s.

The CleanBC plan was released by government in December 2018. It outlines government's plan to reach 75% of its 2030 climate targets through the reduction of greenhouse gas emissions in transportation, buildings and industry. By 2030, CleanBC could require incremental energy of approximately 4,000 gigawatt-hours over and above currently projected demand growth to electrify key segments of the economy. This is equivalent to increasing BC Hydro's system-wide capacity by about 8%. While it is expected that this increase in electricity demand can be mostly met with existing and planned resources, BC Hydro may require additional volumes of new clean electricity to B.C. after 2030 to achieve the remaining 25% of emissions reductions needed to meet government's climate targets for 2030 and beyond. As a result, achieving the government's climate targets could ultimately require additional capital projects.

In 2019, the second phase of the Review is expected to look at changing energy markets, new utility models, emerging technologies and strategies to deliver on CleanBC's longer-term electrification goals.

Although BC Hydro has implemented strategies to contain cost increases where possible, total annual energy acquisition costs are forecast to increase from $1.4 billion in Fiscal 2018 to $1.7 billion by Fiscal 2024. Over the remaining life of the portfolio of existing Electricity Purchase Agreements, $51 billion has been committed, which will be recovered from BC Hydro's ratepayers as energy is received over time.

The cost of energy purchased by BC Hydro from Independent Power Producers has increased dramatically over time. Projected increases in costs between Fiscal 2018 and Fiscal 2024 relate to a number of factors, such as:

- A growing number of projects with existing Electricity Purchase Agreements that have recently come into service (as of October 2018, there were 124 projects in operations) and the nine additional projects with agreements that are currently in development and not yet in service.
- Price escalation, as provided for under existing Electricity Purchase Agreements.
- New Electricity Purchase Agreements entered into under the Standing Offer Program or through negotiations related to contractual commitments to First Nations.

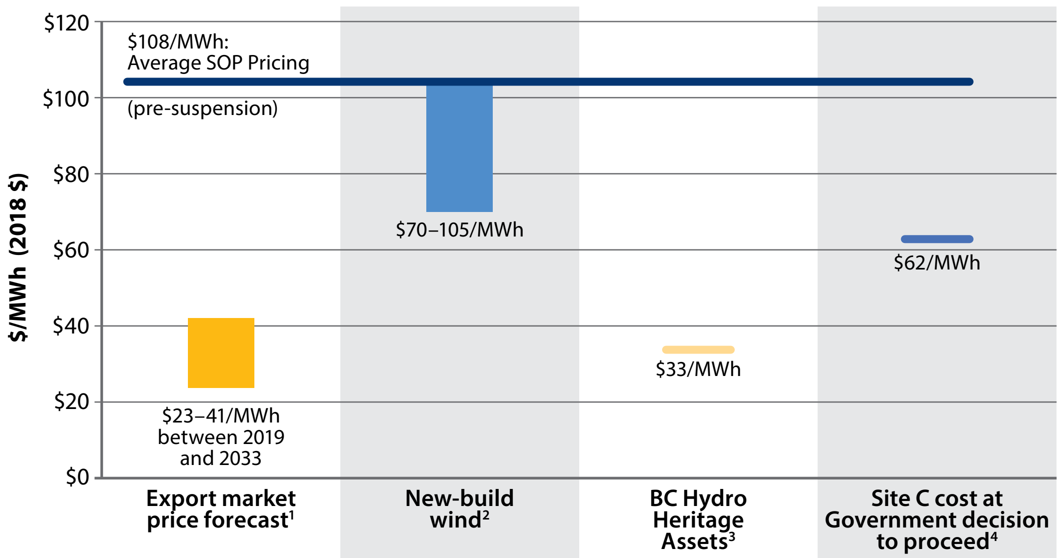
BC Hydro is continuing to manage its portfolio of Electricity Purchase Agreements to ensure that purchases of energy are administered within the terms of the agreements. BC Hydro will continue to exercise its contractual rights to control the costs of energy. However, there is limited flexibility to make significant reductions in energy procurement costs due to the structure of the existing Electricity Purchase Agreements. Existing Electricity Purchase Agreements with Independent Power Producers will not be cancelled as a direct result of Phase 1 of the Review. The primary opportunities for managing costs moving forward relate to expiring biomass agreements and the Standing Offer Program.

The first phase of the Review assessed the current cost to ratepayers of energy procurement and how those costs could be reduced in the future, particularly in view of electricity demand being lower than previously projected. Since the ability to manage cost of energy is largely limited to potential biomass Electricity Purchase Agreement renewals and the Standing Offer Program, actions flowing from the Review focused on these programs.

Figure 4 below shows that current prices for energy from the Standing Offer Program are significantly higher than the cost of generation from Site C and BC Hydro's heritage assets, as well as projected domestic and export market price forecasts.

- Standing Offer Program prices currently average $108 per MWh, which is over three times the cost of energy from BC Hydro heritage assets and nearly 75% higher than that of Site C; and
- Standing Offer Program prices are up to nearly five times higher than export market price forecasts.

Figure 4: Comparison of the Standing Offer Program pricing of an average of $108/MWh to Benchmark Energy Values



1 Source: as of Fall 2017

2 Source: Waneta Expansion regulatory filings (mid 2018)

3 Source: Fiscal Year 2018 Reporting

4 Source: as of December 2017

Please note that the characteristics of the energy products compared vary by product, and as such, Figure 4 is provided for illustrative purposes only in order to show the difference in prices. The illustrative prices also change over time due to market conditions and other factors. For example, prices for new-build wind have been changing and depend upon location, terrain and the prices of turbines and other technologies. Phase 2 of the Review will look at recent developments, trends and possible future scenarios in North American energy markets.

Background on Biomass Electricity Purchase Agreements

BC Hydro has contracted with biomass energy generators, mostly in the pulp and paper sector, since the 1980s. By the late-2000s, the number of biomass Electricity Purchase Agreements grew substantially through a number of procurement processes flowing from the 2007 Energy Plan and 2008 Bioenergy Strategy. Seven of these biomass Electricity Purchase Agreements are due to expire by the end of Fiscal 2022.

To generate electricity for delivery to BC Hydro, these Independent Power Producers burn wood waste generated by the forest sector, primarily from sawmills. This provides benefits to both the biomass generating facilities and the sawmills, as there are limited economically viable alternative uses for this wood waste at this time. In the absence of Electricity Purchase Agreements, some of these biomass generating facilities might no longer operate, which means that the wood waste may then need to be placed in landfills or burned in slash piles, leading to higher emissions of methane and/or particulates.

The pulp and paper sector in British Columbia operates in competitive, evolving global markets, with reduced domestic fibre supply and aging capital infrastructure. Biomass Electricity Purchase Agreements have been an important source of ancillary revenue for some of these companies. Eliminating or significantly scaling back biomass energy volumes and prices could have implications for jobs and the economy in forest-dependent communities, in addition to the environmental implications outlined above.

Five of the seven holders of expiring biomass Electricity Purchase Agreements are also BC Hydro customers. These Electricity Purchase Agreements are not only tied to the viability of the companies, but also to revenues to BC Hydro. The production of biomass energy associated with these Electricity Purchase Agreements advances certain environmental and socio-economic priorities of the government in relation to the forest sector, including maintaining regional fibre balance among various forest sector users and avoiding burning or landfilling of waste biomass.

Approach to Biomass Energy

BC Hydro, in consultation with government, has been working on an approach to biomass energy to determine the best course of action to deal with those biomass generating facilities with Electricity Purchase Agreements due to expire within the next three years. This approach considers fuel supply availability, cost effectiveness, impacts on BC Hydro ratepayers and other government priorities. The end result will be the imminent launch of the Biomass Energy Program.

In addition, the government will work with industry to develop a strategy to accelerate the development and implementation of renewable natural gas and bio-crude production within the forest sector to enhance its longer-term competitiveness and to support the CleanBC plan.

Biomass Energy Program

BC Hydro's Biomass Energy Program is a cost and volume limited, transitional measure intended to allow time for the forest sector to develop and implement new product lines consistent with the sector's industry diversification and competitiveness goals. It also allows for the continued operation of those biomass generating facilities with expiring Electricity Purchase Agreements over the next three years, providing potential optionality for BC Hydro should it require additional supply resources in the future.

Under the Biomass Energy Program, BC Hydro will continue to acquire biomass energy from facilities that have existing Electricity Purchase Agreements due to expire prior to March 31, 2022. BC Hydro will acquire up to 80% of the aggregate volume that these biomass generators have historically delivered to BC Hydro. BC Hydro will procure this energy through a combination of load offset and/or energy purchases. Load offset will be given priority over energy purchases.

Load offset is energy generated by a BC Hydro customer at its customer site to offset the energy the customer currently purchases from BC Hydro to serve its own needs. Eligible facilities will be offered an opportunity to offset load and/or negotiate energy purchase contracts depending on the volume of generation at their site.

BC Hydro could also purchase energy from companies that both BC Hydro customers and non-BC Hydro customers. These energy purchases offer additional revenue opportunities to those biomass energy generators who produce electricity that is surplus to their own needs at their customer site, and to those biomass energy generators that are not eligible for load offset because they are not BC Hydro customers.

To manage impacts on BC Hydro ratepayers, the prices and volumes of the biomass energy to be acquired by BC Hydro as part of this program will be lower relative to current contracts. The costs for this program must be managed within BC Hydro's rates forecast, and caps have been established for pricing, volume and overall costs of the program.

The government intends to provide a direction to the BCUC with respect to the approval of the program documentation and require the costs associated with the Biomass Energy Program to be recovered from ratepayers.

Renewable Fuels Acceleration Strategy

As a separate initiative, the government will work with industry to transition over time to other uses of waste residuals, including the production of higher value renewable energy products like Renewable Natural Gas (RNG) and bio-crude, which are considered to be carbon neutral as they capture methane that would otherwise escape into the atmosphere through the breakdown of organic matter.

The government has set targets to promote higher production levels of these low carbon fuel products under the CleanBC plan, one of a number of initiatives that will substantially reduce greenhouse gas emissions in the transportation, buildings and industrial sectors. Under the CleanBC plan, government has set targets for 15% of British Columbia's domestic natural gas supply to come from RNG and hydrogen, and 650 million litres of bio-crude to be produced from B.C. feedstocks by 2030. The Ministries of Energy, Mines and Petroleum Resources and Forests, Lands, Natural Resource Operations and Rural Development will work with industry to develop a renewable fuels acceleration strategy to assist in this transition.

While a shift to focusing waste fibre to produce biofuels instead of electricity has potential, focused work is required to move from a concept to commercial implementation, and this shift could take a number of years. The government considers the Biomass Energy Program to be a temporary measure, to provide time for the industry to transition to alternate forms of energy that align with longer-term provincial climate objectives.

Background on the Standing Offer Program

The Standing Offer Program is a continuous-intake program for small, permit-ready projects with a capacity of no more than 15 MW. The Standing Offer Program was developed in response to the 2002 Energy Plan. Initially launched in April 2008, it has become a vehicle for small Independent Power Producers, communities, First Nations and others who may lack the capacity to participate in larger, competitive procurement processes. As BC Hydro has not conducted competitive calls for power since 2011, the Standing Offer Program has become the primary energy procurement offering available to any organization seeking to secure a long-term Electricity Purchase Agreement with BC Hydro.

The Standing Offer Program is structured to focus on small projects. BC Hydro offered a set energy price derived from the results of prior market-based BC Hydro calls for power and this set price escalates each year with inflation. Although the Standing Offer Program price has been escalating with inflation since 2011, the cost of renewable generation technologies, especially wind, has been decreasing.

Starting in 2016, BC Hydro, the Ministry of Energy, Mines and Petroleum Resources and Clean Energy BC (Independent Power Producers' industry association) collaboratively examined options for the future of the Standing Offer Program. This review was ultimately halted, in light of concerns about BC Hydro's energy surplus and the government's commitment to carry out the Review.

Under the Standing Offer Program, BC Hydro had been acquiring up to 150 GWh of new supply each year. In August 2017, BC Hydro stopped accepting new project applications as the volume for 2017, 2018 and 2019 was fully subscribed. In March 2018, BC Hydro announced that it would not issue any new Electricity Purchase Agreements pending the completion of the Review, with the exception of five specific projects that are part of Impact Benefit Agreements for First Nations with BC Hydro and/or mature projects that have significant First Nations involvement.

Indefinite Suspension of the Standing Offer Program

Currently, the *Clean Energy Act* requires BC Hydro to maintain the Standing Offer Program and provides the government with the authority to prescribe circumstances that would allow BC Hydro to no longer be required to maintain the program. As a result of the Review, the Standing Offer Program will be suspended indefinitely, based on the current Standing Offer Program contract commitments. No new Electricity Purchase Agreements, other than the five specific projects noted above, will be issued by BC Hydro. This will significantly reduce BC Hydro's future costs for energy, which benefits ratepayers.

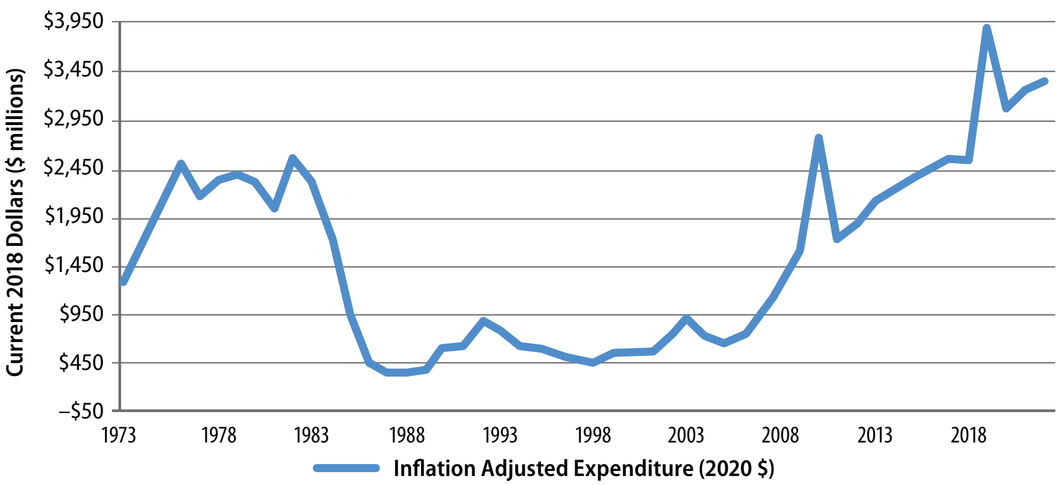
The government has issued a regulation under the *Clean Energy Act* that specifies that when the cumulative capacity of facilities with Standing Offer Program contracts exceeds 100 MW, BC Hydro is no longer obligated to maintain the Standing Offer Program. To date, BC Hydro has contracted with facilities with over 170 MW of capacity under the Standing Offer Program and so has exceeded that threshold. This means that existing Electricity Purchase Agreements remain valid, but BC Hydro will no longer be obligated to continue to maintain a Standing Offer Program, including offering any new Electricity Purchase Agreements.

Many Indigenous Nations have expressed interest in clean energy projects, which can bring economic benefits to their communities, stable sources of independent, long-term revenues to their governments and, for non-integrated areas, opportunities to displace diesel generation with clean electricity. The Ministry of Energy, Mines and Petroleum Resources will be engaging with Indigenous Nations to discuss the extent to which the indefinite suspension of the Standing Offer Program may affect the economic interests of individual Indigenous Nations. Further information about this engagement process is available at ***www.engage.gov.bc.ca/SOPengagement***

4.2.3 Reduce Planned Capital Expenditures and Additions

There are hundreds of BC Hydro capital projects currently underway that, together, make up one of the largest investments in electrical infrastructure in B.C.'s history. These investments maintain BC Hydro's system, much of which was built in the 1960s, 1970s and 1980s and is in need of upgrade and replacement to ensure ongoing safety and reliability for customers. BC Hydro's capital expenditures, starting in 1973 are shown in Figure 5 below.

Figure 5: BC Hydro Capital Expenditures through the years



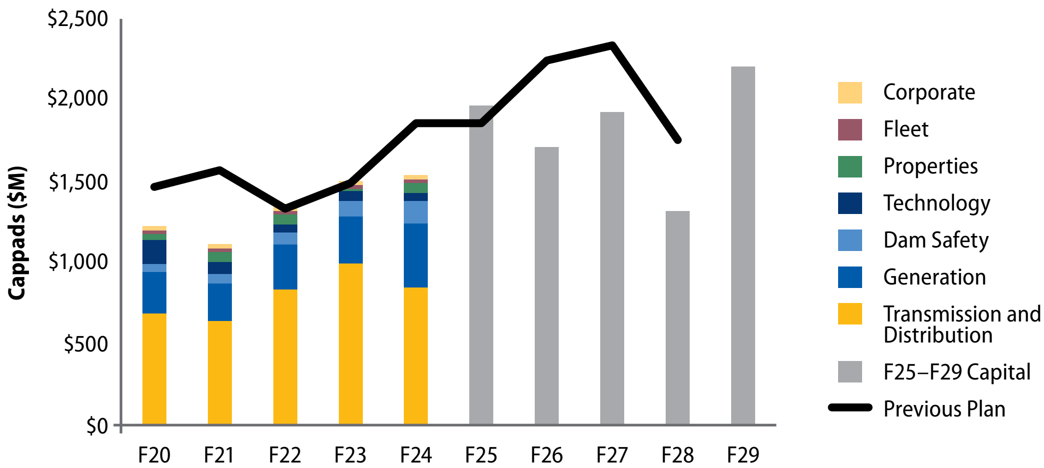
Investments also include projects for growth in the system as the provincial economy expands and the population grows. BC Hydro's 10-Year Capital Plan has been developed and is updated annually.

BC Hydro recovers the cost of its capital assets in rates over the useful life of the assets. Amortization of capital assets begins when the asset is put into service.

BC Hydro was planning capital additions totalling $18.5 billion between Fiscal 2020 and Fiscal 2029 under its 10-Year Capital Plan. BC Hydro undertook a review of the plan as part of the Review and will reduce these capital additions by $2.7 billion, from $18.5 billion to $15.8 billion over the 10-year period.

BC Hydro's Capital Plan includes five years of investment-level detail covering Fiscal 2020 through Fiscal 2024, and a high level projection for Fiscal 2025 to Fiscal 2029. The figure below compares the capital additions from the prior plan with the revised plan described above.

Figure 6: Comparison of Capital Additions in Current and Prior Capital Plans



Note: "Fleet" refers to BC Hydro's vehicle fleet

Of the $2.7 billion reduction in capital additions over the 10-year period, approximately:

- $1.6 billion results from a reduction of sustainment expenditures over the ten-year period, relative to previously planned amounts;
- $0.5 billion relates to the postponement of transmission and distribution projects that are no longer required on the same schedule due to changing load forecast projections; and
- $0.6 billion relates to a change in the need for a sixth generating unit at the Revelstoke generating facility, shifting the forecast in-service date of the project to 2030.

BC Hydro has carefully considered system impacts to ensure that risks to safety and reliability will be managed by targeting remaining investments in its most critical and/or highest risk assets. Investments needed to meet minimum legal, regulatory or tariff compliance requirements will not be reduced.

BC Hydro continues to refine the appropriate balance between asset life, system performance and affordability and believes that by appropriately timing expenditures we will provide more value to both current and future customers.

The 10-Year Capital Plan is informed by BC Hydro's load forecast which will be released in 2019 as part of the Revenue Requirements Application to be filed with the BCUC in February 2019.

The electrification required to meet the targets in the CleanBC plan will increase electricity demand. It is expected that this increase in electricity demand can be mostly met with existing and planned resources and will be further examined as part of Phase 2 of the Review. BC Hydro will consider the outcomes of the second phase of the Review in future annual capital plan updates.

The BCUC will review BC Hydro's capital projects going forward that require a Certificate of Public Convenience and Necessity or are filed under Section 44.2 of the *Utilities Commission*

Act. This excludes those projects that have already been provided with exemptions, or may be exempted in the future because they support certain policy objectives. The BCUC also has the opportunity to review all forecast capital expenditures and additions through BC Hydro's Revenue Requirements Applications.

The BCUC is currently reviewing its regulatory framework with respect how it provides oversight on BC Hydro's capital projects. BC Hydro is participating in this proceeding and a BCUC decision is expected in 2019.

As requested by the BCUC, BC Hydro will file a report regarding the potential applicability of performance-based regulation (PBR) for BC Hydro when it files its upcoming Revenue Requirements Application. Under the current cost of service regulatory framework, the BCUC seeks information to review costs for prudency. Under PBR, for certain costs (possibly including some capital and operating costs), base year costs are set and then adjusted via a formula in future years, including incentives for efficiencies. PBR is used to regulate various utilities in Canada, though there are limited instances in which it is used for Crown corporations. The BCUC will decide whether PBR is an appropriate approach for regulation of BC Hydro.

4.2.4 Tightly Manage Controllable Operating Costs

Over the five-year rates forecast period from Fiscal 2020 to Fiscal 2024, BC Hydro faces increases in projected incremental operating costs due to the Employer Health Tax, pension cost adjustments mandated by the BCUC, labour costs stemming from the upcoming collective bargaining mandate, storm restoration costs and anticipated increases in school property taxes. These incremental costs are partially offset by the elimination of Medical Service Plan premiums.

In addition to the sustained reductions to operating costs made from prior reviews (see section 2.1), BC Hydro will make reductions to other operating costs over the same period to help partially offset operating cost pressures that it is facing. Some of these reductions are a result of process improvements and lower spending on specific projects and initiatives, while others will come from labour utilization savings and further reductions are due to the impact of accounting treatment changes.

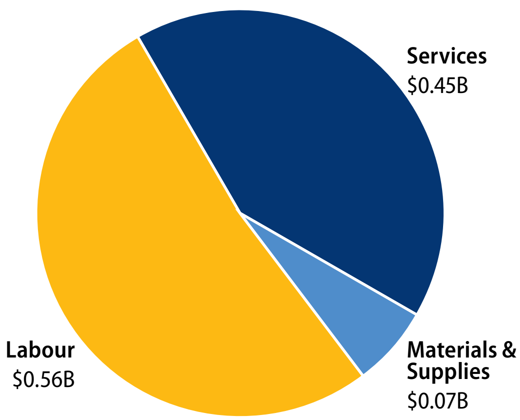
For example, process improvements such as the Enterprise Billing project achieve cost savings by reducing costs through paperless billing and lowering the volume of bill inquiries. BC Hydro will realize savings in future years from the Supply Chain Applications project that is underway and also from its decision to insource certain services that were previously provided by Accenture. BC Hydro has also achieved forecast savings through more efficient use of labour budgets, the elimination of a property lease and lower communications budgets.

BC Hydro's operating cost plan going forward balances affordability for ratepayers, while also making investments in its system.

BC Hydro expects to be able to limit its base operating cost increases below the projected rate of inflation over the five-year rates forecast period. These operating costs will be reviewed by the BCUC as part of the upcoming Revenue Requirements Application proceeding. A further breakdown of BC Hydro's operating costs and how these costs are trending is provided below.

Figure 7: Breakdown of Base Operating Costs in Fiscal 2019 Plan

F2019 Plan Base Operating Cost = $0.77B



Total F2019 Plan Base Operating Costs:

Labour, Services, Materials & Supplies	$1.08B
Capital Overhead	(0.29)B
Recoveries	(0.07)B
Total Plan Operating Costs	**$0.77B**

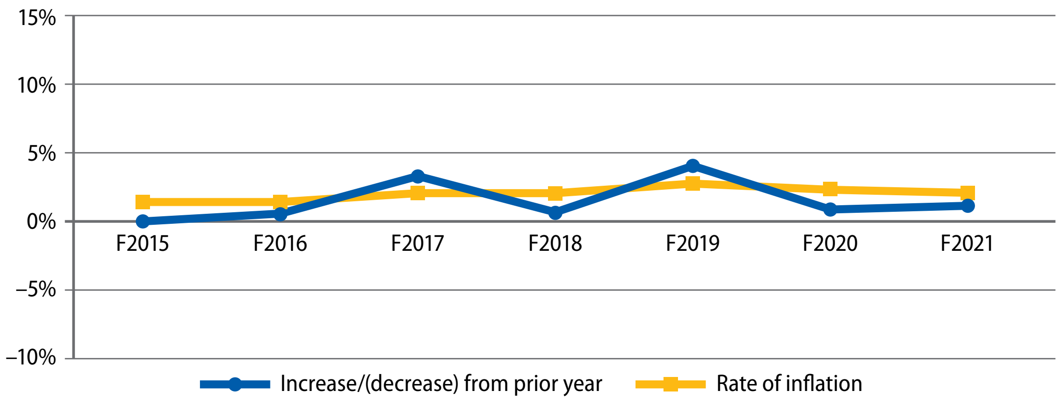
- ***Labour*** *includes personnel costs including salary, wages and benefits for BC Hydro internal labour workforce.*
- ***Services*** *includes costs such as contractor and consulting services, power purchase arrangements treated as leases, insurance, dues and fees, communication and utilities, building and property rent.*
- ***Materials and Supplies*** *include costs such as materials (e.g., connectors, brackets, splitters, batteries, tubing), computer software, office supplies and miscellaneous supplies.*

Within Public Sector Employers Council (PSEC) rules, BC Hydro seeks to provide inflationary wage/salary increases to its staff. When purchasing services and materials from third parties, these costs are also subject to inflation.

Base Operating Costs Trend

Despite inflationary pressures noted above, Figure 8 shows that BC Hydro has been able to limit increases in its base operating costs below inflation in recent years as a result of prudent management and continuous improvement.

Figure 8: BC Hydro Base Operating Cost Trend



1. *Rate of Inflation - Fiscal 2015 to Fiscal 2018 source www.bcstats.gov.bc.ca produced by BC Stats January 2018 (by fiscal year end).*
2. *Rate of Inflation - Fiscal 2019 – F2021 source Consumer Price Index assumptions from Treasury Board, October 5, 2018.*
3. *F2019 includes a $10 million (approx. 1.3%) increase stemming from how BCUC directed BC Hydro to forecast pension costs for rate setting purposes. The actual change in costs may be different and will be known at the end of the fiscal year.*

BC Hydro's average base operating cost increase over the Fiscal 2015 to Fiscal 2021 period is 1.50%, which is 0.44% below the average rate of inflation of 1.94% for the same time period.

4.2.5 Increase Revenues

Increase revenues through sale of Low Carbon Fuel Standard (LCFS) credits

Under the *Greenhouse Gas Reduction (Renewable & Low Carbon Fuel Requirements) Act* and the Renewable and Low Carbon Fuel Requirements Regulation (the Regulation), transportation fuel suppliers in British Columbia must, among other obligations, progressively decrease the average carbon intensity of their fuels to achieve a 10% reduction in 2020 relative to 2010. Further increases in stringency to achieve a 20% reduction in carbon intensity by 2030 were announced in December 2018 as part of the CleanBC plan. Under the current Regulation, fuel suppliers select their own approach for compliance with this requirement. Fuel suppliers can:

- supply more low carbon fuels;
- acquire credits through a Part 3 Agreement; and/or
- trade credits with other suppliers.

The Ministry of Energy, Mines and Petroleum Resources is currently undertaking a review of the LCFS program. As part of this review, regulatory and legislative changes could increase the number of LCFS credits available for sale. If adopted, these changes would generate incremental revenues for Powerex and its parent, BC Hydro, between Fiscal 2020 and Fiscal 2024. This incremental revenue would be incorporated in future rate forecasts.

Work to attract additional customers and increase electricity demand

Phase 1 of the Review explored opportunities to increase electricity demand. BC Hydro continues to forecast that it will have an energy surplus, even with the changes in the future of energy procurement resulting from the Review. Today, BC Hydro sells that surplus into export markets.

BC Hydro is pursuing strategies to grow domestic electricity demand. As part of this, BC Hydro is exploring the option to offer current industrial customers year-round access to real time, market-based pricing for incremental energy purchases. For example, during the freshet period, there are high inflows into BC Hydro's reservoirs, resulting in surplus electricity generation that could potentially be sold at a discounted rate to industrial customers.

BC Hydro is engaging with stakeholders and customers on these options and expects to file an application with the BCUC in 2019 regarding real time market-based pricing. If any of these strategies are approved by the BCUC, the impacts would be incorporated in future rates forecasts.

5. Five Year Rates Forecast

Based on the outcomes of Phase 1 of the Review, BC Hydro's rates forecast covering the five-year period from Fiscal 2020 to Fiscal 2024 would result in an estimated cumulative increase in customer bills of 8.1%. This increase is almost 40% lower than the cumulative target increases of 13.7% in the previous government's 10 Year Rates Plan. It is also approximately 20% lower than the forecast increase in inflation of 10.7% over the same time period and helps to keep electricity bills affordable for customers.

The forecast bill impact of 1.8% in Fiscal 2020 is a result of a forecast rate increase of 6.8% for that year, offset by an expected reduction in the DARR from 5% to 0%.

Table 4: BC Hydro Five Year Rates Forecast

	Fiscal 2020	Fiscal 2021	Fiscal 2022	Fiscal 2023	Fiscal 2024	Cumulative Five Years*
Current Rates Forecast – Annual Rate Increase before reducing the DARR	6.8%	0.7%	2.2%	0.0%	3.2%	n/a
Current Rates Forecast – Annual Bill Impact – including reduction in DARR**	1.8%	0.7%	2.2%	0.0%	3.2%	8.1%
Previous Govt's 10 Year Rates Plan – Annual Bill Impact	2.6%	2.6%	2.6%	2.6%	2.6%	13.7%
Forecast BC Inflation	2.3%	2.0%	2.0%	2.0%	2.0%	10.7%

* *Cumulative rates do not equal the sum of individual rate changes shown for each year due to the effect of compounding.*

** *after reducing the Deferral Account Rate Rider (DARR) from 5% to 0%, beginning in Fiscal 2020. Under the 2013 10 Year Rates Plan, the DARR was set at 5% indefinitely – it was expected to remain at 5% at least through Fiscal 2024. Going forward, the BCUC will now determine how the DARR is set and applied. This change is explained further in section 4.1.3.*

Under the new regulatory model for BC Hydro, rate increases will be determined by the BCUC in future revenue requirements proceedings. That means that future rate increases may be lower or higher than the rates forecast shown above. BC Hydro intends to make all reasonable efforts to maintain rate increases within the projected rates forecast.

6. Next Steps

Government is implementing the changes to ensure sound financial and regulatory oversight of BC Hydro and to keep rates affordable for customers. The outcome of Phase 1 will also inform Phase 2 of the Comprehensive Review, which will focus on transformational aspects to changing energy markets. This second phase will be informed by new government strategies, including the CleanBC plan, and will provide a strategic and long-term view of the future role of BC Hydro.

Phase 1 of the Review also supports BC Hydro in filing its next Revenue Requirements Application with the BCUC. Through this open and transparent regulatory process, stakeholders and the public will be able to comment on BC Hydro's costs, spending and electricity rates.

Government remains committed to keeping electricity rates affordable for British Columbians and positioning BC Hydro for success in the years ahead.

Appendix A:
Phase 1 Terms of Reference

Terms of Reference

2018 Comprehensive Review of BC Hydro – Phase 1

Context

Under the Minister of Energy, Mines and Petroleum Resources' Mandate Letter, the ministry is required to undertake a comprehensive review of BC Hydro, and work with BC Hydro to develop a refreshed plan to keep rates low and predictable over the long-term.

The ministry has received direction to undertake a two-part review. The first part is to focus primarily on BC Hydro's costs and rates, including creating the refreshed plan for rates, and will assist BC Hydro in preparing a Revenue Requirements Application to be filed with the BC Utilities Commission in February 2019.

The second part will focus on transformational aspects to changing energy markets, and respond to the expected Energy Road Map for BC and assist BC Hydro in developing its Integrated Resource Plan in 2019. Terms of reference for this second part will be finalized after the first part of the review has been completed. The remainder of this document focuses on the first part of the review.

Objective

BC Hydro and ministry staff will develop options for consideration to support a new 10 Year Rates Plan, with the ultimate goal of reducing the growth in BC Hydro's electricity rates and ensuring sound financial and regulatory oversight of BC Hydro. The Advisory Group will provide advice and analysis by assessing options and the actions required to achieve them.

Membership

An Advisory Group consisting of staff from BC Hydro, the Ministry of Finance and the Ministry of Energy, Mines and Petroleum Resources (EMPR) will perform the first phase of the review. The Advisory Group may consult with BC Utilities Commission staff.

Advisory Group Co-chairs

- Assistant Deputy Minister, Electricity and Alternative Energy Division, Ministry of Energy, Mines and Petroleum Resources
- A/Chief Financial Officer, BC Hydro

Governance/Accountability

The Advisory Group will report monthly to the Steering Committee. The Steering Committee will provide feedback and advice on options and recommendations to Ministers.

Steering Committee Membership

- Deputy Minister, Ministry of Energy, Mines and Petroleum Resources
- Deputy Minister, Ministry of Finance
- President and COO, BC Hydro
- Executive Chair, BC Hydro

Timeline

The Advisory Group, based on advice from the Steering Committee, will prepare options and recommendations for consideration by Ministers by summer 2018.

A report on the first phase of the review, and Government's response, will be released in the fall of 2018. The report will describe the areas of BC Hydro's finances, programs and operations, that were examined during the review, and decisions by government in response to the Advisory's Group's recommendations.

The report will also inform BC Hydro's next rate application, which will be filed with the B.C. Utilities Commission (BCUC) in early 2019. During the BCUC's review of that application, stakeholders and the public will have a further opportunity to see and comment on how the outcomes of the first phase of the BC Hydro review have influenced BC Hydro's finances, and electricity rates.

Areas of Focus

The Advisory Group has identified the following areas of focus, which include the key components of BC Hydro's revenue requirements, known items that need to be resolved, BCUC feedback from their decision of the Fiscal 2017 – Fiscal 2019 Revenue Requirements Application, and other issues that have been identified:

1. Revenues / Load Forecasting
2. Cost of Energy
3. Operating Costs and other issues
4. 10 Year Capital Plan (excluding Site C)
5. Regulatory Accounts
6. Demand-Side Management
7. Water Rentals
8. Net Income and Dividends
9. Legal Considerations
10. Customer Affordability / Rates
11. Powerex
12. Financial Forecasting (i.e., impact of all of the above on future rates)
13. Debt/Cash Management
14. Enterprise Risk Management

APPENDIX B: FOCUS AREAS OF THE REVIEW

Regulatory Accounts

Work in this area examined the historical context of regulatory accounts, forecast balances and current accounts. Regulatory accounts are commonly used by utilities. They represent costs not yet recovered from, or revenues not yet refunded to, BC Hydro ratepayers. BC Hydro uses regulatory accounts to match costs with benefits for customers, to capture differences between forecast and actual costs and revenues typically related to uncontrollable factors (e.g., interest rates, water inflows, storm restoration costs), to smooth rate increases over time and to manage the impact to ratepayers of changes in accounting rules. As of September 30, 2018, BC Hydro had 29 regulatory accounts with a balance of approximately $4.8 billion.

Work in this area also focused on empowering the BCUC to exercise oversight and make decisions on all future costs and regulatory accounts on a go-forward basis, while ensuring that BC Hydro could continue recovering costs related to previous policy decisions. This area also explored the write-off of the balance of the Rate Smoothing Regulatory Account.

Cost of Energy Acquisition

Work in this area included an assessment of the current cost to ratepayers of energy acquisition programs and how those costs could be reduced in future. Since the ability to manage cost of energy is largely limited to potential biomass Electricity Purchase Agreement renewals and the Standing Offer Program, actions focused on these programs.

Operating Costs

Work in this area examined current base operating costs and forecast future operating cost pressures and savings.

In recent years, BC Hydro has limited the growth in its base operating costs. For example, in its last Revenue Requirements Application, BC Hydro limited its proposed base operating cost increases to below forecast B.C. inflation. These operating costs were approved by the BCUC.

Over the five-year rate forecast period from Fiscal 2020 to Fiscal 2024, BC Hydro faces increases in projected incremental operating costs. These incremental costs are partially offset by the elimination of Medical Service Plan premiums. BC Hydro will make further reductions to contain operating costs over the five-year rate forecast period and, as a result, focuses its efforts to be able to limit its base operating cost increases below the forecast rate of inflation over the Fiscal 2020 to Fiscal 2024 period. Further review of operating costs by the BCUC and interveners will occur in 2019 as part of BC Hydro's next Revenue Requirements Application process.

Capital Plan

Work in this area focused on an updated capital plan as well as asset retirements, dismantling costs and write-offs.

BC Hydro is spending over $2 billion annually on capital projects. BC Hydro recovers the cost of its capital assets in rates through amortization that is included in its revenue requirements. Amortization of capital assets starts when the asset is put into service.

BC Hydro's 10-year Capital Plan is updated annually to ensure that the existing electricity system continues to perform safely and reliably and that upgrades and new facilities are added in time to meet projected growth in electricity demand.

Revenues/Load Forecasting

Work in this area examined sector assumptions, electrification scenarios, new revenue streams, as well as restoring the regulatory oversight and a new timeline for the Integrated Resource Plan.

BC Hydro forecasts its revenues from electricity sales based on the forecasting of load, or demand, for electricity. Forecasting load over the long term is inherently uncertain as it is difficult to predict future trends related to economic and population growth, energy efficiency and technology. In recognition of this uncertainty, BC Hydro plans over a longer term within uncertainty ranges.

As a cost of service utility, BC Hydro's requested revenue requirement is designed to equal its expected costs. Revenues have two components: the rate and the amount of electricity sold. Estimating the amount of electricity that will be sold – the load forecast – is a critical component to determining the rate.

The load forecast for the Fiscal 2017 – Fiscal 2019 Revenue Requirements Application was developed in May 2016. Actual results since May 2016 have closely tracked the May 2016 Load Forecast, falling within 0.5%to 0.7% of actuals for Fiscal 2017 and Fiscal 2018. Nevertheless, BC Hydro's load forecast has since been the subject of a number of reviews, including the 2017 Load Forecast Internal Audit, the Fiscal 2017 – Fiscal 2019 Revenue Requirements Application Decision and the Site C Inquiry Final Report. In response to these reviews and as part of BC Hydro's continuous improvement efforts, BC Hydro has made changes to its load forecast methodology. Key concerns expressed by the BCUC and the BC Hydro's internal audit review have now been addressed. For example, the Five-Year Load Forecast that will be part of BC Hydro's next Revenue Requirements Application reflects the results of a new price elasticity study and modified approach to forecasting demand from Liquefied Natural Gas.

Dividends & Net Income

Work in this area included the setting of BC Hydro's allowed net income, including how to transition this responsibility to the BCUC.

BC Hydro's net income forms part of the government's revenue for Provincial budget purposes. Under the previous 2013 10 Year Rates Plan, BC Hydro's allowed net income was set by government and BCUC was required to approve the set amounts. Typically, a utility's allowed net income is set by its regulator to balance ratepayer and shareholder interests. As a result of the Review, the BCUC will set BC Hydro's allowed net income for rate-setting purposes after a two-year transition period.

BC Hydro's dividend payments provide cash flow to the government and allow the government to reduce its debt requirements. Dividend payments do not directly impact the government's fiscal surplus/deficit, but do impact taxpayer-supported borrowing requirements. Under current government regulation and policies, BC Hydro's dividend for the current fiscal year will be $59 million and $0 thereafter until such time as BC Hydro achieves a 60:40 debt:equity ratio, which is more typical for utilities than BC Hydro's current ratio of approximately 80:20. The approach to dividends will not change at this time as a result of the Review.

Powerex

Work in this area focused on BC Hydro's subsidiary, Powerex, and how it contributes to ratepayer value through its net income. The area also examined the potential to increase Powerex net income through the sale of renewable energy credits.

Powerex is a key participant in energy markets across North America, buying and selling wholesale power, renewable and low-carbon energy and products, natural gas, ancillary services and financial energy products. Powerex's trade activities earn income to lower BC Hydro's customer rates and to help balance its system by being able to import energy to meet domestic demand when there is a supply shortage and exporting energy when there is a supply surplus. Exports are made only after ensuring domestic demand requirements are met.

Demand Side Management

Work in this area examined BC Hydro's demand-side management activities, including its Power Smart programs.

Demand Side Management is an important part of BC Hydro's resource plan, providing the flexibility to meet future supply needs or build efficient load, depending on system needs. Demand Side Management is a low-cost energy resource with little to no environmental impact. This area was examined, and, consistent with the government's focus on affordability, in its upcoming Revenue Requirements Application, BC Hydro will be proposing to increase the amount of spending for the residential sector and low-income ratepayers, while keeping Demand Side Management expenditures at the same level overall.

Water Rentals

Work in this area examined water rentals paid by BC Hydro to the government and whether these charges are appropriate going forward, as well as elements of the *Water Sustainability Act*.

Water Rentals are the fees charged by the government for using its water for hydroelectric production. Water Rental rates for commercial and general power licenses are set by the Water Sustainability Fees, Rentals and Charges Tariff Regulation under the *Water Sustainability Act*. There were no decisions for this area coming out of Phase 1 of the Review.

Other Areas Examined

Debt/Cash Management, Financial Forecasting, Customer Rates and Proactive Enterprise Risk Management were all examined with no additional decisions in these areas coming out of Phase 1 of the Review.

Regulatory Considerations

Work in this area included considering the regulatory implications of the outcomes of the Review and determining how best to implement them. Further information is provided in Appendix D.

Appendix C:
Summary of BCUC Oversight

Area of Focus	Previous Regulatory Oversight	Regulatory Oversight after the Review	Change in Reg. Oversight
Regulatory Accounts	Direction for some	Recover existing balances in rates and BCUC go-forward oversight for almost all accounts	↑
Integrated Resource Plan	No BCUC review	BCUC reviews	↑
Rate Smoothing	BCUC determines after Fiscal 2019	RSRA written off in Fiscal 2019	↑
Rate Setting	Under prescribed cap	BCUC decides	↑
Deferral Account Rate Rider (DARR)	Set at 5% by Direction	BCUC decides	↑
Net Income for rate-setting	Set at $712M by Direction	Set by government at $712M in Fiscal 2020 and Fiscal 2021, then BCUC decides	↑
Biomass Renewals	BCUC determines if new EPAs are in the public interest	Government to provide Direction	↓
Standing Offer Program	Required under *Clean Energy Act*; no prescribed circumstances	Regulation specifies prescribed circumstances that enable indefinite suspension	↔
Rate Rebalancing	Direction to BCUC prohibits	Regulation prohibits unless BC Hydro requests	↔
Expenditures for Export	Direction to BCUC	BCUC to refrain from considering when determining BC Hydro's rates	↔
Powerex	Direction to BCUC	Continues to restrict the BCUC from regulating the activities of Powerex	↔
Retail Access	Direction to BCUC prohibits	Regulation prohibits unless BC Hydro requests	↔

Appendix D:
Summary of New Regulations and Legislation

Regulations:

Integrated Resource Plan
Clean Energy Act: Change of deadline for the IRP
Direction No. 8 to the BCUC
Repeals Directions No. 1,3,6,7 and replaces Direction 7
Prohibits BCUC from disallowing recovery of current regulatory account balances
Allows BC Hydro to recover interest costs on funds borrowed in relation to Rate Smoothing Regulatory Account
Net income: set at $712M for Fiscal 2020 and Fiscal 2021 . In Fiscal 2022 and beyond, BCUC to set allowed net income
Continues existing provisions that limit retail access, rate rebalancing and expenditures for export
Continues to restrict the BCUC from regulating Powerex
Energy Procurement
Indefinite suspension of the Standing Offer Program
Biomass Energy Program: Program direction and required cost recovery (regulation under development)
Financial Directives
Repeal Treasury Board Regulation 257/2010 that exempted BC Hydro from the requirement that rates be set by an independent, third party regulator for rate regulated accounting. Occurred October 2018.
Write off of the Rate Smoothing Regulatory Account (Timing TBC)

Legislative Changes (under development):

IRP timing and oversight
Prohibition of rate rebalancing
Utilities Commission Act does not apply to Powerex
Remove concept of expenditures to export from *Clean Energy Act*
Streamlining of the *Clean Energy Act* (i.e. removing clauses that no longer apply)

Appendix E: Acronyms, Abbreviations and Definitions

10 Year Rates Plan	The 2013 10 Year Rates Plan covered Fiscal 2015 – Fiscal 2024 and had three main components: BC Hydro actions to reduce costs; government actions; and the creation of a Rate Smoothing Regulatory Account.
Auditor General	An independent Officer of the Legislature, who, under a fixed term of office in legislation, has a mandate to conduct audits and performance reviews of government entities, with the intention to report on how well government is managing its responsibilities and resources.
BC Hydro	British Columbia Hydro and Power Authority. A provincial Crown corporation that operates an integrated system of generation, transmission and distribution infrastructure to deliver reliable, affordable and clean electricity to its customers, safely.
BCUC	British Columbia Utilities Commission. The BCUC works to ensure British Columbians get value from their utilities with safe, reliable energy services, while also ensuring the owners of the entities it regulates are able to earn a fair return on their invested capital.
capacity	The maximum sustainable amount of electricity that can be produced or delivered at any instant. Typically measured in kW, MW or GW.
CleanBC plan	The CleanBC plan is the Province's strategy to reach its 2030 climate targets, through the use of clean and renewable energy in transportation, buildings and industry in order to reduce greenhouse gas emissions and build British Columbia's economy.
Clean Energy Act	Passed in 2010, this legislation set the foundation for a new future of electricity self-sufficiency, job creation and reduced greenhouse gas emissions, powered by unprecedented investments in clean, renewable energy across British Columbia.
Crown corporation	Crown corporations are public sector organizations established and funded by the B.C. government to provide specialized goods and services to citizens. They operate at varying levels of government control and report on their planning, governance and accountabilities. BC Hydro is a Crown corporation.
DARR	Deferral Account Rate Rider. Surcharge (currently 5%) that applies to all charges on customer bills, excluding taxes and levies. Funds collected under the DARR were intended to be used to pay down BC Hydro's three energy deferral account balances (the Heritage Deferral Account, the Non-Heritage Deferral Account and the Trade Income Deferral Account).
Demand Side Management	BC Hydro's programs that support energy conservation and encourage the adoption of more energy efficient products and equipment.
dividend	BC Hydro's dividend payments provide cash flow to the government and allow the government to reduce its borrowing requirements. BC Hydro's dividend for the current fiscal year will be $59 million and will be $0 thereafter until such time as BC Hydro achieves a 60:40 debt:equity ratio.
Electricity Purchase Agreement	A commercial agreement that sets out the terms and conditions under which a buyer purchases electricity from a supplier

energy	How much is consumed or produced over a period of time
expenditures for export	To ensure the costs of pursuing such opportunities for electricity export were not passed along to the ratepayer, the *Clean Energy Act* required the BCUC to ensure that BC Hydro's rates would not allow BC Hydro to recover "expenditures for export."
government	Government of British Columbia
***Greenhouse Gas Reduction (Renewable & Low Carbon Fuel Requirements) Act* and Renewable and Low Carbon Fuel Requirements Regulation**	Requires transportation fuel suppliers in B.C. to progressively decrease the average carbon intensity of their fuels to achieve a 10% reduction in 2020 relative to 2010.
Heritage assets	Defined in the *Clean Energy Act* to include all of the transmission and distribution infrastructure in place when the Act was passed as well as those generating facilities identified in Schedule 1 to the Act.
GWh	A unit of energy, where 1 MWh is the amount of energy produced from a generator operating at 1 MW capacity for a period of 1 hour 1 gigawatt hour = 1,000 MWh
IFRS	International Financial Reporting Standards
Impact Benefit Agreement	An agreement between BC Hydro and a First Nation to address adverse impacts arising from the construction of BC Hydro's projects that cannot be avoided, mitigated or otherwise accommodated.
IPP	Independent Power Producer
IRP	Integrated Resource Plan
load	Demand for electricity, measured in terms of energy (MWh or GWh) and capacity (MW or GW)
load forecast	Estimates the amount of electricity that will be sold. The load forecast is a critical component to determining BC Hydro's rates.
load offset	Energy generated by a BC Hydro customer at its customer site to offset the energy the customer currently purchases from BC Hydro to serve its own needs.
LCFS credits	Low Carbon Fuel Standard credits
MW	A unit of energy generating capacity 1 megawatt = 1,000 kilowatts = 1 million watts
net income	The return that BC Hydro is allowed to earn in a given year. BC Hydro's net income forms part of the government's revenue for government budget purposes.
PBR	Performance based regulation. Under PBR, for certain costs base year costs are set and then adjusted via a formula in future years, including incentives for efficiencies.
Powerex	Powerex Corp. BC Hydro subsidiary and a key participant in energy markets across North America, buying and selling wholesale power, renewable and low-carbon energy and products, natural gas, ancillary services and financial energy products.

rate rebalancing	Increasing or decreasing rates for each customer class by a different amount in order to align the revenues received from each class with the cost the utility incurs to serve each class
Rate Smoothing Regulatory Account	Established in 2014 as a result of government direction. Used to smooth the higher annual rate increases that would have been required to cover BC Hydro's costs in the early years of the 2013 10 Year Rates Plan by enabling BC Hydro to defer collection of revenues from ratepayers to the later years of the Plan.
retail access	Ability for customers to secure electricity from the market via a third-party provider rather than the local utility
regulatory accounts	BC Hydro uses regulatory accounts to match costs with benefits for customers, to capture differences between forecast and actual costs and revenues typically related to uncontrollable factors (e.g., interest rates, water inflows, storm restoration costs), to smooth rate increases over time and to manage the impact of changes in accounting rules.
Review	Comprehensive, two-phased review of BC Hydro, first phase commenced in June 2018 and completed with the release of this report. Second phase to commence in 2019.
revenue requirements	BC Hydro's forecasts of the revenue that it needs to collect from its customers in order to cover its costs.
Revenue Requirements Application	Application to the BCUC in which BC Hydro proposes the revenue it needs to collect in order to cover its costs. BC Hydro's most recent Revenue Requirements Application was for Fiscal 2017 – Fiscal 2019.
RNG	Renewable Natural Gas
Utilities Commission Act	The BCUC operates under and administers this Act. BC Hydro is a public utility under this Act.
water rental rates	Fees charged by the government for using its water for hydroelectric production
Water Sustainability Fees, Rentals and Charges Tariff	Water Rental rates for commercial and general power licenses are set by this Regulation under the *Water Sustainability Act*

Government Regulations

PROVINCE OF BRITISH COLUMBIA

ORDER OF THE LIEUTENANT GOVERNOR IN COUNCIL

Order in Council No. 051 , *Approved and Ordered* February 14, 2019

Lieutenant Governor

Executive Council Chambers, Victoria

On the recommendation of the undersigned, the Lieutenant Governor, by and with the advice and consent of the Executive Council, orders that

(a) Direction to the British Columbia Utilities Commission Respecting the Iskut Extension Project, B.C. Reg. 137/2013, is amended as set out in section 1 of the attached Appendix A,

(b) Special Direction No. 9 to the British Columbia Utilities Commission, B.C. Reg. 157/2005, is amended as set out in section 2 of the attached Appendix A,

(c) Direction No. 1 to the British Columbia Utilities Commission, B.C. Reg 105/2009, is repealed,

(d) Direction No. 3 to the British Columbia Utilities Commission, B.C. Reg. 105/2012, is repealed,

(e) Direction No. 6 to the British Columbia Utilities Commission, B.C. Reg. 29/2014, is repealed, and

(f) Direction No. 7 to the British Columbia Utilities Commission, B.C. Reg. 28/2014, is repealed and Direction No. 8 to the British Columbia Utilities Commission, set out in the attached Appendix B, is made.

DEPOSITED

February 14, 2019

B.C. REG. 24/2019

Minister of Energy, Mines and Petroleum Resources

Presiding Member of the Executive Council

(This part is for administrative purposes only and is not part of the Order.)

Authority under which Order is made:

Act and section: *Utilities Commission Act*, R.S.B.C. 1996, c. 473, ss. 3 and 22

Other: OIC 1107/2003; OIC 2015/2009; OIC 314/2012; OIC 96/2014; OIC 97/2014; OIC 182/2013

APPENDIX A

1 *Section 4 (1) of Direction to the British Columbia Utilities Commission Respecting the Iskut Extension Project, B.C. Reg. 137/2013, is repealed.*

2 *Section 2.1 of Special Direction No. 9 to the British Columbia Utilities Commission, B.C. Reg. 157/2005, is repealed.*

APPENDIX B

DIRECTION NO. 8 TO THE BRITISH COLUMBIA UTILITIES COMMISSION

Contents

Definitions

1 In this direction:

"Act" means the *Utilities Commission Act*;

"deemed equity" means, for any fiscal year, the product obtained by multiplying the rate base relating to that year by 30%;

"distributable surplus" has the same meaning as in Heritage Special Directive No. HC1 to the British Columbia Hydro and Power Authority;

"DSM regulatory account" means the regulatory account of the authority established under commission order G-55-95;

"F2020" means the authority's fiscal year commencing April 1, 2019 and ending March 31, 2020;

"F2021" means the authority's fiscal year commencing April 1, 2020 and ending March 31, 2021;

"rate smoothing regulatory account" means the rate smoothing regulatory account approved by commission order G-48-14;

"rate base" means, in relation to a fiscal year of the authority, the amount determined in accordance with the following equation and notes:

$$RB = WCA + (A + B + C)/2 - (D + E + F)/2$$

where

RB	=	rate base;
WCA	=	working capital amount of $250 million;
A, B, D, E and F	=	the sum of an amount the authority forecasts will be listed as follows in the authority's audited financial statements at the end of the previous fiscal year and the amount the authority forecasts will be similarly listed at the end of the applicable fiscal year:
A		is the amount listed as property, plant and equipment in service, less accumulated amortization;
B		is the amount listed as intangible assets in service, less accumulated amortization;
D		is the amount listed as contributions in aid of construction;
E		is the amount listed as contributions arising from the Columbia River Treaty;
F		is the amount listed as leased assets included in A, less accumulated amortization;
C	=	the sum of the balance the authority forecasts for DSM regulatory account at the beginning of the fiscal year and the balance the authority forecasts for the same account at the end of the fiscal year.

Notes:

1 In determining rate base for a fiscal year, the amounts A, B and F must have subtracted from them any amount included in them that is an expenditure incurred by the authority, on or after April 1, 2011, that the commission determines under the Act must not be recovered by the authority in rates.

2 In determining rate base for a fiscal year, the amount D must have subtracted from it any amount included in it that is related to an expenditure referred to in note 1.

Application

2 This direction is issued to the commission under section 3 of the Act.

Basis for establishing authority revenue requirements

3 In regulating and setting rates for the authority for F2020 and F2021, the commission must ensure that those rates allow the authority to collect sufficient revenue in each fiscal year to enable the authority to achieve an annual rate of return on deemed equity that would yield a distributable surplus of $712 million.

Cost recovery

4 (1) In setting rates for the authority, the commission must not disallow for any reason the recovery in rates of the balance of the authority's regulatory accounts as at March 31, 2019 and the costs incurred by the authority with respect to the following:

(a) the construction of extensions to the authority's plant or system that came into service before April 1, 2016;

page 3 of 4

(b) energy supply contracts entered into before April 1, 2016;

(c) debt servicing costs on amounts borrowed in relation to the rate smoothing regulatory account.

(2) Subsection (1) (c) does not limit the power of the commission to allow the recovery in rates of debt servicing costs related to the authority's regulatory accounts not referred to in that subsection.

Rate rebalancing

5 In setting rates for the authority for F2020 and F2021, the commission must not set rates for the purpose of changing the revenue-cost ratio for a class of customers.

Expenditures for export

6 The commission must not comply with section 4 (5) of the *Clean Energy Act* when setting rates for the authority for F2020 and F2021.

Retail access

7 Except on application by the authority, the commission must not set rates for the authority that would result in the direct or indirect provision of unbundled transmission services to retail customers in British Columbia, or to those who supply such customers.

Powerex

8 The commission may not exercise any power or perform any duty under Part 3 of the Act in regard to Powerex Corp.

PROVINCE OF BRITISH COLUMBIA

ORDER OF THE LIEUTENANT GOVERNOR IN COUNCIL

Order in Council No. 052 *, Approved and Ordered* February 14, 2019

Lieutenant Governor

Executive Council Chambers, Victoria

On the recommendation of the undersigned, the Lieutenant Governor, by and with the advice and consent of the Executive Council, orders that the Standing Offer Program Regulation, B.C. Reg. 320/2010, is amended as set out in the attached Schedule.

DEPOSITED

February 14, 2019

B.C. REG. 23/2019

Minister of Energy, Mines and Petroleum Resources

Presiding Member of the Executive Council

(This part is for administrative purposes only and is not part of the Order.)

Authority under which Order is made:

Act and section: *Clean Energy Act*, S.B.C. 2010, c. 22, ss. 15 and 35

Other: OIC 697/2010

SCHEDULE

1 *The Standing Offer Program Regulation, B.C. Reg. 320/2010, is amended by adding the following section:*

Prescribed circumstance

4 (1) In this section, **"applicable facility"** means an eligible facility used in relation to the fulfillment of obligations under an electricity purchase agreement entered into by the authority under the standing offer program.

(2) For the purposes of section 15 (2) of the Act, a prescribed circumstance is that the aggregate nameplate capacity of all applicable facilities equals or exceeds 100 megawatts.

PROVINCE OF BRITISH COLUMBIA

ORDER OF THE LIEUTENANT GOVERNOR IN COUNCIL

Order in Council No. 743 , *Approved and Ordered* December 10, 2018

Lieutenant Governor

Executive Council Chambers, Victoria

On the recommendation of the undersigned, the Lieutenant Governor, by and with the advice and consent of the Executive Council, orders that the following regulation is made:

BC HYDRO INTEGRATED RESOURCE PLAN REGULATION

Prescribed submission date

1 For the purposes of section 3 (6) (b) of the *Clean Energy Act*, February 28, 2021 is prescribed as the submission date for an integrated resource plan.

DEPOSITED

Clean Energy Act

GREENHOUSE GAS REDUCTION (CLEAN ENERGY) REGULATION

[includes amendments up to B.C. Reg. 114/2017, March 22, 2017]

Contents

Definitions

1 In this regulation:

"Act" means the *Clean Energy Act*;

"eligible vehicle or machine" means

(a) a specified vehicle,

(b) a marine vehicle,

(c) an asphalt paver,

(d) a fracture pump unit,

(e) a mine haul truck, and

(f) a locomotive

that uses, as a fuel source, compressed natural gas or liquefied natural gas;

"heavy-duty vehicle" means a truck, other than a mine haul truck, or tractor-trailer with a manufacturer's gross vehicle weight rating of 11 793 kg or more;

"medium-duty vehicle" means a vehicle, including a waste-haulage truck, with a manufacturer's gross vehicle weight rating of more than 5 360 kg but less than 11 793 kg;

"non-bypass customer" means a customer of a public utility that receives service under a rate that is not specific to the customer;

"operating costs", in relation to a fuelling station or to distribution or storage infrastructure, means

(a) operating and maintenance expenses,

(b) electricity expenses,

(c) interest expenses,

(d) taxes, including property taxes,

(e) return on equity,

(f) extraordinary retirement costs, and

(g) amounts with respect to the depreciation of the

(i) capital costs,

(ii) construction carrying costs,

(iii) feasibility and development costs,

(iv) sustaining capital costs, and

(v) decommissioning and salvaging costs

determined with reference to the remaining service life of the fuelling station or distribution or storage infrastructure, as estimated by the commission in setting rates;

"safety guidelines" means safety guidelines adopted by the British Columbia Safety Authority;

"shore-side asset" means any of the following:

(a) boil-off gas recovery equipment;

(b) an LNG cryogenic loading manifold;

(c) an LNG cryogenic pipeline and vessel loading berth;

(d) an LNG cryogenic storage tank;

(e) an LNG measurement apparatus;

"specified vehicle" means a heavy-duty vehicle, medium-duty vehicle, school bus or transit bus;

"tanker truck load-out" means equipment for transferring liquefied natural gas from a storage tank to a liquefied natural gas tank trailer;

"undertaking period" means the period that ends on March 31, 2022.

[am. B.C. Regs. 235/2013, s. 1; 98/2015, s. 1; 214/2016, s. 1; 114/2017, s. 1.]

Prescribed undertakings

2 (0.1) In this section:

"contracted demand" means the total compressed natural gas and liquefied natural gas demand under take-or-pay agreements with the public utility during the undertaking period;

"early adopter vehicle or machine" means an eligible vehicle or machine, other than a vehicle referred to in subsection (3.1) (a), used primarily in a market segment set out in column 1 of the following table, if

(a) the contracted demand for the market segment does not exceed, in any of years 5 through 11 of the undertaking period, the annual amount set out in the corresponding row of column 2 of the table, or

(b) the total number of persons who receive grants or zero-interest loans does not exceed, in the undertaking period, the number set out in the corresponding row of column 3 of the table:

Column 1 Market Segment	Column 2 Contracted Demand (GJ)	Column 3 Number of Persons who Receive Grants or Zero-Interest Loans
Wholesale distribution of food or beverages by truck	100 000	5
Short-haul trucking between a port and any of a railway, warehouse or trucking depot	100 000	5
Medium-duty vehicle and heavy-duty vehicle leasing	100 000	5
Passenger transportation by charter bus, other than a transit bus or school bus	100 000	5
Package courier service by truck	200 000	5
Off-highway mine hauling by truck	1 million	3
Transportation of goods or passengers by rail	1 million	3
Dump truck services	100 000	5
Transportation of cement in cement-mixing trucks	100 000	5
Bucket and digger trucking services	100 000	5
Pipe cleaning or hydro-vacuum excavation trucking services	100 000	5
On-highway hauling in trucks with a manufacturer's gross vehicle weight rating of more than 36 000 kg	1 million	10
Off-highway earth excavation, grading and moving for construction or mining	1 million	5
Asphalt paving services	100 000	6
Fracture pump unit services	200 000	4
Shipping, passenger transportation or commercial services by marine vehicle that will use fuel purchased from a public utility	10 million	13
Street sweeping services	100 000	5

"major transportation corridor" means Highway 1, 3, 3A, 4, 5, 7, 16, 19, 33, 37, 91, 95, 97 or 99.

(1) Subject to subsection (3.3), a public utility's undertaking that is in the class defined as follows is a prescribed undertaking for the purposes of section 18 of the Act:

(a) the public utility provides, through an open and competitive application process,

(i) grants or zero-interest loans to persons in British Columbia for the purchase of an eligible vehicle or machine to be operated in British Columbia, or

(ii) grants to persons in British Columbia

(A) to implement safety practices, or

(B) to improve maintenance facilities

to meet safety guidelines for operating and maintaining an eligible vehicle or machine;

(b) subject to subsection (1.2), an expenditure on a grant or zero-interest loan for an eligible vehicle or machine does not, in any year of the undertaking, exceed the percentage difference as indicated in the following table:

	Year of Undertaking										
	1	2	3	4	5	6	7	8	9	10	11
Percentage of the difference between the cost of the eligible vehicle or machine and the cost of a comparable vehicle that uses gasoline or diesel	100	80	70	60	50	40	30	25	20	10	0

(c) total expenditures on the undertaking during the undertaking period, including expenditures on administration, marketing, training and education, do not exceed $177.9 million less the total expenditures, if any, on an undertaking described in subsection (3.1), and

(i) Repealed. [B.C. Reg. 98/2015, s. 2 (e).]

(ii) expenditures on the undertaking during the undertaking period

(A) Repealed. [B.C. Reg. 214/2016, s. 3 (e).]

(B) on grants referred to in paragraph (a) (ii) do not exceed $6 million.

(1.1) Despite the reference in subsection (1) (a) to an open and competitive application process, a public utility may, in carrying out the undertaking described in subsection (1), give priority to a person in British Columbia who fuels an eligible vehicle or machine using natural gas delivered through the public utility's pipeline system.

(1.2) The percentage difference indicated in the table in subsection (1) (b) may be increased

(a) by up to 50 for each of years 5 through 11 of the undertaking period if the eligible vehicle or machine is an early adopter vehicle or machine, and

(b) by up to 20 for each of years 5 through 11 of the undertaking period if the vehicle is a specified vehicle, is not an early adopter vehicle or machine or a vehicle referred to in subsection (3.1) (a) and is owned or operated by a person who agrees, as a condition of receiving a grant or zero-interest loan, to

(i) complete or arrange for the completion of, within 3 years of the agreement, the construction of a compressed natural gas or liquefied natural gas fuelling station that

(A) is within 25 km of a major transportation corridor, and

(B) provides fuelling services to one or more other persons, or

(ii) operate or arrange for the operation of a fuelling station described in clauses (A) and (B).

(1.3) Despite subsections (1) (a) (i) and (1.1), grants or loans referred to in subsection (1) in relation to an early adopter vehicle or machine respecting the market segment described in the table in paragraph (b) of the definition of "earlier adopter vehicle or machine" as "Shipping, passenger transportation or commercial services by marine vehicle that will use fuel purchased from a public utility" may be made to persons who are not in British Columbia.

(1.4) Despite subsection (1) (c), the total expenditures referred to in that subsection may exceed $177.9 million by $40 million if the $40 million is for expenditures in relation to eligible vehicles or machines operated on liquefied natural gas or compressed natural gas all of which is derived from biogas or biomass.

(2) A public utility's undertaking that is in the class defined as follows is a prescribed undertaking for the purposes of section 18 of the Act:

(a) the public utility, before March 31, 2022, enters into a binding commitment to

(i) construct and operate, or

(ii) purchase and operate

one or more compressed natural gas fuelling stations, including storage, compression and dispensing equipment and facilities, within the service territory of the public utility for the purposes of providing compressed natural gas fuel and fuelling services to owners of vehicles that operate on compressed natural gas;

(b) total expenditures on the undertaking during the undertaking period, including expenditures on administration and marketing, do not exceed $12 million, and

(i) the average expenditure on stations, in any year of the undertaking, does not exceed $2 million per station, and

(ii) expenditures, during the undertaking period, on administration and marketing do not exceed $240 000;

(c) at least

(i) 80% of the station's forecast total operating costs for the first 5 years of the operation are recovered from one or more persons under a take-or-pay agreement with a minimum term of 5 years, or

(ii) 60% of the station's forecast total operating costs for the first 7 years of the operation are recovered from one or more persons under a take-or-pay agreement with a minimum term of 7 years.

(3) A public utility's undertaking that is in the class defined as follows is a prescribed undertaking for the purposes of section 18 of the Act:

(a) the public utility, before March 31, 2022, enters into a binding commitment to construct and operate, or purchase and operate, one or more of the following:

(i) one or more liquefied natural gas tank trailers or liquefied natural gas fuelling stations for the purposes of providing within British Columbia liquefied natural gas fuel and fuelling services to owners of vehicles that operate on liquefied natural gas;

(ii) one or more tanker truck load-outs for the purposes of providing within British Columbia liquefied natural gas fuel and fuelling services to owners of vehicles that operate on liquefied natural gas or to owners or operators of marine vehicles that operate on liquefied natural gas;

(b) total expenditures on the undertaking during the undertaking period, including expenditures on administration and marketing, do not exceed $50.5 million, and

(i) in any year of the undertaking period an expenditure on a station does not exceed $2.75 million, and

(ii) expenditures during the undertaking period on a tanker truck load-out do not exceed $10 million, and on administration and marketing do not exceed $250 000;

(c) at least

(i) 80% of the station's forecast total operating costs for the first 5 years of the operation are recovered from one or more persons under a take-or-pay agreement with a minimum term of 5 years, or

(ii) 60% of the station's forecast total operating costs for the first 7 years of the operation are recovered from one or more persons under a take-or-pay agreement with a minimum term of 7 years.

(3.1) A public utility's undertaking that is in the class defined as follows is a prescribed undertaking for the purposes of section 18 of the Act:

(a) the public utility provides, through an open and competitive application process, grants or zero-interest loans to owners or operators in British Columbia of specified vehicles for the conversion of those vehicles to operate on compressed natural gas or liquefied natural gas;

(b) total expenditures on the undertaking during the undertaking period, including expenditures on administration, marketing, training and education,

(i) do not exceed the lesser of the following amounts:

(A) the amount required for the conversion of 50 vehicles;

(B) $5 million, and

(ii) expenditures on the undertaking during the undertaking period on administration, marketing, training and education do not exceed $1.5 million.

(3.2) Subject to subsection (3.3), a public utility's undertaking that is in the class defined as follows is a prescribed undertaking for the purposes of section 18 of the Act:

(a) the public utility provides, through an open and competitive application process, grants or zero-interest loans to persons in British Columbia for

(i) the purchase or lease of generators, boilers, burners or kilns that use, as a fuel source, compressed natural gas or liquefied natural gas, or

(ii) the conversion of generators, boilers, burners or kilns to use, as a fuel source, compressed natural gas or liquefied natural gas

if the generators, boilers, burners or kilns will be operated at a location that, at the time of the expenditure, is not

(iii) within the authority's integrated area, or

(iv) connected to a natural gas transmission or distribution system;

(b) the total expenditures on the undertaking during the undertaking period, other than expenditures on administration, marketing, training and education, do not exceed $6.1 million.

(3.3) The undertakings referred to in subsections (1) and (3.2) are prescribed undertakings for the purposes of section 18 of the Act only if the total combined expenditures on the two undertakings, during the undertaking period on administration, marketing, training and education, do not exceed $8.1 million.

(3.4) A public utility's undertaking that is in the class defined as follows is a prescribed undertaking for the purposes of section 18 of the Act:

(a) the public utility, before March 31, 2022, enters into a binding commitment to

(i) construct and operate, or

(ii) purchase and operate

LNG distribution and storage infrastructure, other than liquefied natural gas fuelling stations, in British Columbia, including LNG rail tank cars, ISO containers and shore-side assets, for the purpose of reducing greenhouse gas emissions;

(b) total expenditures on the undertaking during the undertaking period, including expenditures on administration, marketing, training and education, do not exceed $40 million, and

(c) at least

(i) 80% of the forecast total operating costs of the distribution and storage infrastructure for the first 5 years of the operation are recovered from one or more persons under a take-or-pay agreement with a minimum term of 5 years, or

(ii) 60% of the forecast total operating costs of the distribution and storage infrastructure for the first 7 years of the operation are recovered from one or more persons under a take-or-pay agreement with a minimum term of 7 years.

(3.5) A public utility's undertaking that is in the class defined in subsection (3.6) is a prescribed undertaking for the purposes of section 18 of the Act.

(3.6) The public utility, during the undertaking period, expends amounts on feasibility and development costs in relation to shore-side assets that do not exceed $5 million.

(3.7) A public utility's undertaking that is in the class defined in subsection (3.8) is a prescribed undertaking for the purposes of section 18 of the Act.

(3.8) The public utility acquires renewable natural gas

(a) for which the public utility pays no more than $30 per GJ, and

(b) that, subject to subsection (3.9), in a calendar year, does not exceed 5% of the total volume of natural gas provided by the public utility to its non-bypass customers in 2015.

(3.9) The volume referred to in subsection (3.8) (b) does not include renewable natural gas acquired by the public utility that the public utility provides to a customer in accordance with a rate under which the full cost of the following is recovered from the customer:

(a) the acquisition of the renewable natural gas;

(b) the service related to the provision of the renewable natural gas.

(4) In subsections (1), (2), (3), (3.1), (3.2) and (3.4), **"expenditures"** includes, except with respect to expenditures on administration and marketing, binding

commitments to incur expenditures in the future.

[am. B.C. Regs. 235/2013, s. 2; 98/2015, s. 2; 214/2016, ss. 2 to 8; 114/2017, ss. 2 to 8.]

Repealed

3 Repealed. [B.C. Reg. 235/2013, s. 3.]

Prescribed undertaking — electrification

4 (1) In this section:

"benefit", in relation to an undertaking in a class defined in subsection (3) (a) or (b), means all revenues the public utility reasonably expects to earn as a result of implementing the undertaking, less revenues that would have been earned from the supply of undertaking electricity to export markets;

"cost", in relation to an undertaking in a class defined in subsection (3) (a) or (b), means costs the public utility reasonably expects to incur to implement the undertaking, including, without limitation, development and administration costs;

"cost-effective" means that the present value of the benefits of all of the public utility's undertakings within the classes defined in subsection (3) (a) or (b) exceeds the present value of the costs of all of those undertakings when both are calculated using a discount rate equal to the public utility's weighted average cost of capital over a period that ends no later than a specified year;

"natural gas processing plant" means a facility for processing natural gas by removing from it natural gas liquids, sulphur or other substances;

"specified year", in relation to an undertaking within a class defined in subsection (3), means

(a) a year determined by the minister with respect to an identified public utility, or

(b) if the minister does not make a determination for the purposes of paragraph (a), 2030;

"undertaking electricity" means electricity that is provided to customers in British Columbia as a result of an undertaking and is in addition to electricity that would have been provided had the undertaking not been carried out.

(2) A public utility's undertaking that is in a class defined as follows is a prescribed undertaking for the purposes of section 18 of the Act:

(a) for the purpose of reducing greenhouse gas emissions in British Columbia, the public utility constructs or operates an electricity transmission or distribution facility, or provides for temporary generation until the completion of the construction of the facility, in northeast British Columbia primarily to provide electricity from the authority to

(i) a producer, as defined in section 1 (1) of the Petroleum and Natural Gas Royalty and Freehold Production Tax Regulation, B.C. Reg. 495/92, or

(ii) an owner or operator of a natural gas processing plant;

(b) the public utility reasonably expects, on the date the public utility decides to carry out the undertaking, that the facility will have an in-service date no later than December 31, 2022.

(3) Subject to subsection (4), a public utility's undertaking that is in a class defined in one of the following paragraphs is a prescribed undertaking for the purposes of section 18 of the Act:

(a) a program to encourage the public utility's customers, or persons who may become customers of the public utility, to use electricity, instead of other sources of energy that produce more greenhouse gas emissions, by

(i) educating or training those customers respecting energy use and greenhouse gas emissions, carrying out public awareness campaigns respecting those matters, or providing energy management and audit services, or

(ii) providing funds to those persons to assist in the acquisition, installation or use of equipment that uses or affects the use of electricity;

(b) a program to encourage the public utility's customers, or persons who may become customers of the public utility, to use electricity instead of other sources of energy that produce more greenhouse gas emissions, by

(i) educating, training, providing energy management and audit services to, or carrying out awareness campaigns respecting energy use and greenhouse gas emissions for, or

(ii) providing funds to

persons who

(iii) design, manufacture, sell, install or, in the course of operating a business, provide advice respecting equipment that uses or affects the use of electricity,

(iv) design, construct, manage or, in the course of operating a business, provide advice respecting energy systems in buildings or facilities, or

(v) design, construct or manage district energy systems;

(c) a project, program, contract or expenditure for research and development of technology, or for conducting a pilot project respecting technology, that may enable the public utility's customers to use electricity instead of other sources of energy that produce more greenhouse gas emissions;

(d) a project, program, contract or expenditure supporting a standards-making body in its development of standards respecting

(i) technologies that use electricity instead of other sources of energy that produce more greenhouse gas emissions, or

(ii) technologies that affect the use of electricity by other technologies that use electricity instead of other sources of energy that produce more greenhouse gas emissions;

(e) a project for the construction, acquisition or extension of a plant or system, that the public utility reasonably expects is necessary to meet the public utility's incremental load-serving obligations arising as a result of an undertaking defined in paragraph (a), (b), (c) or (d), if the public utility reasonably expects any one such project to cost no more than $20 million.

(4) An undertaking is within a class of undertakings defined in paragraph (a) or (b) of subsection (3) only if, at the time the public utility decides to carry out the undertaking, the public utility reasonably expects the undertaking to be cost-effective.

Utilities Commission Act

DIRECTION TO THE BRITISH COLUMBIA UTILITIES COMMISSION RESPECTING UNDERTAKING COSTS

Definitions

1 In this direction:

"Act" means the *Utilities Commission Act*;

"DSM regulatory account" means the regulatory account of the authority established under commission order G-55-95;

"undertaking costs" means all costs incurred by the authority to implement an undertaking within a class defined in section 4 (3) (a), (b), (c) or (d) of the Greenhouse Gas Reduction (Clean Energy) Regulation.

Application

2 This direction is issued to the commission under section 3 of the Act.

Undertaking costs

3 The commission must allow the authority to defer to the DSM regulatory account amounts equal to the undertaking costs.

[Provisions relevant to the enactment of this regulation: *Utilities Commission Act*, R.S.B.C. 1996, c. 473, section 3]

PROVINCE OF BRITISH COLUMBIA

ORDER OF THE LIEUTENANT GOVERNOR IN COUNCIL

Order in Council No. 404 *, Approved and Ordered* July 14, 2015

Lieutenant Governor

Executive Council Chambers, Victoria

On the recommendation of the undersigned, the Lieutenant Governor, by and with the advice and consent of the Executive Council, orders that the attached Direction to the British Columbia Utilities Commission Respecting the Authority's TMP Program is made.

DEPOSITED

July 15, 2015

B.C. REG. **139/2015**

Minister of Energy and Mines and Minister Responsible for Core Review

Presiding Member of the Executive Council

(This part is for administrative purposes only and is not part of the Order.)

Authority under which Order is made:

Act and section: *Utilities Commission Act*, R.S.B.C. 1996, c. 473, s. 3

Other:

May 19, 2015 R/182/2015/27

page 1 of 2

DIRECTION TO THE BRITISH COLUMBIA UTILITIES COMMISSION RESPECTING THE AUTHORITY'S TMP PROGRAM

Definitions

1 In this direction,

"Act" means the *Utilities Commission Act*;

"DSM regulatory account" means the regulatory account of the authority established under commission order G-55-95;

"TMP program" means the authority's program to provide funding to increase the electrical energy efficiency of mills that use thermo-mechanical pulping processes.

Application

2 This direction is issued to the commission under section 3 of the Act.

TMP program

3 (1) Subject to subsection (2), in setting rates for the authority, the commission must not disallow for any reason the recovery in rates of the costs incurred by the authority in carrying out the TMP program.

(2) The costs recovered by rates referred to in subsection (1) must not exceed $100 million.

(3) The commission must, in regard to the DSM regulatory account, allow the authority to defer to that account the authority's costs incurred as a result of carrying out the TMP program.

B.C. Reg. 326/2008
M271/2008

Deposited November 7, 2008

This consolidation is current to September 18, 2018.

Utilities Commission Act

DEMAND-SIDE MEASURES REGULATION

[includes amendments up to B.C. Reg. 117/2017, March 24, 2017]

Contents

Definitions

1 In this regulation:

"Act" means the *Utilities Commission Act*;

"bulk electricity purchaser" means a public utility that purchases electricity from the authority for resale to the public utility's customers;

"charity program" means a program to reduce energy consumption in buildings

(a) owned and used by a charity that provides assistance to low-income persons, or

(b) leased by a charity that provides assistance to low-income persons, if the benefits of the program accrue primarily to the charity;

"clean or renewable resource" has the same meaning as in the *Clean Energy Act*;

"community engagement program" means a program delivered by

(a) a public utility to a public entity either

(i) to increase the public entity's awareness about ways to increase energy conservation and energy efficiency or to encourage the public entity to conserve energy or use energy efficiently, or

(ii) to assist the public entity to increase the public's awareness about ways to increase energy conservation and energy efficiency or to encourage the public to conserve energy or use energy efficiently, or

(b) a public utility in cooperation with a public entity to increase the public's awareness about ways to increase energy conservation and energy efficiency or to encourage the public to conserve energy or use energy efficiently;

"education program" means an education program about energy conservation and efficiency, and includes the funding of the development of such a program;

"energy efficiency training" means training for persons who

(a) manufacture, sell or install energy-efficient products or products that conserve energy,

(b) design, construct or act as a real estate broker with respect to energy-efficient buildings,

(c) manage energy systems,

(d) conduct energy efficiency and conservation audits,

(e) on behalf of an organization, manage or advise with respect to the conservation or efficient use of energy in the organization's facilities, or

(f) in an organization, educate other persons about the benefits of energy efficiency and conservation;

"energy management program" means a program to assist customers to optimize energy use;

"energy-using product" has the same meaning as in the *Energy Efficiency Act* (Canada);

"expenditure portfolio" means the class of demand-side measures that is composed of all of the demand-side measures proposed by a public utility in an expenditure schedule submitted under section 44.2 of the Act;

"low-income household" means a household whose residents receive service from the public utility and

(a) the residents have, in a taxation year, a before-tax annual household income equal to or less than the low-income cut-off established by Statistics Canada for that year for households of that size, multiplied by 1.3, or

(b) the account holder receives one or more of the following:

(i) guaranteed income supplement under the *Old Age Security Act* (Canada);

(ii) allowance under the *Old Age Security Act* (Canada) for persons aged 60 to 64 with spouses or common-law partners who receive a pension under that Act and are eligible for a guaranteed income supplement;

(iii) survivor's allowance under the *Old Age Security Act* (Canada);

(iv) disability benefits under the *Canada Pension Plan* (Canada);

(v) National Child Benefit Supplement;

(vi) shelter aid for elderly renters under the *Shelter Aid for Elderly Renters Act*;

(vii) income assistance for persons with persistent multiple barriers to employment under the *Employment and Assistance Act*;

(viii) Provincial senior's supplement under the *Employment and Assistance Act*;

(ix) income assistance under the *Employment and Assistance Act*;

(x) hardship assistance under the *Employment and Assistance Act*;

(xi) disability assistance under the *Employment and Assistance for Persons with Disabilities Act*;

(xii) rental assistance provided by the British Columbia Housing Management Commission;

"plan portfolio" means the class of demand-side measures that is composed of all of the demand-side measures proposed by a public utility in a plan submitted under section 44.1 of the Act;

"public awareness program" means a program delivered by a public utility

(a) to increase the awareness of the public, including the public utility's customers, about ways to increase energy conservation and energy efficiency or to encourage the public, including the public utility's customers, to conserve energy or use energy efficiently, or

(b) to increase participation by the public utility's customers in other demand-side measures proposed by the public utility in an expenditure portfolio or a plan portfolio

but does not include a program to increase the amount of energy sold or delivered by the public utility;

"public entity" means

(a) a local government,

(b) a first nation,

(c) a society incorporated under the *Societies Act*, other than a member-funded society as defined in section 190 of that Act, or

(d) a trade union;

"regulated item" means

(a) a product or system that uses energy or controls or affects the use of energy,

(b) an energy-using product,

(c) a building design,

(d) Repealed. [B.C. Reg. 228/2011, s. 1 (d).]

(e) a building site design or building site selection plan, or

(f) a community design;

"school" means a school regulated under the *School Act* or the *Independent School Act*;

"specified demand-side measure" means

(a) a demand-side measure referred to in section 3 (c) or (d),

(b) the funding of energy efficiency training,

(c) a community engagement program,

(c.1) an energy management program,

(d) a technology innovation program, or

(e) financial or other resources provided

(i) to a standards-making body to support the development of standards respecting energy conservation or the efficient use of energy, or

(ii) to a government or regulatory body to support the development of or compliance with a specified standard or a measure respecting energy conservation or the efficient use of energy in the Province;

"specified proposal" means

(a) a proposal respecting an amendment to the regulation referred to in paragraph (a) of the definition of "specified standard", if the proposal is published by the government;

(b) a proposal respecting an amendment to the regulations referred to in paragraph (b) of the definition of "specified standard", if the proposed amendment is published in the Canada Gazette;

(c) a proposal respecting an amendment to the regulation referred to in paragraph (c) of the definition of "specified standard", if the proposal is published by the government;

(d) a proposal respecting

(i) a new bylaw, or

(ii) an amendment to a bylaw

referred to in paragraph (d) of the definition of "specified standard", if the proposal has been given first reading by the council of the local authority;

(e) a proposal respecting

(i) a new law, or

(ii) an amendment to a law

referred to in paragraph (e) of the definition of "specified standard", if the proposal has been published by the governing body referred to in that paragraph;

"specified standard" means a standard in any of the following:

(a) the Energy Efficiency Standards Regulation, B.C. Reg. 389/93;

(b) the Energy Efficiency Regulations SOR/94-651;

(c) the British Columbia Building Code, if the standard promotes energy conservation or the efficient use of energy;

(d) a bylaw of a local authority, if the standard promotes energy conservation or the efficient use of energy in the Province;

(e) a law passed by a governing body of a first nation, if the standard promotes energy conservation or the efficient use of energy in the Province;

"step code", in relation to a building to which Part 3 or 9 of the British Columbia Building Code (the Code) applies, means energy efficiency requirements in a regulation made under section 3 of the *Building Act* that are more stringent than the requirements in

(a) Sentence 10.2.1.1. (1) of the Code, for buildings to which Part 3 of the Code applies, or

(b) Subsections 9.36.2. to 9.36.4. of the Code, for buildings to which Part 9 of the Code applies;

"technology innovation program" means a program

(a) to develop, use or support the increased use of a technology, a system of technologies, a building design or an industrial facility design that is

(i) not commonly used in British Columbia, and

(ii) the use of which could directly or indirectly result in significant reductions of energy use or significantly more efficient use of energy,

(b) to do what is described in paragraph (a) and to give demonstrations to the public of any results of doing what is described in paragraph (a), or

(c) to gather information about a technology, a system of technologies, a building design or an industrial design referred to in paragraph (a).

[am. B.C. Regs. 228/2011, s. 1; 141/2014, s. 1; 117/2017, Sch., s. 1.]

Application

2 (1) Repealed. [B.C. Reg. 326/2008, s. 2 (2).]

(2) Effective June 1, 2009,

(a) subsection (1) is repealed, and

(b) section 3 does not apply to a public utility that is owned or operated by a local government or has fewer than 10 000 customers.

Adequacy

3 (1) A public utility's plan portfolio is adequate for the purposes of section 44.1 (8) (c) of the Act only if the plan portfolio includes all of the following:

(a) a demand-side measure intended specifically

(i) to assist residents of low-income households to reduce their energy consumption, or

(ii) to reduce energy consumption in housing owned or operated by

(A) a housing provider that is a local government, a society as defined in section 1 of the *Societies Act*, other than a member-funded society as defined in section 190 of that Act, or an association as defined in section 1 (1) of the *Cooperative Association Act*, or

(B) the governing body of a first nation, if the benefits of the reduction primarily accrue to

(C) the low-income households occupying the housing,

(D) a housing provider referred to in clause (A), or

(E) a governing body referred to in clause (B) if the households in the governing body's housing are primarily low-income households;

(b) if the plan portfolio is submitted on or after June 1, 2009, a demand-side measure intended specifically to improve the energy efficiency of rental accommodations;

(c) an education program for students enrolled in schools in the public utility's service area;

(d) if the plan portfolio is submitted on or after June 1, 2009, an education program for students enrolled in post-secondary institutions in the public utility's service area;

(e) one or more demand-side measures to provide resources as set out in paragraph (e) of the definition of "specified demand-side measure", representing no less than

(i) an average of 1% of the public utility's plan portfolio's expenditures per year over the portfolio's period of expenditures, or

(ii) an average of $2 million per year over the portfolio's period of expenditures;

(f) one or more demand-side measures intended to result in the adoption by local governments and first nations of a step code or more stringent requirements within a step code.

(2) The commission, when considering whether a plan portfolio is adequate under subsection (1), may consider a demand-side measure that is not included in the plan portfolio to be a part of the plan portfolio.

[am. B.C. Reg. 141/2014, s. 2; 117/2017, Sch., s. 2.]

Cost effectiveness

4 (1) Subject to subsections (1.5), (4) and (5), the commission, in determining for the purposes of section 44.1 (8) (c) or 44.2 (5) (d) of the Act the cost-effectiveness of a demand-side measure proposed in an expenditure portfolio or a plan portfolio, may compare the costs and benefits of

(a) the demand-side measure individually,

(b) the demand-side measure and other demand-side measures in the portfolio, or

(c) the portfolio as a whole.

(1.1) Subject to subsection (2), the commission must make determinations of cost effectiveness by applying the total resource cost test as follows and in the order set out:

(a) subject to subsections (1.2) and (1.3), the avoided natural gas cost, if any, respecting a demand-side measure, in addition to the avoided capacity cost, is the amount that the commission is satisfied represents the authority's long-run marginal cost of acquiring electricity generated from clean or renewable resources in British Columbia;

(b) subject to subsection (1.3), the avoided electricity cost, if any, respecting a demand-side measure, in addition to the avoided capacity cost, is

(i) in the case of a demand-side measure of FortisBC Inc., an amount that the commission is satisfied represents FortisBC Inc.'s long-run marginal cost of acquiring electricity generated from clean or renewable resources in British Columbia, and

(ii) in the case of a demand-side measure not referred to in subparagraph (i), an amount that the commission is satisfied represents the authority's long-run marginal cost of acquiring electricity generated from clean or renewable resources in British Columbia;

(c) with respect to a demand-side measure that is not referred to in section 3 (1) (a) and that is not a charity program, do the following:

(i) increase the benefits of the demand-side measure by an amount that does not exceed an amount proposed by the public utility for this purpose, if the commission is satisfied that the amount represents the participant or utility non-energy benefits of the demand-side measure;

(ii) if the benefits of a demand-side measure have not been increased under subparagraph (i) or if the benefits of the expenditure portfolio of which the demand-side measure is a part has not been increased by 15% or more as a result of an increase under subparagraph (i), increase the benefit of the demand-side measure by an amount that

(A) increases by 15% the benefits of the expenditure portfolio of which the demand-side measure is a part, and

(B) is equal to the increase made under this subparagraph for all the other demand-side measures that are part of the expenditure portfolio;

(d) the benefit of the demand-side measure is what it would have been had no step code been adopted in the Province.

(1.2) Subsection (1.1) (a) does not apply to a demand-side measure that reduces the use of natural gas but does not reduce greenhouse gas emissions associated with that use of natural gas.

(1.3) Subsection (1.1) (a) and (b) does not apply to a demand-side measure that encourages a switch from the use of oil or propane to the use of natural gas or electricity such that the switch would decrease greenhouse gas emissions in British Columbia.

(1.4) In considering a demand-side measure that, in the commission's opinion, will increase the use of a regulated item with respect to which there is either

(a) a specified standard that has not yet commenced, or

(b) a specified proposal,

the commission, after applying subsection (1.1), may increase the benefit of the demand-side measure by an amount that represents a portion of the avoided capacity and energy costs that, in the commission's opinion, will result from the commencement and application of the specified standard, amendment or new bylaw proposed by the specified proposal, assuming that the standard, amendment or new bylaw comes into force.

(1.5) Despite subsection (1.1) and subject to subsections (1.9), (4) and (5), the commission must determine that a demand-side measure, other than a demand-side measure referred to in section 3 (1) (a) or a charity program, that is part of an expenditure portfolio and that is cost effective when applying subsection (1.1) is not cost effective if

(a) the demand-side measure is not cost-effective without applying subsection (1.1), and

(b) the total expenditures respecting

(i) the demand-side measure, and

(ii) all other demand-side measures that are part of the expenditure portfolio, that are not cost effective without applying subsection (1.1) and that are cost effective when applying subsection (1.1),

are more than

(iii) 40% of the total expenditures for the expenditure portfolio, in the case of a utility that recovers the expenditures in gas rates, or

(iv) 10% of the total expenditures for the expenditure portfolio, in the case of a utility that recovers the expenditures in electricity rates.

(1.6) For greater certainty, if the commission determines under subsection (1.5) that a demand-side measure that is part of an expenditure portfolio is not cost effective, the commission must exclude that demand-side measure from consideration when determining under that subsection whether another demand-side measure that is part of the expenditure portfolio is cost effective.

(1.7) For the purposes of subsections (1.1) (c) and (1.5), the commission, when considering the benefits or expenditures respecting a public utility's expenditure portfolio, may consider a demand-side measure of the public utility that is not included in the expenditure portfolio to be a part of the expenditure portfolio.

(1.8) Despite subsection (1.1), the commission may determine that a demand-side measure, other than

(a) a specified demand-side measure,

(a.1) a charity program,

(b) a public awareness program,

(c) a demand-side measure referred to in section 3 (1) (a), or

(d) a demand-side measure that is cost effective without applying subsection (1.1) but after applying subsection (1.4)

is not cost effective if the demand-side measure would not be considered cost-effective under the utility cost test.

(1.9) The references in subsections (1.5) and (1.8) to subsection (1.1) must be read as references

(a) to subsection (1.1) (a), (b) and (c) for the purposes of a demand-side measure that is part of an expenditure portfolio for any period before January 1, 2015, and

(b) to subsection (1.1) (a) and (c) for the purposes of a demand-side measure that is part of an expenditure portfolio for any period after December 31, 2014.

(2) In determining whether a demand-side measure referred to in section 3 (1) (a) or a charity program is cost effective, the commission must,

(a) in addition to conducting any other analysis the commission considers appropriate, use the total resource cost test, and

(b) in using the total resource cost test, make the adjustments referred to in subsection (1.1) (a) and (b) and then increase the value of the benefit of the demand-side measure by 40%.

(3) Repealed. [B.C. Reg. 228/2011, s. 2 (d).]

(4) The commission must determine the cost-effectiveness of a specified demand-side measure proposed in a plan portfolio or an expenditure portfolio by determining whether the portfolio is cost effective as a whole.

(5) If the commission is satisfied that a public awareness program proposed in a plan portfolio or an expenditure portfolio is likely to accomplish the goals set out in paragraph (a) or (b) of the definition of "public awareness program", the commission must determine the cost-effectiveness of the program by determining whether the portfolio is cost-effective as a whole.

(6) The commission may not determine that a proposed demand-side measure is not cost effective on the basis of the result obtained by using a ratepayer impact measure test to assess the demand-side measure.

(7) Repealed. [B.C. Reg. 228/2011, s. 2 (d).]

[am. B.C. Regs. 228/2011, s. 2; 141/2014, s. 3; 117/2017, Sch., s. 3.]

[Provisions relevant to the enactment of this regulation: *Utilities Commission Act*, R.S.B.C. 1996, c. 473, section 125.1]

Volume 51, No. 22 B.C. Reg. 326/2008	The British Columbia Gazette, Part II November 18, 2008

B.C. Reg. 326/2008, deposited November 7, 2008, pursuant to the **UTILITIES COMMISSION ACT** [Section 125.1 (4) (e)]. Ministerial Order M271/2008, dated November 6, 2008.

I, Richard Neufeld, Minister of Energy, Mines and Petroleum Resources, order that the attached regulation is made.

— R. NEUFELD, *Minister of Energy, Mines and Petroleum Resources.*

DEMAND-SIDE MEASURES REGULATION

Definitions

1 In this regulation:

"Act" means the *Utilities Commission Act*;

"bulk electricity purchaser" means a public utility that purchases electricity from the authority for resale to the public utility's customers;

"community engagement program" means a program delivered by

(a) a public utility to a public entity either

(i) to increase the public entity's awareness about ways to increase energy conservation and energy efficiency or to encourage the public entity to conserve energy or use energy efficiently, or

(ii) to assist the public entity to increase the public's awareness about ways to increase energy conservation and energy efficiency or to encourage the public to conserve energy or use energy efficiently, or

(b) a public utility in cooperation with a public entity to increase the public's awareness about ways to increase energy conservation and energy efficiency or to encourage the public to conserve energy or use energy efficiently;

"education program" means an education program about energy conservation and efficiency, and includes the funding of the development of such a program;

"energy device" has the same meaning as in the *Energy Efficiency Act*;

"energy efficiency training" means training for persons who

(a) manufacture, sell or install energy-efficient products,

(b) design, construct or act as a real estate broker with respect to energy-efficient buildings,

(c) manage energy systems in buildings, or

(d) conduct energy efficiency audits;

"energy-using product" has the same meaning as in the *Energy Efficiency Act* (Canada);

"expenditure portfolio" means the class of demand-side measures that is composed of all of the demand-side measures proposed by a public utility in an expenditure schedule submitted under section 44.2 of the Act;

"low-income household" means a household whose residents receive service from the public utility and who have, in a taxation year, a before-tax annual household income equal to or less than the low-income cut off established by Statistics Canada for that year for households of that type;

"plan portfolio" means the class of demand-side measures that is composed of all of the demand-side measures proposed by a public utility in a plan submitted under section 44.1 of the Act;

"public awareness program" means a program delivered by a public utility

(a) to increase the awareness of the public, including the public utility's customers, about ways to increase energy conservation and energy efficiency or to encourage the public, including the public utility's customers, to conserve energy or use energy efficiently, or

(b) to increase participation by the public utility's customers in other demand-side measures proposed by the public utility in an expenditure portfolio or a plan portfolio

but does not include a program to increase the amount of energy sold or delivered by the public utility;

"public entity" means a local government, first nation, non-profit society incorporated under the *Society Act* or trade union;

"regulated item" means

(a) an energy device,

(b) an energy-using product,

(c) a building design, or

(d) thermal insulation;

"school" means a school regulated under the *School Act* or the *Independent School Act*;

"specified demand-side measure" means

(a) a demand-side measure referred to in section 3 (c) or (d),

(b) the funding of energy efficiency training,

(c) a community engagement program, or

(d) a technology innovation program;

"specified standard" means a standard in any of the following:

(a) the Energy Efficiency Standards Regulation, B.C. Reg. 389/93;

(b) the Energy Efficiency Regulations S.O.R./94-651;

(c) the British Columbia Building Code, if the standard promotes energy conservation or the efficient use of energy;

"technology innovation program" means a program

(a) to develop a technology, a system of technologies, a building design or an industrial facility design that is

(i) not commonly used in British Columbia, and

(ii) the use of which could directly or indirectly result in significant reductions of energy use or significantly more efficient use of energy,

(b) to do what is described in paragraph (a) and to give demonstrations to the public of any results of doing what is described in paragraph (a), or

(c) to gather information about a technology, a system of technologies, a building design or an industrial design referred to in paragraph (a).

Application

2 (1) This regulation applies only with respect to demand-side measures proposed by the authority.

(2) Effective June 1, 2009,

(a) subsection (1) is repealed, and

(b) section 3 does not apply to a public utility that is owned or operated by a local government or has fewer than 10,000 customers.

Adequacy

3 A public utility's plan portfolio is adequate for the purposes of section 44.1 (8) (c) of the Act only if the plan portfolio includes all of the following:

(a) a demand-side measure intended specifically to assist residents of low-income households to reduce their energy consumption;

(b) if the plan portfolio is submitted on or after June 1, 2009, a demand-side measure intended specifically to improve the energy efficiency of rental accommodations;

(c) an education program for students enrolled in schools in the public utility's service area;

(d) if the plan portfolio is submitted on or after June 1, 2009, an education program for students enrolled in post-secondary institutions in the public utility's service area.

Cost effectiveness

4 (1) Subject to subsections (4) and (5), the commission, in determining for the purposes of section 44.1 (8) (c) or 44.2 (5) (d) of the Act the cost-effectiveness of a demand-side measure proposed in an expenditure portfolio or a plan portfolio, May compare the costs and benefits of

(a) the demand-side measure individually,

(b) the demand-side measure and other demand-side measures in the portfolio, or

(c) the portfolio as a whole.

(2) In determining whether a demand-side measure referred to in section 3 (a) is cost effective, the commission must,

(a) in addition to conducting any other analysis the commission considers appropriate, use the total resource cost test, and

(b) in using the total resource cost test, consider the benefit of the demand-side measure to be 130% of its value when determined without reference to this subsection.

(3) In determining whether a demand-side measure of a bulk electricity purchaser is cost-effective, the commission must consider the benefit of the avoided supply cost to be the authority's long-term marginal cost of acquiring new electricity to replace the electricity sold to the bulk electricity purchaser and not the bulk electricity purchaser's cost of purchasing electricity from the authority.

(4) The commission must determine the cost-effectiveness of a specified demand-side measure proposed in a plan portfolio or an expenditure portfolio by determining whether the portfolio is cost effective as a whole.

(5) If the commission is satisfied that a public awareness program proposed in a plan portfolio or an expenditure portfolio is likely to accomplish the goals set out in paragraph (a) or (b) of the definition of "public awareness program", the commission must determine the cost-effectiveness of the program by determining whether the portfolio is cost-effective as a whole.

(6) The commission May not determine that a proposed demand-side measure is not cost effective on the basis of the result obtained by using a ratepayer impact measure test to assess the demand-side measure.

(7) In considering the benefit of a demand-side measure that, in the commission's opinion, will increase the market share of a regulated item with respect to which there is a specified standard that has not yet commenced, the commission May include in the benefit a proportion of the benefit that, in the

commission's opinion, will result from the commencement and application of the specified standard with respect to the regulated item.

Volume 54, No. 23 228/2011	The British Columbia Gazette, Part II December 13, 2011

B.C. Reg. 228/2011, deposited December 8, 2011, pursuant to the **UTILITIES COMMISSION ACT** [section 125.1 (4) (e)]. Ministerial Order M335/2011, dated December 8, 2011.

I, Rich Coleman, Minister of Energy and Mines and Minister Responsible for Housing, order that the Demand-Side Measures Regulation, B.C. Reg. 326/2008, is amended as set out in the attached schedule.

— R. COLEMAN, *Minister of Energy and Mines and Minister Responsible for Housing*.

Schedule

1 Section 1 of the Demand-Side Measures Regulation, B.C. Reg. 326/2008, is amended

(a) by adding the following definition:

"clean or renewable resource" has the same meaning as in the *Clean Energy Act*; ***,***

(b) by repealing the definition of* "energy device"*,

(c) by repealing the definition of* "energy efficiency training" *and substituting the following:

"energy efficiency training" means training for persons who

(a) manufacture, sell or install energy-efficient products or products that conserve energy,

(b) design, construct or act as a real estate broker with respect to energy-efficient buildings,

(c) manage energy systems,

(d) conduct energy efficiency and conservation audits,

(e) on behalf of an organization, manage or advise with respect to the conservation or efficient use of energy in the organization's facilities, or

(f) in an organization, educate other persons about the benefits of energy efficiency and conservation; ***,***

(d) by repealing paragraphs (a) and (d) in the definition of* "regulated item" *and substituting the following:

(a) a product or system that uses energy or controls or affects the use of energy,

(e) a building site design or building site selection plan, or

(f) a community design; **,**

(e) in the definition of* "specified demand-side measure" *by adding the following paragraph:

(e) financial or other resources provided

(i) to a standards-making body to support the development of standards respecting energy conservation or the efficient use of energy, or

(ii) to a government or regulatory body to support the development of or compliance with a specified standard or a measure respecting energy conservation or the efficient use of energy in the Province; **,**

(f) by adding the following definition:

"specified proposal" means

(a) a proposal respecting an amendment to the regulation referred to in paragraph (a) of the definition of "specified standard", if the proposal is published by the minister responsible for the *Energy Efficiency Act* and specifically refers to this regulation;

(b) a proposal respecting an amendment to the regulations referred to in paragraph (b) of the definition of "specified standard", if the proposed amendment is published in the Canada Gazette;

(c) a proposal respecting an amendment to a standard referred to in paragraph (c) of the definition of "specified standard", if the proposal is published by the government and specifically refers to this regulation;

(d) a proposal respecting

(i) a new bylaw, or

(ii) an amendment to a bylaw

referred to in paragraph (d) of the definition of "specified standard", if the proposal has been given first reading by the council of the local authority;

(e) a proposal respecting

(i) a new law, or

(ii) an amendment to a law

referred to in paragraph (e) of the definition of "specified standard", if the proposal has been published by the governing body referred to in that paragraph; **,**

(g) in the definition of* "specified standard" *by adding the following paragraphs:

(d) a bylaw of a local authority, if the standard promotes energy conservation or the efficient use of energy in the Province;

(e) a law passed by a governing body of a first nation, if the standard promotes energy conservation or the efficient use of energy in the Province; ***, and***

(h) in paragraph (a) of the definition of **"technology innovation program"** ***by adding "***, use or support the increased use of***" after "***to develop***".***

2 Section 4 is amended

(a) in subsection (1) by striking out "Subject to subsections (4) and (5)***" and substituting "***Subject to subsections (1.5), (4) and (5)***",***

(b) by adding the following subsections:

(1.1) The commission must make determinations of cost effectiveness by applying the total resource cost test as follows and in the order set out:

(a) subject to subsections (1.2) and (1.3), the avoided natural gas cost, if any, respecting a demand-side measure, in addition to the avoided capacity cost, is the amount that the commission is satisfied represents the authority's long-run marginal cost of acquiring electricity generated from clean or renewable resources in British Columbia, multiplied by 0.5;

(b) subject to subsection (1.3), the avoided electricity cost, if any, respecting a demand-side measure, in addition to the avoided capacity cost, is

(i) in the case of a demand-side measure of FortisBC Inc., an amount that the commission is satisfied represents FortisBC Inc.'s long-run marginal cost of acquiring electricity generated from clean or renewable resources in British Columbia, and

(ii) in the case of a demand-side measure not referred to in subparagraph (i), an amount that the commission is satisfied represents the authority's long-run marginal cost of acquiring electricity generated from clean or renewable resources in British Columbia;

(c) with respect to a demand-side measure not referred to in section 3 (a), do the following:

(i) increase the benefits of the demand-side measure by an amount that does not exceed an amount proposed by the public utility for this purpose, if the commission is satisfied that the amount represents the participant or utility non-energy benefits of the demand-side measure;

(ii) if the benefits of a demand-side measure have not been increased under subparagraph (i) or if the benefits of the expenditure portfolio of which the demand-side measure is a part has not been increased by 15% or more as a result of an increase under subparagraph (i), increase the benefit of the demand-side measure by an amount that

(A) increases by 15% the benefits of the expenditure portfolio of which the demand-side measure is a part, and

(B) is equal to the increase made under this subparagraph for all the other demand-side measures that are part of the expenditure portfolio.

(1.2) Subsection (1.1) (a) does not apply to a demand-side measure that reduces the use of natural gas but does not reduce greenhouse gas emissions associated with that use of natural gas.

(1.3) Subsection (1.1) (a) and (b) does not apply to a demand-side measure that encourages a switch from the use of oil or propane to the use of natural gas or electricity such that the switch would decrease greenhouse gas emissions in British Columbia.

(1.4) In considering a demand-side measure that, in the commission's opinion, will increase the use of a regulated item with respect to which there is either

(a) a specified standard that has not yet commenced, or

(b) a specified proposal,

the commission, after applying subsection (1.1), may increase the benefit of the demand-side measure by an amount that represents a portion of the avoided capacity and energy costs that, in the commission's opinion, will result from the commencement and application of the specified standard, amendment or new bylaw proposed by the specified proposal, assuming that the standard, amendment or new bylaw comes into force.

(1.5) Despite subsection (1.1) and subject to subsections (4) and (5), the commission must determine that a demand-side measure that is part of an expenditure portfolio and that is cost effective when applying subsection (1.1) is not cost effective if

(a) the demand-side measure is not cost-effective without applying subsection (1.1), and

(b) the total expenditures respecting

(i) the demand-side measure, and

(ii) all other demand-side measures that are part of the expenditure portfolio, that are not cost effective without applying subsection (1.1) and that are cost effective when applying subsection (1.1),

are more than

(iii) 33% of the total expenditures for the expenditure portfolio, in the case of a utility that recovers the expenditures in gas rates, or

(iv) 10% of the total expenditures for the expenditure portfolio, in the case of a utility that recovers the expenditures in electricity rates.

(1.6) For greater certainty, if the commission determines under subsection (1.5) that a demand-side measure that is part of an expenditure portfolio is not cost effective, the commission must exclude that demand-side measure from consideration when determining under that subsection whether another demand-side measure that is part of the expenditure portfolio is cost effective.

(1.7) For the purposes of subsections (1.1) (c) and (1.5), the commission, when considering the benefits or expenditures respecting a public utility's expenditure portfolio, may consider a demand-side measure of the public utility that is not included in the expenditure portfolio to be a part of the expenditure portfolio.

(1.8) Despite subsection (1.1), the commission may determine that a demand-side measure, other than

(a) a specified demand-side measure,

(b) a public awareness program,

(c) a demand-side measure referred to in section 3 (a), or

(d) a demand-side measure that is cost effective without applying subsection (1.1) but after applying subsection (1.4)

is not cost effective if the demand-side measure would not be considered cost-effective under the utility cost test.

(c) in subsection (2) (b) by adding "but after applying subsection (1.1)***" after "***without reference to this subsection***", and***

(d) by repealing subsections (3) and (7).

Volume 57, No. 13 141/2014	The British Columbia Gazette, Part II July 15, 2014

B.C. Reg. 141/2014, deposited July 10, 2014, under the **UTILITIES COMMISSION ACT** [section 125.1]. Ministerial Order M233/2014, dated June 4, 2014

I, Bill Bennett, Minister of Energy and Mines and Minister Responsible for Core Review, order that the Demand-Side Measures Regulation, B.C. Reg 326/2008, is amended as set out in the attached Schedule.

— W. R. BENNETT, *Minister of Energy and Mines and Minister Responsible for Core Review*.

SCHEDULE

1 Section 1 of the Demand-Side Measures Regulation, B.C. Reg. 326/2008, is amended by repealing the definition of* "low-income household" *and substituting the following:

"low-income household" means a household whose residents receive service from the public utility and

(a) the residents have, in a taxation year, a before-tax annual household income equal to or less than the low-income cut-off established by Statistics Canada for that year for households of that size, multiplied by 1.3, or

(b) the account holder receives one or more of the following:

(i) guaranteed income supplement under the *Old Age Security Act* (Canada);

(ii) allowance under the *Old Age Security Act* (Canada) for persons aged 60 to 64 with spouses or common-law partners who receive a pension under that Act and are eligible for a guaranteed income supplement;

(iii) survivor's allowance under the *Old Age Security Act* (Canada);

(iv) disability benefits under the *Canada Pension Plan* (Canada);

(v) National Child Benefit Supplement;

(vi) shelter aid for elderly renters under the *Shelter Aid for Elderly Renters Act*;

(vii) income assistance for persons with persistent multiple barriers to employment under the *Employment and Assistance Act*;

(viii) Provincial senior's supplement under the *Employment and Assistance Act*;

(ix) income assistance under the *Employment and Assistance Act*;

(x) hardship assistance under the *Employment and Assistance Act*;

(xi) disability assistance under the *Employment and Assistance for Persons with Disability Act*;

(xii) rental assistance provided by the British Columbia Housing Management Commission;

2 Section 3 (a) is repealed and the following is substituted:

(a) a demand-side measure intended specifically

(i) to assist residents of low-income households to reduce their energy consumption, or

(ii) to reduce energy consumption in housing owned or operated by

(A) a housing provider incorporated under the *Society Act* or the *Cooperative Association Act*, or

(B) a band within the meaning of the *Indian Act* (Canada),

if the benefits of the reduction primarily accrue to

(C) the low-income households occupying the housing,

(D) a housing provider referred to in clause (A), or

(E) a band referred to in clause (B) if the households in the band's housing are primarily low-income households;

3 Section 4 is amended

(a) in subsection (1.1) (a) by striking out ", multiplied by 0.5***",***

(b) in subsection (1.5) by striking out "subject to subsections (4) and (5),***" and substituting "***subject to subsections (1.9), (4) and (5),***",***

(c) by adding the following subsection:

(1.9) The references in subsections (1.5) and (1.8) to subsection (1.1) must be read as references

(a) to subsection (1.1) (a), (b) and (c) for the purposes of a demand-side measure that is part of an expenditure portfolio for any period before January 1, 2015, and

(b) to subsection (1.1) (a) and (c) for the purposes of a demand-side measure that is part of an expenditure portfolio for any period after December 31, 2014. ***, and***

(d) in subsection (2) (b) by striking out "130%***" and substituting "***140%***".***

Volume 60, No. 5 117/2017	The British Columbia Gazette, Part II March 28, 2017

B.C. Reg. 117/2017, deposited March 24, 2017, under the **UTILITIES COMMISSION ACT** [section 125.1]. Ministerial Order M138/2017, dated March 22, 2017.

I, Bill Bennett, Minister of Energy and Mines and Minister Responsible for Core Review, order that

(a) the Demand-Side Measures Regulation, B.C. Reg. 326/2008, is amended as set out in the attached Schedule, and

(b) the amendments made in accordance with paragraph (a) of this order do not apply with respect to the application for acceptance, under section 44.2 of the *Utilities Commission Act*, of the demand-side management expenditure schedule included in the revenue requirement application submitted by the authority to the commission on July 28, 2016.

— W. R. BENNETT, *Minister of Energy and Mines and Minister Responsible for Core Review*.

SCHEDULE

1 Section 1 of the Demand-Side Measures Regulation, B.C. Reg. 326/2008, is amended

(a) by adding the following definitions:

"charity program" means a program to reduce energy consumption in buildings

(a) owned and used by a charity that provides assistance to low-income persons, or

(b) leased by a charity that provides assistance to low-income persons, if the benefits of the program accrue primarily to the charity;

"energy management program" means a program to assist customers to optimize energy use; ***,***

(b) by repealing the definition of **"public entity"** ***and substituting the following:***

"public entity" means

(a) a local government,

(b) a first nation,

(c) a society incorporated under the *Societies Act*, other than a member-funded society as defined in section 190 of that Act, or

(d) a trade union; ***,***

(c) in the definition of **"specified demand-side measure"** ***by adding the following paragraph:***

(c.1) an energy management program, ***,***

(d) by repealing paragraphs (a) and (c) of the definition of **"specified proposal"** ***and substituting the following:***

(a) a proposal respecting an amendment to the regulation referred to in paragraph (a) of the definition of "specified standard", if the proposal is published by the government;

(c) a proposal respecting an amendment to the regulation referred to in paragraph (c) of the definition of "specified standard", if the proposal is published by the government; ***, and***

(e) by adding the following definition:

"step code", in relation to a building to which Part 3 or 9 of the British Columbia Building Code (the Code) applies, means energy efficiency requirements in a regulation made under section 3 of the *Building Act* that are more stringent than the requirements in

(a) Sentence 10.2.1.1. (1) of the Code, for buildings to which Part 3 of the Code applies, or

(b) Subsections 9.36.2. to 9.36.4. of the Code, for buildings to which Part 9 of the Code applies.

2 Section 3 is amended

(a) by renumbering the section as section 3 (1),

(b) by repealing subsection (1) (a) (ii) (A) and (B) and substituting the following:

(A) a housing provider that is a local government, a society as defined in section 1 of the *Societies Act*, other than a member-funded society as defined in section 190 of that Act, or an association as defined in section 1 (1) of the *Cooperative Association Act*, or

(B) the governing body of a first nation, ***,***

(c) by repealing subsection (1) (a) (ii) (E) and substituting the following:

(E) a governing body referred to in clause (B) if the households in the governing body's housing are primarily low-income households; ***,***

(d) in subsection (1) by adding the following paragraphs:

(e) one or more demand-side measures to provide resources as set out in paragraph (e) of the definition of "specified demand-side measure", representing no less than

(i) an average of 1% of the public utility's plan portfolio's expenditures per year over the portfolio's period of expenditures, or

(ii) an average of $2 million per year over the portfolio's period of expenditures;

(f) one or more demand-side measures intended to result in the adoption by local governments and first nations of a step code or more stringent requirements within a step code. ***, and***

(e) by adding the following subsection:

(2) The commission, when considering whether a plan portfolio is adequate under subsection (1), may consider a demand-side measure that is not included in the plan portfolio to be a part of the plan portfolio.

3 Section 4 is amended

(a) in subsection (1.1) by striking out "The commission***" and substituting "***Subject to subsection (2), the commission***",***

(b) in subsection (1.1) (c) by striking out "not referred to in section 3 (a)***" and substituting "***that is not referred to in section 3 (1) (a) and that is not a charity program***",***

(c) in subsection (1.1) by adding the following paragraph:

(d) the benefit of the demand-side measure is what it would have been had no step code been adopted in the Province. ***,***

(d) in subsection (1.5) by adding ", other than a demand-side measure referred to in section 3 (1) (a) or a charity program,***" after "***must determine that a demand-side measure***",***

(e) in subsection (1.5) (b) (iii) by striking out "33%***" and substituting "***40%***",***

(f) in subsection (1.8) by adding the following paragraph:

(a.1) a charity program, ***,***

(g) in subsection (1.8) (c) by striking out "section 3 (a)***" and substituting "***section 3 (1) (a)***",***

(h) in subsection (2) by striking out "section 3 (a)***" and substituting "***section 3 (1) (a) or a charity program***", and***

(i) by repealing subsection (2) (b) and substituting the following:

(b) in using the total resource cost test, make the adjustments referred to in subsection (1.1) (a) and (b) and then increase the value of the benefit of the demand-side measure by 40%.

Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Appendix E

Government Mandate Letter and BC Hydro Service Plan

BRITISH COLUMBIA

April 18, 2018

Mr. Kenneth G. Peterson
Chair
BC Hydro
18th Floor, 333 Dunsmuir Street
Vancouver, BC V6B 5R3

Dear Mr. Peterson:

On behalf of Premier John Horgan, thank you for your service to the people of British Columbia. The Province remains committed to working with our Crown agency partners to deliver on the Government's commitments to British Columbians; to help make life more affordable for people, invest in services and build a strong, sustainable economy.

This Mandate Letter outlines the guiding principles of the Government which should inform the preparation of your three-year Service Plan for *Budget 2018*. This Mandate Letter also confirms your organization's mandate, provides Government's annual strategic direction and sets out key performance expectations for the 2018/19 fiscal year.

The Government made three key commitments to British Columbians. All ministries and Crown agencies are expected to work together to help the Government achieve these commitments.

Our first commitment is to make life more affordable. We expect all public sector organizations to support the Government's agenda to help manage the daily cost of living for British Columbians.

Our second commitment is to deliver the services that people count on. Many of the programs and services that British Columbians access on a regular basis are delivered by Crown agencies. We want to build on programs that are working well, and make improvements where needed, to ensure British Columbians get quality and timely customer service from public sector organizations across the Province.

Our third key commitment is to build a strong, sustainable, innovative economy that works for everyone. The Government believes that public sector organizations have a key role to play in supporting broad-based economic growth in every region of the Province.

To support true and lasting reconciliation with Indigenous Peoples in British Columbia, the Government is fully adopting and implementing the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP), and the Calls to Action of the Truth and Reconciliation Commission (TRC). Please ensure that going forward your organization incorporates the UNDRIP and TRC, given the specific mandate and context of your organization.

As the Minister responsible for BC Hydro, I expect that you will make substantive progress on the following priorities and incorporate these priorities when developing the goals, objectives and performance measures for inclusion in the Service Plan:

- Complete the Site C Project by November 2024, at a total cost of no more than $10.7 billion, provide quarterly progress reports in accordance with the June 2015 Reporting and Accountability Framework, and:
  - enhance project oversight by adding an independent expert Project Assurance Team to supplement the Site C Project Board;
  - work with the Ministry of Transportation and Infrastructure and Treaty 8 First Nations to re-design the re-alignment of Highway 29, and where possible, provide opportunities to Treaty 8 First Nations to participate in delivering this work;
  - work with the Ministry of Transportation and Infrastructure and Treaty 8 First Nations to re-design the re-alignment of Highway 29, and work with project contractors to ensure that project benefits assist local communities and increase opportunities for apprentices, Indigenous workers, and other equity groups, with the aim to provide meaningful jobs and training;
  - continue to engage with Treaty 8 First Nations to seek additional solutions to mitigate the adverse impacts of Site C, and to advance reconciliation;
- Implement affordability measures, such as low income rates and expanded demand-side management programs targeted to low income ratepayers;
- Develop, in cooperation with the Ministry of Energy, Mines and Petroleum Resources (EMPR), a refreshed plan to keep electricity rates low and predictable over the long-term while making significant investments to expand the system and maintain aging infrastructure;
- Work with the Ministry to complete and begin to act on a comprehensive review of BC Hydro's activities, performance and organizational structure to identify potential efficiencies and revenue generating opportunities that could benefit ratepayers, and ensure that the organization is positioned to deliver on BC Hydro's objectives and the Government's priorities;

.../3

- Support the creation of a roadmap for the future of BC energy that will drive innovation and the electrification of BC's economy, expand energy efficiency and conservation programs, generate new energy responsibly and sustainably, and create lasting good jobs across the Province;
- Provide leadership in advancing the Government's climate action strategies, including through electrification, fuel switching, and energy efficiency initiatives in the built environment, transportation, oil and gas, and other sectors;
- Work with EMPR, the Ministry of Finance and Indigenous groups to make recommendations by fall 2018 for new Indigenous-focused clean energy and/or clean capacity power procurement;
- Provide comprehensive quarterly and annual performance reports to the Deputy Minister of EMPR on the status of BC Hydro finances and forecasts, as well as other initiatives and directions approved by the BC Hydro Board and the Minister of EMPR. As and when appropriate, also update the Deputy Minister of EMPR on other emerging trends and issues as they occur;
- Continue to deliver planned capital projects on time and on budget to maintain the reliability of the system, while providing community benefits and training and apprenticeship opportunities;
- Perform system upgrades where necessary to ensure that BC Hydro is well-positioned to connect future customers in a timely and cost-effective manner; and
- Maintain or improve customer satisfaction by providing timely and responsive service.

The Crown Agencies and Board Resourcing Office (CABRO) at the Ministry of Finance has lead responsibility for overseeing and maintaining the Public Sector Organizations Governance Framework and provides leadership for the merit-based appointment of qualified and competent individuals to the boards of Crown agencies.

BC Hydro is asked to work closely with CABRO through your ministry contact on board appointments, all governance matters including orientation and training of board members, and meeting public sector reporting requirements under the *Budget Transparency and Accountability Act*.

Each board member is required to acknowledge the direction provided in this Mandate Letter by signing this letter. The Mandate Letter is to be posted publicly on your organization's website after Budget Day 2018 following the release of your organization's Service Plan.

.../4

I have appreciated your support as Board Chair to me as Minister responsible in the first few months of our Government's term in office. I look forward to ongoing dialogue and engagement going forward through our scheduled meetings and other communication channels between my Ministry and your organization. Part of that engagement process includes regular meetings between your communications staff and the appropriate Government Communications and Public Engagement staff who provide support to your ministry responsible.

Once again, thank you to you and your Board of Directors for your commitment to public service. Together, we will work to build a better British Columbia.

Sincerely,

Michelle Mungall
Minister of Energy, Mines and Petroleum Resources

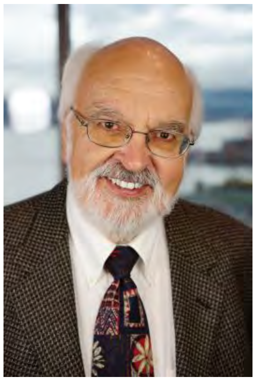
Board Chair Accountability Statement



The 2019/20 – 2021/22 BC Hydro Service Plan was prepared under the Board’s direction in accordance with the *Budget Transparency and Accountability Act*. The plan is consistent with government's strategic priorities and fiscal plan. The Board is accountable for the contents of the plan, including what has been included in the plan and how it has been reported. The Board is responsible for the validity and reliability of the information included in the plan.

All significant assumptions, policy decisions, events and identified risks, as of January 31, 2019 have been considered in preparing the plan.
The performance measures presented are consistent with the *Budget Transparency and Accountability Act*, BC Hydro’s mandate and goals, and focus on aspects critical to the organization’s performance. The targets in this plan have been determined based on an assessment of BC Hydro’s operating environment, forecast conditions, risk assessment and past performance.

Kenneth G. Peterson
Board Chair

Table of Contents

Strategic Direction and Alignment with Government Priorities

BC Hydro is one of the largest electric utilities in Canada and is publicly owned by the people of British Columbia. We generate and provide electricity to 95 per cent of B.C.'s population and serve over four million people. The electricity we generate and deliver to customers throughout the province powers our economy and quality of life.

Our mission is to safely provide reliable, affordable, clean electricity throughout B.C. We have set out a three-year plan with strategies, performance measures and targets, aligned with the objectives in the B.C. Government's Mandate Letter to BC Hydro, to fulfill our mission on behalf of our customers and the Province.

BC Hydro's electricity system was largely built in the 1960s, 1970s and 1980s, and B.C.'s population and economy continue to grow. BC Hydro is upgrading and maintaining aging assets and building new infrastructure so that our customers continue to receive reliable and clean electricity. To ensure sustained economic and social benefits for ratepayers, we manage our capital portfolio with an emphasis on cost consciousness, respect for the environment and communities in which we work, and in particular, strengthening our relationships with First Nations communities.

We have the important responsibility to keep electricity rates affordable for our customers, while funding necessary investments in our electricity system. To support this goal, we are implementing the outcomes from Phase 1 of the Comprehensive Review of BC Hydro (the Comprehensive Review) and have made the necessary adjustments to our operating and capital expenditures. We will continue to strive to limit rate increases for our customers, and we will actively participate in Phase 2 of the Comprehensive Review to strategically position the corporation for long-term success in the context of rapid shifts in the global and regional energy sectors, technological changes, and provincial and federal climate strategies.

BC Hydro will continue making investments to expand the system and maintain aging infrastructure to meet our customers' growing needs, while managing our costs, keeping rates affordable and improving our service.

BC Hydro is aligned with the Government's key priorities:

Government Priorities	BC Hydro Aligns with These Priorities By:
Making life more affordable	• Ensuring our customers will benefit from affordable bills while managing our costs, exploring innovative solutions to support our customers and making investments to maintain and expand our electricity system. (Objective 3.1)
Delivering the services people count on	• Reliably meeting the electricity requirements of customers and responding to their evolving expectations by planning and investing in the system to meet future needs and by consistently improving our service. (Objective 2.1)
A strong, sustainable economy	• Continuing to implement the updated 10 Year Capital Plan so that our customers can continue to receive clean, reliable and affordable electricity. (Strategy under Objective 3.1) • Supporting the implementation of the CleanBC plan to increase British Columbians' use of cleaner energy in key sectors of the economy and shift away from reliance on fossil fuels for transportation, industry, and housing. (Strategy under Objective 4.1)

Operating Environment

As a utility that operates in a high hazard industry, we are committed to ensuring our workforce goes home safely every day and that the public is safe around our system. We are continuously working to improve our performance by understanding hazards, ensuring appropriate design of assets and related work procedures and building and strengthening our safety culture and competencies.

BC Hydro is regulated by the British Columbia Utilities Commission (BCUC). As the independent regulator of BC Hydro, the BCUC is responsible for ensuring that our customers receive safe, reliable and non-discriminatory energy services at fair rates. Current and upcoming proceedings to support affordable rates for our customers include the Fiscal 2020-Fiscal 2021 Revenue Requirements Application, which will be submitted to the BCUC in February 2019, and various Rate Design Applications. The Revenue Requirements Application will be informed by the results of Phase 1 of the Comprehensive Review, which included a full review of our business, with an emphasis on cost consciousness.

BC Hydro is developing and evaluating a number of rate design options that would help make our customers' electricity bills more affordable and provide customers with more choices. We will also continue to advance other affordability initiatives to help our customers save money on their electricity bills.

To help keep electricity more affordable for our customers, we will implement the outcomes resulting from Phase 1 of the Comprehensive Review. We will make all reasonable efforts to limit rate increases, while continuing to make significant investments to expand the system and maintain aging infrastructure.

We continue to advance critical projects to meet our long-term energy needs, including completing the Site C project by November 2024 at a cost of no more than $10.7 billion. Over the past five years (2013/14-2017/18), we have delivered 493 capital projects at a total cost of $6.9 billion, which is 0.40 per cent over budget overall, and well within BC Hydro's +5% to -5% target. We work across teams, suppliers and experts to ensure thoughtful assessment of how to successfully deliver these projects on time and on budget while respecting the unique community, environmental and Indigenous interests associated with each project.

The electricity we generate and deliver throughout B.C. meets a high standard of reliability, but we are always looking for ways to improve our service to our customers, support climate action and help power British Columbia's sustainable, innovative economy.

We are focused on delivering our renewed customer service strategy, with the goal of making it easier to do business with us and helping our customers make smart energy choices through our conservation and energy management programs, including encouraging our customers to use our clean and reliable electricity to power their homes, vehicles and businesses. We will support and align with the Province's new CleanBC plan, which outlines significant greenhouse gas (GHG) reduction measures, by powering British Columbia's economic growth with clean and renewable electricity.

BC Hydro's extensive electricity system, along with our reinvestment and expansion plans, means a significant number of Indigenous communities across the province are, or will be, impacted by our infrastructure. We continue to work to develop and sustain positive long-term relationships and better understand Indigenous interests so that their priorities are recognized in our capital programs and business operations. Our approach and results have been recently recognized through certification at a gold level through the Canadian Council of Aboriginal Business' Progressive Aboriginal Relations program. We are working to further incorporate the Calls to Action in the Truth and Reconciliation Report, the Draft 10 Principles that Guide the Province of British Columbia's Relationship with Indigenous Peoples and the United Nations Declaration on the Rights of Indigenous Peoples into our business and operations.

With thoughtful planning and prudent decision-making, BC Hydro is well positioned to safely deliver affordable, reliable, clean electricity throughout B.C., today and into the future.

Performance Plan

We have identified four key goals that reflect successful delivery of our mission: our workforce and the public will be safe; customers will experience reliable and responsive service; we will help keep electricity affordable for our customers; and, we will help make renewable, clean electricity British Columbia's leading energy source. The Safety Above All goal has moved from Goal 4 in previous Service Plan documents to Goal 1 to better reflect our commitment to safety. Other Performance Measure changes are outlined in the Discussion sections of this document.

These four key goals guide our actions, each supported by corresponding strategies, performance measures and targets. Each performance measure has a definition and rationale, as well as relevant benchmarking measures that allow a comparison of performance over time. These measures track our progress on delivering on our mission to our customers and the Province. BC Hydro's management is responsible for measuring performance against targets. Results are reported to the Board on a quarterly basis and publicly in the Annual Service Plan Report.

Goal 1: Safety Above All

Objective 1.1: Safety at BC Hydro is a core value. We are committed to ensuring our workforce goes home safely every day, and that the public is safe around our system.

Key Strategies:

- Continue to work to achieve zero fatalities and zero permanently disabling injuries. Examples of projects include: reducing electrical hazards, updating Limits of Approach; continued work on arc flash work methods; asbestos program updates; and confined space program and training.
- Reduce lost time injuries and medical aid injuries. Examples of projects include: the field/plant ergonomics program; using near misses and good catches to identify improvement opportunities; and the Return to Work/Stay at Work program.
- Build a culture to achieve excellence in safety. Examples of investments include: regular reviews of safety incidents by the senior management team; timely implementation of corrective actions that reduce risk of injuries; and completion of Safe Work Observations that identify hazards before injuries occur.
- Meet regulatory requirements. Examples of planned work include: evaluating the fall protection program; evaluating and implementing a new tracking program; identifying and ensuring compliance with new regulatory requirements when they are enacted; field-based safety audits; and building a new confined space training and certification program, ensuring worker safety and compliance with all regulations while in confined spaces.
- Build corporate systems and tools supporting excellence in safety. Examples of projects include: Safety & Health Management System; Field Access to Safety Information, which continues to improve the quality of safety information; and track Worker Protection Authorizations through a consolidated system.
- Monitor our safety performance and identify safety risks to our workers and the public.

Performance Measure(s)[1]	2017/18 Actuals	2018/19 Forecast	2019/20 Target	2020/21 Target	2021/22 Target
1.a Zero Fatality & Serious Injury[2] [Loss of life or the injury has resulted in a permanent disability]	0	0	0	0	0
1.b Lost Time Injury Frequency [Number of employee injury incidents resulting in lost time (beyond the day of the injury) per 200,000 hours worked]	0.88	1.07	0.80	0.80	0.75
1.c Timely Completion of Corrective Actions (%)	93[3]	97	95	95	97

[1] Performance Measure descriptions, rationale, data source information and benchmarking is available online at www.bchydro.com/performance

[2] Zero Fatality and Serious Disabling Injury – BC Hydro's safety performance measures do not include contractor or public safety injuries or fatalities.

[3] Previously reported as 100 per cent in the 2017/18 Annual Service Plan report, based on the previous definition for Timely Completion of Actions (see explanation in Discussion section below).

Linking Performance Measures to Objectives:

1.a Achieving our target of Zero Fatality and Serious Disabling Injury supports our objective that everyone goes home safely, every day.

1.b Focusing on Lost Time Injury Frequency indicates if our workers are experiencing fewer work place injuries. The earlier an injured worker is able to safely return to productive employment and maintain a positive connection to the workplace, the more likely the worker will experience a quick recovery.

1.c Timely Completion of Corrective Actions reduces the probability that more workers will be injured and demonstrates that we are a learning organization that is committed to addressing identified deficiencies that have a direct impact on the safety of our workforce. By implementing corrective actions in a timely manner, we will experience fewer work place injuries as systemic deficiencies are corrected.

Discussion:

In 2019/20, BC Hydro will begin to use leading indicators such as Serious Incident and Fatality Frequency to further mitigate safety risks.

Lost Time Injury Frequency's targets trend downward to reinforce our commitment to reduce workplace injuries. However, based on the number of lost time injuries we have seen year-to-date in 2018/19, we do not expect to meet our lost time frequency target of 0.85. The 2020/21 Lost Time Injury Frequency target has been adjusted from 0.75 to 0.80, based on our 2018/19 forecasted result. The implementation of the Safety & Health Management System, together with the following initiatives, will support BC Hydro in achieving future targets: 1) increased safe work observations by managers; 2) increased and more consistent use of the Return to Work/Stay at Work program; 3) increased use of Incident Management System (IMS) review calls with executive; 4) expansion of the ergonomics program; and 5) regional safety discussion calls with crews.

Our Timely Completion of Corrective Actions targets trend upward to continue focusing on meeting the due dates of these actions. 2017/18 Actuals were reported as 100 per cent in the 2017/18 Annual Service Plan Report, based on the previous definition for Timely Completion of Actions (the percentage of safety corrective actions closed within 30 days of the original scheduled due date on an annual basis). Results are now reported using the new definition of the measure (introduced in the 2018/19 – 2020/21 Service Plan): the percentage of safety corrective actions closed on or before the scheduled due date on an annual basis, with an aim to improve over time.

Goal 2: Set the Standard for Reliable and Responsive Service

Objective 2.1: BC Hydro will reliably meet the electricity requirements of customers and respond to their evolving expectations by planning and investing in the system to meet future needs and by consistently improving our service.

Key Strategies:

- Ensure the reliability of the generation, transmission and distribution system by effectively implementing capital and maintenance programs to manage overall condition of the power system and secure supply to meet customer load throughout the year.
- Safeguard the system with risk-prioritized security solutions and prepare our operations with well-practiced emergency response plans to improve overall system reliability.
- Sustain the highest, gold-level certification under the Progressive Aboriginal Relations program by maintaining leading practices focused on Indigenous employment, business development, community relationships and leadership actions.
- Continue to advance reconciliation by incorporating the United Nations Declaration on the Rights of Indigenous Peoples, the Draft 10 Principles that Guide the Province of British Columbia's Relationship with Indigenous Peoples and the Calls to Action of the Truth and Reconciliation Commission into our business.
- Continue to make it easier for customers to do business with us through a series of customer facing improvements such as increased mobile access; enabling more self-service features; exploring new, innovative rate options; expanding in-person service areas; and enhancing customer service training for employees.

- Support customers with initiatives that help them make smart energy management choices through conservation and energy efficiency, capacity reduction and low carbon electrification.

Performance Measure(s)[1]	2017/18 Actuals	2018/19 Forecast	2019/20 Target	2020/21 Target	2021/22 Target
2.a SAIDI (System Average Interruption Duration Index)[2] [Total outage duration (in hours) of sustained interruptions experienced by an average customer in a year]	3.07	3.10	3.25	3.20	3.20
2.b SAIFI (System Average Interruption Frequency Index)[2] [Total number of sustained interruptions experienced by an average customer in a year (excluding major events)]	1.51	1.37	1.40	1.40	1.40
2.c Key Generating Facility Forced Outage Factor (%)	1.81	1.80	1.80	1.80	1.80
2.d CSAT Index[3] [Customer Satisfaction Index: % of customers satisfied or very satisfied]	86.0	86.0	85.0	85.0	85.0
2.e Progressive Aboriginal Relations Designation[4]	Gold	Gold	Gold	Gold	Gold

[1] Performance Measure descriptions, rationale, data source information and benchmarking is available online at www.bchydro.com/performance

[2] Reliability targets are based on specific values, however performance within 10 per cent is considered acceptable given the reliability projection modelling uncertainty, the wide range of variations in weather patterns and the uncontrollable elements that can significantly disrupt the electrical system. BC Hydro measures reliability under normal circumstances, because major events are not predictable and largely uncontrollable. The reliability measure is therefore based on data that excludes major events. BC Hydro reviews performance during major events and takes the performance into consideration in reliability improvement initiatives.

[3] Customer Satisfaction Index (CSAT) is an index measuring customer satisfaction of BC Hydro's three main customer groups (residential, commercial and key accounts). The index is comprised of the five key drivers of satisfaction weighted equally across the three customer types.

[4] The Canadian Council of Aboriginal Business' Progressive Aboriginal Relations (PAR) Program is a certification program designed to help Canadian businesses benchmark, improve and signal their commitment to progressive relationships with Indigenous communities, businesses and people. It requires companies to set goals and assess themselves in four areas: leadership actions; employment; business development; and community relations. Each company must be certified every three years through a comprehensive review process that involves independent verification. BC Hydro was recertified at the gold level in 2018/19.

Linking Performance Measures to Objectives:

2.a & 2.b Customer reliability is measured using the System Average Interruption Duration Index (SAIDI) and System Average Interruption Frequency Index (SAIFI). These, along with correlated cause analysis for customer outages, support targeted investment, planning and process improvements to meet our customers' needs for reliability.

By measuring the average number of service interruptions and number of hours of sustained interruptions experienced by the average customer in a year, we are able to track our ability to reliably meet the electricity requirements of customers.

2.c A forced outage occurs when a generating unit is unable to start generating or does not stay on line as long as needed. The Key Generating Facility Forced Outage Factor will show the trend of how the generation assets are performing and support investment decisions to maintain asset reliability.

2.d The Customer Satisfaction (CSAT) Index measures customer satisfaction of BC Hydro on five key drivers: value for money; commitment to customer service; providing reliable electricity; acting in the best interest of British Columbians; and efforts to communicate to customers and communities. This measure gauges the degree to which BC Hydro is meeting customers' electricity and service needs.

2.e The Canadian Council of Aboriginal Business's Progressive Aboriginal Relations (PAR) Gold certification offers validation of BC Hydro's sustained actions towards enhanced Indigenous relations. Given BC Hydro's extensive footprint throughout the province, and its role as a Crown corporation, the comprehensiveness of the PAR certification acts as a measure for BC Hydro to ensure it is establishing relationships with First Nations built on mutual respect and that appropriately reflect the interests of First Nations communities.

Discussion:

System Average Interruption Duration Index (SAIDI) and System Average Interruption Frequency Index (SAIFI) targets are based on a number of factors including long-term historic reliability trending, current year performance, previous years' investments and future years' investment plans. SAIDI's 2020/21 target has been lowered to align with improved historical performance, trends resulting from investment, planning and process improvements.

There are seven Key Generating Facilities, representing those plants with installed capacity greater than 200 MW[1]. Together they provide 90 per cent of the average annual electricity generated by BC Hydro's facilities. Key Generating Forced Outage Factor is reported as a five year rolling average and defined as the total forced outage time in a period relative to the total number of hours in the same period (usually one year). Annually, the Forced Outage Factor can be relatively volatile, and applying the historical five year rolling average can smooth the range to provide a more stable measure for which targets can be set. The objective is to keep the Forced Outage Factor below 1.8 per cent of the total number of hours per year.

Progressive Aboriginal Relations Designation – BC Hydro attained the highest, gold-level designation from the Canadian Council for Aboriginal Business in 2018/19, which is valid for a three year period.

[1] The Waneta Generating Station is not included in the Forced Outage Factor Performance Measure because BC Hydro does not manage or operate the facility.

Goal 3: Help Keep Electricity Affordable for our Customers

Objective 3.1: BC Hydro customers will benefit from affordable bills while we manage our costs, explore innovative solutions to support our customers, and make investments to maintain and expand our electricity system.

Key Strategies:

- Advance affordability initiatives and rate structures with the BCUC to help our customers manage their electricity bills.
- Make all reasonable efforts to keep rates affordable by acting on the outcomes of Phase 1 of the Comprehensive Review, including strategies to reduce future energy procurement costs.
- Submit a Revenue Requirements Application consistent with the rates forecast released in Phase 1 of the Comprehensive Review.
- Participate in Phase 2 of the Comprehensive Review, which will strategically position BC Hydro for long-term success, within the context of a rapidly evolving international and continental energy sector and provincial and federal climate action strategies.
- Implement an updated 10 Year Capital Plan so that our customers can continue to receive clean, reliable and affordable electricity.
- Continue to refine and enhance our systematic and disciplined project delivery methodology to ensure that our projects are put into service safely, on time, on budget and to a high standard of quality.
- Under the oversight of the independent Project Assurance Board, complete the Site C Project by November 2024 at a cost of no more than $10.7 billion, and provide quarterly progress updates to Treasury Board.
- Improve how we operate by improving our processes and supply chain strategies.

Performance Measure(s)[1]		2017/18 Actuals	2018/19 Forecast	2019/20 Target	2020/21 Target	2021/22 Target
3.a	Affordable Bills[2]	1st quartile	1st quartile	1st quartile	1st quartile	1st quartile
3.b	Project Budget to Actual Cost[3]	+0.40% on $6.9 billion[4]	+0.46% on $8.0 billion[5]	Within +5% to -5% of budget excluding project reserve amounts	Within +5% to -5% of budget excluding project reserve amounts	Within +5% to -5% of budget excluding project reserve amounts

[1] Performance Measure descriptions, rationale, data source information and benchmarking is available online at www.bchydro.com/performance

[2] BC Hydro calculates a relative index for each usage level within the residential category and then calculates an average of the index to create an overall ranking based on Hydro Quebec's annual report on North American electricity rates. The rankings of the 22 participating utilities are then allocated into quartiles. The 1st quartile ranking represents the six utilities that have the lowest monthly electricity bills on April 1 of a given year.

[3] This measure compares actual project costs at completion to the original approved full scope implementation budgets, not including project reserve amounts, for capital projects that were put into service during the five-year rolling period.

[4] This represents projects that went or were forecasted to go into service for the five-year period 2013/14 to 2017/18.

[5] This represents projects that went or are forecasted to go into service for the five-year period 2014/15 to 2018/19.

Linking Performance Measures to Objectives:

3.a The Affordable Bills measure is based on BC Hydro's ranking in the residential rates category in the annual Hydro Quebec report, Comparison of Electricity Prices in Major North American Cities. The report is used as a benchmark to demonstrate that our bills are affordable and predictable compared to other major North American utilities.

3.b Since 2015/16, BC Hydro has utilized the Project Budget to Actual Cost measure for the delivery of capital projects, with a target of actual project costs to be within +5% to -5% of the budget, excluding project reserves at the portfolio level. BC Hydro has consistently met this performance target, as we continue to prudently manage capital expenditures and keep affordable rates for our customers.

Discussion:

The Competitive Rates performance measure was revised to Affordable Bills to better align with the Government's affordability commitment. Affordable Bills is a more accurate name for this performance measure, as the Hydro Quebec report compares customer electricity bills in its report.

BC Hydro's residential bills have consistently been ranked in the first quartile over the past ten years. This year we are ranked third place within the first quartile based on analysis of the 2018 Hydro Quebec report, Comparison of Electricity Prices in Major North American Cities. In February 2019, BC Hydro will submit the Fiscal 2020 to Fiscal 2021 Revenue Requirements Application that reflects the projected rates forecast from Phase 1 of the Comprehensive Review.

The Project Budget to Actual Cost measure includes Generation, Substation and Transmission Line projects managed by BC Hydro Capital Infrastructure Project Delivery. Annually, BC Hydro reports the past five years' performance at the portfolio level in delivering capital projects.

Goal 4: Help Make Renewable, Clean Power British Columbia's Leading Energy Source

Objective 4.1: BC Hydro will strengthen its legacy of renewable, clean power and conservation investments through its energy-efficiency and conservation programs, capacity reduction initiatives and support of low-carbon electrification.

Key Strategies:

- Support the implementation of the CleanBC plan to increase British Columbians' use of cleaner energy in key sectors of the economy and shift away from reliance on fossil fuels for transportation, industry, and housing.
- Support customers with initiatives that help them make smart energy management choices with conservation, efficiency, capacity reduction and low carbon electrification.
- Implement our energy conservation and energy management plan, which will exceed the *Clean Energy Act* requirement to meet at least two-thirds of future demand growth by 2020.
- Provide customers with the opportunity to access clean, renewable power to displace the use of higher carbon energy sources.
- As part of the CleanBC plan, partner with the Province and the federal government to implement a new Remote Community Clean Energy Strategy to help remote communities, with a focus on Indigenous communities, reduce or eliminate diesel generation and replace it with energy from cleaner sources.

	Performance Measure(s)[1]	2017/18 Actuals	2018/19 Forecast	2019/20 Target	2020/21 Target	2021/22 Target
4.a	Energy Conservation Portfolio (New incremental GWh/year)[2]	741	800	700	700	500
4.b	Clean Energy (%)	98.0	97.6	93.0	93.0	93.0

[1] Performance Measure descriptions, rationale, data source information and benchmarking is available online at www.bchydro.com/performance

[2] Annual targets are part of a longer-term Demand Side Management Plan that is set to fulfill the *Clean Energy Act* requirement to meet at least two-thirds of future demand growth by 2020 and BC Hydro's long term planning needs.

Linking Performance Measures to Objectives:

4.a The Energy Conservation Portfolio performance measure reflects new incremental energy savings from programs, codes and standards and conservation rates that measure BC Hydro's performance against annual energy targets. This measures the success of BC Hydro's planned conservation targets. Targets are rounded values and considered to be achieved if performance is within 10% of the stated values.

4.b The Clean Energy performance measure demonstrates BC Hydro's efforts to supply clean, sustainable, responsibly generated, affordable electricity in order to reduce GHG emissions in the province and continue to meet the 93 per cent minimum clean energy objective in the *Clean Energy Act*. The higher the per cent clean energy that BC Hydro achieves, the lower the GHG emissions in the province.

Discussion:

The targets for Energy Conservation Portfolio are based on BC Hydro's forecast of annual new incremental energy savings and do not reflect past performance and/or adjustments made to energy savings in prior years (e.g., persistence, evaluations, measurement and verification). In some cases, the timing of savings for anticipated codes and standards and timing of large customer projects can shift, which will cause actual incremental energy savings to vary from the targets that have been set for the period. Updated customer information on the timing of thermo-mechanical pulp projects and the timing of energy savings from lighting regulations resulted in increased targets for 2018/19 and 2019/20 of 800 GWh/year (gigawatt-hours per year) and 700 GWh/year respectively, followed by 700 GWh/year in 2020/21. The target of 500 GWh for 2021/22 reflects the forecasted incremental energy savings related to government enacted codes and regulations.

The Clean Energy performance measure represents the minimum threshold generation output in accordance with the B.C. Government's requirement that at least 93 per cent of electricity generation in the province be from clean or renewable resources, as specified in the *Clean Energy Act*. While actual output of the non-clean resources in the system supports system reliability and can vary depending on market conditions and water inflows to our reservoirs, BC Hydro expects that the actual performance will remain close to 98 per cent.

The New Clean Supply performance measure was removed from the 2019/20 –2021/22 Service Plan. BC Hydro will develop a new measure next year to support and align with the Government's new CleanBC plan.

Financial Plan

Summary Financial Outlook

Consolidated Statement of Operations[1, 2] ($ millions)	2018/19 Forecast	2019/20 Budget	2020/21 Budget	2021/22 Budget
Domestic	5,441	5,654	5,708	5,895
Trade	653	651	682	706
Total Revenues	**6,095**	**6,304**	**6,390**	**6,600**
Operating Costs				
Cost of energy	2,094	2,367	2,441	2,500
Personnel expenses, materials & external services[3]	1,259	1,204	1,234	1,209
Amortization	881	925	946	966
Grants and taxes	254	258	271	293
Finance charges	685	756	726	679
Other	82	108	87	94
Total Expenses	**5,255**	**5,619**	**5,704**	**5,741**
Net Income before movement in regulatory balances	**840**	**685**	**686**	**860**
Net movement in regulatory balances	**(1,264)**	**27**	**26**	**(148)**
Net Income (Loss)	**(424)**	**712**	**712**	**712**
Dividends	**59**	**-**	**-**	**-**
Net Debt[4]	**22,233**	**23,419**	**24,654**	**25,857**
Equity	**4,973**	**5,684**	**6,396**	**7,108**
Capital Expenditures[2]	**3,923**	**2,999**	**3,115**	**3,153**

[1] Table may not add due to rounding.
[2] Includes the purchase of the remaining two-thirds interest in the Waneta Dam and Generating Station in 2018/19. The transaction was approved by the BCUC in July 2018.
[3] These amounts are net of capitalized overhead and consist of the following:

	2018/19	2019/20	2020/21	2021/22
Domestic Base Operating Costs	769	778	788	793
Other	489	426	446	416
	1,259	1,204	1,234	1,209

Other largely consists of Powerex & Powertech operating costs, IFRS-ineligible capital overhead into operating costs over a 10-year period, and expenses subject to regulatory deferral.
[4] Debt figures are net of sinking funds and cash and cash equivalents.

Key Forecast Assumptions, Risks and Sensitivities

Key Assumptions	2018/19 Forecast	2019/20 Budget	2020/21 Budget	2021/22 Budget
Growth and Load				
B.C. Real Gross Domestic Product Growth (%)[1]	2.2	1.8	2.0	2.0
Domestic Sales Load Growth (%)[2, 3]	0.96	1.83	(0.59)	(0.30)
Domestic Load (GWh):				
Domestic Sales Volume (GWh)[3]	52,604	53,567	53,253	53,093
Surplus Sales Volume (GWh)	2,230	2,409	3,087	4,402
Line Loss and System Use (GWh)	5,173	5,554	5,553	5,538
Total Domestic Load (GWh)	60,007	61,530	61,893	63,033
Energy Generation				
Total System Water Inflows (% of average)	88	100	100	100
Sources of Supply to Meet Domestic Load:				
Net Hydro Generation (GWh)	43,015	44,268	44,893	45,939
Market Electricity Purchases (GWh)[4]	2,077	1,504	648	404
Independent Power Producers and Long-term Purchases (GWh)	14,631	15,449	16,040	16,346
Thermal Generation & Other (GWh)	284	309	312	344
Sources of Supply for Domestic Load (GWh)	60,007	61,530	61,893	63,033
Average Mid-C Price (U.S.$/MWh)	33.40	25.88	24.97	28.00
Average Natural Gas Price at Sumas (U.S.$/MMBTU)	3.14	2.18	2.01	1.93
Financial				
Canadian Short-Term Interest Rates (%)[5]	1.72	2.37	2.59	2.96
Canadian Long-Term Interest Rates (%)[5]	3.08	3.50	3.86	4.23
Foreign Exchange Rate (U.S.$:Cdn$)[5]	0.7755	0.7910	0.7973	0.8013

[1] Economic assumption based on calendar year, from Ministry of Finance September 2018 First Quarter Report.
[2] Includes the impact of Demand-Side Management programs.
[3] Excludes surplus sales.
[4] Assumes that gas fired power generation capability available to service domestic demand is sometimes displaced by more cost-effective market purchases.
[5] Financial assumptions from Ministry of Finance, October 2018.

Sensitivity Analysis

Factor	Change	Approximate change in 2019/20 earnings before regulatory account transfers (in $ millions)
Customer Load	+/- 1%	35
Interest Rates	+/- 100 basis points	35
Electricity/Gas trade margins	+/- 10%	20
Hydro Generation (GWh)[1]	+/- 1%	10
Exchange rates (US/ CDN)	+/-$0.01	5

[1] Assumes change in hydro generation is offset by corresponding change in net market electricity sales (i.e. increase in hydro generation is offset by increase in net market electricity sales).

Management's Perspective on the Financial Outlook

The results of Phase 1 of the Comprehensive Review were announced by Government in February 2019, and include a number of actions intended to enhance the BCUC's oversight of BC Hydro, keep rates affordable, and mitigate impacts to the Government's Fiscal Plan. The results of Phase 1 of the Comprehensive Review have been included as key assumptions in preparing the current financial projections.

The current financial projections for revenues and expenses through 2021/22 were approved by the BC Hydro Board of Directors and submitted to the Ministry of Finance in January 2019.

Major Capital Projects

Capital Expenditure by Year and Type and Function

($millions)	2018/19 Forecast	2019/20 Forecast	2020/21 Forecast	2021/22 Forecast
Capital Expenditures by Type[1]				
Sustaining	980	978	1,093	1,175
Growth	2,943	2,021	2,022	1,978
Subtotal – BC Hydro Capital Expenditures before CIA	3,923	2,999	3,115	3,153
Contributions-in-Aid (CIA)[2]	(147)	(158)	(148)	(150)
Total – BC Hydro Capital Expenditures net of CIA	3,776	2,841	2,967	3,003
Generation	1,589	345	436	512
Transmission and Distribution	930	895	947	1,175
Properties, Technology and Other	217	229	197	148
Site C Project	1,187	1,530	1,535	1,318
Subtotal – BC Hydro Capital Expenditures before CIA	3,923	2,999	3,115	3,153
CIA	(147)	(158)	(148)	(150)
Total BC Hydro Capital Expenditures net of CIA	3,776	2,841	2,967	3,003

1. BC Hydro classifies capital expenditures as either sustaining capital or growth capital:
   - Sustaining capital includes expenditures to ensure the continued availability and reliability of generation, transmission and distribution facilities. It also includes expenditures to support the business, such as vehicles and information technology.
   - Growth capital includes expenditures to meet customer load growth and other business investments. Growth capital includes expenditures to expand existing generation assets as well as expand and reinforce the transmission and distribution system, and includes Site C and the Waneta 2/3 Interest Acquisition.
2. Contributions in aid of construction are amounts paid by certain customers toward the cost of property, plant and equipment required for the extension of services to supply electricity.

Projects over $50 million

BC Hydro has the following projects, each with capital costs expected to exceed $50 million, listed according to targeted completion date. These projects have been approved by the Board of Directors.

Major Capital Projects (over $50 million)	Targeted Completion Date (Year)	Project Cost to Dec 31, 2018 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Anticipated Total Capital Cost of Project ($ millions)
Projects Recently Put Into Service				
Ruskin Dam Safety and Powerhouse Upgrade This project improved a seismically deficient dam and rehabilitated / replaced powerhouse equipment that was brought into service between 1930 and 1950. The project included: upgrading of the right abutment; redeveloping the dam and powerhouse to meet current seismic standards for earthquakes; and replacing major generation equipment which was in poor or unsatisfactory condition.	2018 In-Service	$621	$21	$642
W.A.C Bennett Dam Riprap Upgrade Project This project addressed inadequate erosion protection on the upstream face of the W.A.C Bennett Dam. The primary driver of the project was safety of the dam itself as well as safety of the public, property, and environment downstream.	2018 In-Service	$118	$1	$119
Waneta 2/3 Interest Acqusition BC Hydro purchased Teck Resources Ltd.'s two-third interest in the Waneta Dam and associated assets in July 2018.	2018 In-Service	$1,220	$1	$1,221
Kamloops Substation This project constructed a new 100MW 138/25kV substation in the west side of Kamloops to meet expected load growth in the Kamloops service area.	2018 In-Service	$50	$6	$56

Major Capital Projects (over $50 million)	Targeted Completion Date (Year)	Project Cost to Dec 31, 2018 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Anticipated Total Capital Cost of Project ($ millions)
Ongoing				
Horne Payne Substation Upgrade Project This project expands the Horne Payne Substation with the addition of two 230/25kV, 150MVA transformers, gas-insulated feeder sections, and a new control building. This project will increase the firm capacity of the substation, add needed feeder positions, facilitate the gradual conversion of the area supply voltage from 12kV to 25kV, and allow for the implementation of an open-loop distribution system.	2019 Targeted In-Service	$63	$30	$93
John Hart Generating Station Replacement This project replaces the existing six-unit 126 MW generating station (in operation since 1947) and adds integrated emergency bypass capability to ensure reliable long-term generation and mitigate earthquake risk and environmental risk to fish and fish habitat. **John Hart forecast and life-to-date amounts include both capital costs and expenditures subject to regulatory deferral.*	2019 Targeted In-Service	$954	$31	$985*
Cheakamus Unit 1 and Unit 2 Generator Replacement This project replaces the two generators at Cheakamus generating station (in operation since 1957) to address their poor condition and known deficiencies, and increase the capacity of each unit from 70 MW to 90 MW.	2019 Targeted In-Service	$52	$22	$74

Major Capital Projects (over $50 million)	Targeted Completion Date (Year)	Project Cost to Dec 31, 2018 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Anticipated Total Capital Cost of Project ($ millions)
South Fraser Transmission Relocation Project* This project is intended to relocate certain sections of two 230kV transmission circuits (Circuit 2L62 and Circuit 2L58) from their present location adjacent to Highway 99 and in the George Massey tunnel to accommodate the replacement of the tunnel. These two 230kV circuits form a critical part of BC Hydro's transmission network supplying power to customers in Richmond, Delta and the Greater Vancouver area. ****Construction work on the South Fraser Transmission Relocation project is currently suspended pending the government's review of the George Massey Tunnel replacement.*	TBD	$32	$44	$76
Bridge River 2 Units 5 and 6 Upgrade Project This project will replace the two generators and other related equipment at Bridge River 2 to restore the historical operating capacity. These two generator units were placed in service in 1960 and are in unsatisfactory condition and unreliable.	2019 Targeted In-Service	$53	$33	$86
Downtown Vancouver Electricity Supply: West End Strategic Property Purchase This project is to acquire property rights to build a new underground substation that will upgrade the aging electricity system in downtown Vancouver.	2020 Targeted In-Service	$67	$14	$81

Major Capital Projects (over $50 million)	Targeted Completion Date (Year)	Project Cost to Dec 31, 2018 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Anticipated Total Capital Cost of Project ($ millions)
Fort St. John and Taylor Electric Supply This project will maintain adequate supply capability, reduce line losses and improve reliability to the loads in the Fort St. John and Taylor areas by re-terminating 138kV transmission lines at the new Site C switchyard, and the addition of a 75 MVA transformer and new feeder positions.	2020 Targeted In-Service	$30	$23	$53
UBC Load Increase Stage 2 Project This project is on behalf of BC Hydro's customer, the University of British Columbia, to continue to reliably meet the growing electricity needs of its Point Grey campus and the surrounding community.	2021 Targeted In-Service	$14	$41	$55
Peace Region Electricity Supply Project This project is needed to provide sufficient transmission system capacity to serve load growth and increase the reliability of electricity supply to existing customers in the South Peace. This project will facilitate reductions in provincial greenhouse gas emissions by enabling electrification of natural gas production, processing, and compression.	2021 Targeted In-Service	$56	$229	$285
LNG Canada Load Interconnection Project This project is to facilitate the interconnection of LNG Canada's facility. A new double circuit 287kV transmission line will be constructed from Minette Substation (MIN) to LNG Canada's facility and system reinforcements at MIN will also be implemented. Under BC Hydro's standard tariffs, the customer is required to pay for a portion of this project's costs.	2021 Targeted In-Service	$4	$78	$82

Major Capital Projects (over $50 million)	Targeted Completion Date (Year)	Project Cost to Dec 31, 2018 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Anticipated Total Capital Cost of Project ($ millions)
Mica Replace Units 1-4 Transformers Project This project will address the reliability and safety risks of the Unit 1-4 Generator Step-up Unit transformers at the Mica Generating Station, which are nearing end of life. There is a heightened reliability and safety risk from continuing to operate these transformers in an underground powerhouse as they age.	2022 Targeted In-Service	$4	$78	$82
G.M. Shrum G1-G10 Control System Upgrade This project will replace the controls equipment, provide full remote control capability from the remote control center, and rectify deficiencies in the current system. The condition of the legacy controls for the GMS generating units, which were originally installed in the 1960s and 1970s, is of growing concern due to increasing maintenance requirements, lack of available spare parts and decreasing reliability. The controls are well beyond their expected life, which causes operating problems and increases the risk of damage to major equipment.	2022 Targeted In-Service	$31	$44	$75
Site C Project This project will construct a third dam and a hydroelectric generating station on the Peace River approximately seven kilometres southwest of Fort St. John. It will be capable of producing approximately 5,100 gigawatt-hours of electricity annually and 1,100 megawatts of capacity. Site C will provide clean, renewable and cost-effective power in B.C. for more than 100 years. **Planned in-service date for all units.* ***Site C forecast and life-to-date amounts include both capital costs and expenditures subject to regulatory deferral. The amount includes a reserve of $708 million.*	2024* Targeted In-Service	$3,206	$7,494	$10,700**

Significant Information Technology (IT) Projects over $20 million

BC Hydro has the following IT project with capital costs expected to exceed $20 million, listed according to targeted completion date. This project has been approved by the Board of Directors.

Significant IT Projects (over $20 million in total)	Targeted Completion Date (Year)	Project Cost to Dec 31, 2018 ($ millions)	Estimated Cost to Complete ($ millions)	Approved Anticipated Total Capital Cost of Project ($ millions)
Ongoing				
Supply Chain Applications Project This project will replace BC Hydro's existing PassPort supply chain information technology (IT) system with an SAP-based IT system and make improvements to BC Hydro's supply chain business processes for third-party materials and service acquisitions. **Anticipated Total Capital Cost for the Implementation Phase portion of the funding is pending approval by the BCUC.*	2020 Targeted In-Service	$27	$41	$68*

Corporate Governance

Information about Corporate Governance can be found at:
http://www.bchydro.com/about/accountability_reports/financial_reports/service_plan.html.

This includes links to information regarding:
- Board of Directors
- Executive Team
- Code of Conduct

Organizational Overview

Information about BC Hydro's organizational overview can be found at:
http://www.bchydro.com/about/accountability_reports/financial_reports/service_plan.html.

This includes links to information about BC Hydro's operations, governance and mandate.

Appendix B: Subsidiaries and Operating Segments

As wholly-owned subsidiaries, and like BC Hydro itself, Powerex Corp. and Powertech Labs Inc. follow best practices in corporate governance and subsidiary activities align with BC Hydro's mandate, strategic priorities and fiscal plan.

Powerex Corp.

Powerex Corp. is a wholly-owned subsidiary of BC Hydro and a key participant in energy markets across North America, buying and supplying wholesale power, renewable and low-carbon energy and products, natural gas, ancillary services, and financial energy products. Established in 1988, its export, marketing and trade business provides significant economic benefits to British Columbia.

Through its contractual agreements with BC Hydro, Powerex supports BC Hydro's electric system requirements by importing and exporting energy. Powerex also markets, through a contractual agreement with the Province, the Canadian Entitlement to the Downstream Power Benefits under the Columbia River Treaty.

The Chief Executive Officer (CEO) of Powerex reports to the Board of Directors of Powerex. The Chair of the Powerex Board ensures the Board of BC Hydro is informed of Powerex's key strategies and business activities. The Powerex CEO keeps the BC Hydro President and Chief Operating Officer (COO) and Executive Team informed of Powerex's key strategies and business activities.

Powerex operates in competitive, complex and volatile energy-markets, which can cause net income in any given year to vary significantly. Market and economic conditions, reduced hydro system flexibility, unrealized mark-to-market gains or losses and the strength of the Canadian dollar can materially impact Powerex net income. The Service Plan forecast includes annual net income from Powerex of approximately $125 million per year for 2019/20 to 2021/22. For more information, visit powerex.com.

Board of Directors:

- Ken Peterson - Chair
- Len Boggio
- James Hatton
- Valerie Lambert
- Chris O'Riley

Powertech Labs Inc.

Powertech Labs Inc., operating in Surrey since its inception in 1979, is a wholly-owned subsidiary of BC Hydro. Powertech is internationally recognized as holding expertise in a range of fields related to the electrical industry and offers services and products including: research and development, testing, technical services, software and advanced technology services to energy clients, including BC Hydro, and other sectors globally.

The President and CEO of Powertech reports to the BC Hydro President and COO. The Powertech Board is chaired by BC Hydro's President and COO and its Directors include senior Executives of BC Hydro.

The Service Plan forecast includes annual net income from Powertech of approximately $4 million per year for 2019/20 to 2021/22. For more information, visit powertechlabs.com.

Board of Directors:

- Chris O'Riley - Chair
- David Lebeter
- Mark Poweska

Other Subsidiaries

BC Hydro has created or retained a number of other subsidiaries for various purposes, including holding licences in other jurisdictions, to manage real estate holdings and to manage various risks.

All the staff and management needs of the active subsidiaries below are fulfilled by BC Hydro employees, who perform these duties without additional remuneration. Three of these subsidiaries are considered active:

BCHPA Captive Insurance Company Ltd.
Procures insurance products and services on behalf of BC Hydro.

Columbia Hydro Constructors Ltd.
Administers and supplies the labour force to specified projects.

Tongass Power and Light Company
Provides electrical power to Hyder, Alaska from Stewart, B.C. due to its remoteness from the Alaska electrical system.

Nominee Holding Companies and/or Inactive/Dormant Subsidiaries
BC Hydro's remaining subsidiaries either serve as nominee holding companies (indicated with an *) or are considered to be inactive/dormant. The inactive/dormant subsidiaries do not carry on active operations. As of December 31, 2018, these other subsidiaries consisted of the following:

1. British Columbia Hydro International Limited
2. British Columbia Power Exchange Corporation
3. British Columbia Power Export Corporation
4. British Columbia Transmission Corporation
5. Columbia Estate Company Limited*
6. Edmonds Centre Developments Limited*
7. Fauquier Water and Sewerage Corporation
8. Hydro Monitoring (Alberta) Inc.*
9. Victoria Gas Company Limited
10. Waneta Holdings (US) Inc.*
11. 1111472 BC Ltd.

The Honourable Darryl Plecas
Speaker of the Legislative Assembly
Province of British Columbia
Parliament Buildings
Victoria, British Columbia
V8V 1X4

Dear Mr. Speaker:

I have the honour to transmit to the Speaker of the Legislative Assembly of British Columbia the report, *Independent Audit of Capital Asset Management in BC Hydro.*

We conducted this audit under the authority of section 11(8), of the *Auditor General Act* and in accordance with the standards for assurance engagements set out by the Chartered Professional Accountants of Canada (CPA) in the CPA Handbook – Canadian Standard on Assurance Engagements (CSAE) 3001 and Value-for-money Auditing in the Public Sector PS 5400.

Carol Bellringer, FCPA, FCA
Auditor General
Victoria, B.C.
December 2018

The Office of the Auditor General of British Columbia would like to acknowledge with respect that we conduct our work on Coast Salish territories. Primarily, this is on the Lkwungen-speaking people's (Esquimalt and Songhees) traditional lands, now known as Victoria, and the W̱SÁNEĆ people's (Pauquachin, Tsartlip, Tsawout, Tseycum) traditional lands, now known as Saanich.

AUDITOR GENERAL'S COMMENTS

ELECTRICITY IS A NECESSITY IN OUR PROVINCE – to drive our industries and economy, and to keep our hospitals, schools, public institutions and homes functioning. BC Hydro provides more than 90% of the electricity in B.C. through a province-wide generation, transmission and distribution system.

CAROL BELLRINGER, FCPA, FCA
Auditor General

BC Hydro manages about $25 billion in assets — more than any other government entity. About 80% of these assets are thing like dams, generators, power lines and poles, substations, and transformers, which are used to provide reliable electrical service to the people of British Columbia.

BC Hydro's assets are a mix of old and new, with some approaching 100 years of service and others coming on-line this year. To manage these assets economically and efficiently requires sound asset management processes.

Asset management is the purposeful and long-term processes that aim to get the greatest efficiency, for the lowest cost, out of an asset over its lifetime. From April 1, 2017 to March 31, 2018, BC Hydro invested almost $2.5 billion to renew, repair or replace the assets it manages. For BC Hydro, good asset management practices ensure the supply and flow of electricity in British Columbia.

For this audit, we looked at whether BC Hydro is managing its assets well through appropriate information, practices, processes and systems. We found that it is. BC Hydro has good asset management practices, not by accident, but as a result of a decade-long plan and associated efforts.

Over ten years ago, BC Hydro made asset management an organizational priority. Since then, it has worked to implement international guidelines and good practice standards. It has also had its practices independently verified.

AUDITOR GENERAL'S COMMENTS

I am pleased to say that because BC Hydro is managing its assets well, we made no recommendations in this audit.

Going forward, we will continue to provide legislators and the public with information about BC Hydro's operations and programs through my office's role as BC Hydro's independent financial statement auditor and through the performance audits we plan to carry out on BC Hydro's operations.

My thanks to everyone that we spoke with for their co-operation and support during this audit.

purposeful and long-term processes to get the **greatest efficiency,** for the **lowest cost,** out of an asset over its lifetime

NO SIGNIFICANT DEFICIENCIES SO
NO RECOMMENDATIONS

RESPONSE FROM BC HYDRO

BC Hydro appreciates the Office of the Auditor General's report on the audit of our Capital Asset Management Practices. The report highlights the progress BC Hydro has made over the past decade to define and develop our asset management processes. We are proud that the Office of the Auditor General recognizes BC Hydro's capital asset management systems and practices have generally reached an advanced level of maturity.

Although no recommendations were made as a result of the audit, BC Hydro is committed to ongoing improvements of our asset management processes to help us continue to deliver clean, reliable, and affordable electricity to our customers. One example is a recent organizational change which merged all of our power system asset management groups into one department to increase alignment and get the highest value from investments in our system. In addition, we have a number of initiatives underway that will further strengthen asset management with a focus on:

- mitigating high priority safety, environmental and financial risks;
- managing our assets using a life-cycle approach; and,
- meeting customer demand growth.

BC Hydro would like to thank the Office of the Auditor General for conducting the audit of our Capital Asset Management Practices. The conclusions of the audit confirm that BC Hydro has taken the right direction in developing its asset management capabilities.

ABOUT THE AUDIT

BACKGROUND

BC Hydro operates the largest electricity generation, transmission and distribution network in British Columbia (Exhibit 2). The network largely comprises assets such as dams, electricity generation equipment, transmission lines, transformers and power poles, all of which must be kept under scrutiny, periodically maintained and eventually renewed or replaced.

BC Hydro operates equipment and facilities that range widely in age. Its electricity generation and distribution system was largely established and expanded between 1940 and 1985. Some facilities, such as the Ruskin Dam (Exhibit 1), near Mission, are even older.

The average age of BC Hydro's generating units is over 40 years, with a number of components in the oldest facilities exceeding 85 years. The older generating, transmission and distribution assets continue to contribute to the network at or near their full capacity, and an increasing number of assets are reaching the end of their service life. Some have exceeded their life expectancy and require replacement or major investment to extend their service life.

In any aging population of assets, maintenance requirements can be expected to increase and performance to decline because of degradation over time. The oldest parts of BC Hydro's network, including assets such as transmission lines, dams

Exhibit 1: Ruskin Dam and its generating station, which began operating in 1930, are currently being improved and seismically upgraded.

ABOUT THE AUDIT

and power generating facilities, are already receiving attention or are due for renewal.

For example, as part of the John Hart Generating Station Replacement Project, BC Hydro is replacing generating facilities from the late 1940s that had a less efficient power output. Exhibit 3 shows the specification plate for a generator at the facility, near Campbell River, that has been in service continuously since 1948.

Exhibit 3: Generator at John Hart Generating Station, in continuous service since 1948

Source: Office of the Auditor General of British Columbia

BC Hydro's assets are typically costly to renew or replace, even though the return in service life is long. Electricity-generating assets, for example, have average expected lifespans of 40 to 50 years. The Mica Dam facility (Exhibit 4) near Revelstoke has operated for 45 years. Its powerhouse was recently modified to include two new 500-megawatt generating units, which translates into enough power to supply 80,000 homes.

Over the last five years, BC Hydro has completed 493 capital projects at a total cost of $6.9 billion. For the fiscal year that ended in March 2018, completed capital projects aimed at renewing and expanding the generation, transmission and distribution system totalled $1.6 billion. For the period 2017 to 2026, BC Hydro has forecast an annual average of approximately $2.3 billion per year to refurbish, upgrade and expand its existing generation, transmission, distribution, property and technology assets.

This audit focuses on the system BC Hydro uses for looking after its assets. Asset management at BC Hydro, as at any other asset-intensive business in

ABOUT THE AUDIT

WHAT IS A CAPITAL ASSET, A CAPITAL PROJECT AND A CAPITAL PROGRAM?

A capital asset includes property of any kind that provides service to an organization for more than one year. Examples are land, buildings and furniture, computers and software, power plants and machinery, vehicles, power poles and towers.

A capital project is an activity that creates a new capital asset or improves the capacity or life span of an existing one. A capital program is a series of capital projects.

the public sector, involves knowing where all assets are located and their condition at a given time. It also involves having a plan in place, and the funding available, to repair, renew or replace assets without interrupting electrical service to the public.

We undertook this audit because good asset management is critical to BC Hydro's success as a reliable energy provider. Our independent assurance work provides BC Hydro with feedback on its self-assessed level of management capability in this area, and also provides the Legislative Assembly of British Columbia with an assessment indicating how well developed BC Hydro's asset management practices are relative to best practices worldwide.

AUDIT SCOPE

We looked at whether BC Hydro has the information, practices, processes and systems needed to support good asset management. We looked specifically at their generation, distribution and transmission assets and not things like vehicles, buildings and computers. In order to assess this, we looked at the following specific elements:

- information collection:
  - setting strategic asset management direction
  - establishing service levels required
  - forecasting future demand for assets
  - collecting information and knowledge about assets
  - monitoring asset performance and condition
- life-cycle management:
  - life-cycle decision making
  - risk management
  - operational planning
  - capital investment planning
  - financial planning
- systems and practices:
  - asset management leadership and teams
  - asset management plans
  - management systems
  - asset management information systems and tools
  - service delivery models
  - audit and improvement

ABOUT THE AUDIT

Good performance in these elements greatly improves the likelihood of good asset management—but doesn't guarantee it. Other factors, such as the available funding, are also key to success. We did not look at whether capital expenditure levels were sufficient to obtain good asset management results at BC Hydro, as that responsibility lies with BC Hydro and its regulator, the BC Utilities Commission.

We conducted our fieldwork between September 2016 and December 2017. Subsequently, we reviewed our finalized assessments with BC Hydro to determine whether additional evidence was available. Our work was not continuous over this period or afterward, as staff worked on multiple audits at the same time.

AUDIT METHOD

We asked BC Hydro to self-assess its asset management maturity by applying an agreed-upon set of internationally developed asset management maturity criteria. BC Hydro returned its self-assessment results along with documentation supporting its assessment scores.

We considered BC Hydro's assertions and its documentation as part of our own examination. We supported our examination by interviewing BC Hydro professionals on their asset management practices and requesting additional documentation. We followed up on specific issues where we needed clarification. We also made site visits, including visits to the John Hart Generating Station near Campbell River, the G.M. Shrum powerhouse and the W.A.C. Bennett Dam, and BC Hydro's administration offices in Burnaby.

This report is dated November 27, 2018—the date on which we received and accepted BC Hydro's acknowledgement that it had provided all the information we needed in order to conclude on the objective of our audit.

AUDIT OBJECTIVE AND CONCLUSION

AUDIT OBJECTIVE

The objective of this audit was to determine whether BC Hydro has good asset management practices.

AUDIT CONCLUSION

We concluded that BC Hydro had demonstrated good asset management practices.

AUDIT CRITERIA SUMMARY

We derived a set of asset management maturity criteria from the 2015 *International Infrastructure Management Manual* (IIMM). The particular self-assessment grid we used was developed by, and used with the permission of, the New Zealand Tertiary Education Commission (see Appendix). This New Zealand grid reflects the most recent 2015 edition of the IIMM. This approach provided an international perspective on good asset management practice. BC Hydro accepted the use of these maturity criteria.

We chose this set of criteria with a view to applying them to other asset-intensive public-sector organizations. We hope to thereby promote asset management literacy and continuous development toward best practices in asset management within the B.C. public sector.

KEY FINDINGS

OVERALL, WE FOUND THAT BC HYDRO'S CAPITAL ASSET MANAGEMENT SYSTEMS AND PRACTICES REACHED GENERALLY ADVANCED MATURITY LEVELS

WE FOUND NO SIGNIFICANT deficiencies in BC Hydro's asset management practices. Based on mutually agreed audit criteria, we found that BC Hydro:

- has collected the information it needs to support good asset management practices
- has asset life-cycle management processes that meet good practice principles
- has systems and practices in place that enable good asset management practices

BC Hydro has reached its generally advanced level of asset management maturity as a result of a concerted effort, over at least 10 years, to build its asset management practices (see Exhibit 5). This included adopting the publicly available specification for the optimal management of physical assets and a variety of internal and external assessments, which have motivated a range of improvements that are still changing the organization.

Changes to date have included identification and reduction of deficiencies, as well as reduction of barriers between organization units. Many of the good processes and practices that we observed at BC Hydro are a direct result of the efforts of the past decade.

PUBLICLY AVAILABLE SPECIFICATION FOR THE OPTIMAL MANAGEMENT OF PHYSICAL ASSETS (PAS55)

PAS 55 set out the requirements for an asset management system for the management of physical assets and asset systems over their life cycles. The specification was produced in 2004 by the UK firm BSI, in response to demand from industry for a standard for asset management.

At the time BC Hydro used it, the standard applied to any organization where physical assets were a principal means to achieving an organization's goals. PAS55 has now been superseded by international standard ISO 55001 which has similar objectives.

Source: BSI Group, https://bsigroup.com/

KEY FINDINGS

Information collection

Asset information is current and reliable

BC Hydro has collected the information it needs to support good asset management practices.

BC Hydro knows the service requirements that its electricity-generating, transmission and distribution capability must meet. This knowledge is informed by information about its assets that is current, comprehensive and routinely updated. Within its asset knowledge base, BC Hydro keeps records of asset condition and monitors asset performance, information that in turn informs decision-making and planning functions.

BC Hydro uses an equipment health rating methodology, which captures in a standardized way the actual performance of equipment, relative to design specifications and operational expectations, as well as maintenance activity and service life estimates. BC Hydro has been working to ensure that these records are all up to date and has put in place monthly inter-unit meetings to discuss emerging equipment issues or unanticipated events that could affect asset performance and trigger needed action.

Load forecasting process is robust

BC Hydro has a load-forecasting capability that compares favourably with industry standards. The process it uses includes three components:

- projecting what will drive residential and commercial demand at a future date
- conducting sensitivity analyses to adjust for various demand outcomes
- producing a set of demand probability scenarios (low, medium and high peak load forecasts) which can be applied to strategic planning

BC Hydro uses electricity load forecasting to estimate the timing, location and size of capital investments needed to meet anticipated electricity demand. Many of the assets BC Hydro uses to meet demand, such as dam facilities, generating stations, transmission lines, and rights of way on land, take many years to plan, permit, construct and commission. This lead time means BC Hydro must act at the right time to ensure that it has the energy capacity its customers will draw from many years from now.

Forecasting future peak demand enables asset managers to evaluate, plan, reconfigure and implement a revised system to supply enough energy to meet the expected load on the electrical grid.

The primary factors that BC Hydro considers in estimating future peak energy demands include forecasts of housing starts, trends in energy use, projections of the province's gross domestic product, and estimates of changes in employment and retail sales. Calculations of future demand also attempt to take into account the impact of commercial expansions or reductions and emerging trends, such as growth in reliance on electrical vehicles and use of LED lighting. For their largest 190 customers, BC Hydro develops individual projections based on information provided by these customers plus government data and third party expert reports.

KEY FINDINGS

Other factors, however, such as unforeseen labour disruptions, recessions, changes in resource commodity prices for timber and minerals, and temporary or permanent closures of businesses that affect voltage at specific locations, create uncertainty. BC Hydro's predictive demand scenario modelling factors in: gross domestic product, likely weather impacts, and external variables, such as commodity prices affecting energy consumption.

Life-cycle management

Life-cycle planning meets expectations

BC Hydro has asset life-cycle management processes that follow good practice principles.

Continual improvement based on lessons learned is built into operational plans. For example, asset maintenance standards and instructions and safety procedures are regularly reviewed. Subject matter experts and engineering reports are used to identify root causes and trends when a failure or incident occurs. Preventive maintenance required to meet regulatory requirements is always funded and resourced to the full extent.

Management has identified the most critical assets and works to sustain them by focusing on the following factors:

- safety and security of assets
- current condition of assets
- asset characteristics and specifications
- availability of skilled professionals and materials
- time when assets can be out of service
- changes in regulation and standards
- procurement lead times for materials and labour

BC Hydro manages the interaction between these factors and its service delivery objective, which is to produce a reliable supply of energy. For example, some degree of equipment redundancy is built into the network, so that if a component fails the service demand can be met in other ways.

BC Hydro also has a mature and well-documented asset maintenance program that is aligned with its objectives as an organization.

Capital planning balances asset investment with the need to manage cost

The three priorities for expenditure in BC Hydro's current 10-year capital investment plan are managing growth, maintaining and renewing assets, and dam safety. BC Hydro is funding improvement and expansion projects in all three areas within an annual funding cap. That means, for example, changes in foreign currency, trade tariffs or new technologies that drive up costs must be accommodated without exceeding the cap.

Capital investment plans are developed after all of the business units have identified their specific needs; programs and projects are then created to meet those needs as the plans are developed. An annual prioritization process decides which of the many projects will proceed and which will have to wait to keep capital spending caps from being exceeded.

KEY FINDINGS

The prioritization allows certain projects to advance toward completion each year and pushes others further out. Near term focus on capital expenditure by BC Hydro takes precedence over projects that will be funded later.

BC Hydro's ten year plan is made up of projects with different levels of cost certainty. Projects starting in the first three years of the plan have the most accurate cost estimates. Projects starting after year three are rougher forecasts. To compensate for this uncertainty and keep future costs close to the plan, Hydro uses an annual funding target (limit). Given that costs typically rise over time, projects may have to be delayed or scaled back to keep the overall plan within the funding target. Hydro therefore achieves a higher level of certainty about the cost of projects by reducing the level of certainty that projects in the later years of the plan will be built as planned.

BC Hydro explained that it is prohibitively costly to prepare full cost estimates for projects that won't start for several years.

However, it also means that BC Hydro cannot always determine the full cost associated with delaying projects, because it only has detailed costs for the near term. Impacts can include real cost increases, such as labour and equipment, loss of revenue, and increased maintenance and operational costs. Cost changes could also be decreases resulting from new technologies or alternative energy sources. BC Hydro looks at these impacts in its annual project prioritization if a project will be deferred by three years. This means that some cost consequences of delay within the 10-year capital plan are unknown.

However, advanced maturity requires a high level of project cost certainty throughout a 10-year capital plan. This is a higher level of certainty than what is achieved in years 4-10 of Hydro's plan. However, in BC Hydro's case, this is not a deficiency, and as a result we are not making a recommendation.

BC Hydro's practices in this regard make sense. Consider, for example, the needs of BC Hydro compared with those of a school district experiencing declining enrolment. The school district will not need to plan for new assets and can focus on the maintenance and possible retirement of existing facilities. It should therefore be able to cost-effectively meet all the significant indicators of advanced maturity for capital investment planning. By contrast, BC Hydro must make a complex estimation of the need for power and the resulting income from customers available to grow capacity while allocating investments across a wide array of asset types of different ages and manufacture. Additionally, accurately costing the largest projects requires costly professionals like designers, engineers and quantity surveyors to put in significant amounts of time. Greater certainty therefore takes a lot of time and comes at a significant cost.

More specific to BC Hydro's situation is the dynamic environment in which it operates. In planning it must try to estimate the impacts of emerging technologies and energy efficiency gains on electricity demand, while at the same time responding to government policy direction, such as that associated with the *Clean Energy Act*. BC Hydro's regulator, the BC Utilities Commission, looks at this operating environment to the degree which it is allowed to given government direction.

KEY FINDINGS

Systems and practices

Leadership and teams are supported by learning, development and trades training strategies

We expected BC Hydro's commitment to asset management to be reflected in the leadership roles in the business units. We found there is alignment of asset management objectives, such as reliability, with asset management methodology and responsibilities of professionals involved. The technical capacity in the business units is sufficient to design projects for the 10-year plan of capital investments.

Asset management plans are updated each year

We found that asset performance expectations and future demand forecasts are applied to asset management planning. Significant levels of stakeholder engagement are factored into planning. One example is the facility planning process BC Hydro uses to keep stakeholders informed of known issues and opportunities. Asset management plans are reviewed, improved and updated annually.

Service delivery focus is on best value

BC Hydro has to buy supplies and services from external sources to support its asset management maintenance programs and capital projects. We expected that the risks, benefits and costs of various service delivery options had been considered and that the option with the best value was implemented. In BC Hydro's capital asset management framework, all projects over $50M must be assessed for suitability for alternative procurement.

We found there are slightly different procurement plans/policies in place for different departments within BC Hydro. There is a plan to align procurement policies to ensure consistency of practices across the organization.

BC Hydro has a generally advanced level of maturity in asset management, as indicated in Exhibit 5. Its success in this regard is a result of concerted effort over several years by a set of skilled professionals focused on ensuring that a reliable source of electrical power will be supported by a mature asset management practice.

Exhibit 5: BC Hydro's Asset Management maturity score - out of 100 points

AUDIT QUALITY ASSURANCE

We conducted this audit under the authority of section 11 (8) of the *Auditor General Act* and in accordance with the standards for assurance engagements set out by the Chartered Professional Accountants of Canada (CPA) in the CPA Handbook – Canadian Standard on Assurance Engagements (CSAE) 3001 and Value-for-money Auditing in the Public Sector PS 5400. These standards require that we comply with ethical requirements, and that we conduct the audit to independently express a conclusion on whether or not the subject matter complies in all significant respects to the applicable criteria.

We apply the CPA Canadian Standard on Quality Control 1 (CSQC) and, accordingly, maintain a comprehensive system of quality control, including documented policies and procedures regarding compliance with ethical requirements, professional standards, and applicable legal and regulatory requirements. In this respect, we have complied with the independence and other requirements of the code of ethics applicable to the practice of public accounting issued by the Chartered Professional Accountants of British Columbia, which are founded on the principles of integrity, objectivity and professional competence, as well as due care, confidentiality and professional behaviour.

APPENDIX: COMPLETE AUDIT CRITERIA

FOR BC HYDRO asset managers, asset planners, operators, maintainers and developers, the IIMM manual offers a reference within which the various components of a system of asset management are situated and interrelated. For those specialists at the periphery, such as regulatory, IT and financial professionals, the manual provides an asset management framework with examples.

Audit Criteria as adapted from the *International Infrastructure Management Manual*

Maturity Scale →	Aware Maturity 0-20	Basic Maturity 25-40	Core Maturity 45-60	Intermediate Maturity 65-80	Advanced Maturity 85-100
Understanding and Defining Requirements					
Setting the Strategic Direction Asset management (AM) policy supports an organization's strategic objectives. It articulates the principles, requirements and responsibilities for AM. It articulates the objectives, practices and action plans for AM improvement, audit and review processes. The AM Policy and Strategy may be incorporated into the AM Plan.	The organization is aware of the need to develop an AM Policy, but hasn't yet completed this work.	Corporate expectations are expressed in relation to the development of AM plans and objectives, such as "all departments must have a current AM plan".	AM policy and objectives are developed and aligned with corporate goals and strategy.	The scope of AM is defined and documented. How AM fits into the wider corporate environment is analyzed and implications for AM are documented in the Strategic AM Plan or AM Strategy. AM policy and objectives are reflected in departmental plans and priorities.	AM Policy and Strategy is fully integrated into the organization's business processes and subject to defined audit, review, and updating procedures.
Establishing Levels of Service Levels of service are the cornerstone of asset management and provide the platform for all life-cycle decision making. Levels of service are the outputs a customer receives from the organization. One of the first steps in developing asset management plans or processes is to find out what levels of service customers are prepared to pay for, then understand the organization's capability to deliver the levels of service.	The organization understands level of service requirements but has not documented or quantified them.	The organization has defined how assets contribute to the organizations objectives and levels of service. Customer/ user groups have been defined and their needs are informally understood.	Level of service benchmarks are in place for each major client, user or asset group. Customer/ user needs have been analyzed.	Customers/users have been consulted on significant service levels and options. The relationship between the level of service and costs is understood by the organization.	Levels of service and benchmarks are integrated into decision making, business planning and performance reporting.
Forecasting Future Demand This AM activity involves predicting changes in demand for specific service requirements over the life of the AM plan or the life of the asset pool. The ability to predict demand enables an organization to plan ahead and meet that demand, or manage risks of not meeting demand.	The organization generally understands future demand requirements but they are not documented or quantified.	Demand forecasts are based on predictions by experienced staff, with consideration of known past demands, trends and likely future growth patterns.	Demand forecasts are based on robust projections of a primary demand factor (e.g. population growth) and extrapolation of historic trends. Risks associated with changing demand are broadly understood and documented.	Demand management is considered during long term capital planning. Demand forecasts are based on mathematical analysis of past trends and primary demand factors. A range of demand probability scenarios is developed (e.g. high, med, low) as part of risk management.	Demand management is considered in strategic and project decisions. Risk assessments of different demand scenarios with mitigation actions are in place.

APPENDIX

Maturity Scale →	Aware Maturity 0-20	Basic Maturity 25-40	Core Maturity 45-60	Intermediate Maturity 65-80	Advanced Maturity 85-100
Understanding and Defining Requirements *(continued)*					
Collecting Asset Information (Asset Knowledge) Credible asset data is the foundation for enabling most AM functions. Effective planning for asset maintenance, renewal, upgrade, and replacement cannot proceed until organizations know the nature, location, capacity, and reliability of the assets they rely on for service delivery.	The organization has asset information in a variety of formats. There is an awareness of the need for an integrated asset register.	Essential asset information (e.g. type, design size / capacity, age, location) is recorded in spread sheets or data bases, but is based primarily in historical records such as "as-built". Asset information is updated and verified periodically.	As for Basic, plus there is sufficient information for valuations, replacement costs, asset age, remaining service life. Asset information generally supports planning and prioritization. Asset hierarchy, identification and attribute systems are documented. Asset data is routinely updated and tested for reliability.	As for Core, plus a reliable register of physical, financial and risk attributes recorded in an information system with data analysis and flexible reporting functionality. Systematic and documented data collection process are in place. High level of evidence based confidence in asset data.	As for Intermediate, plus detailed (component level) information on work history, type and cost, condition, performance, etc. is recorded and utilized in data analysis. Systematic and fully optimised data collection program in place with supporting metadata. There is a complete data base for core assets with minimal assumptions for non core assets.
Monitoring Asset Performance and Condition Assets are central to service delivery and meeting strategic objectives. Timely and complete performance and condition information is essential for AM and supports life cycle decision making, risk management, and operational, capital and financial planning.	Asset condition and performance data is not formally documented, or is collected in limited quantities.	Asset information and data is adequate to confirm current asset performance against AM objectives.	Asset condition and performance information is suitable to plan maintenance and renewal over the near term (5 years or less).	As for Core, plus asset condition and performance information is modelled to assess whether AM condition and level of service objectives are being met over the long-term (> 5 years). Contextual information such as forecasting demand variances is used to estimate potential performance variances.	As for Intermediate, plus the type, quality and amount of asset data are optimised to the financial and technical decisions being made. Asset performance and condition data is modeled for development and reporting of continuous improvement strategies. The data collection program is adapted to reflect asset lifecycles.
Lifecycle Planning					
Lifecycle Decision Making Lifecycle based AM planning is essential to achieve sustainable, appropriate, and affordable levels of services.	The organization recognises the benefits of lifecycle-based decision making but currently bases decisions primarily on staff judgement.	Organizational priorities are reflected in AM decision making.	As for Basic, plus formal decision making analysis/techniques are applied to major projects and programs, where criteria are based on organizational AM objectives.	As for Core, plus formal decision making and prioritization techniques are applied to operational and capital programs at the business unit, asset component level, or budget category. Past assumptions, forecasts, estimates, and decision making methodologies are tested against actual results.	As for Intermediate, plus AM objectives and targets are based on formal decision making techniques and are supported by the estimated cost and benefit or achieving targets. The decision making framework enables projects and programs to be optimized across the organization. Formal risk based sensitivity analysis is carried out and informs subsequent management decision cycles.

APPENDIX

Maturity Scale →	Aware Maturity 0-20	Basic Maturity 25-40	Core Maturity 45-60	Intermediate Maturity 65-80	Advanced Maturity 85-100
Lifecycle Planning *(continued)*					
Risk Management Risk management helps identify higher frequency and higher consequence risks, and identifies actions to mitigate those risks. This process reduces the organization's exposure to asset related risks and drives maintenance rehabilitation and renewal programs and decision making.	The organization has identified formal risk management, related to AM, as a future improvement.	Critical service and asset risks are understood and considered by senior staff involved in maintenance and renewal decisions.	A risk framework is developed. Critical assets and high risks are identified. There are documented risk management strategies for critical assets and high risks.	As for Core, plus systematic risk analysis assists key decision-making. The risk register is regularly monitored, updated and reported. Risk is managed consistently across the organization. An infrastructure resilience strategy and program is in place including defined levels of service for resilience.	As for intermediate, plus a formal risk management policy in place. Risk is quantified and risk mitigation options evaluated. Risk and resilience are integrated into all aspects of decision making.
Operational Planning Operational plans document how assets will be operated on a day to day basis including activities aimed at keeping assets in service and meeting AM objectives. Operations encompasses both operational and maintenance activities. Effective operational strategies can mitigate risk, defer the need for asset replacement, minimize service downtime, reduce the impact from asset failures, increase service affordability and reduce lifecycle costs.	Operational plans and procedures (operations and maintenance) are based on historical practices (things are largely done the way they always have been).	Operating plans and procedures are available for critical operational processes.	The organizations operational structure is in place, documented and roles are assigned.	As for Core, plus operating plans and procedures (maintenance and operational) are available for all operational processes. Support requirements/ resources are in place and risk and opportunity planning is completed.	As for Intermediate, plus operational objectives and intervention levels are defined and implemented. Operational planning's alignment with organizational objectives can be demonstrated. Continual improvement can be demonstrated for all operational processes.
Capital Investment Planning Capital investment includes the upgrade, creation and/or purchase of new assets, typically to address growth or changes in levels of service requirements, or for the periodic renewal of existing assets to maintain service levels. Organizations need to plan for the long term asset requirements relative to forecasted demand and future levels of service.	Capital investment projects are identified during the annual budgeting process.	There is a schedule of proposed capital projects, with associated costs, for the next 3-5 years, based on staff judgement of future requirements.	Proposed projects have been collected from a wide range of sources and collated into a project register. Capital projects for the next three years are fully scoped and estimated. A prioritization framework is in place to rank the importance of capital projects. Asset condition, performance and levels of service are variables used to prioritize projects.	As for Core, plus formal options analysis and business case development has been completed. Priority capital projects proposed in the 3-5 year period are consistent with capital programs, reflecting the requirements of the next 10-20 years. Priority projects and programs have full cost estimates available.	Long term capital investment programs are developed using decision techniques such as predictive modeling. The organization has a reliable and approved 10-year view of its future capital requirements to meet forecast level of service requirements and the strategic choices available to meet changing fiscal or level of service requirements.
Financial Planning Poor long term financial management can lead to higher life cycle costs, and financial "shocks". Good collaboration between financial and technical asset managers is important, especially in relation to long term financial forecasts and asset condition and level of service related decisions. Robust financial budgets are a key output of any asset management planning process.	Financial planning is largely an annual budget process but there is intention to develop longer term forecasts.	10-year financial forecasts are based on extrapolation of past trends and broad assumptions about the future.	10 year+ financial forecasts are based on current comprehensive AM plans. Significant assumptions are stated. Expenditures are captured at a level useful for AM analysis.	10 year+ financial forecasts are based on current comprehensive AM plans with detailed supporting assumptions and reliability factors. Significant assumptions are specific and well reasoned. Asset expenditures are easily linked to finance databases.	10 year+ financial forecasts based on comprehensive, advanced AM plans with detailed underlying assumptions and high confidence in accuracy. Advanced financial modeling provides sensitivity analysis, demonstrable whole life costing and cost analysis for level of service options.

Asset Management Enablers					
AM Leadership and Teams Effective asset management requires a committed and co-ordinated effort across all sections of an organization.	Organization leadership is supportive of AM.	AM functions are carried out by small groups. Position descriptions incorporate AM roles.	AM coordination processes are established. Leadership demonstrates ownership and support for AM. There is an awareness of AM across most of the organization and broad organizational structures that support AM.	There is a consistent approach to AM across the organization and an established internal communication plan. AM is resourced, key AM roles are in place and AM duties are included in position descriptions.	Roles reflect AM requirements and AM is defined in all relevant position descriptions. There is a formal documented assessment of AM capability and capacity requirements needed to achieve AM objectives. There is a demonstrate alignment between AM objectives, AM systems and individual responsibilities.
AM Plans An asset management plan is a written representation of intended capital and operational programs for its new and existing infrastructure, based on the organizations understanding of demand, customer requirements and its own network of assets.	The organization has stated an intention to develop AM plans.	AM plans contain basic information on assets, service levels, planned work and financial forecasts (5-10 years) and identifies future AM improvements actions.	AM objectives are defined within the overall strategic context. The AM plan includes basic level attributes plus the following: - the approach to risk and critical assets is described - a top-down condition and performance assessment - future demand forecasts - descriptions of supporting AM processes - 10-year financial forecasts - a 3-year AM improvement plan.	AM strategic context analyzed with risks, issues and responses described. The AM plan includes core attributes plus the following: - analysis of asset condition and performance trends - customer engagement in setting levels of service - optimized decision making and risk techniques applied to major programs.	The AM plan includes intermediate attributes plus the following: - evidence of programs driven by comprehensive optimized decision making techniques - risk management programs and level of service/cost trade off analysis AM plan improvement program is largely complete with focus on ongoing maintenance of current practices.
Management Systems Effective management systems allow organizations to improve effectiveness and efficiency, increase customer satisfaction and better manage asset condition, performance, service delivery, risk and other factors.	The organization is aware of the need to formalize AM systems and processes but has yet to document and implement a management system with specific policies, processes, procedures, systems and reporting frameworks.	Simple process documentation in place for service critical AM activities.	A basic quality management system is in place that covers financial and technical activities. Critical AM processes are documented, monitored and subject to review.	As for core plus process documentation is implemented in accordance with AM system to an appropriate level of detail. Internal financial and technical management systems are aligned.	As for intermediate plus strong integration of all management systems within the organization. Ongoing staff training supports the effective and consistent use of management systems. Outcomes are measured and reported to support continuous improvement.

APPENDIX

Asset Management Enablers *(continued)*					
AM Information Systems and Tools AM systems are an essential tool for the timely and cost effective management of assets in order to affordably meet service obligations. The large amounts of data associated with assets and AM requires information systems and tools in order to effectively deal with the extent of analysis required to fully manage assets.	The organization recognizes the benefits of using asset management information systems(AM IS), but does not have one in place.	The AM IS or asset register can record core asset attributes such as size, material etc. Asset information reports can be manually generated for AM plan input.	The AM IS or asset register enables hierarchical reporting (from component to facility level). Customer request tracking and planned maintenance functionality is enabled. The system enables manual reports to be generated for valuation and renewal forecasting.	As for core plus, there is more automated analysis, forecasting and reporting on a wider range of information including operations, maintenance, condition, performance and financial.	Financial, asset and customer service systems are integrated, interactive and enable advanced AM functions. There is forecasting of AM activity including prioritized expenditures to refurbish and upgrade assets. Asset optimization analysis can be completed.
Service Delivery Models The cost effectiveness of asset management planning is proven in the efficient and effective delivery of services at an operational level.	The organization has clearly allocated service delivery roles (internal and external) and generally follows historic approaches.	Service delivery roles are clearly allocated internally and externally and generally follow historic approaches or industry customs and practices.	Core functions are defined. A procurement strategy/policy is in place. Internal service level agreements are in place with primary internal service providers and contracts for primary external service providers.	Risks, benefits and costs of various outsourcing options are determined and considered. Competitive tendering practices are applied with integrity and accountability. Periodic reviews are conducted to identify the best value delivery mechanism for each major AM activity.	All potential service delivery mechanisms have been reviewed and formal analysis carried out. Risks, benefits and costs of various service delivery options have been considered and the best value arrangement has been identified and is being implemented.
Audit and Improvement Well performing organizations recognize the value that can be obtained from continuously improving AM policies, processes, systems and capabilities. The focus is on ensuring AM practices are appropriate to the current and long term business objectives.	The organization recognizes the need to improve AM processes and practises, but has yet to develop an improvement plan.	Improvement actions have been identified and responsibility has been allocated to appropriate staff.	Current and future AM performance is assessed and identified gaps are used to drive improvement actions. Improvement plans identify objectives, timeframes, deliverables, resource requirements and responsibilities.	As for Core, plus formal monitoring and reporting on the improvement program to the Executive Team. Project briefs have been developed for all key improvement actions. Resources have been allocated to the improvement actions.	As for Intermediate, plus improvement plans specify key performance indicators (KPIs) for monitoring AM improvement. Improvement plan key performance indicators are routinely reported.

Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Appendix G

Fiscal 2017 and Fiscal 2018
Variance Explanations

Table of Contents

List of Tables

1 Introduction

This appendix provides variance explanations for BC Hydro's energy sales and revenues, energy supply and energy costs, operating costs and capital expenditures and additions between the plan amounts in the Fiscal 2017 to Fiscal 2019 Revenue Requirements Application (**Previous Application**) and actual results in those fiscal years.

2 Energy Sales and Revenue Variance Explanations (Chapter 3)

Chapter 3 of the Application addresses BC Hydro's load and revenue forecast for the test period. This section compares domestic energy sales and revenue actual amounts for fiscal 2017 and fiscal 2018 with the Plan amounts from the Previous Application.

Load and revenues always have a degree of variability between forecast and actual amounts, but, as described below, the load variances are relatively small in fiscal 2017 and fiscal 2018, ranging from 0.1 per cent to 0.5 per cent. These variances are captured by the Cost of Energy Variance Regulatory accounts, meaning that customers pay only actual costs.

2.1 Domestic Energy Sales Variance Explanations

2.1.1 Domestic Energy Sales Variance Explanations - Fiscal 2017

Table G-1 compares fiscal 2017 domestic energy sales actual amounts (in GWh) against the fiscal 2017 RRA Plan, with variance explanations below the table.

Table G-1 Fiscal 2017 Domestic Energy Sales Variance

	(GWh)	Schedule Reference	F2017 RRA	F2017 Actual	F2017 Diff	F2017 % Diff
			1	2	3 = 2 - 1	4 = 3 / 1
1	Residential	14.0 L1	18,036	18,068	31	0.2%
2	Light-Industrial and Commercial	14.0 L2	18,832	18,968	136	0.7%
3	Large Industrial	14.0 L2+L9	13,380	13,176	(204)	-1.5%
4	Other	14.0 L3 to L8	1,611	1,683	72	4.5%
5	Total	14.0 L10	51,860	51,895	35	0.1%

Actual domestic energy sales in fiscal 2017 were 35 GWh (or 0.1 per cent) higher than the demand projections included in the fiscal 2017 RRA Plan.

Actual energy sales to the residential sector were 31 GWh (or 0.2 per cent) higher than the fiscal 2017 RRA Plan, primarily due to slightly colder temperatures partially offset by lower net usage per account and lower account growth than plan.

Actual energy sales to the light industrial and commercial sector were 136 GWh (or 0.7 per cent) higher than the fiscal 2017 RRA Plan due to higher than anticipated growth in leading economic drivers, such as net employment in the province.

Actual energy sales to the large industrial sector were 204 GWh (or 1.5 per cent) lower than the fiscal 2017 RRA Plan. Most of the variance was in the oil and gas sector and LNG. Specifically, there were delays in start-up of gas loads in the oil and gas sector. Additionally, FortisBC Tilbury LNG plant operations did not increase in production as anticipated in the fiscal 2017 RRA Plan.

Actual energy sales to other customer sector were 72 GWh (or 4.5 per cent) higher than the fiscal 2017 RRA Plan, primarily due to higher than expected sales to FortisBC.

2.1.2 Domestic Energy Sales Variance Explanations - Fiscal 2018

Table G-2 compares fiscal 2018 domestic energy sales actual amounts (in GWh) against the fiscal 2018 RRA Plan, with variance explanations below the table.

Table G-2 Fiscal 2018 Domestic Energy Sales – Actuals

	(GWh)	Schedule Reference	F2018			
			RRA	Actual	Diff	% Diff
			1	2	3 = 2 - 1	4 = 3 / 1
1	Residential	14.0 L1	18,112	18,150	39	0.2%
2	Light-Industrial and Commercial	14.0 L2	18,785	18,874	89	0.5%
3	Large Industrial	14.0 L2+L9	13,323	13,440	117	0.9%
4	Other	14.0 L3 to L8	1,618	1,638	19	1.2%
5	Total	14.0 L10	51,838	52,102	264	0.5%

Actual domestic energy demand in fiscal 2018 was 264 GWh (or 0.5 per cent) higher than the demand projections included in the fiscal 2018 RRA Plan.

Actual residential sector energy sales were 39 GWh (or 0.2 per cent) higher than the fiscal 2018 RRA Plan. Identical to fiscal 2017, this was primarily due to slightly colder temperature differences than the assumed normalized values, and partially offset by lower usage per account and lower account growth than plan.

Actual light industrial and commercial sector energy sales were 89 GWh (or 0.5 per cent) higher than the fiscal 2018 RRA Plan, primarily due to sales growth to manufacturing customers.

Actual large industrial sector energy sales were 117 GWh (or 0.9 per cent) higher than the fiscal 2018 RRA Plan. Actual sales were greater than plan in the mining, wood and chemical sectors. Actual sales were also above plan in the pulp and paper sector, and the positive variance in this sector was partially offset by an unfavourable variance in the oil and gas sector as well as the FortisBC Tilbury LNG plant. Sales were above plan in the pulp and paper sector primarily due to closure risk adjustments, which were partially offset by lower than expected self-generation by our customers. Sales were below plan in the oil and gas sector due to delays in gas projects driven by various factors such as market conditions and delays in the ramp up of production at FortisBC Tilbury explains the variance in LNG sales.

Actual energy sales to the other customer sector were 19 GWh (or 1.2 per cent) higher than the fiscal 2018 RRA Plan. This variance was primarily due to higher sales than expected to FortisBC, partly offset by lower sales to the City of New Westminster.

2.2 Domestic Revenue Variance Explanations

2.2.1 Domestic Revenue Variance Explanations - Fiscal 2017

Table G-3 compares fiscal 2017 domestic revenue actuals (in $million) against the fiscal 2017 RRA Plan, with variance explanations below the table.

Table G-3 Fiscal 2017 Domestic Revenues – Variance

	($ million)	Schedule Reference	F2017 RRA	F2017 Actual	F2017 Diff	F2017 % Diff
			1	2	3 = 2 - 1	4 = 3 / 1
1	Residential	14.0 L11	1,915	1,916	1	0.1%
2	Light-Industrial and Commercial	14.0 L12	1,703	1,715	11	0.7%
3	Large Industrial	14.0 L13+L19	749	733	(16)	-2.1%
4	Other	14.0 L14 to L18	120	122	2	1.5%
5	Subtotal		4,487	4,486	(1)	0.0%
6	Revenue from Deferral Rider	14.0 L21	223	224	1	0.1%
7	Total	14.0 L22	4,710	4,710	0	0.0%

Actual domestic revenues in fiscal 2017 were the same as the fiscal 2017 RRA Plan, with slightly lower large industrial revenues offset by higher light industrial and commercial revenue. These revenue variances were driven by the load variances described in section 2.1.1.

2.2.2 Domestic Revenue Variance Explanations - Fiscal 2018

Table G-4 compares fiscal 2018 domestic revenue actuals (in $million) against the fiscal 2018 RRA Plan, with variance explanations below the table.

Table G-4 Fiscal 2018 Domestic Revenues – Variance

	($ million)	Schedule Reference	F2018 RRA	F2018 Actual	F2018 Diff	F2018 % Diff
			1	2	3 = 2 - 1	4 = 3 / 1
1	Residential	14.0 L11	1,991	1,997	5	0.3%
2	Light-Industrial and Commercial	14.0 L12	1,758	1,771	12	0.7%
3	Large Industrial	14.0 L13+L19	775	772	(2)	-0.3%
4	Other	14.0 L14 to L18	124	122	(2)	-1.6%
5	Subtotal		4,649	4,662	13	0.3%
6	Revenue from Deferral Rider	14.0 L21	231	233	2	0.8%
7	Total	14.0 L22	4,880	4,895	15	0.3%

Actual domestic revenues in fiscal 2018 were $15 million (or 0.3 per cent) higher than the fiscal 2018 RRA Plan. This increase is largely driven by higher light industrial and commercial load, as described in section 2.1.2. The higher load in the large industrial sector did not result in higher revenue as the actual average rate was lower than anticipated in the fiscal 2018 RRA Plan due to the different proportions of load at the various tariff rates.

3 Cost of Energy Variance Explanations (Chapter 4)

Chapter 4 of the Application addresses BC Hydro's Cost of Energy for the test period. This section compares sources of energy supply and Cost of Energy actual amounts for fiscal 2017 and fiscal 2018 with the Plan amounts from the Previous Application.

3.1 Sources of Supply Variance Explanations

3.1.1 Sources of Supply Variance Explanations – Fiscal 2017

Table G-5 compares fiscal 2017 energy supply sources actuals (in GWh) against the fiscal 2017 RRA Plan, with variance explanations below the table.

Table G-5 Fiscal 2017 Sources of Supply

	(GWh)	Schedule Reference	F2017 RRA	Actual	Diff	% Diff
			1	2	3 = 2 - 1	4 = 3 / 1
1	Water Rentals	4.0 L1	48,560	48,736	176	0%
2	IPPs and Long-Term Commitments	4.0 L5	13,375	13,644	269	2%
3	Market Electricity Purchases	4.0 L8	230	131	(98)	(43%)
4	Natural Gas for Thermal Generation	4.0 L2	224	74	(151)	(67%)
5	Surplus Sales	4.0 L9	(4,962)	(5,756)	(794)	16%
6	Net Purchases (Sales) from Powerex	4.0 L10	(267)	138	404	(152%)
7	Non-Integrated Area	4.0 L6	117	118	0	0%
8	Exchange Net	4.0 L3	(115)	(253)	(138)	120%
9	Total	4.0 L12	57,162	56,832	(331)	(1%)

Actual fiscal 2017 energy supplied was 331GWh (or 1 per cent) lower than the fiscal 2017 RRA Plan. Higher surplus sales which were needed for reservoir management were partially offset by higher purchases by Powerex due to BC Hydro system constraints which limited Powerex's opportunity to export for trade and higher deliveries from independent Power Producers (**IPPs**).

3.1.2 Sources of Supply Variance Explanations – Fiscal 2018

Table G-6 compares fiscal 2018 energy supply sources actuals (in GWh) against the fiscal 2018 RRA Plan, with variance explanations below the table.

Table G-6 Fiscal 2018 Sources of Supply

	(GWh)	Schedule Reference	F2018 RRA	F2018 Actual	F2018 Diff	F2018 % Diff
			1	2	3 = 2 - 1	4 = 3 / 1
1	Water Rentals	4.0 L1	47,219	47,926	707	1%
2	IPPs and Long-Term Commitments	4.0 L5	15,002	14,354	(648)	(4%)
3	Market Electricity Purchases	4.0 L8	747	150	(597)	(80%)
4	Natural Gas for Thermal Generation	4.0 L2	232	91	(141)	(61%)
5	Surplus Sales	4.0 L9	(5,556)	(5,072)	484	(9%)
6	Net Purchases (Sales) from Powerex	4.0 L10	(253)	(557)	(304)	120%
7	Non-Integrated Area	4.0 L6	119	115	(5)	(4%)
8	Exchange Net	4.0 L3	(323)	599	923	(285%)
9	Total	4.0 L12	57,187	57,606	419	1%

Actual fiscal 2018 energy supplied was 419 GWh (1 per cent) higher than the fiscal 2018 RRA Plan. Inflows to the system during fiscal 2018 were 98 per cent of average. The below average inflows were due to dry weather in the Peace region, partially offset by higher snowmelt contribution in the Columbia region, and resulted in fewer surplus sales during the year. Despite lower inflows, hydro generation was higher than forecast in fiscal 2018. This was due to fewer deliveries from IPPs, fewer domestic market purchases and higher net sales to Powerex due to greater market trading opportunities. In addition, higher net exchange volumes were largely driven from higher than planned generation related to the Canal Plant and Keenleyside coordination agreements.

3.2 Cost of Energy Variance Explanations

3.2.1 Cost of Energy Variance Explanations – Fiscal 2017

Table G-7 compares fiscal 2017 Cost of Energy actual amounts (in $millions) against the fiscal 2017 RRA Plan, with variance explanations below the table.

Table G-7 Fiscal 2017 Cost of Energy

		Schedule	F2017			
	($ million)	Reference	RRA	Actual	Diff	% Diff
			1	2	3 = 2 - 1	4 = 3 / 1
1	Water Rentals	4.0 L23+L32	386.7	387.0	0.4	0%
2	IPPs and Long-Term Commitments	4.0 L29	1,234.4	1,213.1	(21.3)	(2%)
3	Market Electricity Purchases	4.0 L34	8.6	3.4	(5.2)	(61%)
4	Natural Gas for Thermal Generation	4.0 L24	14.9	9.5	(5.4)	(36%)
5	Domestic Transmission - Other	4.0 L25	22.6	22.5	(0.1)	(1%)
6	Domestic Transmission - Export	4.0 L37	31.8	28.3	(3.5)	(11%)
7	Columbia River Treaty Related Agreements	4.0 L26	(23.1)	(23.3)	(0.2)	1%
8	Surplus Sales	4.0 L35	(118.1)	(132.8)	(14.6)	12%
9	Net Purchases (Sales) from Powerex	4.0 L36	(6.5)	2.3	8.8	(136%)
10	Non-Integrated Area	4.0 L30	24.6	25.0	0.4	1%
11	Gas & Other Transportation	4.0 L31	10.6	11.7	1.1	11%
12	Remissions and Other	4.0 L27	(37.3)	(41.3)	(4.0)	11%
13	Total	4.0 L39	1,549.3	1,505.5	(43.8)	(3%)

Actual fiscal 2017 Cost of Energy was $43.8 million (or 3 per cent) lower than the fiscal 2017 RRA Plan. This was primarily due to:

- Lower costs from IPPs largely due to delayed commercial operation dates for several projects; and
- Higher Surplus Sales as higher export volumes were needed to manage spill risk at Williston reservoir and maintain downstream Arrow reservoir levels. In addition, higher Mid-C prices during the summer also resulted in higher than planned surplus sales revenues during that period, which were partially offset by lower Surplus Sales later in the fiscal year due to lower inflows and softer prices.

Partially offset by:

- Higher Net Purchases from Powerex compared to planned net sales as a result of BC Hydro system constraints which limited Powerex's opportunity to export for trade.

3.2.2 Cost of Energy Variance Explanations – Fiscal 2018

Table G-8 compares fiscal 2018 Cost of Energy amounts (in $millions) against the fiscal 2018 RRA Plan, with variance explanations below the table.

Table G-8 Fiscal 2018 Cost of Energy

	($ million)	Schedule Reference	F2018 RRA	F2018 Actual	F2018 Diff	F2018 % Diff
			1	2	3 = 2 - 1	4 = 3 / 1
1	Water Rentals	4.0 L23+L32	356.8	361.6	4.8	1%
2	IPPs and Long-Term Commitments	4.0 L29	1,369.7	1,311.6	(58.1)	(4%)
3	Market Electricity Purchases	4.0 L34	30.2	3.7	(26.6)	(88%)
4	Natural Gas for Thermal Generation	4.0 L24	10.5	3.4	(7.1)	(68%)
5	Domestic Transmission - Other	4.0 L25	22.3	22.5	0.2	1%
6	Domestic Transmission - Export	4.0 L37	35.4	25.2	(10.2)	(29%)
7	Columbia River Treaty Related Agreements	4.0 L26	(10.4)	(40.6)	(30.2)	291%
8	Surplus Sales	4.0 L35	(150.4)	(139.4)	11.0	(7%)
9	Net Purchases (Sales) from Powerex	4.0 L36	(6.0)	(10.9)	(4.9)	83%
10	Non-Integrated Area	4.0 L30	27.4	26.5	(0.9)	(3%)
11	Gas & Other Transportation	4.0 L31	10.1	13.1	3.0	29%
12	Remissions and Other	4.0 L27	(37.8)	(38.0)	(0.1)	0%
13	Total	4.0 L39	1,657.8	1,538.7	(119.2)	(7%)

Actual fiscal 2018 actual Cost of Energy was $119.2 million (or 7 per cent) lower than the fiscal 2018 RRA Plan. This was primarily due to:

- Lower costs from IPPs, mainly driven by delayed commercial operation dates and terminated projects;
- Lower Market Electricity Purchases due to market purchases not being required to meet the domestic load requirements as supply from other sources was sufficient;

- Lower Natural Gas for Thermal Generation costs due to an outage at the Fort Nelson Generating Station which resulted in lower thermal generation;
- Lower domestic transmission charges as a result of lower Surplus Sales;
- Higher recoveries from water transactions associated with the Columbia River Treaty related agreements primarily due to more releases from storage as a result of strong market prices and dryer weather in the U.S.; and
- Higher Net Sales to Powerex due to greater market trading opportunities.

Partially offset by:

- Lower Surplus Sales primarily due to lower system inflows.

4 Operating Costs Variance Explanations (Chapter 5)

Chapter 5 of the Application addresses BC Hydro's Operating Costs.

This section compares gross operating costs and provisions actual amounts for fiscal 2017 and fiscal 2018 with the Plan amounts from the Previous Application.

4.1 Operating Costs Variance Explanations - Fiscal 2017

Table G-9 compares fiscal 2017 gross operating cost and provisions actual amounts against the fiscal 2017 RRA Plan, with variance explanations below the table.

Table G-9 Fiscal 2017 Operating Costs and Provisions Variances

	($ million)	Schedule Reference	F2017 RRA	F2017 Actual	F2017 Diff	F2017 % Diff
			1	2	3 = 2 - 1	4 = 3 / 1
1	Integrated Planning	5.0 L1	271.3	284.8	13.5	5%
2	Capital Infrastructure Project Delivery	5.0 L2	79.7	79.2	(0.5)	-1%
3	Operations	5.0 L3	206.1	204.2	(1.9)	-1%
4	Safety	5.0 L4	54.6	55.9	1.4	3%
5	Finance, Technology, Supply Chain	5.0 L5	263.3	253.8	(9.5)	-4%
6	People, Customer, Corporate Affairs	5.0 L6	124.3	115.2	(9.1)	-7%
7	Other	5.0 L7	(252.7)	(256.6)	(3.9)	2%
8	F17-F19 RRA Compliance Filing Adjustment	5.0 L8	10.1	0.0	(10.1)	-100%
9	**Base Operating Costs**	5.0 L9	756.6	736.6	(20.0)	-3%
10	IFRS Ineligible Capitalized Overhead	5.0 L10	102.9	102.9	0.0	0%
11	Independent Power Producers Capital Leases	5.0 L11	28.2	28.2	0.0	0%
12	Waneta 2/3	5.0 L12	0.0	0.0	0.0	0%
13	Customer Crisis Fund	5.0 L13	0.0	0.0	0.0	0%
14	**Net Operating Costs**	5.0 L15	887.7	867.6	(20.0)	-2%
15	Operating Costs Deferral Account Additions	5.0 L52	0.0	(9.0)	(9.0)	0%
16	Operating Costs Regulatory Account Additions	5.0 L63	231.3	242.9	11.6	5%
17	**Total Gross Operating Costs**	L14+L15+L16	1,119.0	1,101.5	(17.4)	-2%
18	Provisions before Regulatory Accounts	5.0 L77	64.7	83.0	18.3	28%
19	Deferral Account Additions - Provisions	5.0 L102	0.0	0.0	0.0	0%
20	Regulatory Account Additions - Provisions	5.0 L109	1.2	(19.5)	(20.7)	-1672%
21	Total Gross Provisions and Other	5.0 L110	66.0	63.6	(2.4)	-4%
22	**Total Gross Operating Costs and Provisions and Other**	L17+L21	1,185.0	1,165.1	(19.9)	-2%

As shown in Table G-9, overall, actual fiscal 2017 actual gross operating costs and provisions and other were $19.9 million (or 2 per cent) lower than the fiscal 2017 RRA Plan. Of this amount, $18.1 million (the sum of lines 15, 16, and 20) related to variances in transfers to regulatory accounts, and $1.8 million (the sum of lines 14 and 18) related to variances unrelated to regulatory account transfers.

Variances related to the regulatory transfers of $18.1 million were primarily due to the following:

- Decrease in the Demand-Side Management Regulatory Account (within line 16) of $16.3 million due to delayed project completions and project cancellations in the commercial and industrial sectors;
- Decrease in the Environmental Provisions Regulatory Account (within line 20) of $28.0 million resulting from a decrease to the Rock Bay provision of $16.8 million due to a change in the project cost estimate. In addition, there was a decrease in the Polychlorinated Biphenyl provision of $9.8 million and the Asbestos Remediation provision of $1.4 million mainly due to an increase in the discount rate (resulting in a decrease in the present value of the forecast remediation expenditures); and
- Decrease in the Non-Heritage Deferral Account (within line 15) of $8.9 million resulting from a decrease of $9.1 million due to delayed commercial operation dates for two IPPs projects, and an increase of $0.2 million due to a deferral of Burrard costs pursuant to Order No. G-48-14.

Partially offset by:

- Increase in the Storm Restoration Costs Regulatory Account (within line 16) of $18.6 million due to a harsh winter which led to higher than planned expenditures for storm restoration;
- Increase in the Post Employment Benefit Current Pension Costs Regulatory Account (within line 16) of $10.1 million pursuant to Order No. G-47-18, Directive 18, which directed BC Hydro to use the discount rate in effect at the time the forecast was prepared to calculate current service costs; and
- All other regulatory account variances (primarily within line 20), totalling an increase of $6.4 million.

The variance of $1.8 million unrelated to regulatory accounts transfers are primarily due to:

- Lower than plan costs (within line 9) of $10.1 million due to the fiscal 2017 adjustment being made prospectively in fiscal 2018 pursuant to BCUC Order No. G-47-18, Directive 18, which directed BC Hydro to use the discount rate in effect at the time the forecast was prepared to calculate current service costs;
- Lower than plan costs (within line 9) of $10.0 million primarily due to lower than planned labour costs, partially offset by higher capital project dispute resolution costs. Individual variances within the business groups (lines 1 through 7) include reallocation of costs attributed to a reorganization which had no impact to the overall base operating cost variance (line 9); and
- All other variances (within line 18), totalling a decrease of $5.5 million.

Partially offset by:

- Higher than plan capital expenditure write-offs and capital asset retirements (within line 18) of $23.8 million, primarily comprised of $15.0 million in unplanned capital expenditure write-offs relating to projects that were cancelled in fiscal 2017 and $6.4 million relating to two unanticipated capital asset retirements.

4.2 Operating Costs Variance Explanations - Fiscal 2018

Table G-10 compares fiscal 2018 gross operating cost and provisions actual amounts against the fiscal 2018 RRA Plan, with variance explanations below the table.

Table G-10 Fiscal 2018 Operating Costs and Provisions Variances

	($ million)	Schedule Reference	F2018 RRA	F2018 Actual	F2018 Diff	F2018 % Diff
			1	2	3 = 2 - 1	4 = 3 / 1
1	Integrated Planning	5.0 L1	269.4	283.8	14.4	5%
2	Capital Infrastructure Project Delivery	5.0 L2	81.1	79.9	(1.2)	-2%
3	Operations	5.0 L3	208.2	206.7	(1.5)	-1%
4	Safety	5.0 L4	54.6	53.3	(1.3)	-2%
5	Finance, Technology, Supply Chain	5.0 L5	264.4	246.7	(17.7)	-7%
6	People, Customer, Corporate Affairs	5.0 L6	121.8	116.8	(5.1)	-4%
7	Other	5.0 L7	(252.2)	(244.0)	8.2	-3%
8	F17-F19 RRA Compliance Filing Adjustment	5.0 L8	10.2	0.0	(10.2)	-100%
9	**Base Operating Costs**	5.0 L9	757.5	743.1	(14.4)	-2%
10	IFRS Ineligible Capitalized Overhead	5.0 L10	125.3	125.3	0.0	0%
11	Independent Power Producers Capital Leases	5.0 L11	63.6	63.6	0.0	0%
12	Waneta 2/3	5.0 L12	0.0	0.0	0.0	0%
13	Customer Crisis Fund	5.0 L13	0.0	0.0	0.0	0%
14	**Net Operating Costs**	5.0 L15	946.3	931.9	(14.4)	-2%
15	Operating Costs Deferral Account Additions	5.0 L52	0.0	(35.3)	(35.3)	0%
16	Operating Costs Regulatory Account Additions	5.0 L63	212.7	179.8	(32.9)	-15%
17	**Total Gross Operating Costs**	L14+L15+L16	1,159.0	1,076.4	(82.6)	-7%
18	Provisions before Regulatory Accounts	5.0 L77	71.0	115.2	44.2	62%
19	Deferral Account Additions - Provisions	5.0 L102	0.0	1.6	1.6	0%
20	Regulatory Account Additions - Provisions	5.0 L109	(10.0)	35.4	45.4	-454%
21	Total Gross Provisions and Other	5.0 L110	61.0	152.3	91.2	150%
22	**Total Gross Operating Costs and Provisions and Other**	L17+L21	1,220.0	1,228.7	8.7	1%

As shown in Table G-10, overall, actual fiscal 2018 gross operating costs and provisions and other were $8.7 million (1 per cent) higher than fiscal 2018 RRA Plan. Of this amount, $29.8 million (the sum of lines 14 and 18) was variances unrelated to regulatory account transfers, which was partially offset by $21.1 million (the sum of lines 15, 16, 19 and 20) in variances related to regulatory account transfers.

Variances of $29.8 million unrelated to regulatory accounts transfers were primarily due to:

- Higher capital expenditure write-offs and capital asset retirements (within line 18) of $30.9 million primarily due to $13.6 million from the cancellation of the construction of the new Terrace to Kitimat Transmission line, with the remaining $17.3 million variance due to the reduction in scope of various projects;
- Higher than plan costs (within line 9) of $10.1 million due to fiscal 2017 actual adjustment being made prospectively in fiscal 2018 pursuant to BCUC Order No. G-47-18, Directive 18, which directed BC Hydro to use the discount rate in effect at the time the forecast was prepared to calculate current service costs. Individual variances within the business groups (lines 1 through 7) include reallocation of costs attributed to a reorganization which had no impact to the overall base operating cost variance (line 9);
- Higher litigation costs (within line 18) of $6.9 million related to a capital project;
- $4.0 million from termination of an Electricity Purchase Agreement (within line 18); and
- All other variances (within line 18), totalling an increase of $2.4 million.

Partially offset by:

- Lower costs (within line 9) of $24.5 million primarily due to lower than planned expenditures on external services.

Variances related to regulatory account transfers of $21.1 million were primarily due to:

- A decrease in the Non-Heritage Deferral Account (within lines 15 and 19) of $34.0 million resulting primarily from delayed commercial operation dates for two IPP projects;
- A decrease in the Demand-Side Management Regulatory Account (within line 16) of $36.9 million primarily due to delayed project completions and cancellations;
- A decrease in the Post Employment Benefit Current Pension Costs Regulatory Account (within line 16) of $10.1 million pursuant to BCUC Order No. G-47-18, Directive 18, which directed BC Hydro to use the discount rate in effect at the time the forecast was prepared to calculate current service costs; and
- All other regulatory account variances (within lines 15,16, and 20) totalled a net decrease of $4.8 million.

Partially offset by:

- An increase in the Dismantling Costs Regulatory Account (within line 20) of $31.7 million primarily due to work performed on the unplanned Salmon River Diversion Decommissioning Project which was originally planned to be upgraded, and dismantling work on projects from prior years that was delayed to this fiscal year;
- An increase in the Real Property Sales Regulatory Account (within line 20) of $16.8 million due to lower than planned gains from property sales; and
- An increase in the Storm Restoration Costs Regulatory Account (within line 16) of $16.2 million due to a series of wildfires in the interior of British Columbia, heavy snowfall in Vancouver Island and the Lower Mainland, and freezing rain

and ice in the Fraser Valley during the winter which led to higher than planned expenditures for storm restoration.

5 Capital Expenditures and Capital Additions Variance Explanations (Chapter 6)

Chapter 6 of the Application addresses BC Hydro's capital expenditures and capital additions for the test period. This section compares capital expenditure and capital addition actual amounts for fiscal 2017 and fiscal 2018 with the Plan amounts from the Previous Application.

Generally, explanations are provided where variances between actual and planned amounts are greater than 10 per cent, with a minimum variance threshold of $10 million, for the main asset categories provided in the following tables. Variances are provided for each main asset category in the tables below. The amounts presented in the tables in this section may not add due to rounding.

5.1 Overall Capital Expenditures and Additions Variance Explanations - Fiscal 2017 and Fiscal 2018

On an annual basis, BC Hydro actively manages over 900 projects and programs in various project phases and of various sizes. Capital expenditures and capital additions variances are mainly due to project progression and changes in project timing. Other factors include changes in scope to meet business requirements or cost changes due to market conditions or other factors. In addition, capital projects frequently extend over several years before completion and any variances from plan in a particular year can be offset by project expenditures and additions shifting to a subsequent year. While year-over-year capital project cash flows may vary from annual plan amounts, overall BC Hydro is delivering its capital plan on time and on budget. This is discussed further in Chapter 6, sections 6.1 and 6.2.

Table G-11 and Table G-12 compare fiscal 2017 and fiscal 2018 capital expenditures and capital additions actual amounts against the fiscal 2017 and fiscal 2018 RRA Plan by main asset category, with variance explanations below the tables.

Table G-11 BC Hydro Fiscal 2017 and Fiscal 2018 RRA Plan and Actual Capital Expenditures

($ millions)	F2017				F2018			
	RRA	Actual	Variance	% Variance	RRA	Actual	Variance	% Variance
	1	2	3=2-1	4=3/1	1	2	3=2-1	4=3/1
Generation	550.0	584.8	34.8	6%	536.4	544.1	7.7	1%
Site C Project	742.5	662.7	(79.8)	-11%	716.5	704.9	(11.6)	-2%
Transmission & Distribution	927.3	966.0	38.7	4%	941.8	1,021.4	79.6	8%
Business Support								
Technology	83.9	76.5	(7.4)	-9%	93.4	71.2	(22.2)	-24%
Properties	95.7	86.6	(9.1)	-10%	75.1	63.5	(11.6)	-15%
Fleet / Other	204.7	58.9	(145.8)	-71%	48.6	59.6	11.0	23%
Total Gross	2,604.1	2,435.5	(168.6)	-6%	2,411.8	2,464.7	52.9	2%
Less: Contribution in Aid	(86.4)	(138.4)	(52.0)	60%	(100.2)	(156.2)	(56.0)	56%
Total	2,517.7	2,297.1	(220.6)	-9%	2,311.6	2,308.5	(3.1)	0%

In fiscal 2017, actual capital expenditures were $168.6 million (or 6 per cent) below the fiscal 2017 RRA Plan, excluding contribution in aid, primarily due to:

- Under plan expenditures of $145.8 million in the Fleet/Other category primarily due to two planned land purchases not completed as a result of schedule delays and due to requirements for additional planning work; and
- Delayed expenditures of $79.8 million on the Site C Project due to shifting certain activities to future years, as discussed further below.

The above variances were partially offset by:

- Generation expenditures above plan by $34.8 million primarily due to the earlier than planned progression of the W.A.C. Bennett Dam Rip-Rap Upgrade project, which was ahead of schedule and under budget; and
- Transmission and Distribution expenditures above plan by $38.7 million primarily due to higher than planned expenditures in system expansion and

improvement related to performance and safety issues, and also pole asset replacements.

Contributions in Aid were $52 million (or 60 per cent) above the fiscal 2017 RRA Plan primarily due to the higher than planned Customer Driven Distribution capital expenditures.

In fiscal 2018, actual capital expenditures were $52.9 million (or two per cent) above the fiscal 2018 RRA Plan, primarily due to:

- Higher than planned expenditures of $86 million on the Interior to Lower Mainland Transmission Line Project due to an arbitrator decision on a contractor claim, which increased the cost of the project.

This variance was partially offset by:

- Lower than planned Technology expenditures of $22 million primarily due to the Supply Chain Application Project, which was delayed pending regulatory approval.

Contributions in Aid were $56 million (or 56 per cent) above the fiscal 2018 RRA Plan primarily due to the higher than planned Customer Driven Distribution capital expenditures.

Additional capital expenditure variance details are provided for each asset category further below in this section.

Less: Contribution in Aid	(90.1)	(103.7)	(13.6)	15%	(88.0)	(129.6)	(41.6)	47%
Total	**1,647.4**	**1,365.0**	**(282.5)**	**-17%**	**1,401.9**	**1,414.2**	**12.3**	**1%**

Planned capital additions are based on the primary asset category of the planned project or program; however, the actual capital additions are based on the actual assets constructed. For example, a project which is considered primarily a Transmission project for planning purposes may include the construction of assets that are Distribution or Technology assets. While the total cost of the project would be reflected in Transmission category for planning purposes, the capital addition actuals are based on the actual assets constructed, and additions may appear in Transmission, Distribution or Technology capital additions. A portion of the capital addition variances for the various asset categories may be due to this difference.

In fiscal 2017, actual capital additions were $268.9 million below the fiscal 2017 RRA Plan, primarily due to:

- Delayed additions for planned land purchases of approximately $110 million as noted above in the capital expenditures explanations; and
- Delayed additions of $118 million on the Ruskin Dam Safety and Powerhouse Upgrade project due to schedule delays which shifted placing certain assets in-service to future years.

Contributions in Aid were $14 million (or 15 per cent) above the fiscal 2017 RRA Plan primarily due to the higher than planned Customer Driven Distribution capital additions.

In fiscal 2018, actual capital additions were $53.9 million above the fiscal 2018 RRA Plan, primarily due to:

- Higher than planned additions on the Ruskin Dam Safety and Powerhouse Upgrade project of $74 million due to shifting capital additions from fiscal 2017 to fiscal 2018.

The above higher than planned additions were partially offset by:

- Lower than planned additions on the Bridge River 1 Replace Transformers T1 and T2 project of $33 million. The project was placed in-service at the end of fiscal 2018; however, the capital additions were not recognized until early fiscal 2019.

Contributions in Aid were $42 million (or 47 per cent) above the fiscal 2018 RRA Plan primarily due to the higher than planned Customer Driven Distribution capital additions.

Additional information on capital additions variance for each asset category is provided further below in this section.

5.2 Generation Capital Expenditures and Additions Variance Explanations - Fiscal 2017 and Fiscal 2018

Table G-13 and Table G-14 compare fiscal 2017 and fiscal 2018 capital expenditures and capital additions actual amounts against the fiscal 2017 and fiscal 2018 RRA Plan for the Generation asset category. Sections 5.2.1 to 5.2.4 provide comparisons by sub-category for Generation. Results exclude the Site C Project which is provided separately in section 5.6.

Table G-13 Fiscal 2017 and Fiscal 2018 Generation Plan and Actual Capital Expenditures (excluding Site C Project)

5.2.1 Growth Capital Expenditures and Additions

Capital expenditure variances

Fiscal 2017 capital expenditures were comparable to plan.

Fiscal 2018 capital expenditures were $7.8 million above fiscal 2018 RRA Plan primarily due to the Upper Columbia Capacity Additions at Mica Units 5 and 6 project spending $5.0 million more in fiscal 2018 than planned to complete deficiency work, and the Revelstoke Install Unit 6 project spending $2 million more than planned in fiscal 2018 due to increased costs to complete the environmental assessment process.

Capital addition variances

Fiscal 2017 capital additions were comparable to the fiscal 2017 RRA Plan.

Fiscal 2018 capital additions were $8.7 million above the fiscal 2018 RRA Plan primarily due to the capital expenditure increase as noted above.

5.2.2 Redevelopment/Rehabilitation Capital Expenditures and Additions

Capital expenditure variances

Fiscal 2017 and fiscal 2018 capital expenditures were comparable to the fiscal 2017 and fiscal 2018 RRA Plan.

Capital addition variances

Fiscal 2017 capital additions were $120.9 million (40 per cent) below the fiscal 2017 RRA Plan primarily due to the Ruskin Dam Safety and Powerhouse Upgrade project being $117.8 million under plan as a result of construction delays, which shifted activities to future years.

Fiscal 2018 capital additions were $74.4 million (40 per cent) above the fiscal 2018 RRA Plan due to the Ruskin Dam Safety and Powerhouse Upgrade project Unit 2 in-service date moving from fiscal 2017 to fiscal 2018 as noted above.

5.2.3 Dam Safety Capital Expenditures and Additions

Capital expenditure variances

Fiscal 2017 capital expenditures were $32.2 million (56 per cent) above the fiscal 2017 RRA Plan primarily due to the W.A.C. Bennett Dam Rip Rap Upgrade project being $37.2 million above plan as a result of construction progressing ahead of schedule.

Fiscal 2018 capital expenditures were $23.7 million (25 per cent) below the fiscal 2018 RRA Plan primarily due to:

- Bridge River 1 Improve Slope Drainage project – implementation of the project was delayed as risk mitigation alternatives were explored, which resulted in expenditures being $13.2 million below plan;
- GMS Spillway Gate Upgrade Project – the award of a key contract was delayed which resulted in expenditures being $5.9 million below plan; and
- W.A.C. Bennett Dam Upgrade Rip Rap – some project expenditures were shifted to fiscal 2017, as described above.

Capital addition variances

Fiscal 2017 capital additions were $29.7 million (52 per cent) below the fiscal 2017 RRA Plan primarily due to:

- Jordan River Mitigate Diversion Dam Seismic Risks project was $11.7 million below plan due to property purchases incurred in fiscal 2017 that were not recognized as capital additions until fiscal 2018;
- Bridge River 1 Install Penstock Leak Detection and Protection project was $6.0 million below plan due to delays in installing equipment;
- GMS WAC Bennett Dam Core Upgrade was $3.2 million under plan due to construction delays which moved the in-service date to fiscal 2018; and
- Hugh Keenleyside Spillway Reliability Gate Upgrade was $3.4 million under plan due to lower than expected costs.

Fiscal 2018 capital additions were $13.9 million (21 per cent) above the fiscal 2018 RRA Plan, primarily due to the W.A.C. Bennett Dam Rip Rap Upgrade project being partially put into service ahead of schedule.

5.2.4 Sustaining - Other - Capital Expenditure and Additions Variances

Capital expenditure variances

Fiscal 2017 capital expenditures were $31.6 million (21 per cent) below the fiscal 2017 RRA Plan due to a large number of projects having small variances as a result of scheduling, scope or cost changes.

Fiscal 2018 capital expenditures were $49.2 million (24 per cent) below the fiscal 2018 RRA Plan primarily due to:

- Bridge River 2 Upgrade Units 5 and 6 project was $16.9 million below plan due to delays in completion of the Unit 5 caused by the supplier's quality issues in manufacturing and installation of the generator;
- Kootenay Canal Upgrade Powerhouse Crane project was $13 million below plan as a result of a scope reduction of certain runway deficiency work which was deemed no longer necessary; and
- Mica Upgrade 600 V Circuit Breakers project was $8 million below plan as a result of combining the Mica Essential Bus and Diesel Generator project with this project due to interdependencies.

Capital addition variances

Fiscal 2017 capital additions were $16.1 million (16 per cent) below the fiscal 2017 RRA Plan due to the Puntledge Improve Water Level Gauges and Public Safety Warning System project being $7.0 million below plan as a result of the in-service date delay to fiscal 2018. The remaining variances were due to a number of projects with smaller variances.

Fiscal 2018 capital additions were $71.8 million (58 per cent) below the fiscal 2018 RRA Plan, primarily due to:

- Bridge River 1 Replace Transformers T1 and T2 was $33.2 million below plan due to the capital expenditures not being converted to capital additions until after the fiscal year, although the project was put into service before year-end;
- Wahleach Reduce Fire Risk - Phase 2 project was $7.5 million below plan as the in-service date for the project was delayed to fiscal 2019 to complete the engineering specifications;
- G.M. Shrum G1 to 10 Control System Upgrade project was $7.9 million below plan because the G9 unit in-service date was delayed to fiscal 2019 due to outage scheduling and sequencing; and
- Ladore Install Powerhouse and Tailrace Crane project was $8.7 million below plan as the in-service date was delayed to fiscal 2019 as a longer lead time was required for crane manufacturing.

5.2.5 Non-Integrated Areas and Diesel and Thermal Generation

Fiscal 2017 and fiscal 2018 capital expenditures and additions were comparable to the fiscal 2017 and fiscal 2018 RRA Plan.

5.3 Transmission Capital Expenditures and Additions Variance Explanations - Fiscal 2017 and Fiscal 2018

Table G-15 and Table G-16 compare the fiscal 2017 and fiscal 2018 capital expenditures and capital additions actuals against the fiscal 2017 and fiscal 2018 RRA Plan for the Transmission asset category. Sections 5.2.1 to 5.2.4 provide comparisons by sub-category for Transmission.

Table G-15 Fiscal 2017 and Fiscal 2018 Transmission Plan and Actual Capital Expenditures

($ millions)	F2017				F2018

In the Transmission tables above ‘Generator Interconnections’ was formerly known as ‘Transmission IPPs’, ‘Transmission Load Interconnections’ was formerly known as ‘Customer Requested Projects’ and ‘Third Party Requested Transmission Line Relocations’ was formerly known as ‘OH/UG Relocations’. The composition of the renamed asset classifications has not changed.

5.3.1 Transmission Growth

5.3.1.1 Regional System Reinforcement

Capital expenditure variances

Fiscal 2017 capital expenditures were $28.6 million (31 per cent) above the fiscal 2017 RRA Plan primarily due to the fiscal 2017 RRA Plan amounts for a land purchase being included in Business Support - Other, while the actual expenditures are reported as Transmission as the land purchase relates to a future substation development.

Fiscal 2018 capital expenditures were $20.8 million (30 per cent) above the fiscal 2018 RRA Plan due to the Kamloops Substation project being above plan by $7.7 million due to design specification changes and increased costs from higher than expected market prices for equipment and materials. In addition, the Peace Region Electric Supply project was $8.7 million over plan due to advancement of definition phase activities from later years into fiscal 2018.

Capital addition variances

Fiscal 2017 capital additions were $28.4 million (24 per cent) above the fiscal 2017 RRA Plan due to the land purchase noted above.

Fiscal 2018 capital additions were comparable to the fiscal 2018 RRA Plan.

5.3.1.2 Bulk System Reinforcement

Capital expenditure variances

Fiscal 2017 capital expenditures were comparable to the fiscal 2017 RRA Plan.

Fiscal 2018 capital expenditures were $108 million above the fiscal 2018 RRA Plan due to unplanned expenditures of approximately $86 million on the Interior to Lower Mainland Transmission Line project due to an arbitrator decision on a contractor claim which increased the costs to the project.

Capital addition variances

Fiscal 2017 capital additions were comparable to the fiscal 2017 RRA Plan.

Fiscal 2018 capital additions were $19.4 million (73 per cent) below the fiscal 2018 RRA Plan primarily due to the Peace Region Load Shedding Remedial

Action Scheme (**RAS**) Project. The project was in service before year-end but the capital expenditures were not recognized as capital additions until after the fiscal year-end.

5.3.1.3 Station Expansion and Modification

Capital expenditure variances

Fiscal 2017 capital expenditures were $15.7 million (18 per cent) below the fiscal 2017 RRA Plan primarily due to a delay in land acquisition to review the project scope and a number of projects with small variances .

Fiscal 2018 capital expenditures were $18.2 million (25 per cent) below the fiscal 2018 RRA Plan primarily due to:

- Westbank Substation Upgrade project was $10 million under plan as the Identification Phase was deferred to fiscal 2019 pending a decision on the preferred alternative for the West Kelowna Transmission Project. The scope of this project is dependent on the alternative that will be selected for the West Kelowna Transmission Project, which is also described in Appendix J; and
- Capilano Substation 25 kV Conversion project was $5.8 million under plan due to longer than anticipated Identification and Definition phases of the project, to address required engineering and geotechnical studies.

Capital addition variances

Fiscal 2017 capital additions were comparable to the fiscal 2017 RRA Plan.

Fiscal 2018 capital additions were $23.8 million (16 per cent) below the fiscal 2018 RRA Plan, primarily due to the Campbell River Substation Capacity Upgrade Project which was $22.9 million under plan. During project Implementation, it was identified that ground conditions were inadequate to address seismic risks during site construction, therefore requiring additional planning and construction time and extending the project's in-service date to fiscal 2019.

5.3.1.4 Feeder Position/Section Additions

Fiscal 2017 and fiscal 2018 capital expenditures and additions were comparable to the fiscal 2017 and fiscal 2018 RRA Plans.

5.3.1.5 Generator Interconnections and Transmission Load Interconnections

These capital expenditures and additions are third-party driven and, as a result, the timing and scope of these projects are highly uncertain. BC Hydro only includes projects with a high probability of proceeding in its capital forecasts. Variances from forecast are due to changes in scope and timing of planned projects as well as the addition of new projects.

5.3.2 Transmission Sustain – Stations

5.3.2.1 Circuit Breakers

Capital expenditure variances

Fiscal 2017 capital expenditures were comparable to the fiscal 2017 RRA Plan. Fiscal 2018 actual capital expenditures were $16.2 million (87 per cent) above the fiscal 2018 RRA Plan due to the addition of the Barnard 60kV Circuit Breaker and Relay Building Replacement project and advancing the 60kV Circuit Breaker Replacement program to manage system risks.

Capital addition variances

Fiscal 2017 capital additions were $39.5 million (70 per cent) above the fiscal 2017 RRA Plan, primarily due to the 230 kV Airblast Circuit Breaker Replacements program and the 60/138 kV Circuit Breaker Replacements program having schedule delays which resulted in $26.6 million of additions shifting from fiscal 2016 to fiscal 2017.

Fiscal 2018 capital additions were comparable to the fiscal 2018 RRA Plan.

5.3.2.2 Other Power Equipment

Capital expenditure variances

Fiscal 2017 capital expenditures were $29 million (60 per cent) above the fiscal 2017 RRA Plan primarily due to:

- Bob Quinn 287 kV Shunt Reactor Spare project was $6.2 million above plan due to scope being added to control high voltage levels in the area in the event of a reactor failure;
- Kalum Outdoor Metalclad Switchgear Replacement project was $6.3 million above plan due to increased costs from higher than expected market prices for construction; and
- Unplanned emergency transformer replacements at Kelly Lake and Kidd 2 substations totalling $6.3 million.

The balance of the variance is due to a number of projects with smaller variances.

Fiscal 2018 capital expenditures were $26.4 million (33 per cent) under plan primarily due to the Mainwaring Station Upgrade Project being $31.3 million under plan due to the delay of the start of Implementation phase to re-evaluate project alternatives.

Capital addition variances

Fiscal 2017 capital additions were comparable to the fiscal 2017 RRA Plan.

Fiscal 2018 capital additions were $43.4 million (118 per cent) above the fiscal 2018 RRA Plan primarily due to:

- Several projects that were due to enter service in prior years, but entered service in fiscal 2018 due to schedule delays;
- Cost increases on Outdoor Metalclad Switchgear Replacement projects of $19.3 million; and
- Several unplanned emergency equipment replacements totalling $14.2 million for transformers at Kelly Lake substation, the Kidd 2 substation and a reactor at the GM Shrum Generation Station.

5.3.2.3 Protection and Control

Fiscal 2017 capital expenditures and capital additions were comparable to the fiscal 2017 RRA Plan.

Capital expenditure variances

Fiscal 2018 actual capital expenditures were $14.9 million (67 per cent) below the fiscal 2018 RRA Plan due to the NERC CIPv5 Compliance at Medium Impact T&D Stations project, which was based on planning assumptions from June 2015. It was expected that the project would be completed and put in-service on a partial basis in fiscal 2017 and fiscal 2018 and would be completed prior to fiscal 2019. However, the project will now be put in-service only at completion, which will be in fiscal 2019.

Capital additions variances

Fiscal 2018 capital additions were $12.8 million (64 per cent) below the fiscal 2018 RRA Plan due to the NERC CIPv5 Compliance at Medium Impact T&D Stations project discussed above.

5.3.2.4 Stations Auxiliary Equipment

Capital expenditure variances

Fiscal 2017 and fiscal 2018 capital expenditures were comparable to the fiscal 2017 and fiscal 2018 RRA Plan.

Capital addition variances

Fiscal 2017 capital additions were $15.5 million (53 per cent) below the fiscal 2017 RRA Plan, primarily due to several projects related to the Substation Wood Pole Replacements Program taking longer to complete than planned and now expected to be in-service in fiscal 2020 or fiscal 2021. A portion of the variance is also due to the delay in recognition of the capital expenditures as capital additions for the Station Safety and Minor Capital program, which will be completed in fiscal 2019.

Fiscal 2018 capital additions were comparable to the fiscal 2018 RRA Plan.

5.3.2.5 Stations Risk Mitigation and Telecommunications

Fiscal 2017 and fiscal 2018 actual capital expenditures and additions were comparable to the fiscal 2017 and fiscal 2018 RRA Plan.

5.3.3 Transmission Sustain - Lines

5.3.3.1 Cable Sustainment

Fiscal 2017 and fiscal 2018 capital expenditures and additions were comparable to the fiscal 2017 and fiscal 2018 RRA Plan.

5.3.3.2 Overhead Lines Life Extension

Capital expenditure variances

Fiscal 2017 capital expenditures were comparable to the fiscal 2017 RRA Plan.

Fiscal 2018 capital expenditures were $67.2 million (71 per cent) below the fiscal 2018 RRA Plan. This was primarily due to planned expenditures of $48 million for the Terrace to Kitimat Project not being spent. Due to changes to the load growth forecast and increases to the estimated total project cost for a new line, as well as updated asset health information, the leading alternative to construct a new line was revised to a refurbishment of the existing line.

Capital addition variances

Fiscal 2017 capital additions were $49 million (88 per cent) below the fiscal 2017 RRA Plan primarily due to:

- The Copper Conductor Replace – Phase 2 program which was $7.9 million below plan as construction activities proceeded slower than planned due to archaeological monitoring requirements; and
- The fiscal 2017 Overhead Structural Corrosion Protection, Transmission Wood Structure and Framing Replacements, and Spacer Damper programs were $25.7 million below plan due to delays with most of these capital additions being recorded in fiscal 2018 instead of fiscal 2017.

Fiscal 2018 capital additions were $10.3 million (17 per cent) below the fiscal 2018 RRA Plan. This is comprised of $18 million of capital additions planned in fiscal 2017 for Transmission Wood Structure and Spacer Damper Programs shifting to fiscal 2018 offset by delays to the in-service date for Circuit Refurbishment Projects and a Copper Conductor Replacement Project totaling $28 million, as a result of limited outage availability.

All other line items under Transmission Sustain-Lines in fiscal 2017 and fiscal 2018 for both capital expenditures and capital additions were comparable to the fiscal 2017 and fiscal 2018 RRA Plan.

5.4 Distribution Capital Expenditures and Additions Variance Explanations - Fiscal 2017 and Fiscal 2018

Table G-17 and Table G-18 compare the fiscal 2017 and fiscal 2018 capital expenditures and capital additions actuals against the fiscal 2017 and fiscal 2018 RRA Plan for the Distribution asset category. Sections 5.2.1 to 5.2.4 provide comparisons by sub-category for Distribution.

The distribution system improvement portfolio is primarily comprised of small projects, with the average project size in the $1 to 2 million range with short duration. The System Expansion and Improvement portfolio is subject to rapidly changing priorities and the planning processes must be dynamic to respond to the emerging needs on the distribution system. This may result in variances in the timing and selection of projects in the portfolio in a given year.

5.4.1 Distribution Growth

5.4.1.1 Customer Driven

Fiscal 2017 capital expenditures were $24.7 million (16 per cent) above the fiscal 2017 RRA Plan and $61.1 million (37 percent) above the fiscal 2018 RRA Plan due to a significant increase in customer connection work as a result of higher than planned levels of new home construction in the Lower Mainland and South Vancouver Island. This work is difficult to plan as it is dependent on customer requests and their related timing.

Fiscal 2017 capital additions were $21 million (14 per cent) above the fiscal 2017 RRA Plan and the fiscal 2018 actual capital additions were $18.7 million (12 per cent) above the fiscal 2018 RRA Plan primarily due to the increase in capital expenditures noted above. These increases are partially offset by increased contribution in aid, discussed below.

5.4.1.2 System Expansion and Improvement (Growth)

Growth driven system expansion and improvement expenditures address existing capacity constraints to meet the anticipated customer load growth. The priority of growth-driven system upgrades is influenced by new customer load connections and general load growth of existing customers. This category of expenditures is subject to year over year fluctuations from plan as a result of changes in scope, cost and schedule for projects as well as variances between forecast and actual customer load growth.

The majority of capital additions and expenditures consist of the following categories:

- New feeder projects to offload heavily loaded existing feeders or to supply distribution customer load growth;
- Voltage conversion projects to convert the distribution primary voltage from 4 kV to 12 kV or from 12 kV to 25 kV to align with medium to long-term substation plans which require area loads to be transferred to an adjacent supply voltage, or aligned with plans for the existing substation for conversion to a higher voltage; and
- Line upgrades to increase feeder capacity, including 3-phasing, equipment upgrades or conductor upgrades.

Fiscal 2017 capital expenditures were $23.7 million (34 per cent) below the fiscal 2017 RRA Plan primarily due to the following:

- CBL New Feeder South Campbell River (VI-NVI-417) project was $6.7 million below plan due to timing of resourcing requirements;
- LOH 12F52 Voltage Conversion and Standby (LM-BBY-063) project was $5.7 million below plan due to a project delay which moved costs to fiscal 2018; and

- Voltage Conversion of ESQ1258 project (VI-SVI-259) was $5.2 million below plan due to the in-service date changing to fiscal 2018.

Fiscal 2018 capital expenditures were comparable to the fiscal 2018 RRA Plan.

Fiscal 2017 capital additions were $22.2 million (63 percent) above the fiscal 2017 RRA Plan due to a large number of projects less than $3.0 million that were not planned to be in-service during fiscal 2017, partially offset by the implementation of the Voltage Conversion of ESQ1258 (VI-SVI-259) project moving to fiscal 2018.

Fiscal 2018 capital additions were $28.6 million (36 per cent) below the fiscal 2018 RRA Plan which was primarily due to delayed in-service dates for the following projects:

- LOH 12F52 Voltage Conversion and Standby (LM-BBY-063) project for $9 million;
- Three new MLE Feeders to offload CBN (LM-FVE-607) project for $8 million; and
- COK Distribution Egress Reinforcement (LM-COQ-694) project for $5 million.

These projects are now expected to be in-service in fiscal 2019 and fiscal 2020.

5.4.2 Distribution Sustain

5.4.2.1 System Expansion and Improvement (Sustain)

System expansion and improvement sustaining expenditures maintain and improve distribution system performance including addressing customer reliability, safety risks and meeting regulatory, legal or environmental requirements.

Year over year fluctuations are the result of changes in the priority of required sustaining system upgrades which are influenced by recent distribution feeder reliability performance or other risks, including:

- Equipment additions and upgrades to address the worst performing circuits to improve customer reliability;
- Feeder reconfigurations and upgrades to address public or worker safety risks; and
- System upgrades to address other risks identified, including legal risks (e.g., deficient legal rights/statutory rights-of-way), regulatory risks (e.g., removal of PCB filled equipment), or environmental risks (e.g., potential impacts to environmentally sensitive areas, and risks to protected species).

Fiscal 2017 capital expenditures were $17.1 million (35 per cent) above the fiscal 2017 RRA Plan primarily due to higher than planned expenditures in projects to address issues related to the overhead distribution system connected to Illecillewaet Substation, a distribution under-build near Terrace and the advancement of the Quesnel Voltage Conversion Project due to more complicated project scope than planned and higher construction labour costs. In addition, there were higher than planned expenditures in the minor capital program to address system performance deficiencies and opportunity based improvements that were not planned.

Fiscal 2018 capital expenditures were $63.1 million (212 per cent) above the fiscal 2018 RRA Plan, primarily due to:

- Higher than planned expenditures in the minor capital program to address system performance deficiencies and opportunity based improvements;
- Cost increases on the H-Frame Elimination -Chinatown Program and Dawson Creek and Heffley Creek Reconfiguration projects due to more complicated project scope than planned and higher construction labour costs;
- Advancement of the QNL Voltage Conversion (NI-NC-160) project; and

- Unplanned expenditures for the deployment of DC Fast Charger Stations for Electric Vehicle charging.

Fiscal 2017 capital additions were $15.3 million (35 per cent) above the fiscal 2017 RRA Plan. This is primarily due to higher than planned expenditures in the minor capital program to address system performance deficiencies and opportunity based improvements, partially offset by a delayed in-service of a distribution line relocation in the Merritt Area originally planned in fiscal 2016.

Fiscal 2018 capital additions were $39.1 million (148 per cent) above the fiscal 2018 RRA Plan. This is primarily due to higher than planned expenditures in the minor capital program to address system performance deficiencies and opportunity based improvements. The main contributors to the variance are:

- Cost increases for the Heffley Creek Reconfiguration due to design change from overhead to underground plus higher civil costs due to civil construction resource constraints and challenging local work conditions;
- Cost increases for the Duncan Area Capacity project due to design change from overhead to underground, as well as increased scope of civil ductbank to accommodate planned customer load developments;
- Delayed in-service of the Prevost to Lake Cowichan Feeder Tie and the fiscal 2017 Overhead Automation Program moving from fiscal 2017 to fiscal 2018; and
- Unplanned expenditures for the deployment of DC Fast Charger Stations.

5.4.2.2 Asset Replacement

Fiscal 2017 capital expenditures were $22.1 million (16 per cent) above the fiscal 2017 RRA Plan primarily due to a $6 million variance for higher than planned number of wood pole replacements and a $7 million variance for higher than planned concrete pole replacements.

Fiscal 2018 capital expenditures were comparable to the fiscal 2018 RRA Plan.

Fiscal 2017 capital additions were comparable to the fiscal 2017 RRA Plan.

Fiscal 2018 actual capital additions were $16.0 million (12 per cent) above the fiscal 2018 RRA Plan primarily due to higher volumes of pole replacements and the timing of the assets going into service.

5.4.3 Contribution-in-Aid

Distribution expenditures were partially offset by Contribution in Aid of construction, which was $46.3 million (60 per cent) and $62.2 million (79 per cent) above the fiscal 2017 RRA Plan and fiscal 2018 RRA Plan, respectively. This was mainly due to the higher than planned expenditures for Distribution Customer Driven work which is dependent on customer requests.

Distribution additions were partially offset by Contribution in Aid of construction, which was comparable to the fiscal 2017 RRA Plan. Higher than planned volume for Distribution Customer Driven work resulted in fiscal 2018 actual additions of $34.7 million (44 per cent) above fiscal 2018 RRA Plan.

5.5 Business Support Capital Expenditures and Additions Variance Explanations - Fiscal 2017 and Fiscal 2018

Table G-19 and Table G-20 compare fiscal 2017 and fiscal 2018 capital expenditures and capital additions actuals against the fiscal 2017 and fiscal 2018 RRA Plan for the Business Support category (technology, properties, and fleet/other). Sections 5.2.1 to 5.2.4 provide comparisons by sub-category for Business Support.

Table G-19 Business Support Plan and Actual Capital Expenditures Fiscal 2017 and Fiscal 2018

5.5.1 Technology Variance Explanations

Technology's capital plan is dynamic due to emerging needs, opportunities and constraints. Changing business needs and priorities, technologies and resources may result in cost variability across the technology capital portfolio during the plan years. Table G-21 provides Technology plan and actual capital expenditures for fiscal 2017 to fiscal 2018, while Table G-22 provides plan and actual capital additions for fiscal 2017 to fiscal 2018. In these tables, "Technology" refers to technology investments managed by the Technology KBU, while "Other Technology" refers to technology investments managed by other business units.

Table G-21 Technology Plan and Actual Capital Expenditures Fiscal 2017 and Fiscal 2018

($ millions)	F2017				F2018

Total	**81.6**	**81.6**	**0.0**	**0%**	**91.1**	**97.2**	**6.1**	**7%**

Capital expenditure variances

Fiscal 2017 capital expenditures were comparable to the fiscal 2017 RRA Plan.

Fiscal 2018 Technology capital expenditures were $22.0 million (24 per cent) below than the fiscal 2018 RRA Plan amount of $92.4 million. This was primarily due to:

- Delay in the Supply Chain Applications project for a regulatory application resulting in fiscal 2018 actual expenditures $34.2 million under plan;
- A re-organization in fiscal 2017 that moved part of Technology’s Telecommunications & Infrastructure planning function to the Line Asset Planning KBU, resulting in fiscal 2018 actual expenditures $10.9 million under plan; and
- T&D IT spending $5.5 million under plan including a $4.3 million reduction for the Graphic Work Design Tool project cancelled in October 2016.

Partially offset by:

- Infrastructure expenditures $12 million over plan for storage, PCs, and servers, as part of a shift in organizational priorities to focus on system reliability and resilience; and
- Enterprise application expenditures $4.7 million over plan for Microsoft software licenses and Energy Analytics platform upgrade.

The remainder is offset by amounts from various smaller projects.

Capital addition variances

Fiscal 2017 capital additions were comparable to the fiscal 2017 RRA Plan.

Fiscal 2018 Technology actual capital additions were $18.9 million (21 per cent) below the fiscal 2018 RRA Plan. This was primarily due to:

- Cancellation of the Graphic Work Design project in October 2016, resulting in fiscal 2018 actual additions $15 million under plan; and
- Re-organization in fiscal 2017 that moved part of Technology's Telecommunications & Infrastructure planning function to the Line Asset Planning KBU.

The remainder is offset by amounts from various smaller projects.

Capital additions for Other Technology were $25 million above the fiscal 2018 RRA Plan. This category primarily represents technology assets that were constructed as part of other projects that were included in the Business Support –Other capital plan. The actual capital additions for the technology related assets for these projects are included in the capital additions in this category. This includes:

- Energy Management System 3.0 Upgrade project which included $17.4 million of computer hardware and software;
- Physical Key Management project for $4.3 million; and
- Amounts from various smaller projects.

5.5.2 Properties Plan and Actual Capital Expenditures and Additions Fiscal 2017 and Fiscal 2018

Table G-23 Properties Plan and Actual Capital Expenditures Fiscal 2017 and Fiscal 2018

Total	**68.3**	**54.8**	**(13.5)**	**-20%**	**118.2**	**126.9**	**8.7**	**7%**

Capital expenditure variances

Fiscal 2017 capital expenditures were comparable to the fiscal 2017 RRA Plan.

Fiscal 2018 capital expenditures were $11.6 million (15 per cent) below the fiscal 2018 RRA Plan primarily due to deferring several projects:

- The Materials Classification Facility project was put on hold for most of fiscal 2017 as capital funding constraints were being assessed across BC Hydro. This project has now recommenced; and

- The Construction Services/Lower Mainland Transmission Facility project, the Dawson Creek Field Office project, and the Fleet Facility project were all deferred in fiscal 2017 for five years, and are now due to recommence in fiscal 2022 or fiscal 2023.

Capital addition variances

Fiscal 2017 capital additions were $13.5 million (20 per cent) below the fiscal 2017 RRA Plan as several projects that were due to go into service in fiscal 2017 were delayed and went into service in fiscal 2018.

Fiscal 2018 capital additions were comparable to the fiscal 2018 RRA Plan, and reflect the capital additions of some projects delayed from fiscal 2017.

5.5.3 Fleet/Other Plan and Actual Capital Expenditures and Additions Fiscal 2017 and Fiscal 2018

5.5.3.1 Fleet Actual to Plan Variances Fiscal 2017 to Fiscal 2018

Fleet capital expenditures and capital additions for fiscal 2017 and fiscal 2018 were comparable to plan.

5.5.3.2 Other Actual to Plan Variances Fiscal 2017 to Fiscal 2018

The Other category includes expenditures and additions related to Land Purchases, Materials Management upgrades, Field Operations tools and equipment, Control Centre systems upgrades, and workforce training equipment.

Capital expenditure variances

Other capital expenditures for fiscal 2017 were $138.8 million (81 per cent) below the fiscal 2017 RRA Plan mainly due to variances from planned land purchases. One of the planned land purchases was completed and the actuals were recorded in the Transmission Regional System Reinforcement Category as the land will be used for a future substation development. The other planned land purchases were not completed due to delays or due to additional planning being completed. Variances caused by these two planned land purchases were offset by a number of variances less than $5 million per project in each of the 'Other' capital categories.

Fiscal 2018 capital expenditures were $10.9 million (62 per cent) above the fiscal 2018 RRA Plan, primarily due to unplanned work related to Physical Key Management that was necessary for risk mitigation, timing of equipment delivery, and SMI Field Area sustainment work.

Capital addition variances

Fiscal 2017 capital additions were $122.6 million (72 per cent) below the fiscal 2017 RRA Plan primarily due to the variances in planned land purchases discussed above.

Fiscal 2018 capital additions were comparable to the fiscal 2018 RRA Plan.

5.6 Site C Project Capital Expenditures Variance Explanations - Fiscal 2017 and Fiscal 2018

Table G-27 compares fiscal 2017 and fiscal 2018 capital expenditures actuals against the fiscal 2017 and fiscal 2018 RRA Plan for the Site C Project, with variance explanations below the table.

Table G-27 Site C Project Plan and Actual Capital Expenditures Fiscal 2017 to Fiscal 2018

($ millions)	F2017				F2018			
	RRA	Actual	Variance	% Variance	RRA	Actual	Variance	% Variance
	1	2	3=2-1	4=3/1	1	2	3=2-1	4=3/1
Total Site C	**742.5**	**662.7**	**(79.8)**	**-11%**	**716.5**	**704.9**	**(11.6)**	**-2%**

Fiscal 2017 capital expenditures were $79.8 million (11 per cent) below the fiscal 2017 RRA Plan. This was primarily due to a shift of some property purchases and mitigation and compensation expenditures into future periods, as well as delayed expenditures on highways, construction of site telecom, transmission lines and clearing for the lower reservoir.

Fiscal 2018 capital expenditures were comparable to the fiscal 2018 RRA Plan.

There were no capital additions for the Site C Project in fiscal 2017 or fiscal 2018.

Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Appendix H

Fiscal 2020 to Fiscal 2024 Capital Plan

Discussion/Information

BOARD BRIEFING – BC HYDRO F2020 - F2024 CAPITAL PLAN

EXECUTIVE SUMMARY

This briefing provides a summary of BC Hydro's updated Capital Plan (Capital Plan) with an outline of major investments, related risks, and opportunities. The Capital Plan includes five years of investment level detail, for F2020 to F2024, and a high level projection for F2025 to F2029. The F2020-F2024 Capital Plan is guided by the capital scenario that supported the Comprehensive Review. Next year's capital planning will focus on re-building 10 years of investment level detail.

The capital expenditures for the first two years (F2020-F2021) of the Capital Plan forms the basis of the capital information included in the F2020/F2021 Revenue Requirements Application.

This Capital Plan provides a consistent and appropriate approach to the management of risks across all business groups, and supports the delivery of reliable, affordable, clean electricity throughout BC safely. A recent independent audit by the Office of the Auditor General (OAG) found that BC Hydro's capital asset management systems and practices have reached generally advanced maturity levels. The audit concluded that BC Hydro had demonstrated good asset management practices and did not include any recommendations.

Background

To preserve continuity with the Revenue Requirements Application (RRA), the information provided in this briefing is presented based on asset categorization, as shown in previous years.

This fiscal's capital planning processes ran in parallel with the first phase of the Comprehensive Review (Review). The capital scenario included in the Review recommendations informed the targets for Enterprise Capital Planning and was incorporated into BC Hydro's Q1 2018 forecast.

Investment level details were developed for years F2020-F2024, and directional targets are provided for years F2025-F2029. Detailed capital investment requirements beyond F2024 will be informed by future initiatives, including BC Hydro's next Integrated Resource Plan (IRP).

Enterprise Capital Planning

BC Hydro's Enterprise Capital Planning process began with executive level strategic direction in the form of a portfolio level assessment of BC Hydro's long term capital investment needs based on the principles of balancing affordability and system performance, while also continuing to safely operate our system. In June 2018, a capital scenario was established that supported the Review, and was aligned with executive level direction on long-term capital investment levels.

The next step in the development of the Enterprise Capital Plan was bottom up planning within the various business groups. Each business group identified investments to address system needs and risks, while applying the enterprise-wide framework for capital prioritization and considering any labour and financial constraints.

Once bottom up planning and business group portfolio planning concluded, the capital planning data was compiled for peer reviews at the enterprise level. Peer reviews were conducted jointly across the planning groups to review the capital portfolio.

Peer reviews this year focused on three main areas: an overall summary of each portfolio, the quality of a sample set of investment justifications documents which provided detailed information on the investments such as the problem statement, desired outcome and potential alternatives, and the risk profile of the Capital Plan. During the portfolio summary reviews, re-direction of funding within the

Enterprise Portfolio occurred, increasing the amounts allocated to Technology and Properties assets in the earlier years of the plan, so that the investments in these portfolios were more evenly distributed over the long-term. The re-direction was required to smooth investment levels and avoid resourcing variability over the F2020-F2024 period. The re-direction is neutral to all groups over the F2020-F2029 period.

Capital Investment Drivers

The main drivers of the capital plan are common across the business and remain unchanged from prior years.

Ageing Assets – A large portion of BC Hydro's system was built in the 1960s and 1970s and is reaching or exceeding expected end-of-life. A significant proportion of the risks facing BC Hydro's major assets can be attributed to their age. The physical condition, performance, maintenance history, and criticality of equipment and facilities are significant drivers for planning and prioritizing refurbishment or replacement.

Reliability – The reliability of BC Hydro's assets (e.g. equipment associated with the power system, Properties, Technology, and Fleet assets) can be measured over time. Equipment health assessments at each point in time are reflective of the condition of the assets, maintenance practices and long-term investment trends. Long term trends indicate increasing or declining reliability risk for use in asset management.

Capital investment is paramount to the total performance of the system, and the indicators of investment adequacy are consistent performance metrics over time, and the number and impact of in-service failures on critical assets. The BC Hydro Service Plan sets targets for system performance measures, and these lagging indicators continue to indicate that BC Hydro is appropriately managing our service delivery risks.

System Growth – Over the coming years, BC Hydro will continue to experience load growth in some areas of the province, even after taking estimated conservation impacts into account. This includes actual and potential growth due to the oil and gas sector in the Peace and North Coast regions. The need to meet this increased demand while operating the system safely and reliably will influence asset management and capital expenditure decisions. New investments continue to be required in both distribution and transmission infrastructure to meet customer demand growth and to connect new supply of electricity. Integrated information technology improvements will be needed to support expansion in a changing environment.

Prioritization Methodology

The investments in the Capital Plan have been assessed and scored in accordance with the enterprise-wide framework for capital prioritization, to ensure BC Hydro is mitigating asset-related risks in an appropriate way. Dependencies between projects, opportunities to bundle work for more efficient delivery and resource considerations are some of the factors that must also be considered along with the risk or value score, to ensure each Business Group's portfolio of investments aligns with strategic and performance objectives, as well as planning targets.

The framework describes the assessment and prioritization process related to all proposed capital projects that are material in nature. Projects are prioritized based on the primary driver of the proposed project:

Discussion/Information

BOARD BRIEFING – BC HYDRO F2020 - F2024 CAPITAL PLAN

- Capital projects that primarily mitigate risk are scored for prioritization using a methodology that is aligned with the BC Hydro Corporate Risk Matrix (see attachment),
- Capital projects that primarily create value are scored for prioritization using a net value per dollar invested metric. The value prioritization is mainly used for some capital expenditures in the Technology Portfolio.

The framework classifies capital investments into one of three categories:

- Mandatory investments driven by legal and regulatory requirements.
- Committed investments not to be postponed. This category includes projects that are economically unreasonable to stop as deferral of these projects would result in significant additional costs to suspend and then restart at a later date and may result in the loss of warranty protection on major equipment.
- Investments to be prioritized (including projects that will be in the Identification or Definition phase by F2020, and could be re-prioritized without significant economic losses).

Risk profile – Application of the enterprise-wide framework for capital prioritization enabled all Business Groups to calculate risk or value scores, and provide a consistent representation of risk across the enterprise, which involved the following steps:

- Business Groups independently assigning each investment a risk score associated with postponing the investment,
- Comparing similar investments between Business Groups (e.g. roof replacements) to ensure consistent application of the Framework,
- Comparing investments with the same risk score between Business Groups to ensure comparability,
- Verifying and challenging the proposed investments, including the risk scoring and timing.

The risk profile of the F2020-F2024 Capital Plan is shown below by “to be prioritized” capital additions by risk score:

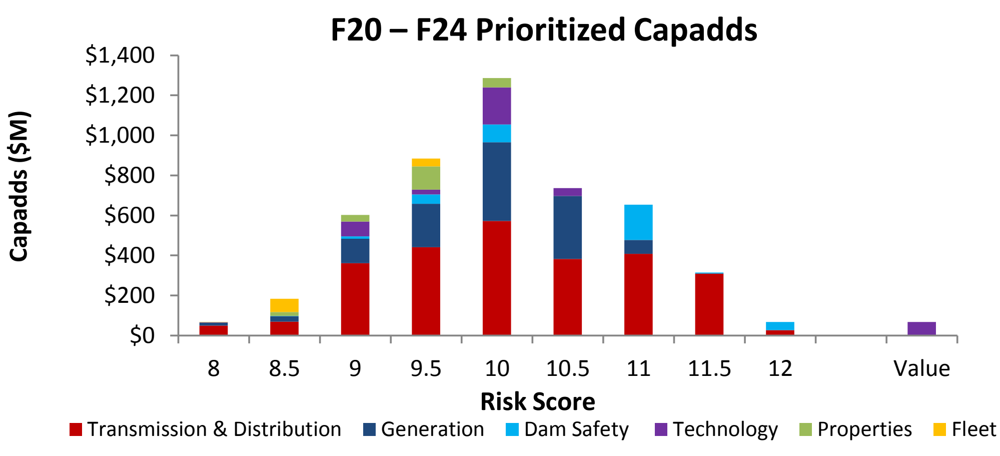

Figure 1: F2020-F2024 Capital Plan Risk Profile

BOARD BRIEFING – BC HYDRO F2020 - F2024 CAPITAL PLAN

To refine BC Hydro's framework for capital prioritization, and develop abilities to optimize investments across the Enterprise Portfolio, the Asset Investment Planning tool project has been initiated to develop an Enterprise Wide Value Framework and common IT platform. This project's objective is to maximize portfolio value at the enterprise level, by providing a framework and tool to optimize the scope and timing of investments. This project is currently in the definition phase, and is forecasting completion between F2020 & F2021.

Capital Plan Delivery Resources

Where labour resources have been identified as a risk to the delivery of the portfolio, the demands on the labour pool required to deliver each investment and the availability of the resources are estimated in consultation with the resource management groups at the portfolio level. The level of investment in this Capital Plan is a reduction from the previous 10-Year Capital Plan, therefore the portfolio analysis completed for the previous plan is still valid, and no significant new resource constraints are expected. The resource availability of some groups identified as constraining resources in previous capital planning cycles, mainly Communications, Protection and Control Technologists, have been managed over the past several years to ensure that higher risk investments are not unduly delayed.

Capital Expenditures & Additions

BC Hydro is forecasting net annual average capital expenditures of approximately $1.6[1] billion per year or total net capital expenditures of $8.2[1] billion for F2020-F2024. For capital additions, BC Hydro is forecasting a net annual average of approximately $1.3[1] billion per year, or total net capital additions of $6.7[1] billion for F2020-F2024. Figures 2 and 3 below show the capital expenditure and additions breakdown.

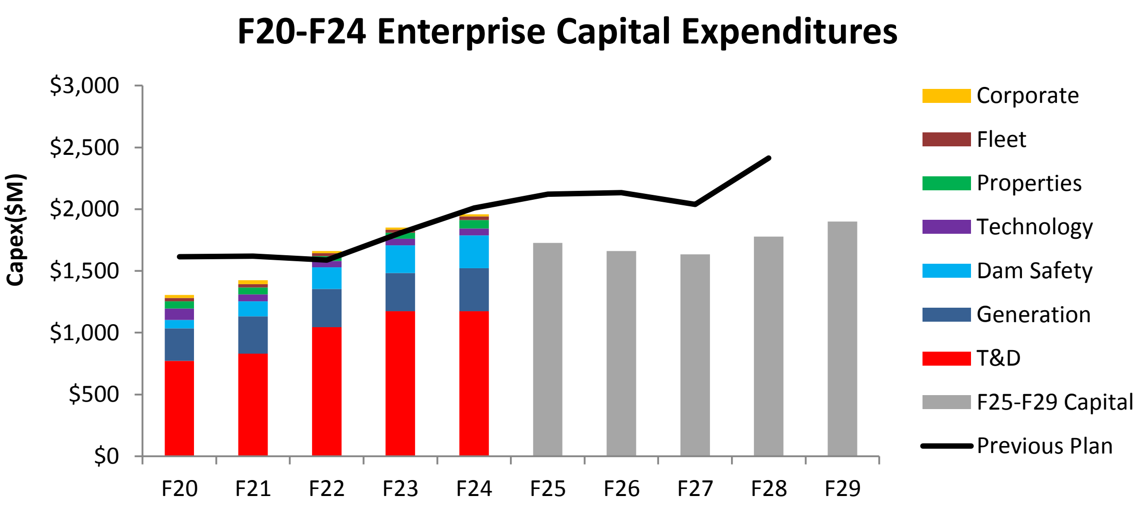

Figure 2: F2020-F2024 Capital Expenditure compared to Previous Plan

[1] Excludes Site C and Waneta

Discussion/Information

BOARD BRIEFING – BC HYDRO F2020 - F2024 CAPITAL PLAN

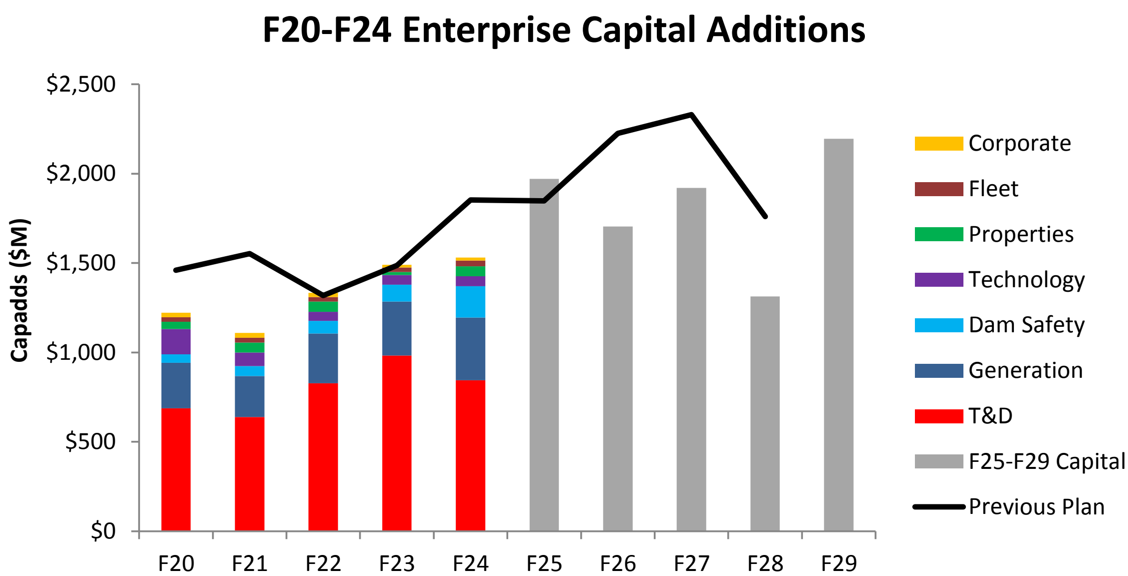

Figure 3: F2020-F2024 Capital Additions Compared to Previous Plan

This Capital Plan has been reduced by a total of approximately $2.7 billion in additions over the 10 year period, in comparison to the Previous Plan and considering forecasted additions for F2029. This reduction in capital supports BC Hydro's strategic goal of keeping electricity rates affordable for our customers. Reductions were defined by the following key principles:

- Excluding investments that are classified as mandatory as per the framework for capital prioritization,
- Minimizing reductions to active/committed investments where the financial impact of deferral/cancellation outweighed the reduction savings,

An exercise to identify potential opportunities to shift growth driven investments in advance of the completion of the updated load forecast was also undertaken. These investments were deferred within this Capital Plan, and these deferrals will be validated against the load forecast in spring 2019. In the F2020 – F2024 period, reductions have been taken from both the Sustain and Growth portfolios keeping the proportions within the portfolio relatively equal. Figure 4 below compares the F2020-F2024 capital additions by growth and sustain versus the Previous Plan totals.

Discussion/Information

BOARD BRIEFING – BC HYDRO F2020 - F2024 CAPITAL PLAN

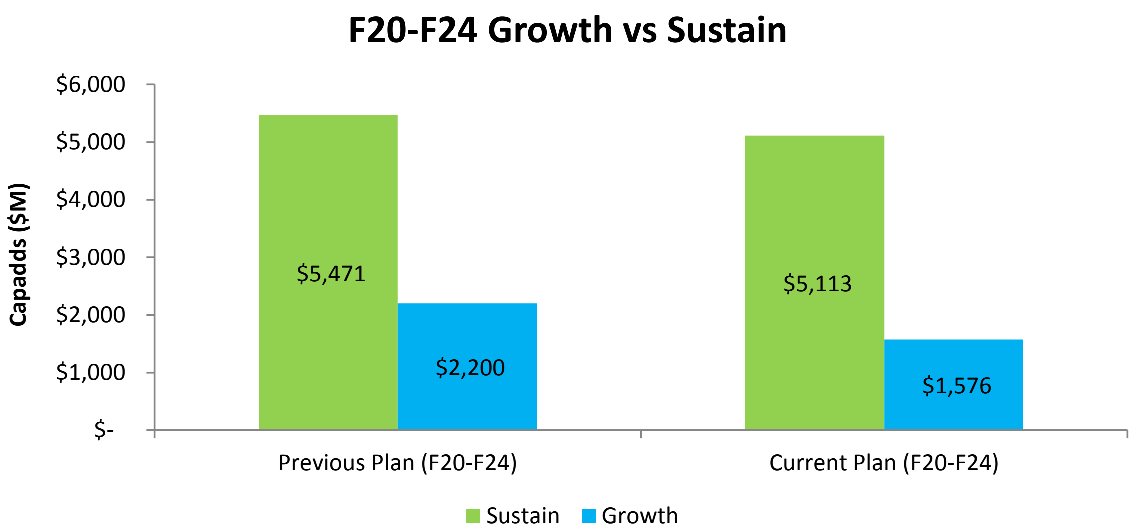

Figure 4: F2020-F2024 Capital Additions by Growth & Sustain

Dam Safety

Despite the overall reduction of capital expenditure from preceding Capital Plans described above, investment in Dam Safety within this Capital Plan has not been reduced in response to affordability considerations. Dam Safety risk reduction targets remain as they were in previous Plans and align with the approach that was approved by the Board in 2014; namely to "manage the whole fleet of dams so that there is no significant deterioration in the risk position and that the overall level of risk is kept well within the limits considered to be tolerable." In practical terms, this Capital Plan aims to reduce the aggregated Vulnerability Index of issues identified in the Dam Safety Issues Database at a rate that will generally offset the historic (and expected) rate of additions to the Vulnerability Index through newly identified or understood issues.

Relative to the previous Capital Plan, however, the current plan does represent a relatively small reduction of capital expenditures and a larger reduction of capital additions within the Dam Safety portfolio over the first half of the Capital Plan, (F2020-F2024). This is primarily due to schedule extensions of the three Campbell River projects that are currently in-flight: the seismic upgrade of John Hart Dam, the seismic and reliability upgrades of the Ladore Falls Dam spillway gates, and the reservoir discharge upgrades at Strathcona Dam. Developing and confirming the preferred alternatives for these three large and complex projects is forecast to be completed approximately one year later than previously thought as new, more beneficial and constructible concepts are being taken through Feasibility Design. The effect of these schedule extensions has been to delay the forecasted construction dates and to shift approximately $170M of capital additions to just outside the F2020-F2024 window. The net effect on the overall F2020-F2029 Capital Plan is ultimately neutral, however, as capital additions in the current plan catch up to those of the previous plan by F2026 when the Campbell River projects are to be completed.

Pursuant to the approach described above, the Capital Plan is right-sized to prevent deterioration of the current risk profile related to BC Hydro's dams and reservoirs and will address several issues that significantly contribute to that risk. By the end of this plan, projects expected to have been completed include the following: the in-flight Campbell River projects that will bring several existing earthquake and flood-related risks—the most pressing and least tolerable ones in our fleet of dams—to within broadly accepted levels; improved flow control at Comox and Puntledge Dams that will significantly reduce public safety risks along the heavily used Puntledge River; seismic and reliability upgrades of the spillways and gate systems at WAC Bennett, Mica and Revelstoke Dams that will assure reliable flood and post-earthquake reservoir discharge at BC Hydro's three largest dams; and seismic upgrades of the power tunnel and ancillary structures between Alouette and Stave Lakes that will assure post-earthquake reservoir discharge and drawdown capability and eliminate the need for expensive upgrades to the spillway at Alouette Dam. Moreover, several important projects to address poor seismic withstand, seepage control and/or deteriorating condition will be nearing completion or well underway at several dams: La Joie, Cheakamus, Duncan, and Peace Canyon. Projects to replace the last wood stave penstocks in the fleet at Ash River and Puntledge will be well advanced. These and several other, smaller projects will allow BC Hydro to meet its stated goal to "manage the whole fleet of dams so that there is no significant deterioration in the risk position..."

The current Capital Plan addresses the same Dam Safety risks over the course of the next ten years as did the previous plan, and further provides for re-initiating and progressing the major upgrade of La Joie Dam. In the interim, the risks related to these works will continue to be managed in the same manner as at present: in the case of Campbell River, by continued public outreach, education and coordination with local authorities, and in the case of La Joie by managing the reservoir to a lower elevation. Risks that are being retained at other dam and reservoir sites—both for those that are to be addressed within this Capital Plan and those that are to be addressed at a later date—will be managed, as warranted and practicable, by similar methods documented in the dams' Operation, Maintenance and Surveillance Manuals or supplemental Interim Dam Safety Risk Management Plans.

Generation

BC Hydro has 30 hydroelectric, 2 thermal generating stations, and 1 synchronous condenser station. This includes a total of 89 units, and 79 dams and civil structures. BC Hydro's generation facilities are divided into three categories of criticality to help focus asset management efforts: Key, Strategic, and Available Energy facilities. The seven Key Generating Facilities represent those with installed capacity greater than 200MW and provide 90% of the average annual electricity generated by BC Hydro. The 18 Strategic Facilities represent 9% of the average annual electricity generated by BC Hydro. The seven remaining facilities are known as Available Energy Generating Facilities and provide 1% of the average annual electricity generated.

The condition of the most critical generating assets are assessed over time through an established methodology. Asset condition is an important component of assessing risk given that assets in worse condition generally have an increased likelihood of failure. The investment strategy has focused on preserving a high level of reliability at the Key facilities given their critical role in the fleet, with a focus being placed on the three largest facilities (GM Shrum, Mica and Revelstoke). Bridge River is the smallest of the Key facilities, and is now receiving an increased level of investment to address a number of asset condition and reliability concerns. There has historically been a lower level of investment in the Strategic facilities (excluding John Hart and Ruskin) and minimal investment in the Available Energy facilities, given resource and capital constraints. To date, end-of-life failures have been experienced at Aberfeldie, Lake Buntzen 2, Alouette, Elko, and Shuswap generating stations and a number of these remain out of service. The expected condition of the generation assets at the end of F2024 are described below by category of criticality and high value assets:

- **Key Facilities:** The overall condition of the critical assets at the Key facilities is anticipated to be relatively constant, with a small improvement over time. The largest contributor to the improvement is the work being undertaken at the Bridge River facility. The largest retained long term risks at the key facilities are the Kootenay Canal Generators 3 & 4 (~290MW at risk), and with Revelstoke Generator 2 (~500MW). These assets will be monitored carefully, as investment in these assets is not anticipated to be completed within the next 10 years.
- **Strategic Facilities:** The Strategic hydroelectric facilities will see an improvement in condition driven by the completion of investments at the Ruskin and John Hart facilities, and with the completion of the generator replacement at Cheakamus expected to be completed shortly. However, the level of investment in a number of smaller strategic facilities has been reduced. Clowhom (33MW) and Ash River (28MW) have multiple assets with known condition issues, and reduced investment levels increase the likelihood of an extended forced outage, or the facilities being forced out of service. Alouette (9MW) is already out of service. The impact of these outages on the transmission system will need to be investigated.
- **Available Energy Facilities:** The seven Available Energy facilities are less critical to system reliability. Aberfeldie is relatively new (F2008), and Whatshan (54MW) is mid-life. Investments in the remaining five Available Energy facilities will be low. The Elko facility (12MW) is out of service, as well as one of the units at Shuswap (3MW). Based on the current plan, these will not be restored in the next 10 years. The other four smallest Available energy facilities are also at or approaching their end of life and all investments will receive a high level of scrutiny to avoid the risk of over investment in the assets. There is a high likelihood that a number of these will experience long outages, or be forced out of service over the next 10 years.
- **Penstocks:** These are important and high value assets. Across the fleet, a number of penstock coatings have failed or are exhibiting significant deterioration. If not mitigated in a timely fashion, the window of opportunity to recoat these penstocks will be missed, leading to corrosion of the underlying material, and a much more expensive future replacement or refurbishment. A number of penstock recoating projects are underway or proposed over the next 5 to 10 years to improve the condition of these very important assets.

Transmission & Distribution

Capital investments on the Transmission & Distribution system are driven by ageing assets, load growth in certain regions of the province, the need to manage customer reliability and address any safety needs on the system. The overall objective of the Transmission & Distribution capital plan is to:

- Address load and system growth through the addition of system capacity. An example of a capital project that will add additional capacity in the system is the Peace Region Electrification System project that is driven by the increase in the forecasted industrial load in the region.
- Manage assets reaching end of life through targeted investments to address critical assets and the highest asset risks.
- Maintain current reliability levels by addressing the worst performing circuits and install automated devices.
- Invest in safety and environmental risk mitigation particularly with regards to removing PCB contaminated oil from the system by December 2025 according to Environment Canada regulation through the replacement of end of life assets.

Discussion/Information

BOARD BRIEFING – BC HYDRO F2020 - F2024 CAPITAL PLAN

The Transmission & Distribution capital additions in the F2020-F2024 Capital Plan total approximately $4.0 billion, split between growth ($1.6 billion) and sustain ($2.4 billion) after Contributions in Aid (CIA) from customers.

The Growth Capital Portfolio reinforces the Transmission & Distribution system to meet increasing firm domestic load and provide generator interconnections and dispatch flexibility. Projects within this portfolio cover bulk transmission system assets, regional transmission system assets, transmission load and Independent Power Producer interconnections and local distribution system assets. The size of the portfolio is reflective of a domestic load that is expected to grow in some areas across the province like the Peace Region. Uncertainty of the load forecast is a risk to this portfolio. For this capital planning cycle, a number of growth driven investments were deferred from the Capital Plan and will be validated against the updated five year energy forecast in spring 2019. Wherever possible, the Growth Portfolio projects are coordinated with the Sustainment Portfolio to develop effective solutions that address both system capacity shortfall and end of life needs.

Another component of the Growth Capital Portfolio includes projects related to new Transmission Voltage customer load and generation interconnections. Projects included in this category of the Capital Plan are either committed or have a high probability of proceeding. Obligation to serve loads and generators is governed through BC Hydro's Open Access Transmission and Electric Tariffs. New customer load requests are a risk for this portfolio, due to uncertainty in timing, location and scope. ,

Also, included in this portfolio are distribution customer connections. The level of economic activity in the province is the single largest influence on the customer capital expenditures. Housing starts, infrastructure investment, and new industries such as cannabis grow operations have contributed to an unprecedented construction boom over the last three years and therefore unprecedented volumes of distribution customer connection requests.

The main objective of the Sustaining Capital Portfolio is to cost-effectively maintain a reliable Transmission & Distribution system and mitigate asset risks including life-safety, environmental, extreme weather, seismic and fire. Expenditures in this portfolio will replace end-of-life assets, manage reliability trends on the system and address other risks. Most of the sustain expenditures are for the replacement of component parts (e.g. circuit breakers and wood poles) with varied life expectancies. Bottom up planning was used to identify the investments required to sustain the most critical assets, and address the highest asset risks. The end-of-life investments were developed to maximize the life cycle value of the Transmission & Distribution assets. While in most instances end-of-life replacements are accomplished through proactive replacements, in some asset classes "run to failure" is used to minimize the life cycle cost of managing the assets where the associated risk of failure is low. Examples of "run to failure" asset classes are overhead distribution transformers and transmission line insulators.

To understand long-term trends in asset replacement needs, asset health for various asset classes is developed using asset survival curves and demographic data to support decisions around the required rate of asset replacements. Funding levels in the current Capital Plan will result in an increase in assets with poor and very poor asset health ratings and potential for a decline in customer reliability. Transmission & Distribution will minimize this risk by targeting investments to critical assets and the highest asset risks, and by monitoring system reliability to determine whether the level of end-of-life replacements need to be adjusted.

Customer reliability expenditures are also part of the Sustaining Capital Portfolio. These expenditures contribute to maintaining the overall system reliability by installing automated devices such as circuit reclosers, and by targeting the distribution circuits that are performing poorly. The scope of customer reliability projects may include new standby feeders, feeder ties, as well as circuit undergrounding or reconfiguration, line relocations and protection upgrades.

BOARD BRIEFING – BC HYDRO F2020 - F2024 CAPITAL PLAN

Properties

Historically, the majority of Properties capital spend has been directed at mitigating Safety or Financial risks across the 100+ building portfolio. Over the past 10 years, major investments around the province, coupled with a sustaining capital program targeted at replacement of the most critical end of life assets, have addressed many of the inherent risks associated with an aging field building stock. In total 37 field buildings have been upgraded and in particular, 7 out of the 8 high criticality large regional field offices have been redeveloped, the scope of which included the operations yards, warehouses, truck bays, security and IT infrastructure, office areas, as well as seismic upgrades.

Going forward the Properties capital investment strategy is summarized as follows:

- Building Development Projects (field building replacement projects): 5 with a total investment of $105M are currently in definition or implementation (e.g. Material Classification Facility, Chilliwack). In addition, the redevelopment of the final high criticality large regional field office located in Kamloops is scheduled to enter definition phase in F2020. By F2025, Properties will also complete those projects that were previously in definition phase and subsequently deferred (e.g. Construction Services/Lower Mainland Transmission facility in Surrey);
- Building Improvement Projects: a reduction from an average annual spend of $20-30M p.a. to $17M in sustaining capital investments is reflective of the investments to date as well as balancing affordability with asset performance and risk. Focus will be on the most critical end of life assets, as well as completion of a modest number of field building interior upgrades and construction/expansion of truck bay facilities (e.g. Hope interior upgrades and Cranbrook truck storage). This reduced capital spend will result in necessary deferral of certain projects across the portfolio and may result in higher facility operating costs and unplanned asset component failures.

Technology

The proposed plan is sufficient to complete all currently active projects through the end of F2021, including the Supply Chain Applications project. However, the plan drops rapidly from F2020 to F2021 to approximately 30% below historical (F2015 to F2019) spend levels and is therefore allocated primarily to compliance and risk mitigation initiatives. Infrastructure will be renewed, information systems will continue to run and bills will be paid. Compliance investments, essential replacements, licensing, upgrades and capacity improvements will also continue to be done. New, enhanced and extended technology foundations and solutions are not funded. This may result in opportunity costs for BC Hydro as technology-based business efficiencies are not enabled.

A focus on operational continuity of data center infrastructure, software platforms and devices will ensure the availability, appropriate access, and integrity of BC Hydro's technology solutions. A lower level of continued investment in business-driven solutions will serve to correct operational issues, and improve cybersecurity, information management, performance and core system resilience. The proposed plan assumes 2% annual inflation and 1% annual growth in demand for IT expenditures in funded categories. This is lower than we've seen in recent years and may be understated.

Business demand for technology solutions is likely to be underserved. This includes IT support for business initiatives and improvements or extensions of existing IT solutions. Business units may seek to fund their own technology solutions as an opportunity to address business needs.

Discussion/Information

BOARD BRIEFING – BC HYDRO F2020 - F2024 CAPITAL PLAN

Fleet Services

Despite routine, preventative maintenance, fleet assets (vehicles, equipment, trailers), relied upon by staff across B.C. to operate our system and deliver on capital projects, inevitably deteriorate as they age and eventually reach end-of-life (EOL). The Fleet Services capital program is a perpetual sustainment program to replenish fleet assets and support safe, efficient operations.

Under this Capital Plan, ~690 End-of-Life (EOL)/poor-condition assets will be replaced by the end of F2024. This plan does not include sufficient capital to replace all assets forecast to reach end-of-life during the period. As a result, the backlog of units deferred for replacement will continue to grow (from ~80 EOL units in F2020 with an estimated replacement value of $11.2M, to ~440 EOL units by the end of F2024 with an estimated replacement value of $39.8M). With these deferred replacements, the fleet assets will continue to age and deteriorate during the plan period.

The plan has no funding/contingency for any net additions or for significant unit upgrades to the fleet that may be required by the business (for example, due to changes in engineering standards, work methods, staffing or operational priorities). These types of requests would need to be funded via approval of ex-plan capital, be denied, or be absorbed into the existing Fleet Services capital budget through deferral.

The following risks are associated with the plan:

- Increased Fleet OMA: deferring replacement and aging of the fleet create pressures due to increased maintenance and repair costs. We will have to work through any resulting cost pressures.
- End-User Departments will experience more vehicle/asset downtime. This is expected to result in decreased productivity & efficiency, less operational flexibility and may impact crew response time. The result may be less project work completed on-time/budget and delays in implementing any desired changes to work methods that rely on acquisition of different fleet assets. Less reliable vehicles and more unexpected breakdowns can also increase safety risks and negatively impact employee engagement.
- A lack of contingency to address cost pressures in the Fleet Services capital plan associated with exchange rate fluctuations and the adoption of new fleet technologies (e.g. fleet greening).

The following actions will help mitigate the associated risks:

- Telematics IT Project: amongst other benefits, telematics enables right-sizing of the fleet and improved asset utilization, both of which will positively impact the capital plan. This IT project is in Identification Phase presently.
- Cross-functional exploration of opportunities to drive improved asset utilization via reallocation of low-utilization assets, creation of vehicle pools in more locations, etc.
- Updates to vehicle/financial policies (e.g. vehicle assignment criteria, policy re: taking BC Hydro vehicles home), increased cross-functional fleet governance and consistency of practice across departments, and escalation of controllable vehicle damage.
- Completion of two Fleet Category Plans related to fleet asset acquisition will drive increased value from new fleet assets along with improvements in supplier capability/capacity, asset acquisition processes and capital delivery.

Discussion/Information

BOARD BRIEFING – BC HYDRO F2020 - F2024 CAPITAL PLAN

Corporate (Other)

This Portfolio is comprised of capital investments from various departments across BC Hydro, supporting corporate driven initiatives, as well as smaller capital needs from departments such as Security, Safety, Materials Management, Learning, Development & Trades Training, Environment, Engineering, Corporate Affairs, and Site Engineering & Acceptance.

Investments within this portfolio total $55 million in capital additions for F2020-F2024 and include:

- Opportunities to Reduce Electrical Contact Incidents/Minimum Approach Distance – Purchase of additional cover up for distribution crews,
- One Worker Protection System– Developing a one worker protection system by combining Power System Safety Protection and Worker Protection Practices,
- Learning, Development & Trades Training construction of an Energized Training Substation,
- Security investments in physical security requirements for NERC compliance.

* 'Capital Expenditures' are recorded when the costs are incurred. 'Capital Additions' refer to when the related asset is placed into service. Certain costs impacting BC Hydro's revenue requirements, such as amortization, return-on-equity, and finance charges, are not recorded until the related asset is placed into service.

BC Hydro Power smart

BOARD BRIEFING – BC HYDRO F2020 - F2024 CAPITAL PLAN

Attachment #2 - Capital Expenditures for Projects Greater than $50M - F2020 to F2024

Projects > $50M with Capital Expenditures Forecasted during F2020 - F2024 ($millions)

Asset Owner	Project	Type	Phase	Forecast ISD	Authorized Amount / Engineering Estimate / Latest Forecast
Generation	Bridge River 1 - Replace Units 1-4 Generators/Governors	Sustaining	Identification	TBD	TBD
Generation	Bridge River 2 - Upgrade Units 5 and 6	Sustaining	Implementation	F2019	$86
Generation	Bridge River 2 - Upgrade Units 7 and 8	Sustaining	Identification	TBD	TBD
Generation	Cheakamus - Dam Improvements	Sustaining	Future	TBD	TBD
Generation	Cheakamus - Units 1 and 2 Generator Replacement	Sustaining	Implementation	F2020	$74
Generation	Clowhom - Unit Upgrade	Sustaining	Future	TBD	TBD
Generation	G.M. Shrum - G1 to 10 Control System Upgrade	Sustaining	Implementation	F2023	$75
Generation	W.A.C. Bennett Dam - Spillway Seismic Upgrade	Sustaining	Future	TBD	TBD
Generation	G.M. Shrum - U1 - U10 Water Passage Refurbishment	Sustaining	Future	TBD	TBD
Generation	W.A.C. Bennett Dam - Rip-Rap Upgrade	Sustaining	In-Service	F2019	$119
Generation	John Hart - Dam Seismic Upgrade	Sustaining	Identification	TBD	TBD
Generation	John Hart - Generating Station Replacement	Sustaining	Implementation	F2019	$985
Generation	Kootenay Canal - U1 - U4 Generators Refurbishment	Sustaining	Future	TBD	TBD
Generation	Lajoie - Dam Improvements	Sustaining	Identification	TBD	TBD
Generation	Ladore - Spillway Seismic Upgrade	Sustaining	Identification	TBD	TBD
Generation	Mica - Discharge Facilities Seismic and Reliability Upgrades	Sustaining	Future	TBD	TBD
Generation	Mica - U1 - U4 Turbine Overhaul	Sustaining	Future	TBD	TBD
Generation	Mica - Reactor 5RX3 and 5RX4 Replacement	Sustaining	Future	TBD	TBD
Generation	Mica - U1 - U4 Circuit Breaker and Iso-phase Bus Replacement	Sustaining	Future	TBD	TBD
Generation	Mica - Replace Units 1 to 4 Generator Transformers	Sustaining	Implementation	F2023	$82
Generation	Revelstoke - Discharge Gate Systems Reliability Improvements	Sustaining	Future	TBD	TBD
Generation	Revelstoke - Install Unit 6	Growth	Definition	F2030	$569 - $317
Generation	Revelstoke - U1 - U4 Stator Replacement	Sustaining	Future	TBD	TBD
Generation	Strathcona - Upgrade Discharge	Sustaining	Identification	TBD	TBD
Generation	Seven Mile - Overhaul Units 1 to 3 Turbines	Sustaining	Identification	TBD	TBD
Generation	Terzaghi - Low-Level Discharge Reliability Improvements	Sustaining	Future	TBD	TBD
Transmission	Peace Region to Kelly Lake 500kV Transmission Reinforcement	Growth	Identification	TBD	TBD
Transmission	Peace Region Electric Supply (PRES)	Growth	Definition	F2022	$348-$197
Transmission	Fort St. John and Taylor Electric Supply	Growth	Implementation	F2021	$53
Transmission	Mount Lehman Substation Upgrade	Growth	Identification	TBD	TBD
Transmission	Kamloops Substation	Growth	In-Service	F2019	$56
Transmission	Horne Payne Substation Upgrade	Growth	Implementation	F2019	$93
Transmission	Northwest Substation Upgrades Project (NSUP)	Growth	Deferred	F2026	TBD
Transmission	Squamish Area Reinforcement	Growth	Identification	TBD	TBD
Transmission	Customer A	Growth	Implementation	F2022	$55
Transmission	Customer C	Growth	Definition	F2022	$102-$72
Transmission	Capilano Substation 25Kv Conversion	Growth	Definition	F2025	$88 - $50
Transmission	Metro North Transmission (MNT)	Growth	Definition	F2025	$530 - $300
Transmission	Langley -Abbotsford - Area Reinforcement	Growth	Future	TBD	TBD
Transmission	West Kelowna Transmission and Westbank Upgrade Projects	Growth	Identification	TBD	TBD
Transmission	5L63 Telkwa Relocation	Sustaining	Identification	TBD	TBD
Transmission	Gulf Islands - Transmission Reinforcement	Sustaining	Future	TBD	TBD
Transmission	Natal Sub - NTL 60-138 kV Rebuild	Sustaining	Identification	TBD	TBD
Transmission	Project A	Growth	Implementation	F2021	$81
Transmission	East Vancouver Substation Construction	Growth	Future	TBD	TBD
Transmission	Metrotown - Property Purchase	Growth	Future	TBD	TBD
Transmission	60L2/3/18 Dewdney Trunk Transmission Copper Conductor Replacement	Sustaining	Future	TBD	TBD
Transmission	West End - Substation Construction and System Reinforcement	Growth	Future	TBD	TBD
Transmission	North Shore Area Transmission Reinforcement	Growth	Identification	TBD	TBD
Transmission	Lower Mainland - Capacitive and Reactive Power Reinforcement	Growth	Future	TBD	TBD
Transmission	2L146 Cable Replacement	Sustaining	Identification	TBD	TBD
Technology	Supply Chain Application	Sustaining	Definition	F2020	$72-$59
Note:	Amounts in the above table are only for capital expenditures on the project.

Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Appendix I

Capital Expenditures > $5 million

Appendix I Provides Information in Compliance with Commission Order No. G-59-8, Review of the Regulatory Oversight of Capital Expenditures and Projects

Appendix I provides information on non-technology capital projects and programs greater than $5 million and on Technology projects greater than $2 million, with capital expenditures and/or capital additions in fiscal 2020 and fiscal 2021. Consistent with section 9 of Exhibit B-7 (**Revised Proposal)**, filed in the Review of the Regulatory Oversight of Capital Expenditures and Projects, BC Hydro has included the following additional information in Appendix I:

- Project or program planning ID number (column A);
- Descriptive project or program naming (column B). Where applicable, the project or program name will include the following three elements in the order specified below:
    1. **Location:** This is the regional area, line route, or the station, facility, or dam where the primary work is taking place or where the primary asset(s) is situated;
    2. **Asset or Service:** Asset refers to either a component (such as a turbine or transformer) or to a group of related assets (such as a substation or a powerhouse). Service refers to the service to be provided by an information technology project or program; and
    3. **Activity:** Activity refers to the type of primary function or work being performed (e.g., redevelopment, upgrade, or reinforcement).

In addition, Appendix I provides the following information, if applicable:

- Whether the project is a system extension (column T);
- Whether the project will or may be subject to CPCN application or an application under section 44.2 of the *Utilities Commission Act* (column U);
- Whether a relevant Strategy, Plan or Study summary is provided in Appendix K (column W); and
- Whether the project is part of a Program of Projects (column X).

BC Hydro looks for opportunities to combine projects where it can result in efficiencies; however, where projects have different schedules or other practical or technical considerations, they are implemented as separate projects even if in the same facility. In section 5.2 of the Revised Proposal BC Hydro provided clarity on what constitutes a capital project and situations where BC Hydro may combine projects.

Note a: Given the nature of the project, a definition phase was not undertaken.

Note b: In the F17-F19 RRA, the Name of this Project was Puntledge Flow Control Improvements.

Notes:

(1) Information provided is current as of the established 'Currency Date' which is April 1, 2018. Information for certain projects in progress has been updated for significant events subsequent to this date.

(2) Some projects that are in service or forecast to be in service at the end of fiscal 2019 may have trailing expenditures that result in capital additions in the test period. These expenditures and associated capital additions have been aggregated and included in the line item "Projects less than $5 million".

(3) Project / Program dollars are generally capitalized starting either in the feasibility stage of Identification phase or in the Definition phase.

(4) Forecast ISD is the expected in-service date (as at the Currency Date) when the project goes into service.

(5) Start Date of Construction is the Implementation Approval Date. For projects in Definition, the Start of Construction is the forecasted Implementation approval date.

(6) Fiscal Year that the project received Definition phase approval.

(7) Implementation Approval $ refers to the 'Authorized' total capital cost of the project when it was first approved by BC Hydro for Implementation.

(8) Pre-Implementation phases are: Future, Identification and Definition. See Chapter 6, section 6.4.7.4 to 6.4.7.7 for further discussion on pre-Implementation phases. Pre-Implementation cost estimates are provided where an engineering estimate is available. Engineering estimates are generally completed during the mid-stage of Identification phase. N/A indicates that an engineering estimate is not yet available, or that the project is in Implementation phase.

(9) Amounts reflect only the capital portion of the Authorized amount.

(10) Implementation Approval ISD refers to the in-service date identified when the project was first approved by BC Hydro for Implementation.

(11) Project meets the current threshold for a CPCN or Section 44.2 Application based on the Project Authorized Cost Amount, or may meet the threshold, based on the planning cost allowance or cost estimate as of the Currency Date (See Note 1), or in accordance with BCUC Direction No. G-47-18.

Use of To Be Determined (TBD):

For projects in Future or Identification phase, To be Determined (TBD) is provided for the Pre Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start Date of Construction, for the following reasons:

For Future phase projects, a problem or opportunity has been identified, but the required response has not yet been determined. In Identification phase, a number of identified alternative responses are being investigated, and each alternative can result in very different project scope, schedule and cost. As a result, Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start of Construction Date are generally only provided for projects in the Definition phase and later phases.

Appendix I - F2020 - F2021 RRA - Transmission
Projects and Programs greater than $5 million with Capital Expenditures in the Test Period and/or Capital Additions in the Test Period (F20-F21) as at April 1, 2018 (1), (2)
$ Million

		Total												**278.6**	**200.4**			**384.0**	**470.7**						

Note a: Definition work for the project was completed under the Site C Clean Energy Project
Note b: Given the nature of the project, a definition phase was not undertaken.
Note c: ISA is in the fiscal year following the ISD because of a 3 month span between project in-service and finalization of the in-service additions by Finance
Note d: An Appendix J is provided for the Peace Region to Kelly Lake - Reactor Replacement Program of Projects.

Notes:

(1) Information provided is current as of the established 'Currency Date' which is April 1, 2018. Information for certain projects in progress has been updated for significant events subsequent to this date.

(2) Some projects that are in service or forecast to be in service at the end of fiscal 2019 may have trailing expenditures that result in capital additions in the test period. These expenditures and associated capital additions have been aggregated and included in the line item "Projects less than $5 million".

(3) Project / Program dollars are generally capitalized starting either in the feasibility stage of Identification phase or in the Definition phase.

(4) Forecast ISD is the expected in-service date (as at the Currency Date) when the project goes into service.

(5) Start Date of Construction is the Implementation Approval Date. For projects in Definition, the Start of Construction is the forecasted Implementation approval date.

(6) Fiscal Year that the project received Definition phase approval.

(7) Implementation Approval $ refers to the 'Authorized' total capital cost of the project when it was first approved by BC Hydro for Implementation.

(8) Pre-Implementation phases are: Future, Identification and Definition. See Chapter 6, section 6.4.7.4 to 6.4.7.7 for further discussion on pre-Implementation phases. Pre-Implementation cost estimates are provided where an engineering estimate is available. Engineering estimates are generally completed during the mid-stage of Identification phase. N/A indicates that an engineering estimate is not yet available, or that the project is in Implementation phase.

(9) Amounts reflect only the capital portion of the Authorized amount.

(10) Implementation Approval ISD refers to the in-service date identified when the project was first approved by BC Hydro for Implementation.

(11) Project meets the current threshold for a CPCN or Section 44.2 Application based on the Project Authorized Cost Amount, or may meet the threshold, based on the planning cost allowance or cost estimate as of the Currency Date (See Note 1), or in accordance with BCUC Direction No. G-47-18.

Use of To Be Determined (TBD):

For projects in Future or Identification phase, To be Determined (TBD) is provided for the Pre Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start Date of Construction, for the following reasons:
For Future phase projects, a problem or opportunity has been identified, but the required response has not yet been determined. In Identification phase, a number of identified alternative responses are being investigated, and each alternative can result in very different project scope, schedule and cost. As a result, Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start of Construction Date are generally only provided for projects in the Definition phase and later phases.

Note a: ISA is in the fiscal year following the ISD because of a 3 month span between project in-service and finalization of the in-service additions by Finance
Note b: This project was approved directly to Implementation and the Definition Phase Activities were completed under the overall Program Management
Note c: An Appendix J is provided for the H-Frame Elimination - Chinatown Program of Projects.

Notes:

(1) Information provided is current as of the established 'Currency Date' which is April 1, 2018. Information for certain projects in progress has been updated for significant events subsequent to this date.

(2) Some projects that are in service or forecast to be in service at the end of fiscal 2019 may have trailing expenditures that result in capital additions in the test period. These expenditures and associated capital additions have been aggregated and included in the line item "Projects less than $5 million".

(3) Project / Program dollars are generally capitalized starting either in the feasibility stage of Identification phase or in the Definition phase.

(4) Forecast ISD is the expected in-service date (as at the Currency Date) when the project goes into service.

(5) Start Date of Construction is the Implementation Approval Date. For projects in Definition, the Start of Construction is the forecasted Implementation approval date.

(6) Fiscal Year that the project received Definition phase approval.

(7) Implementation Approval $ refers to the 'Authorized' total capital cost of the project when it was first approved by BC Hydro for Implementation.

(8) Pre-Implementation phases are: Future, Identification and Definition. See Chapter 6, section 6.4.7.4 to 6.4.7.7 for further discussion on pre-Implementation phases. Pre-Implementation cost estimates are provided where an engineering estimate is available. Engineering estimates are generally completed during the mid-stage of Identification phase. N/A indicates that an engineering estimate is not yet available, or that the project is in Implementation phase.

(9) Amounts reflect only the capital portion of the Authorized amount.

(10) Implementation Approval ISD refers to the in-service date identified when the project was first approved by BC Hydro for Implementation.

(11) Project meets the current threshold for a CPCN or Section 44.2 Application based on the Project Authorized Cost Amount, or may meet the threshold, based on the planning cost allowance or cost estimate as of the Currency Date (See Note 1), or in accordance with BCUC Direction No. G-47-18.

Use of To Be Determined (TBD):

For projects in Future or Identification phase, To be Determined (TBD) is provided for the Pre Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start Date of Construction, for the following reasons:
For Future phase projects, a problem or opportunity has been identified, but the required response has not yet been determined. In Identification phase, a number of identified alternative responses are being investigated, and each alternative can result in very different project scope, schedule and cost. As a result, Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start of Construction Date are generally only provided for projects in the Definition phase and later phases.

Notes:

(1) Information provided is current as of the established 'Currency Date' which is July 1, 2018**. On October 12, 2018, a** Phase Two Application relating to the Supply Chain Applications project was filed with the Utilities Commission. As shown in Appendix J, the information as of September 27, 2018 was an Implementation phase project with Forecast Capital Cost of $68.0M. Refer to Appendix J for further information at this later date.

(2) Some projects that are in service or forecast to be in service at the end of F2019 may have trailing expenditures that result in capital additions in the test period. These expenditures and associated capital additions have been aggregated and included in the line item "Projects and Programs under $2 million".

(3) Project/ Program dollars are generally capitalized starting in the Definition phase.

(4) Forecast ISD is the expected in-service date (as at the Currency Date) when the project goes into service.

(5) Start Date of Construction is the Implementation Approval Date.

(6) Fiscal Year that the project received Definition phase approval.

(7) Implementation Approval $ refers to the 'Authorized' total capital cost of the project when it was first approved by BC Hydro for implementation. "N/A" is used for recurring programs.

(8) Pre-Implementation phases are: Future, Identification and Definition. See Chapter 6, section 6.XXX, for further discussion on pre-Implementation phases. Pre-implementation cost estimates are provided in Definition phase. N/A indicates that an engineering estimate is not yet available, or that project is in implementation phase.

(9) Amounts reflect only the capital portion of the Authorized amount.

(10) Implementation Approval ISD refers to the in-service date date identified when the project was first approved by BC Hydro for implementation. "N/A" is used for recurring programs.

(11) Project meets the threshold for a CPCN or Section 44.2 Application based on the Project Authorized Cost Amount, or may meet the threshold, based on the planning cost allowance or cost estimate as of the Currency Date (See Note

Use of To Be Determined (TBD):

For projects in Future or Identification Phase, To Be Determined (TBD) is provided for the following: Current Pre-Implementation Cost Estimate, Current Forecast In-service Date (ISD) and Current Start Date of Construction, for the following reasons:

For Future phase projects, a problem or opportunity has been identified, but the required response has not yet been determined. In the Identification Phase, a number of identified alternative responses are being investigated, and each alternative can result in a very different project scope, schedule and cost. As a result, Current Pre-Implementation Cost Estimate, Current Forecast In-Service Date (ISD) and Current Start Date of Construction, are only provided for projects in the Definition phase and later phases.

Notes:

(1) Information provided is current as of the established 'Currency Date' which is April 1, 2018. Information for projects in progress has been updated for significant events subsequent to these dates.
(2) Some projects that are in service or forecast to be in service at the end of fiscal 2019 may have trailing expenditures that result in capital additions in the test period. These expenditures and associated capital additions have been aggregated and included in the line item "Projects less than $5 million".
(3) Project / Program dollars are generally capitalized starting either in the feasibility stage of Identification phase or in the Definition phase.
(4) Forecast ISD is the expected in-service date (as at the Currency Date) when the project goes into service.
(5) Start Date of Construction is the Implementation Approval Date. For projects in Definition, the Start of Construction is the forecasted Implementation approval date.
(6) Fiscal Year that the project received Definition phase approval.
(7) Implementation Approval $ refers to the 'Authorized' total capital cost of the project when it was first approved by BC Hydro for Implementation.
(8) Pre-Implementation phases are: Future, Identification and Definition. See Chapter 6, section 6.4.7.4 to 6.4.7.7 for further discussion on pre-Implementation phases. Pre-Implementation cost estimates are provided where an engineering estimate is available. Engineering estimates are generally completed during the mid-stage of Identification phase. N/A indicates that an engineering estimate is not yet available, or that the project is in
(9) Amounts reflect only the capital portion of the Authorized amount.
(10) Implementation Approval ISD refers to the in-service date identified when the project was first approved by BC Hydro for Implementation.
(11) Project meets the current threshold for a CPCN or Section 44.2 Application based on the Project Authorized Cost Amount, or may meet the threshold, based on the planning cost allowance or cost estimate as of the Currency Date (See Note 1), or in accordance with BCUC Direction No. G-47-18.

Use of To Be Determined (TBD):
For projects in Future or Identification phase, To be Determined (TBD) is provided for the Pre Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start Date of Construction, for the following reasons:
For Future phase projects, a problem or opportunity has been identified, but the required response has not yet been determined. In Identification phase, a number of identified alternative responses are being investigated, and each alternative can result in very different project scope, schedule and cost. As a result, Pre-Implementation Cost Estimate, Forecast In-Service Date (ISD) and Start of Construction Date are generally only provided for projects in the Definition phase and later phases.

Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Appendix J

Capital Expenditures > $20 million

Appendix J Summaries

Appendix J, Attachment 1 provides descriptions for capital projects and programs of projects with planned capital expenditures or additions in the test period, with planned total capital expenditures greater than $20 million. Consistent with section 9 of Exhibit B-7 (Compliance with Commission Order No. G-59-18 - Revised Proposal) (**Revised Proposal)**, BC Hydro has included the following additional information in Appendix J:

- A summary of the project's impacts and benefits;
- For projects in the Implementation Phase, the construction start date; and
- A summary of risk(s) and risk treatment for projects in the Implementation Phase.[1]

Consistent our Previous Application, the Appendix J project summaries include information on the key drivers of the capital projects. In this application these key drivers are aligned with the consequence types identified in BC Hydro's Corporate Risk Matrix.

The Corporate Risk Matrix identifies the following "consequence types" or risk impacts:

- Safety – This includes the safety of both the public and BC Hydro workers;
- Environmental – This includes impacts to habitats and species;

[1] Summaries of Implementation Phase risks are provided for those projects in Implementation Phase, with identified high severity and/or high probability consequences, or a combination of moderate severity and probability consequences. The assessment is based on BC Hydro's Project Delivery Risk Matrix which classifies project Implementation risks into three zones, from low (zone 1) to high (zone 3). The Project Delivery Risk Matrix is derived from the Corporate Risk Matrix. As discussed in Chapter 6, sections 6.4.7.7 to 6.4.7.9, project risks are identified starting in the Identification Phase and are finalized in the Implementation Phase.

- Financial Loss (Financial) – This includes direct financial loss or costs;
- Reputational – This includes responses from the public, media and public officials as well as impacts to projects, programs, plans and operations as a result of these responses; and
- Reliability – This includes customer reliability (hours lost per event) and reliability of supply.

The Appendix J capital project summaries identify which of these five categories of consequence types are the key drivers for investments that are risk driven.

<tr><td colspan="3">Description:
The purpose of the Revelstoke Unit 6 project is to install a 500 MW unit in the existing empty Unit 6 bay at the Revelstoke Generating Facility. The scope of the Revelstoke Unit 6 installation project would involve the installation of a sixth penstock, turbine, generator, and all ancillary equipment required in the generating station. In addition, there is a transmission requirement for an additional series capacitor station on the transmission line from Vaseux to Nicola and some enhancements within existing substations.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
There is one remaining empty bay where a sixth unit could be installed to meet the requirement for additional capacity in the BC Hydro system. Revelstoke Unit 6 is the least cost alternative for adding this additional capacity.
Based on the Reference Price Update (December 2018), REV6 is the least cost alternative ($58/kw-yr) for adding additional capacity to the BC Hydro system and, as such, is the next capacity resource option for the BC Hydro system. The load resource balance is in a deficit in fiscal 2023; by fiscal 2028, the load deficit is 500 MW and this increases to 1,250 MW by fiscal 2030.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
Two alternatives were evaluated during Identification phase:
i. Proceed with REV6; and
ii. Defer REV6.
Alternative i. Proceed with REV6 was selected as the preferred alternative based on the 2013 Load Resource Balance (LRB). The project timing has been revised for an In Service Date (ISD) of fiscal 2030 to align with current load growth expectations.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits: • Provide dependable capacity to meet LRB capacity requirements.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: "Revelstoke Unit 6, a project to install an additional turbine and related works and equipment at Revelstoke", is an exempt project pursuant to section 7(c) of the *Clean Energy Act*.

Investment Planning ID: **G000656**	**Project Name:** **W.A.C. Bennett Dam Spillway Gate Upgrade**	
Forecast Capital Cost: $47.5 million	**Forecast In-Service Date:** Fiscal 2021	**Start Date of Construction:**[1] Fiscal 2018
Development Phase: Implementation	**Filing Reference:** Amended F12-F14 RRA: • Amended Appendix I, line 76; • Amended Appendix J, page 40 F17-F19 RRA: • Appendix I, line 10, Appendix J page 12, • BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1	

Description:

This purpose of this project is to enhance reliability of the existing electrical, mechanical and protection and control equipment of the spillway gate system at the W.A.C. Bennett Dam.

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

The age, condition and design of the electrical, mechanical, protection and control equipment that support the three radial Spillway Operating gates at G.M. Shrum Generating Facility (**GMS**) do not ensure the reliable and safe operation of the equipment under a wide range of possible conditions. Uncertain outcomes when operating the equipment is due to obsolescence, lack of redundancy in original design, and deficiencies in protection and control systems. Any or all of these factors may result in common-cause or single-point failures that could lead to either inadvertent operation or limits status and alarm indication, making diagnosis of cause more difficult. The project will address 18 identified issues, including condition of the gears and gearbox in the Spillway Operating Gate (**SPOG**) hoist drivetrain, addition of a backup power supply, reliability of gate controls and limit switches, and will mitigate the impacts of inadvertent or uncontrolled gate operation if either should occur.

If the powerhouse is unable to process enough water to limit reservoir elevations due to transmission disruption, post-seismic conditions, unanticipated high inflows or other causes, the only safe way to release this energy is by diverting water down the spillway. This diversion is only possible if the Spillway Operating gates operate on demand.

Discussion of Alternatives:

Four alternatives were considered in Identification Phase to address the deficiencies in the WAC Bennett Dam spillway gate systems:

i. **Do Nothing**;

ii. **Comprehensive project** to address all non-power release facilities at WAC Bennett Dam, including mechanical equipment (spillway gates, low level outlet, and sluice gates), as well as civil infrastructure (the spillway);

iii. **A project to address all aspects of Spillway Operating Gate operation**: including structural integrity, civil components, and mechanical operability, electrical supply, and protection and control concerns; and

iv. **A project limited to Spillway Operating Gate reliability**, and focussing on immediate concerns related to the deteriorated or obsolete equipment in place, as well as design issues that might give rise

[1] Start Date of Construction is the Implementation Approval Date.

to common-cause failures. The scope of this project would be limited to electrical, hoist drive-train mechanical, and P&C issues. Alternative iv, A project limited to Spillway Gate reliability, was selected as the preferred alternative based on a balance of cost and risk-reduction benefits. The first "Do Nothing" alternative was rejected due to the existing identified deficiencies in the SPOG systems, while the second alternative was rejected due to the complexity, costs, and extended delay before it could be undertaken: it will require lengthy studies to determine the best course with both the Sluice Gates and the Low Level Outlet (**LLO**), extending the exposure to the SPOG risks if the three NPR facilities (and possibly the spillway) are combined into a single project. The third alternative, of a comprehensive SPOG rehabilitation project would address all SPOG issues, but would be very expensive, not least due to the need for Single-Device Isolation certification for the spillway stoplogs. It was determined that a limited project as described by the fourth alternative could be implemented at a reasonable cost, while obtaining a significant reduction in the risk that the SPOGs will not operate on demand.
Project Impacts and Benefits: It is anticipated that the Project will fully or partially resolve the following issues including, but not limited to: gear condition, gate control limit switches, gearbox and motor heating systems, reliability of spillway gate controls, alarm on heater failure, hoist rope loading and equalization, and limit switches.

Project Implementation Phase Risk:	**Risk Treatment:**
This project currently does not have any identified Zone 3 Implementation Phase risks	N/A

Investment Planning ID: G000011	**Project Name:** Alouette Improve Headworks & Surge Tower Seismic Stability	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** New	

Description:

The purpose of this project is to address seismic deficiencies of the Alouette Dam so that this facility can be relied upon for operations post an earthquake event.

Key Drivers:

- Safety
- Environmental
- Financial Loss
- Reputational

Issues Being Addressed:

The Alouette Dam has been classified as an "Extreme" consequence dam based on BC Dam Safety Regulation. A seismic performance deficiency investigation of the dam and power tunnel was completed in 2011, and it concluded that the spillway would be damaged and cannot be relied upon post maximum design earthquake (**MDE**) to pass the inflow of water. Spilling water through the damaged spillway may lead to its failure and uncontrolled release of water, potentially resulting in fatalities, financial loss, environmental consequences and reputational impact.

With the spillway not being reliable in the event of a MDE, the only means to control elevation in the reservoir would be to use the Alouette power tunnel and adit tunnel to allow a controlled discharge into Stave Lake. The seismic assessment indicated that in the event of a MDE, damage to a number of structures associated with the power tunnel is expected, which could result in the inoperability of the power tunnel and / or adit tunnel. As such, a decision was made to upgrade the power tunnel, and related structures, to ensure safety and reliable operation of Alouette Dam after a MDE.

Discussion of Alternatives:

Three alternatives were evaluated during the Identification Phase:

i. **Do nothing:** defer, either temporarily or permanently, the correction of the seismic deficiencies of the Alouette Dam,
ii. **Upgrade the dam spillway**, and
iii. **Upgrade the power tunnel and related structures,** to allow for water conveyance from Alouette Lake after a MDE.

Alternative iii. Upgrade the power tunnel and related structures was selected as the leading alternative to achieve the project objectives.

Project Impacts and Benefits:

- Improve safety by addressing seismic deficiencies of the power tunnel and related structures, so that this facility can be relied upon for operations post an earthquake event.
- Reduce potential financial loss, environmental consequences and reputational impact due to an uncontrolled release of water from Alouette Reservoir, in the event of a MDE.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

• Appendix I, line 15, Appendix J page 16
• BCUC IRs 1.70.3,2.249.8, 2.260.4, BCOAPO IR 1.36.1</td></tr>
<tr><td colspan="3">Description:
The purpose of this project is to improve the ability to manage water conveyance at Comox-Puntledge in a controlled and safe manner.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Reliability
• Environmental
• Financial Loss
• Reputational.</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The water passing through Puntledge Dam goes into one of two parallel watercourses:
• Generation water is conveyed through the power intake and penstock. Most of the water is conveyed through the single turbine to produce power; and
• The balance of the water overflows Puntledge Dam into a public watercourse which is heavily used for recreation, especially in summer.
Appropriate control of both watercourses is imperative for public safety, dam safety, reliable generation and downstream fish migration and habitat. Potential uncontrolled flow impacts could result in fatalities, financial loss and reputational damage.
There are a number of weaknesses within the system which could cause an upset of flow control, such as spurious gate openings or closing, or gates failing to operate on demand at the dam and penstock.
The seriousness of potential public safety issues was highlighted by a June 2002 incident in Ontario when a rarely used gate at the Barrett Chute hydroelectric dam on the Madawaska River was opened to drain off excess water, engulfing a group of sunbathers in a surge of water that swept them over a 10-metre-high cliff. Charges of criminal negligence against Ontario Power Generation and two of its employees were dismissed.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
Eight alternatives were evaluated during Identification Phase, that consisted of various combinations of the following nine “Concept Groups”:
i. Improve Support for Operational Decisions: improve the clarity and certainty in making operational decisions to avoid incidents (such as providing additional tools, training, and data collection and</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

monitoring capability to personnel on site);

ii. **Comox Sluiceway Reliability Improvements:** improve the reliability of the gate controls (such as additional protection and controls equipment and improving the current mechanical gate hoist);

iii. **Generation Conveyance Control System Upgrades:** reduce the probability of a malfunction, lack of function, or other error on the equipment and control systems from the Puntledge intake to the powerhouse (such as improvements to intake trashrack, intake operating gate, fish screen, penstock protection, turbine inlet valve, communication monitoring and control);

iv. **Provide Storage Buffer at Puntledge Diversion Dam:** attenuate the impacts of a stoppage of flow by using available storage in the low gradient Puntledge headpond (such as providing control of discharge at Puntledge Dam in real-time and strengthening the diversion);

v. **Comox Dam Safety Upgrades:** reduce the probability of unusual, very rapid flow increases due to right abutment failure (such as addressing concerns with sloughing of the right bank upstream from the sluiceway and with the robustness to resisting overtopping and piping during extreme floods),

vi. **Modify Puntledge Intake Layout:** Reduce the likelihood of flow control failures in the Puntledge intake and fish screens (such as construction of new fish bypass facilities, new intake bays and penstock work);

vii. **Puntledge Powerhouse By-pass:** Provide flow continuity around the powerhouse (such as construction of a new valve with emergency submerged discharge on the upstream side of the powerhouse);

viii. **Restrict Summer Generation:** Reduce flow control risks; and

ix. **Fully Restrict Generation:** Eliminate flow control risks.

The alternative selected is comprised of Concept Groups i, ii, iii, iv and v above. It was selected as the leading alternative because it meets the project objectives and provides the best balance of flow improvement versus cost to implement. Other combinations of concept groups including Full Restriction are either higher cost than other alternatives that provide an equal or better flow improvement benefit, or provide less flow improvement benefit than alternatives of similar cost. Concept Groups i, ii, iii, iv and v appears at a 'knee' in the cost/benefit curve - to the right of that alternative better scores for flow improvements come at a very high cost, while to the left of and below of the selected relatively small cost reductions are accompanied by relatively large reductions in the flow improvement score.

Project Impacts and Benefits:

- Improve safety by addressing uncontrolled flow at Comox-Puntledge, so that safe downstream recreation can continue.
- Reduce potential financial loss and reputational impact due to uncontrolled flow events.
- Provide long-term operability and maintainability at Comox-Puntledge, at a high level of reliability.
- Minimize environmental risk associated with uncontrolled flow impacts on upstream and downstream fish migration and habitat.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

A related project to improve the public warning sytems for this reach of the Puntledge River was recently implemented to address the unreliability and poor data quality of the Water Level Monitoring System and Public Safety Warning System at Comox-Puntledge. With the exception of the Water Level Monitoring sites at Browns River (Gauge 7), Tsolum River (Gauge 9) and Lewis Park (Gauge 10) the project was placed into service on October 27, 2017. The three final water gauge sites were placed into service on August 1, 2018.

Investment Planning ID: **G000755**	**Project Name:** **Duncan Dam Replace Spillway Gates**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** F17-F19 RRA: • Appendix I, • BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1	
Description: The purpose of this project is to conduct an updated inspection and condition assessment of the Duncan Dam spillway gates to confirm they are fit for purpose and if not provide recommendation for the long-term management of the gates		
Key Drivers: • Safety • Environmental • Financial Loss • Reputational		
Issues Being Addressed: The existing vertical lift spillway gate structures are not designed to facilitate safe maintenance. Their interiors are confined spaces, with asbestos coating and lead paint. Some of the rollers are difficult to access, and challenging to remove for repair or replacement. Due to worker safety risks, proper maintenance has not been carried out over the years, resulting in pervasive corrosion and seized rollers as revealed in recent inspections. Based on a review of the available inspection reports and records of the spillway gate condition in January 2016, Generation Operations site personnel suggested that the spillway gates should not be relied upon for operation beyond five years, unless all re-coating work is completed in accordance with the report (Hatch, 2009; Powertech, 2009) recommendations and a structural engineer confirms that the gates are structurally sound for continued operation. For this reason, it is recommended that the project carry out an updated inspection and condition assessment of the two vertical lift spillway gate structures at Duncan Dam, and to provide recommendations for the long-term management of the gates. The inability to operate the spillway gates would mean that Duncan Dam will have to rely on the two low-level gates for flood routing. Their discharge capacity is inadequate for extreme floods, during which Duncan Dam could overtop potentially resulting in fatalities, environmental impacts and reputational damage. In the event that lack of maintenance renders the spillway gates inoperable (rollers seized) and/or become vulnerable as water barrier (corroded through), the facility will be forced to operate with a much lower maximum normal reservoir level, and may not be able to conform to the Columbia River Treaty (for which Duncan Dam was built). Inability to conform to Columbia River Treaty would lead to significant reputational and financial issues.		

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives: Three alternatives are being evaluated during Identification Phase: i. **Do nothing:** defer any work on the spillway gate structures until 2028, and continue only with monitoring / inspection; ii. **Limited refurbishment** to achieve life extension of the existing gates; and iii. **Replacement** of existing gates. The project is currently in Needs Stage, and an updated inspection and condition assessment was undertaken in 2018. The report will assess the three alternatives and provide recommendations for the long-term management of the gates.	
Project Impacts and Benefits: • Improve safety with gates that are seismically resilient, capable to withstand overtopping, safe and reasonably easy to maintain, inspect and test. • Reduce potential financial loss, environmental consequences and reputational impact by improving the ability to pass water in the event of an extreme flooding even. • Reduce potential reputational impact and financial loss from inability to conform to the Columbia River Treaty, in the event of having to operate with a much lower maximum normal reservoir level.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.

<tr><td colspan="3">Description:
The purpose of this project is to address seismic deficiencies of the John Hart Dam so that this facility can be relied upon for post-earthquake operation.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Financial
• Reputational</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The John Hart Dam is classified as an Extreme consequence dam and therefore the expected seismic performance is for no uncontrolled release for the Maximum Design Earthquake (MDE). A seismic performance investigation was carried out and it was determined that the withstand of the various component dams and spillway gate system is less than the MDE. Damage from a seismic event could lead to uncontrolled release of water from the reservoir, potentially resulting in fatalities, financial loss and reputational damage. Therefore, seismic upgrades to the dam and spillway gates system are required.
In addition to the seismic-related deficiencies, there is a risk of overtopping the John Hart dam due to unplanned generation flow imbalance between John Hart and the upstream Ladore facility. A free overflow spillway is planned to address this concern.
The scope of this project includes the design and construction of the following:
• Upgrades to the Middle Earthfill dam and Power Intake Dam;
• Upgrades to the North Earthfill dam;
• Upgrades to the concrete dam, including incorporation of a free overflow spillway; and
• Upgrades to the spillway gates system.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives: Four alternatives are being evaluated: i. **Do nothing:** defer, either temporarily or permanently, the correction of the seismic deficiencies of the John Hart Dam. Could include an interim response plan such as: including availability of 24/7 electricians post-earthquake to control operation of the dam or improving instrumentation at the dam such as addition of cameras in an effort to be able to provide a more rapid evaluation of the state of the dam post-earthquake; ii. **Decommission** the dam; iii. **Permanently lower the reservoir** to reduce loading on the dam; and iv. **Upgrade** the John Hart Dam**,** to ensure: a) no uncontrolled release of reservoir following a MDE; and b) the dam suffers only minor damage such that an immediate deep or prolonged drawdown is not required to maintain post-seismic river flow control. Alternative iv. Upgrade the John Hart Dam was selected as the leading alternative as this is the only alternative that satisfies dam safety requirements. Alternative ii Decommission will not be consistent with the implementation of the John Hart Replacement Project. Alternative iii permanently lowering the reservoir elevation has economic and environmental consequences, as it reduces generation at the John Hart Generating Station due to the reduced head, and exposes the currently inundated reservoir areas. More importantly, on further investigations it was determined that reducing the reservoir elevation would not improve the seismic withstand of the Dam, and nor would it materially reduce the consequences of a Dam failure; hence, reservoir lowering does not represent an adequate response to the current condition of the Dam. The project also considers Special Direction 10.6(2) (February 3, 2012), "In deciding whether to issue a certificate to the authority under section 46 of the Act for the John Hart Generating Station Replacement Project, the commission must assume that the authority requires, in order to meet its electricity supply obligations, the 806 gigawatt hours per year of firm energy and 128 megawatts of dependable capacity that the project is capable of delivering by 2018 and continuing to deliver over the expected life of the project."
Project Impacts and Benefits: • Improve safety by addressing seismic deficiencies of the John Hart Dam so that this facility can be relied upon for post-earthquake operation. • Avoid potential financial loss and reputational impact due to an uncontrolled release of water from the reservoir, in the event of an MDE.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information: As the planning level estimate for this project is over $100 million, BC Hydro expects that BCUC approval will be required for this project. Planning is currently underway for upgrades at the upstream Strathcona and Ladore facilities (Strathcona Discharge Upgrade Project, G000525; and Ladore Spillway Seismic Upgrade Project, G000668). Planning for these two projects is being considered in conjunction with the John Hart Dam Seismic Upgrade project for the following reasons: • The projects are planned with similar and potentially overlapping construction schedules; • The projects are relatively close geographically to one another; • The projects have some similar scope elements that will require similar contractor expertise; and • The projects all reside on the Campbell River and the work will need to be considered from a river system management perspective and coordinated accordingly. The project teams will develop an Integrated Regulatory Strategy for the three projects.

<tr><td colspan="3">Key Drivers:
• Safety
• Financial
• Reputational</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Ladore Dam is classified as an Extreme consequence dam and therefore the expected seismic performance is for no uncontrolled release for the Maximum Design Earthquake (MDE). A seismic performance investigation was carried out, and it was determined that the withstand of the spillway gates and hoist structure is less than the MDE, and damage could lead to an uncontrolled release of water from the reservoir. Failure of the Ladore gates could lead to a flow imbalance at John Hart Dam, located about 1 km downstream, with potential for overtopping of the John Hart Dam, potentially resulting in fatalities, financial loss and reputational damage.
The scope of this project includes upgrades to the Ladore spillway to ensure that:
• In the event of a MDE, the spillway and water conveyance system act as an integral water barrier to retain the Ladore Reservoir;
• The spillway can release water in a controlled manner after a seismic event up to MDE; and
• Electromechanical systems that operate the spillway have an acceptable level of reliability.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

Three alternatives were evaluated during Identification Phase:

i. **Refurbishment** of gates, towers and hoists;

ii. **Replacement** of gates and **refurbishment** of towers and hoists; and

iii. **Replacement** of gates, towers and hoists.

Alternative iii Replacement of the spillway gates, towers and hoists was selected as the leading alternative. Alternative iii. is considered to be the best long term solution because it will provide a more reliable and robust design, increase the ease of maintenance and safety for BC Hydro operation staff, and reduce environmental impacts during and after construction.

Project Impacts and Benefits:

- Improve safety by addressing seismic deficiencies of the Ladore Dam, so that this facility can be relied upon for post-earthquake operation.
- Reduce potential financial loss and reputational impact due to an uncontrolled release of water from the reservoir, in the event of an MDE.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

As the planning level estimate for this project is over $100 million, BC Hydro expects that BCUC approval will be required for this project.

Planning is currently underway for upgrades at the upstream Strathcona facility and downstream John Hart facility (Strathcona Discharge Upgrade Project, G000525; and John Hart Dam Seismic Upgrade Project, G000585). Planning for these two projects is being considered in conjunction with the Ladore Spillway Seismic Upgrade project for the following reasons:

- The projects are planned with similar and potentially overlapping construction schedules;
- They are relatively close geographically to one another;
- They have some similar scope elements that will require similar contractor expertise; and
- They all reside on the Campbell River and the work will need to be considered from a river system management perspective and coordinated accordingly.

The project teams will develop an Integrated Regulatory Plan for all three projects.

<table>

<tr><td colspan="3">Description:
The purpose of this project is to provide deep reservoir drawdown capability at Strathcona Dam to mitigate dam safety risks associated with seismic events and seepage deficiencies of the dam, and to enable potential future projects to be undertaken to upgrade the dam itself.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Financial
• Reputational</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Strathcona Dam is classified as an Extreme consequence category dam and therefore the expected seismic performance is for no uncontrolled release for the Maximum Design Earthquake (MDE). Strathcona Dam has seismic and seepage deficiencies and there is no means of enacting a deep reservoir drawdown. Also, there are reliability and seismic issues with the existing gated spillway that may limit the ability to operate on demand or cause it to fail following a seismic event. In a post-seismic event, there is a potential that the intake gates may not be able to be closed, pressurizing the power intake tunnel underlying the dam, which could result in further damage to the dam or result in uncontrolled release of water. Uncontrolled water release from the reservoir could create significant risk to life and damage to downstream residents, as water would flow downstream toward the City of Campbell River, overtopping and damaging both Ladore and John Hart dams, as the Lower Campbell and John Hart reservoirs are not large enough to contain such a release. This type of event could potentially result in fatalities, financial loss and reputational damage.
The provision of a new Low Level Outlet (LLO), with a new inlet founded on a rock abutment rather than in the earth dam itself, will not only provide emergency deep drawdown of the reservoir, but will allow for future decommissioning of the current intake and water passage, which will provide further protection to the dam.
The project scope also includes conversion of the existing gated spillway to a free-crest spillway at a higher elevation. This conversion will eliminate the need to refurbish the existing spillway gates and reinforce the spillway piers. Ordinary spillway functionality will be provided by sizing the LLO to allow current spillway volumes.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

Four alternatives were evaluated during Identification Phase:

i. **Construct a LLO**;
ii. **Build a seismically robust power system:** relocation of current power conduit;
iii. **Rehabilitate existing dam**; and
iv. **Construct a new downstream dam**.

Alternative i Construct a LLO was identified as the leading alternative. It provides dam safety risk reduction at the lowest cost and with the fastest delivery. The project team determined that the LLO should be the first alternative implemented, with a power conduit and dam rehabilitation to follow as future conditions dictate. Alternative iii is not viable as a stand alone project due to the need for reservoir control during construction, but would be viable after either LLO or new powerhouse project is in place. Alternative iv is not economically justified and requires LLO prior to construction.

Project Impacts and Benefits:

- Improve safety by partially addressing seismic deficiencies of the Strathcona Dam, so that this facility can be relied upon for post-earthquake operation.
- Reduce potential financial loss and reputational impact due to an uncontrolled release of water from the reservoir in the event of an earthquake.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

As the planning level estimate for this project is over $100 million, BC Hydro expects that BCUC approval will be required for this project.

Planning is currently underway for upgrades at the downstream John Hart and Ladore facilities (John Hart Dam Seismic Upgrade Project, G000585; and Ladore Spillway Seismic Upgrade Project, G000668). Planning for these two projects is being considered in conjunction with the Strathcona Discharge Upgrade project for the following reasons:

- The projects are planned with similar and potentially overlapping construction schedules,
- The projects are relatively close geographically to one another,
- The projects have some similar scope elements that will require similar contractor expertise, and
- The projects all reside on the Campbell River and the work will need to be considered from a river system management perspective and coordinated accordingly.

The project teams will develop an Integrated Regulatory Plan for all three projects.

Investment Planning ID: **G003554**	**Project Name:** **W.A.C. Bennett Dam Recommission / Seal Spillway Sluice Gates**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** F17-F19 RRA: • Appendix I, line 23, • BCUC IRs 1.70.3, 1.85.1 to 1.85.7, 2.249.8, 2.260.4, BCOAPO IR 1.36.1	

Description:

The primary objective of the Project is to address the dam safety risks posed by the deteriorating condition of the sluice gates on the spillway of the W.A.C. Bennett Dam, including considering rehabilitating or decommissioning some or all of the sluice gates.

Key Drivers:

- Safety
- Financial Loss
- Reputational

Issues Being Addressed:

At the time the W.A.C. Bennett Dam was built, there were two intended functions of the sluiceways and slide gates:

i. The spillway, including the contribution from the sluiceways, was designed for a maximum flood level capacity of 325,000 cubic feet per second (**cfs**), including flood inflows from the McGregor River Diversion. The McGregor River Diversion was not constructed and is prohibited under the Clean Energy Act passed in 2010. Without the McGregor River Diversion, the sluiceways are not needed to pass the design flood;

ii. The slide gates were designed to provide compensation flow release during and after the reservoir filling period, and were apparently included in the design to relieve the low level outlets from operation as early as practical. Once the reservoir reached the elevation where the spillway gates could provide the minimum flow release, this back-up role was transferred to the spillway gates.

All nine slide gates have been inoperable since 1987 after issues with opening the gates were experienced as well as leakage after closure. Subsequent inspections have revealed further deterioration of components of the slide gates.

The slide gate bonnet covers are in Poor condition. There is a risk that one or more of the bonnet covers may fail, which would result in uncontrolled water release from the slide gate gallery to the drainage tunnels running below the earth filled dam. The drainage tunnels connect to both the powerhouse and the low level outlets, are generally unlined and are only intended to handle drainage and provide access.

Leakage or failure of one or more of the slide gates would also result in uncontrolled water release to the spillway chute, which may prevent inspection, repair and maintenance of the spillway chute, and ultimately may impair flood discharge capability.

Single device isolation (**SDI**) certification of all nine slide gates is required to access the spillway chute for inspection and maintenance. Continued SDI certification in the longer term will become more difficult and eventually will require refurbishment or replacement of the slide gates or decommissioning the gates to eliminate the hazard.

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

Three alternatives were evaluated during Identification Phase:

i. **Do nothing:** the condition and leakage on the slide gates and bonnet covers will continue to be monitored. Decommissioning of the sluiceways or refurbishment (or replacement) of the slide gates and bonnet covers deferred into the future;

ii. **Decommission** nine sluiceways**.** The sluiceways will be plugged with reinforced concrete downstream of the slide gates and the slide gate gallery will be partially filled with reinforced concrete, embedding the slide gate hydraulic cylinder assembly and bonnet covers;

iii. **Rehabilitate** six sluiceways. This alternative recommissions two of the three sluiceways in each of the three spillway bays. For the sluiceways to be recommissioned, the slide gates and hydraulic cylinders will be refurbished or replaced, the slide gate control cabinet will be replaced, and the downstream surfaces of the sluiceways will be repaired. The remaining sluiceways will be permanently decommissioned with a reinforced concrete plug upstream of the slide gate.

Alternative ii, Decommission nine sluiceways, was selected as the leading alternative because it addresses dam safety risks, minimizes capital expenditure, and avoids future inspection, operation and maintenance efforts.

Project Impacts and Benefits:

- Improve safety by addressing deteriorating condition of the sluiceways and slide gates.
- Reduce potential financial loss and reputational impact due to an uncontrolled release of water from the reservoir.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

There are two concurrent projects that may be impacted by this project:

- W.A.C. Bennett Dam Seal Low Level Outlets (G003555)

  This project will decommission the low level outlets under the W.A.C. Bennett Dam. The work will likely involve backfilling by concrete plugs and removing equipment. The project is currently in the Conceptual Design Stage. The targeted project in-service date is January 2024. While resource and laydown conflicts are not anticipated, the projects will coordinate to ensure that any overlaps in construction timing are managed effectively.

- W.A.C. Bennett Dam Spillway Gate Upgrade (G000656)

  This project is implementing upgrades to the spillway operating gates, which are located in the same spillway headworks structure as the sluiceways and slide gates. The “Recommission / Seal Spillway Sluice Gates (G003554)” project team has therefore scheduled its Feasibility field investigations to avoid interfering with spillway operating gate construction planned for F2020, and will coordinate all investigations through the Construction and Contract Management team.

Investment Planning ID: G003555	**Project Name:** GMS Seal Low Level Outlets	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** F17-F19 RRA: • Appendix I, line 24, Appendix J, page 18, • BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1	

Description:

The purpose of this project is to safely decommission the three low level outlets under the W.A.C. Bennett Dam to mitigate the hazard (uncontrolled water release from the reservoir) posed by long-term deterioration of the low level outlets.

Key Drivers:

- Safety
- Financial Loss
- Reputational

Issues Being Addressed:

Three low level outlets (**LLOs**) are located beneath the embankment dam, in rock, in the diversion tunnels that were used to divert Peace River during dam construction. The inlets to the tunnels are located at a depth of about 160 m below the surface of the maximum normal operating level of Williston Reservoir. The LLOs were designed as temporary discharge devices for use during first filling and were not intended for use as discharge devices at normal reservoir operating levels. The LLOs are currently out-of-service and regular testing and inspections are not carried out due to worker safety concerns. The condition of these assets, almost 50-years old, is deteriorating, making them a potential hazard to the dam. An uncontrolled release of water due to component structural failures would eventually result in damage to the dam if the flow was not shut off. Such a release would be very difficult to curtail given the high head and depth of the LLOs.

Discussion of Alternatives:

Four alternatives were evaluated prior to the start of this project, as part of a long term strategy for the future role of the LLOs in the operation of the W.A.C. Bennett Dam:

i. **Do Nothing:** maintain the status quo or deferral;
ii. **Refurbishment** of the existing LLOs for flow release as currently designed;
iii. **Re-purposing** the LLOs for reservoir evacuation capability or for installation of additional generating units; and
iv. **Decommissioning** (either permanently or with the option to re-open the LLOs at some time in the future).

Alternative iv, decommissioning, was selected as the only viable alternative. Do Nothing is not considered an acceptable response given the age of the LLOs and their deteriorated condition which would eventually lead to a component failure and uncontrolled release of the reservoir behind an Extreme Consequence dam. No future operating scenario was identified that warrants the refurbishment of the existing LLOs for flow release as currently designed. Based on an engineering study, the technical feasibility of the re-purposing option is uncertain and near term project drivers and/or benefits were not identified.

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits:

- Reduce safety risks by decommissioning the LLOs.
- Reduce potential financial loss and reputational impact due to an uncontrolled release of water from Williston Reservoir.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

There are two concurrent projects that may be impacted by this project:

- W.A.C. Bennett Dam Recommission / Seal Spillway Sluice Gates (G003554):

  This project will address the dam safety risks posed by the deteriorating condition of the sluiceways and slide gates on the spillway of the W.A.C. Bennett Dam. The project is currently in the Conceptual Design Stage. The targeted project in-service date is November 2022. While resource and laydown conflicts are not anticipated, the projects will coordinate to ensure that any overlaps in construction timing are managed effectively; and
- W.A.C. Bennett Dam Spillway Gate Upgrade (G000656):

  This project is implementing upgrades to the spillway operating gates, which are located in the same spillway headworks structure as the sluiceways and slide gates. The “Recommission / Seal Spillway Sluice Gates (G003554)” project team has therefore scheduled its Feasibility field investigations to avoid interfering with spillway operating gate construction planned for fiscal 2020, and will coordinate all investigations through the Construction and Contract Management team.

Investment Planning ID: G000556	**Project Name:** Hugh Keenleyside - Spillway and Low Level Outlets Concrete Upgrade	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Future	**Filing Reference:** New	

Description:

The objective of this project is to upgrade the damaged concrete structures of the Hugh Keenleyside Dam's spillway and low level outlets, restoring them to original or near-original condition. This upgrade will extend these structures' service lives and permit a wider range of operational options relating to the passage of water over and through the dam.

Refer to Appendix K – Hugh Keenleyside Facility Asset Plan for additional information.

Key Drivers:

- Financial
- Reliability

Issues Being Addressed:

- Since the dam was put into operation in 1968, there has been localized loss of concrete to the spillway and low level outlets due to erosion, abrasion and cavitation. Reinforcing bars are exposed in a number of locations. Low Level Outlets 1 and 4 have sustained the largest amount of damage and are close to the point of being taken out of service.
- Due to loss of concrete in some locations, rates of damage progression are unpredictable, and there is the potential need for a portion of the spillway or low level outlet to be taken out-of-service with little or no advance notice. In this event, immediate repairs implemented under urgent or emergency conditions would be required.
- With the benefit of modern numerical hydraulic modelling, we have implemented operational changes that restrict use of the low level outlets which are expected to slow (but not stop) the progression of damage. The operational changes, however, have reduced operational flexibility in passing flows.
- Maintenance and repairs to the concrete have been carried out over the years, but with limited success. Due to the progression of damage, the required frequency, extent, and cost of repairs (largely underwater) is expected to grow with diminishing effectiveness.

Discussion of Alternatives:

- The option of retaining the status quo and continuing to operate and maintain the spillway and low level outlets as at present is not sustainable, as:
  - Repairs are expected to become increasingly expensive and decreasingly effective over time;
  - These structures comprise a critical safety feature of the dam and cannot be run to failure; and
  - The point in time at which these structures will no longer be fit for safe use cannot be predicted.
- Owing to Hugh Keenleyside Dam's importance to the Columbia River system and its role under the terms of the Columbia River Treaty, decommissioning of the dam or temporarily taking it out of service from a water storage perspective is not viable.

The single remaining viable alternative is to upgrade the concrete structures of the spillway and low level outlets by replacing the damaged portions of reinforced concrete, restoring their condition to as close to "new" as possible. This upgrade is required before the damage progresses to the point where the low level outlets and/or the spillway must be taken out-of-service. The upgrade will require either underwater work or the construction of temporary cofferdams to allow construction "in the dry".

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits:

- Extended life of the spillway and low level outlet structures.
- Reduction of anticipated maintenance costs and outages.
- Elimination of concerns that a sudden progression of damage will force some or all of these discharge facilities to be taken out of service, requiring even more costly interventions under urgent or emergency conditions.
- Increased flexibility of operations to pass flows that preserve the integrity and service life of the structure while mitigating environmental impacts.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

Operations at Hugh Keenleyside Dam have international impacts on flow regulation, power generation and flood control under the terms of the Columbia River Treaty.

Investment Planning ID: G003365	**Project Name:** Mica - Discharge Facilities Seismic and Reliability Upgrades	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Future	**Filing Reference:** New	

Description:

Mica Dam discharge facilities include both a three-gated spillway and a two-gated outlet works. The objective of this project is to upgrade these discharge facilities to provide for continued safe containment of the reservoir during an earthquake, safe discharge of water from the reservoir after such an earthquake, and sufficiently reliable operation for all other service conditions, including during periods of high inflows up to extreme floods.

Refer to Appendix K – Mica Facility Asset Plan for additional information.

Key Drivers:

- Safety
- Reliability

Issues Being Addressed:

- The design earthquake has been updated since the dam's design and construction and demands from the current design earthquake exceeds the original design capacities. Seismic deficiencies have been identified in various spillway and outlet works structures. Moreover, the gates' mechanical, electrical, control and power supply equipment has not been seismically qualified and cannot be relied upon to operate after an earthquake. Inability to safely operate the discharge facilities after an earthquake:
  - Would preclude a drawdown of the reservoir for dam inspections, repairs or other emergency measures; and
  - Could lead to eventual overtopping of the earthfill dam, resulting in erosion and possible dam failure.

  The discharge facilities require a general and extensive seismic upgrade in order that their post-earthquake operability can be relied upon.
- The discharge gates at Mica Dam do not have sufficient reliability to sufficiently ensure operability when needed during periods of high inflows and reservoir levels, such as during freshet and floods. Failure of the discharge facilities to operate during or after floods could lead to eventual overtopping of the earthfill dam, resulting in erosion and possible dam failure. Operational reliability improvements to the gate systems in accordance with current BC Hydro principles—including mechanical, electrical, control and power supply sub-systems—are required in order that they can be relied upon to operate when needed.

Discussion of Alternatives:

Given the safety and reliability issues identified and the extreme consequences of a failure at Mica Dam, long-term retention of the status quo is not acceptable. The only viable alternative is to upgrade the deficient components to meet the current seismic and operational reliability requirements. Specific scope items will be determined in the project's Identification Phase.

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits: • Assured reservoir containment up to and including extreme earthquakes and provision of safe and reliable post-earthquake discharge and drawdown capability to allow for dam inspection, repairs and other emergency measures, as required. • Increased operational reliability to reasonably assure discharge function and prevent dam overtopping during high inflows up to and including extreme flood events.	
Project Implementation Phase Risk: This project is not yet in Implementation.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: Mica Dam provides flow regulation, power generation and flood control under the terms of the Columbia River Treaty.

<tr><td colspan="3">Description:
The purpose of this project is to restore the reliability of the Unit 5 and 6 generators and other related equipment, and to restore lost water conveyance capacity within the Bridge River system.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Environmental
• Reputational</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Issues Being Addressed:

The primary drivers for this project are the lost capacity, unacceptable condition and unreliability of the Bridge River 2 Generating Units 5 and 6.

The Generating Station is in Poor condition. The Equipment Health Rating of the generators is Unsatisfactory. Both generators have been de-rated by 32 per cent due to multiple winding insulation failures. There is a high risk of further winding failures, which would result in an unplanned unit outage of up to 18 months.

The Equipment Health Rating of the governors is Poor due to their condition, life expectancy, high rate of oil leakage in the distributing valve, and lack of spare parts. Similarly, the unit circuit breakers are rated Poor due to significant wear, lack of spare parts, and declining technical support. The exciters are also rated Poor due to degradation, age and difficulty in obtaining technical support.

The operating regime for both Bridge River 1 and 2 has been impacted by a Dam Safety requirement from February 2015 to lower the maximum elevation of the upstream Downton Reservoir to manage LaJoie Dam seismic safety risks. This change in operations means there is 50 per cent less storage in Downton Reservoir, resulting in increased seasonal inflow to Carpenter Reservoir. Reduced capability to divert water from Carpenter Reservoir to Seton Lake, via the Bridge River generating stations, has increased the likelihood and magnitude of spills from Terzaghi Dam to the Lower Bridge River beyond the Water Use Plan Order (**WUP Order**) targets for annual average flows and those same targets set forth in settlement agreements with the St'át'imc Nation. BC Hydro has been, and currently is, operating under a variance to our Water Use Plan order, approved by the Comptroller of Water rights (February 16, 2017).

Discussion of Alternatives:

Alternatives evaluated during Identification phase:

i. **Do nothing:** Replace components as they fail;

ii. **Minimum refurbishment:** Replace the stator winding, stator core and rotor pole insulation; no uprate of the generators would be achieved. Other equipment required for reliable operation (e.g., governors, circuit breakers, exciters) would also be replaced;

iii. **Refurbish the generators with increased capacity:** Replace most generator components (e.g., stator frame, winding, cores; and rotor insulation, poles, winding) and reuse other generator components (e.g., rotor rim, spider, shaft). Other equipment required for reliable operation would also be replaced (similar to minimum refurbishment); and

iv. **Replace the generators with increased capacity:** Replace all stator and rotor components. Other equipment required for reliable operation would also be replaced (similar to minimum refurbishment).

Alternative iv Replace the generators with increased (historical) capacity (75 MW) was selected as the preferred alternative as it provides a long-term (50 years) improvement to generator reliability, improves water management on the Bridge and Seton Rivers, restores the units historical operating capacity, and is the lowest risk from a construction and future operating perspective.

Project Impacts and Benefits:

- Improve reliability of Bridge River 2 Units 5 & 6.
- Extend the service life of the main generator components by at least 50 years.
- Improve the operating capability at Bridge River 2 Units 5 & 6 from a total of 96 MW to a total of 150 MW (75 MW per unit).
- Provide reliable water conveyance capacity within the Bridge River system.
- Reduce the likelihood and magnitude of spills from Terzaghi Dam to Lower Bridge River, in order to minimize potential effects on fish, riparian habitat, and First Nations values.
- Maintain BC Hydro's relationship with the St'at'imc Nation.
- Reduce potential reputational impact due to spill events.

Project Implementation Phase Risk;	**Risk Treatment;**
If the completion of the Units is significantly delayed into 2019, there is a risk of increased spilling in the Lower Bridge River.	• Drawdown reservoirs prior to the outage. • BC Hydro will continue to engage St'át'imc regarding project status and potential impact on flows. • Monitor progress of construction and accelerate if needed.
Additional Information: The project will be constructed considering the planned outages for Bridge River 2 maintenance and other projects. The Bridge River System lies within the traditional territory of the St'át'imc Nation. BC Hydro and St'át'imc have a set of Agreements (signed in 2011) that settle all past, present and future claims related to the Bridge River facilities and provide legal certainty around continued operations of the Bridge River facilities and inform ongoing relationship development. BC Hydro is engaging the St'át'imc Nation in a manner consistent with our Agreements and continues to work with the St'át'imc to address issues and concerns around this project.

<tr><td colspan="3">Description:
The purpose of this project is to replace the two generators at Cheakamus which are in Poor condition. The project will also result in an increase in operating capacity from 70 MW to 90 MW for each unit.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Issues Being Addressed: Inspection and testing of one of the generators in 2006 identified three areas of concern: stator core waves, hot spots and sole plate cracking. The two generators were assigned a Poor Equipment Health Rating in 2012 and 2013. Some of the issues which adversely affect the health rating include high stator winding insulation leakage current, deterioration of the stator and rotor insulation, stator core waves, and bearing oil leaks. A failure of a stator winding would likely result in an unplanned unit outage of up to 18 months and lost opportunity costs.	
Discussion of Alternatives: Three alternatives were evaluated during Identification phase: i. **Do nothing:** replace the stator winding, stator core and rotor pole insulation at failure; ii. **Refurbish** the generators via replacement of the stator core, stator winding and rotor pole insulation; no uprate of the generators would be achieved; and iii. **Replace** the generators with increased capacity. Replacing the generators with increased capacity was selected as the preferred alternative based on a net present value analysis and is being implemented.	
Project Impacts and Benefits: • Improve reliability of the generators. • Increase operating capacity from 70 MW to 90 MW for each unit.	
Project Implementation Phase Risk: This project currently does not have any identified Zone 3 (high) Implementation Phase risks.	**Risk Treatment:** N/A
Additional Information: N/A

• BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1</td></tr>
<tr><td colspan="3">Description:
This purpose of this project is to modernize Units 1 to 10 control systems, replace Units 6 to 10 governor control systems, replace Units 9 and 10 exciters, replace the controls for plant auxiliary systems, and replace the control room controls at G.M. Shrum Generating Facility (GMS).</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The GMS Units 6 to 8 governors have an Equipment Health Rating (EHR) of Poor due to the tendency of the analog controls to drift out of calibration, limited technical support, governor frequency control being out of specification during standardized tests, and limited availability of spare parts. The Unit 9 analog governor has an EHR of Poor due to the forced outages attributed to the governor, limited technical support and limited spare parts availability. The Unit 10 analog governor, which is from the same manufacturer as Unit 9, has an EHR of Fair.
The GMS Units 9 and 10 Westinghouse Rapcon exciters have analog controls and are based on obsolete technology. Unit 9 has an EHR of Fair, and Unit 10 has an EHR of Poor. Concerns include component failures, limited availability of spare parts, and limited technical support.
Concerns on all the equipment to be replaced include lack of vendor support due to system age, limited or no availability of spare parts, units drifting off settings due to control deficiencies, and unit outages caused by component failure or misoperation.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
The GMS Controls Upgrade Project Team considered three alternatives:
i. Full-scope,
ii. Controls-only scope, and
iii. Deferral.- continue to operate GMS (and Peace Canyon Generating Facility) in their current condition
Alternative i. Full-scope was selected because it minimizes the total outage time and avoids the need to design and implement interfaces between new and old technology. The project was broken into three identified tranches of work, with a separate approval for each tranche.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date for all Tranches of this project.

- Tranche 1: Units 1 to 5 controls and plant Local Area Network (completed);
- Tranche 2: Units 6 to 10 controls, Units 6 to 10 governor controls, and Units 9 to10 exciters (in Implementation); and
- Tranche 3: Spillway, switchyard and intake controls, and GM Shrum control room (in Implementation).

This approach allows lessons learned on earlier tranches to be adopted in subsequent tranches. More importantly, each tranche will be estimated and scheduled shortly before it enters Implementation Phase, based on current supplier and market understanding, and avoids a commitment to cost and schedule targets over a decade in the future.

It was recognized that due to the long duration of the project, control improvements could be available during the course of the project. BC Hydro has implemented a strategy of evaluating the benefits of any changes in controls, and if warranted, adopts a new control approach both prospectively and retrospectively, updating completed work to match any newly adopted designs. This strategy balances the advantages of new or improved technology with the benefits of standardization across all units in the plant.

Project Impacts and Benefits:

- Allows both local and remote operation of both GMS and the Peace Canyon generating stations.
- Governors on Units 6 to10 and exciters on Units 9 to10 will be new, improving availability of both spares and vendor support.
- New controls and control room will improve the operators' situational awareness and ability to respond to problems.

Project Implementation Phase Risk:	**Risk Treatment:**
There is a risk that the equipment currently deployed by the Generating Operational Asset Architecture Logic (**GOAAL**) standard will not provide the functionality to support the required plant control room alarm management features	This is being avoided by evaluating commercially available Supervisory Control and Data Acquisition (**SCADA**) control packages for the new plant control room design with the intention of including this alarm management capability in the GOAAL standard

• BCOAPO IR 1.36.1</td></tr>
<tr><td colspan="3">Description:
The purpose of this project is to replace twelve single-phase generating unit transformers at the Mica Generating facility with explosion-resistant transformers for safe and reliable operation.</td></tr>
<tr><td colspan="3">Key Drivers:
• Safety
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
Twelve single-phase transformers connect the Unit 1 to 4 Mica generators to the transmission network by stepping up the generator output voltage of 16 kV to transmission voltage of 500 kV. The reliability and safety risks associated with these transformers are increasing as the assets age and degrade.
The Equipment Health Rating (EHR) of 10 of the transformers is Poor. After nearly 40 years of service, several of the transformers are showing signs of overheating while others have indications of insulation degradation. The Mica transformers are located in an underground powerhouse, and a failure presents a safety risk for people working in the underground powerhouse in addition to the reliability risks associated a forced outage.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
Three alternatives were considered during Identification Phase:
i. Do nothing: replace transformers at failure;
ii. Refurbishment and partial replacement; and
iii. Replace with new single phase explosion-resistant transformers.
Alternative iii. Replace with new single phase explosion-resistant transformers was recommended as the preferred alternative for the following reasons:
• The Mica Units 5 and 6 Project and Mica GIS Replacement Project have already evaluated the risks associated with working near live oil filled transformers in the underground facility at Mica. This work resulted in the selection of an explosion-resistant transformer design for the new Mica Units 5 and 6;
• Full replacement of the Mica 1 to 4 generator step up transformers is the only technically feasible alternative that met the project objectives; and
• BC Hydro has recently awarded a Master Supply Agreement (MSA) to a vendor for the supply of transformers. This project will be able to take advantage of this MSA as it includes the specifications for explosion-resistant transformers.</td></tr>
<tr><td colspan="3">Project Impacts and Benefits:
• Improve transformer reliability.
• Reduce safety risk.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	**Risk Treatment:**
Due to the age of the old transformers, and the work taking place underground while some other units are operating and energized, there is a risk of serious worker injury or fatality in the event of a transformer explosion in the underground chamber.	To mitigate this risk, the project will develop a Safety Plan (conforming with BC Hydro's Contractor Safety Program) and utilize the procedures, knowledge and experience gained from the Mica GIS and Mica 5 and 6 projects as both of these projects performed work in the transformer chamber with energized transformers.
Additional Information:

<tr><td colspan="3">Description:
The purpose of this project is to address the expected housing shortage at Mica Creek and to provide a long-term accommodation solution to support future capital projects housing needs.</td></tr>
<tr><td colspan="3">Key Drivers:
• Financial</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Mica facility is in a remote location, approximately 130 km north of the town of Revelstoke. The Mica Townsite, owned by BC Hydro, consists of a number of permanent buildings for staff accommodation and recreation. The buildings were originally built in the 1960s, and house approximately 50 staff who maintain and operate the plant on an on-going basis.
Additionally, in 2011, a temporary construction camp was built and leased to BC Hydro at the townsite to accommodate up to 400 temporary additional staff working on large capital projects at the Mica facility. The construction camp was scheduled to be removed in 2015 after completing the installation of Units 5 and 6 at Mica. However, with the timing of current and planned capital projects at Mica, there is a need to modify and extend the life of the camp to accommodate project related staff over the next 10 to 15 years.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
Three alternatives were evaluated during Identification phase:
i. Purchase portions of the temporary Mica 5 and 6 dormitory units and the camp kitchen/dining area and renovate them. (This renovated kitchen and dining area is separate from the current main Townsite kitchen and dining area used by existing plant personnel);
ii. Purchase portions of the temporary Mica 5 and 6 dormitory units and renovate them; and expand the existing Townsite kitchen and dining area to accommodate these additional users, for a single kitchen/dining solution; and
iii. Build new accommodation units and expand the existing Townsite kitchen and dining area to accommodate these additional users, for a single kitchen/dining solution.
Alternative ii, Purchase portions of the temporary Mica 5 and 6 dormitory units and renovate them, and expand the existing Townsite kitchen and dining area, was recommended as the preferred alternative as it was the lowest cost alternative and provided a single kitchen solution that re-uses existing dormitory units.</td></tr>
<tr><td colspan="3">Project Impacts and Benefits:
• Deliver long-term solution to accommodation shortage at Mica Creek.
• Support long-term strategy of a consolidated Townsite.</td></tr>
<tr><td>Project Implementation Phase Risk:
This project currently does not have any identified Zone 3 (high) Implementation Phase risks</td><td colspan="2">Risk Treatment:

• BCOAPO IR 1.36.1</td></tr>
<tr><td colspan="3">Description:
The purpose of this project is to upgrade the main powerhouse cranes at the Mica Generating Facility to lift a generator rotor.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The primary drivers for the Project are: 1) the age and poor condition of the existing cranes and runway support structures; and 2) the requirement for two powerhouse cranes, each with a rated load capacity of 525 tons, to lift a generator rotor. Currently, the existing powerhouse cranes have been de-rated to a load capacity of 315 tons each and are inadequate for lifting a generator rotor.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
The following three alternatives were assessed in Identification Phase:
i. Install only the cranes;
ii. Install the cranes and perform runway structure upgrades; and
iii. Do nothing or defer the Project.
Alternative ii, Install the cranes and perform runway structure upgrades, was selected as the preferred alternative as it was the only alternative that would meet the maximum lifting load requirements in the Mica powerhouse.
The new cranes will reduce the risk of control system failure caused by overheating, fire and age related degradation of components. The existing electrical and control systems on the Mica powerhouse cranes are original from when the cranes were installed in 1974 and have reached end of life. As well, safety will be improved with the new cranes as they have braking redundancy, variable speed control and tandem lift synchronization.</td></tr>
<tr><td colspan="3">Project Impacts and Benefits:
This Project will increase the lifting capacity of the powerhouse cranes to 525 tons which will enable the powerhouse cranes to meet the maximum lifting load capacity requirements at Mica. The new crane and runway upgrade are expected to significantly reduce the outage duration if there is a rotor failure.</td></tr>
<tr><td>Project Implementation Phase Risk:

N/A</td></tr>
<tr><td colspan="3">Additional Information:
N/A</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: **G000057**	**Project Name:** **Cheakamus Recoat Units 1 and 2 Penstocks (Interior and Exterior)**	
Forecast Capital Cost: $45.4 million to $25.7 million	**Forecast In-Service Date:** Fiscal 2023	Start Date of Construction:[1] TBD
Development Phase: Definition	**Filing Reference:** BC Hydro's F2014 Annual Report to the BCUC: • Attachment to Section 8 – Part 2 Appendix I, line 120 Appendix J, page 4 F2017-F2019 RRA: • Appendix I, Appendix J page 30, • BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1	

Description:

The purpose of this project is to strip the old failed coatings on the exterior and interior steel surfaces of Cheakamus penstocks 1 and 2, and steel lined tunnel, and recoat them with a new coating system to prevent further corrosion, and extend the life of the penstocks and tunnel.

Key Drivers:

- Reliability
- Safety
- Financial

Issues Being Addressed:

The protective coatings on the exterior and interior of the Cheakamus steel penstocks and steel tunnel liner are exhibiting signs of coating failure. The Equipment Health Rating (**EHR**) is rated as Unsatisfactory.

Without recoating, the extent of corrosion will increase to the the point where recoating is no longer an option and a penstock replacement is required. Over time, continued corrosion will impact the structural integrity of the steel material, impacting the penstock's ability to reliably and safely convey water to the Cheakamus generating units.

Discussion of Alternatives:

The following alternatives were considered in Identification phase:

i. **Do Nothing and Monitor**;
ii. **Strip and Recoat Exterior Surface of Steel Penstocks**;
iii. **Strip and Recoat Exterior and Interior Surfaces of Steel Penstocks**; and
iv. **Complete Replacement of Steel Penstocks**.

Alternative iii. Strip and Recoat Exterior and Interior Surfaces of Steel Penstocks was selected as the preferred alternative as it would address safety and reliability objectives, and extend the penstock life. Alternative i (Do Nothing) or Alternative ii (Strip and Recoat Exterior Penstock Surfaces) would not deliver a significant overall penstock life extension because corrosion of the uncoated and unprotected steel penstock sections would not be achieved. Loss of steel would persist, potentially undermining the structural integrity of the penstock, which are considered high pressure vessels conveying significant volumes of water and are key water passage components used for generation. Penstock failures may cause extensive economic and infrastructure damage.

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits: • Improve equipment reliability and safety. • Extend asset (penstock and steel tunnel) life.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: Cost savings due to reduced mobilization and de-mobilization are expected to be realized by recoating all exterior and interior surfaces as part of one project.

• BCUC IRs 1.70.3. 2.249.8, 2.260.4, BCOAPO IR 1.36.1</td></tr>
</table>

Description:

The purpose of the G.M. Shrum (**GMS**) Upgrade Heating Ventilation and Air Conditioning (**HVAC**) System project is to address the degrading condition of the HVAC system at the G.M. Shrum Generating Facility.

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

The project will address the reliability risk of forced unit outages due to HVAC system failures. Recent forced outage reports have indicated that heating systems in the Circuit Breaker Buildings may be a contributing cause to improper operation of the unit circuit breakers. In addition, the cooling coils and related piping for the Low Voltage Lead Shaft powerhouse supply fans are nearing end of life and have been a source of water leaks. Although the HVAC system is classified as an ancillary system, it has impacts to the reliable and safe operation of units at the GMS Generating Facility.

Discussion of Alternatives:

Three alternatives were considered during Identification phase:

i. **Limited Refurbishment** of HVAC System,
ii. **Modernization** of HVAC System, and
iii. **Modernization and Selected Upgrades** of HVAC system.

Alternative iii Modernization (like for like modern equivalent replacements) and Selected Upgrades (upgrade to improve performance of certain components) of the HVAC System was selected as the preferred alternative as it will meet the project objectives of improving reliability, and reducing worker safety risks.

Project Impacts and Benefits:

- Improve reliability by reducing forced outages
- Reduce worker safety risks

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when project reaches Implementation.

Additional Information:

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: G000241	Project Name: Puntledge Recoat Interior and Exterior of Steel Penstock	
Forecast Capital Cost: $55.9 million to $31.7 million	**Forecast In-Service Date:** Fiscal 2022	**Start Date of Construction:**[1] TBD
Development Phase: Definition	**Filing Reference:** BC Hydro's F2014 Annual Report to the BCUC: • Attachment to Section 8 – Part 2 Appendix I, Appendix J, page 26 F19-F19 RRA: • Appendix I, line 59, Appendix J page 33, • BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1	

Description:

The purpose of this project is to address safety and reliability risks associated with the Puntledge Generating Station penstock, and achieve an asset life extension through a strip and recoat intervention.

Key Drivers:

- Reliability
- Safety
- Financial

Issues Being Addressed:

The penstock at the Puntledge Generating Station has been in-service since 1954. The long steel penstock sections are exhibiting signs of coating failure. The Equipment Health Rating (**EHR**) for the long steel sections of the penstock is Unsatisfactory.

Without recoating, the extent of corrosion damage will increase and, over time will impact the structural integrity of the steel material to the point where recoating is no longer an option and a penstock replacement is required. Continued corrosion may require the penstock to be removed from service when it is no longer safe to operate.

Discussion of Alternatives:

The following alternatives were considered in the Identification phase:

i. **Do Nothing and Monitor**;
ii. **Strip and Recoat Only Exterior Surface of Steel Penstocks**;
iii. **Strip and Recoat Exterior and Interior Surfaces of Steel Penstocks**; and
iv. **Complete Replacement of Penstocks**.

Alternative iii Strip and Recoat Exterior and Interior Surfaces of Steel Penstocks is the preferred alternative. It would address safety and reliability objectives, and extend the penstock life. Alternative i (Do Nothing) or Alternative ii (Strip and Recoat Exterior Penstock Surfaces) would not deliver a significant overall penstock life extension because corrosion of the uncoated and unprotected steel penstock sections would not be achieved. Loss of steel would persist, potentially undermining the structural integrity of the penstock, which are considered high pressure vessels conveying significant volumes of water and are key water passage components used for generation. Penstock failures may cause extensive economic and infrastructure damage.

• BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1</td></tr>
</table>

Description:

The purpose of this project is to address safety and reliability risks associated with the Wahleach Generation Facility (**WAH**) penstock and achieve an asset life extension through a strip and recoat intervention.

Key Drivers:

- Reliability
- Safety
- Financial

Issues Being Addressed:

The original WAH steel penstock sections are over 60 years old. The steel sections of the penstocks are exhibiting signs of coating failure. The Equipment Health Rating (**EHR**) for the steel sections of the penstock is rated as Unsatisfactory.

Without recoating, the extent of corrosion damage will increase to the point where recoating is no longer an option and a penstock replacement is required. Continued corrosion may also eventually impact the structural integrity of the steel material. Safe and reliabile operation is important, as the WAH facility is close to key infrastructure, including railway lines, pipelines and the Trans-Canada Highway, which could be impacted by a penstock failure.

Discussion of Alternatives:

The following alternatives were considered in Identification Phase:

i. **Do Nothing** and Monitor,
ii. **Strip and Recoat Only Exterior** Surface of Steel Penstocks,
iii. **Strip and Recoat Exterior and Interior** Surfaces of Steel Penstocks, and
iv. **Complete Replacement** of Penstocks**.**

Alternative iii, Strip and Recoat the Exterior and Interior Surfaces Steel Penstocks, was selected as the preferred alternative as it would address safety and reliability objectives and extend the penstock life by up to 20 years at a lower cost than the Complete Replacement alternative. Alternative i (Do Nothing) or Alternative ii (Strip and Recoat Exterior Penstock Surfaces) would not deliver a significant overall penstock life extension because corrosion of the uncoated and unprotected steel penstock sections would not be achieved. Loss of steel would persist, potentially undermining the structural integrity of the penstock, which are considered high pressure vessels conveying significant volumes of water and are key water passage components used for generation. Penstock failures may cause extensive economic and infrastructure damage.

Project Impacts and Benefits:

- Improve equipment reliability and safety
- Extend penstock life

---

1 Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: G000485	**Project Name:** Bridge River 1 - Strip and Recoat Penstocks 1-4 Interior	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** New	

Description:

The purpose of this project is to ensure safe and reliable operation of the four steel penstocks at the Bridge River 1 Generating Facility for another 40 years by addressing the active corrosion of the interior which is resulting in loss of metal thickness and strength.

Key Drivers:

- Reliability
- Safety
- Financial

Issues Being Addressed:

The internal coating system on all four penstocks at Bridge River 1 (**BR1**) is failing with significant defects throughout the coated surface. The Equipment Health Rating for the penstocks is Unsatisfactory and they are showing signs of coating failure and corrosion. Stripping and recoating the penstocks will extend their useful life.

If no action is taken, the interior penstock surfaces will corrode. Over time, this will undermine the structural integrity and safety of the penstocks. The penstocks would then need to be replaced when they are no longer safe to operate.

Discussion of Alternatives:

Three alternatives will be evaluated during Identification Phase:

i. **Do nothing:** monitor the corrosion and replace penstocks when no longer safe to operate,
ii. **Defer project** until the next outage opportunity, and
iii. **Strip and recoat penstock interior during a planned outage.**

Project Impacts and Benefits:

- Reduce financial loss by carrying out essential stripping and recoating work during an already planned outage.
- Improve safety by addressing deteriorating condition of the penstocks.
- Reduce potential financial loss due to an uncontrolled release of water from the reservoir.

Project Implementation Phase Risk	**Risk Treatment**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

To minimize lost opportunity costs associated with a long unit outage, it would be beneficial to coordinate with the planned unit refurbishment outage windows for the generator upgrade planned from fiscal 2022 to fiscal 2025.

The Bridge River System lies within the traditional territory of the St’át’imc Nation. BC Hydro and St’át’imc have a set of Agreements (signed in 2011) that settle all past, present and future claims related to the Bridge River facilities and provide legal certainty around continued operations of the Bridge River facilities and inform ongoing relationship development. BC Hydro is engaging the St’át’imc Nation in a manner consistent with our Agreements and continues to work with the St’át’imc to address issues and concerns around this project.

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: **G000776**	**Project Name:** **Bridge River 1 Replace Units 1-4 Generators / Governors**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** BC Hydro 2014 Annual Report to the BCUC • Attachment to Section 8 – Part 2 Appendix I, page line 139 Appendix J, page 2 F17-F19 RRA • Appendix I, Appendix J, page 28 • BCUC IRs 1.70.3, 2.249.8, 2.260.4 • BCOAPO IR 1.36.1	
Description: The purpose of the project is to improve generation reliability due to the Poor and Unsatisfactory health conditions of the Bridge River 1 Generating Facility Units 1 to 4 generators and related equipment, and to provide reliable water conveyance capacity within the Bridge River system.		
Key Drivers: • Reliability • Environmental • Reputational		
Issues Being Addressed: The four generators in the Bridge River 1 plant are in Poor to Unsatisfactory condition. Unit 4 was re-wound in 1977 but was de-rated after a stator winding failure during testing in 2011. The de-rating of Unit 4 restricts the water flow through the unit, limiting water conveyance capabilities. In addition to the loss in operating capability due to the de-rating of Bridge River 1 Unit 4, the operating regime for both Bridge River 1 and 2 has been impacted by a Dam Safety requirement from February 2015 to lower the maximum elevation of the upstream Downton Reservoir to manage LaJoie Dam seismic safety risks. This change in operations means there is 50 per cent less storage in Downton Reservoir, resulting in increased seasonal inflow to Carpenter Reservoir. Reduced capability to divert water from Carpenter Reservoir to Seton Lake, via the Bridge River generating stations, has increased the likelihood and magnitude of spills from Terzaghi Dam to the Lower Bridge River beyond the Water Use Plan Order (**WUP Order**) targets for annual average flows and those same targets set forth in settlement agreements with the St'át'imc Nation. BC Hydro has been, and currently is, operating under a variance to our Water Use Plan order, approved by the Comptroller of Water rights (February 16, 2017).		

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

Four alternatives were evaluated during the Identification Phase:

i. **Do Nothing:** maintain the existing units and replace the generators and other related components upon failure;
ii. **Rewind** the generator stators and replace or refurbish other components, as needed, to ensure each unit can maintain its original 50 MW rating;
iii. **Refurbish** the generators and replace the exciters and governors to match the current capacity of the turbines and operate within the limitations of the existing physical plant and constraints of the existing Water Use Plan Order; and
iv. **Replace** the generators, exciters and governors to match the current capacity of the turbines and operate within the limitations of the existing physical plant and constraints of the existing Water Use Plan Order.

Alternative iv, Replace the generators, exciters and governors, was selected as the leading alternative because it offers improvements to generator reliability and water management capabilities. This alternative also has the longest service life, more extensive warranties from the manufacturer, and minimizes the likelihood of additional scope from as-found conditions that would risk extending the outage schedule and increasing costs versus the refurbish alternative. In addition, this alternative allows for the full utilization of the licensed flow amounts through the generator and management of the Water License Order targets from Terzaghi Dam into the Lower Bridge River.

Project Impacts and Benefits:

- Improve generation reliability by replacing the Units 1 to 4 generators and related equipment;
- Provide reliable water conveyance capacity within the Bridge River system.
- Reduce the likelihood and magnitude of spills from Terzaghi Dam to Lower Bridge River, in order to minimize potential effects on fish, riparian habitat, and First Nations values.
- Maintain BC Hydro's relationship with the St'at'imc Nation.
- Reduce potential reputational impact due to spill events.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when this project reaches Implementation.

Additional Information:

This project, and reinforcement to the transmission system will ensure generation can be delivered at all times of the year in the Bridge River Area, without additional spill at Terzaghi Dam into Lower Bridge River and at Seton River. The reinforcement work is being carried out through the Bridge River Transmission Project (92423).

As the planning level estimate for this project is over $100 million, BC Hydro expects that BCUC approval will be required for this project.

The Bridge River System lies within the traditional territory of the St'át'imc Nation. BC Hydro and St'át'imc have a set of Agreements (signed in 2011) that settle all past, present and future claims related to the Bridge River facilities and provide legal certainty around continued operations of the Bridge River facilities and inform ongoing relationship development. BC Hydro is engaging the St'át'imc Nation in a manner consistent with our Agreements and continues to work with the St'át'imc to address issues and concerns around this project.

<tr><td colspan="3">Description:
The purpose of this project is to restore the reliability of the Unit 7 and 8 generators and other related equipment, and to restore lost water conveyance capacity within the Bridge River system.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Environmental
• Reputational</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The primary drivers for this project are the lost capacity, unacceptable condition and unreliability of the Bridge River 2 generating Units 7 and 8. Bridge River 2 generating Units 7 and 8 were placed into service in 1960. Both Units 7 and 8 were de-rated after an age-related stator winding failure on Unit 6 in 2011. In addition, Unit 8 was further de-rated in 2015 after experiencing a fault. The equipment de-rating restricts the water flow through the units, limiting water conveyance capabilities.
As of April 2018, the Unit 7 generator has a Poor and Unit 8 generator has an Unsatisfactory Equipment Health Rating. A failure of a major component could result in an unplanned unit outage of up to 18 months.
Operating regime for both Bridge River 1 and 2 has been impacted by a Dam Safety requirement from February 2015 to lower the maximum elevation of the upstream Downton Reservoir to manage LaJoie Dam seismic safety risks. This change in operations means there is 50 per cent less storage in Downton Reservoir, resulting in increased seasonal inflow to Carpenter Reservoir. <tr><td colspan="3">Discussion of Alternatives:
Three alternatives were evaluated during the Identification Phase:
i. Do nothing: repair or replace equipment at failure,
ii. Refurbish generators with a system output of 71 MW per unit, and
iii. Replace generators with a system output of 75 MW per unit.
Alternative iii Replace generators with a system output of 75 MW per unit was selected as the leading alternative as it addresses all project objectives and provides the greatest financial benefit.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits:	
• Improve generator reliability and restore lost firm capacity of 30 MW. • Provide reliable water conveyance capacity within the Bridge River system. • Reduce the likelihood and magnitude of spills from Terzaghi Dam to Lower Bridge River, in order to minimize potential effects on fish, riparian habitat, and First Nations values. • Maintain BC Hydro's relationship with the St'at'imc Nation. • Reduce potential reputational impact due to spill events.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when project reaches Implementation.
Additional Information: The Bridge River System lies within the traditional territory of the St'át'imc Nation. BC Hydro and St'át'imc have a set of Agreements (signed in 2011) that settle all past, present and future claims related to the Bridge River facilities and provide legal certainty around continued operations of the Bridge River facilities and inform ongoing relationship development. BC Hydro is engaging the St'át'imc Nation in a manner consistent with our Agreements and continues to work with the St'át'imc to address issues and concerns around this project.	

Investment Planning ID: **000952**	**Project Name:** **Kootenay Canal Modernize Controls**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** F17-F19 RRA: • BCUC IR 1.73.1, BCOAPO IR 1.36.2	

Description:

The purpose of this project is to improve the long-term reliability, maintainability and operability of the control systems, exciters and governors for all four generating units at Kootenay Canal Generating Station.

Key Drivers:

- Reliability

Issues Being Addressed:

Reliability, technical support and spare parts obsolescence increase the reliability risks associated with the control systems, exciters and governors. Over the past 10 years, Kootenay Canal Generating Station has experienced auxiliary control relay failures, and has experienced five forced outages in the past two years due to the aged control relays, indicating the relays are nearing end of design life.

The exciters are based on obsolete technology and have analogue controls that are reaching end of industry life expectancy (40 years). This model of exciter is no longer manufactured nor technically supported, and spare parts are no longer available from the manufacturer

The governor controls are original and have obsolescence issues (except for the mechanical speed switches which were replaced in 2014). Spare parts are not available from the manufacturer and there is minimal technical support. A failure of the hydraulic control valves may result in an extended outage while parts are reverse engineered.

Discussion of Alternatives:

Three alternatives are being evaluated for the control systems, exciters and governors during Identification Phase:

i. **Do nothing:** continue operating the units under current condition until fail;
ii. **Refurbish:** retains 40-plus-year old design practices which in many cases does not reflect current standards for safety, and does not increase functionality of existing equipment; equipment refurbishment requires custom fabrication or reverse-engineering of obsolete components, and raises issues about future spare part and technical support availability; and
iii. **Replace** the unit control, exciter and governor controls.

Additionally, three alternatives for the unit AC/DC Power Distribution Boards and Governor Mechanical systems are being evaluated during Identification Phase.

i. **Do Nothing:** continue operating the units with current condition and maintain and replace components as they fail;
ii. **Refurbish** system components to extend service life; and
iii. **Replace** system components to extend service life.

Project Impacts and Benefits:

- Improve the long-term reliability, maintainability and operability of the control systems, exciters and governors.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

TBD</td></tr>
<tr><td>Development Phase:
Identification</td><td colspan="2">Filing Reference:
F17-F19 RRA:
• BCUC IR 2.258.2</td></tr>
</table>

Description:

The purpose of this project is to improve the reliability of the Unit 1 generating equipment at the Ladore Generating Facility (**LDR**).

Key Drivers:

- Reliability

Issues Being Addressed:

Unit 1 at the Ladore facility has been in service since 1956. The equipment is mostly original, with the exception of the exciter which was replaced in 2002. There are increased reliability risks associated with the unit. The generator and turbine are in poor condition, increasing the likelihood of an extended forced without a significant intervention.

Discussion of Alternatives:

Five alternatives are being evaluated during Identification Phase:

i. **Do nothing:** run to failure;
ii. **Refurbish** following an evaluation of each asset, re-using as much of the existing equipment as possible;
iii. **Combined refurbish / replacement** by replacing the assets in Poor condition and refurbish those in Fair condition;
iv. **Replacement** of exciter, generator, governor, transformer and turbine except for embedded components. Refurbish embedded components; and
v. **New unit construction** in the Unit 3 bay.

Project Impacts and Benefits:

- Improve reliability at the Ladore Generating Facility

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when project reaches Implementation.

Additional Information:

There are four concurrent projects that may be impacted by this project:

i. GY-0234 LDR Install PH & Tailrace Crane must be, and is scheduled to be, completed to enable construction work for this project, as there is currently no powerhouse crane at LDR. This project is currently in Implementation Phase.
ii. GM-0044 LDR Upgrade Communication Systems should be implemented prior to, or simultaneously with this project. This project is currently in Identification Phase, Needs Stage.
iii. GM-0045 LDR Upgrade Protection & Control System is intricately linked with this project. As a result, a decision was made in Needs stage to merge GM-0045 into this project (G000741, GM-0043).
iv. LDR Redevelop Unit 2 does not yet have a project identifier, but is planned to follow redeveloping Unit 1. Consideration should be given to Unit 2 in design and procurement for Unit 1.

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: G003026	**Project Name:** Seton - Upgrade Unit	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** New	

Description:

The purpose of this project is to upgrade the unit equipment to ensure safe and reliable operation at the Seton Generating Station.

Key Drivers:

- Reliability
- Safety
- Environment
- Reputational

Issues Being Addressed:

The Seton Generating Station is operated almost continuously except for fisheries and maintenance requirements. Both the Seton generator and turbine are original equipment (1956) and are in Poor condition.

Due to the age and condition of the generator and turbine there is a risk that they could fail leading to loss of generation and an extended outage. This would result in high flows down Seton River and Lower Bridge River which could cause deviations to the Bridge/Seton system operating regime. We are engaging St'át'imc Nation and regulators as part of regularly scheduled meetings to discuss flows on these two rivers, and in the event of an unplanned outage we would notify all parties to discuss how to best manage the system. Also, if water needs to be diverted through Lower Bridge River, then this could result in an increased likelihood and magnitude of spills from Terzaghi Dam to Lower Bridge River beyond the Water Use Plan (**WUP Order**) targets for annual average flows and those same targets set forth in settlement agreements with the St'át'imc Nation. BC Hydro has been, and currently is, operating under a variance to our Water Use Plan order, approved by the Comptroller of Water rights (February 16, 2017).

Discussion of Alternatives:

Seven alternatives are being evaluated during Identification Phase:

i. **Do Nothing:** operate to failure;

ii. **Refurbish Unit With Unchanged Nameplate Rating.** It is expected that this approach could extend the unit life another 35 years;

iii. **Replace Unit With Unchanged Nameplate Rating.** It is expected that this approach would result in a new life of 40 to 50 years;

iv. **Refurbish Unit With Increased Nameplate Rating.** It is likely this approach would involve replacement of some elements of the unit and refurbishment of others, and could extend the unit life another 35 years;

v. **Replace Unit With Increased Nameplate Rating.** It is expected that this approach would result in a new life of 40 to 50 years;

vi. **Decommission Unit**, which would see Seton being used for water passage only. The dam, canal, and intakes would be retained. The unit mechanical and electrical components would be removed or reconfigured to provide the energy dissipation needed to discharge the water safely through the powerhouse to Fraser River; and

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">vii. Install Bypass Unit, which would involve installing a powerhouse bypass in a suitable location and of a suitable size to divert water from the main powerhouse during outages and/or in times of high inflows. This would allow the production of power from the bypassed water and also help to dissipate the stored energy before discharging to Fraser River.</td></tr>
<tr><td colspan="2">Project Impacts and Benefits:
• Improve the reliability of the Seton Generating Station;
• Provide reliable water conveyance capacity within the Bridge River system;
• Reduce the likelihood and magnitude of spills from Seton Lake Reservoir to Seton River and from Terzaghi Dam to Lower Bridge River, to minimize potential effects on fish, riparian habitat, and First Nations values;
• Maintain BC Hydro’s relationship with the St’at’imc Nation; and
• Reduce potential reputational impact due to high flow or spill events.</td></tr>
<tr><td>Project Implementation Phase Risk:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.</td><td>Risk Treatment:
To be determined when the project reaches Implementation.</td></tr>
<tr><td colspan="2">Additional Information:
Other capital projects currently underway at Seton Generating Station include:
• G003268 GM-0075 Governor replacement (currently in Definition Phase)
• G000992 GY-0191 Protection and Control Upgrade (currently in Implementation Phase)
Some Generation P&C scope of work was not completed under Seton Upgrade Unit Protection & Control Project (GY0191) or the Seton Replace Governor Project (GM0075). This scope of work will be completed under this project.
The Bridge River System lies within the traditional territory of the St’át’imc Nation. BC Hydro and St’át’imc have a set of Agreements (signed in 2011) that settle all past, present and future claims related to the Bridge River facilities and provide legal certainty around continued operations of the Bridge River facilities and inform ongoing relationship development. BC Hydro is engaging the St’át’imc Nation in a manner consistent with our Agreements and continues to work with the St’át’imc to address issues and concerns around this project.</td></tr>
</table>

Investment Planning ID: **G000796**	**Project Name:** **Seven Mile Overhaul Units 1 to 3 Turbines**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** F17-F19 RRA: • Appendix I, line 69, Appendix J, page 35 • BCUC IRs 1.70.3, 1.93.1-1.93.6, 2.249.8, 2.260.4, 2.262.1, • BCOAPO IR 1.36.1	

Description:

The purpose of this project is to improve the reliability of the Units 1 to 3 turbines that presently have seal erosion and runner blade cavitation issues at the at the Seven Mile Generating Station.

Key Drivers:

- Reliability
- Financial

Issues Being Addressed:

Seven Mile Units 1 to 3 have been in service for almost 40 years without a major turbine overhaul. The units are now demonstrating an elevated level of wear increasing the risk of turbine failure. The two main issues with the turbines are excessive runner crown and band seal erosion, and runner cavitation requiring cavitation repairs every two years.

The efficiency of the units has also been reduced over time. The Unit 1 to 3 turbines weighted average efficiency was measured in 1984 at 91.0 per cent. This was lower than the original guaranteed weighted average efficiency of 92.7 per cent. It is expected that turbine efficiency has been further reduced since then mainly because of changes in runner blade profile and runner seal erosion (seal clearance is larger than design).

Discussion of Alternatives:

Three alternatives were evaluated during Identification Phase:

i. **Do Nothing:** continue with cavitation weld repairs on turbine runners and routine inspections;

ii. **Turbine Refurbishment:** Refurbish and repair the runner and major components by sandblasting, welding, machining, repainting as applicable; and

iii. **Turbine Upgrade:** Re-design and replace the runner and wicket gates to eliminate cavitation, and achieve higher turbine efficiency and higher maximum capacity. Efficiency gains with a modern designed runner and wicket gates are expected to be in the range of 2.5 per cent to 3 per cent. This alternative would increase the total turbine capacity by 106.5 MW based on future turbine rated output of 213 MW (the existing rated turbine output 177.5 MW) x 3 units.

Alternative iii, Turbine Upgrade, was selected as the only viable alternative for the project. This alternative will adequately improve turbine performance and operating reliability, mitigate cavitation issues, and significantly increase useful life by more than another 50 years. Additionally, this alternative provides an opportunity to increase the efficiency, and possibly the operating range of the turbine runners, resulting in additional energy benefits.

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">Project Impacts and Benefits:
• Improve reliability by resolving the runner seal erosion and runner cavitation issues.
• Reduce operations and maintenance costs by resolving the runner seal erosion and runner cavitation issues.
• Reduce the risk of turbine failure.
• Increase turbine efficiency (by 2.5 per cent to 3 per cent) and operating range (by 106.5 MW).</td></tr>
<tr><td>Project Implementation Phase Risk:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.</td><td>Risk Treatment:
To be determined when the project reaches Implementation.</td></tr>
<tr><td colspan="2">Additional Information:
As the planning level estimate for this project is over $100 million, BC Hydro expects that BCUC approval will be required for this project.
There are a number of capital projects at the Seven Mile Generating Facility scheduled for the next seven to 10 years. These include the intake gate project, Powerhouse (PH) crane synchronization, fire protection upgrade, governor controls upgrade, and cooling water. Some of the projects will need to be completed ahead of the turbine project (e.g., PH crane synchronization, intake gate refurbishment, and fire protection upgrade). Some of the projects are planned to be completed during the same outage as the turbine project and will require scope and boundary definition (e.g., governor controls upgrade and cooling water). The project team will coordinate with the requirements of these other projects.</td></tr>
</table>

<table>
<tr><td colspan="1">Investment Planning ID:
G001047</td><td colspan="2">Project Name:
Waneta Unit 3 Life Extension</td></tr>
<tr><td>Forecast Capital Cost:
TBD</td><td>Forecast In-Service Date:
TBD</td><td>Start Date of Construction:[1]
TBD</td></tr>
<tr><td>Development Phase:
Identification (Teck Stage Gate 3)</td><td colspan="2">Filing Reference:
New</td></tr>
</table>

Description:

The purpose of this project is to reduce the risk of failure of Waneta Unit 3 hydroelectric generator.

Key Drivers:

- Reliability

Issues Being Addressed:

The primary issue being addressed is the condition of the stator winding and core. Inspections of Unit 3 stator have revealed a number risks:

- Lamination migration – the steel laminations which form the generator stator core have come loose and are moving. This can result in physical damage to the stator winding or contact with the rotor which can result in an electrical fault;
- Loose wedges – the wedges which hold the stator winding in place in the stator core have come loose. This can result in physical damage to the stator winding which can result in an electrical fault;
- Core buckling – the steel laminations which form the generator stator core have come loose and can buckle. This can lead to physical or thermal damage to the stator laminations and winding which can result in an electrical fault
- Loss of circularity – the generator stator core can lose its circularity which can result in hotspots or vibrations which can lead to further damage or an electrical fault.

In addition, Unit 3 suffers from a number of issues which will be considered during this project;

- Runner cavitation – the runner experiences frequent cavitation resulting in extensive welding repairs
- Runner cracking – extensive welding will lead to the build up of thermal stresses which, over time, can lead to cracking of the runner .
- Protection and Controls – the controls are original 1963 electromechanical relays and contain asbestos wiring; and
- Governor – original 1963 mechanical governor. Parts and maintenance support is limited.

Discussion of Alternatives:

Four alternatives were evaluated during Identification phase:

i. **Do nothing:** Replace the stator winding, stator core at failure;
ii. **Re-wedge** the stator winding;
iii. **Re-stack** the stator; and
iv. **Replace** the stator core and windings.

Alternative iv, replace the stator core and windings with a modern design, was chosen as the lead alternative as this is the only alternative that would address the root causes of the major defects reported with the stator.

In addition, the downtime required to address the stator yields the opportunity to replace other major components that are nearing end of life. These components include the runner, governor, protection and controls. Further risk assesments will be completed during Stage Gate 4 to confirm whether or not the following addional components need to be included as well:

Additional Information:

On July 26, 2018, BC Hydro became the sole owner of Waneta. Teck Metals Ltd (**TML**) continues to act as the Operator of the facility during the 20-year lease term. In that role, Teck is required to operate, manage, and maintain Waneta in accordance with the terms of the Co-Possessors and Operating Agreement (**COPOA**), which includes capital planning and operating to a prudent owner standard, exercising the degree of care and skill of an experienced dam operator and acting in accordance with Good Utility Practice.

There are a number of projects that TML has agreed to complete as detailed in Schedule C of the COPOA, including this Unit 3 Life Extension project. As Operator at Waneta, TML will oversee the execution of the project and will provide regular updates to BC Hydro's Operating Committee representatives.

BC Hydro will retain an oversight role as part of the Waneta Operating Committee, including reviewing the annual operating plans for Waneta; however, as TML is the Operator of Waneta, processes that BC Hydro generally uses for internal asset management and planning purposes will not be applied.

Investment Planning ID: **G000130**	**Project Name:** **G.M. Shrum - U1 - U10 Water Passage Refurbishment**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Future	**Filing Reference:** New	

Description:

The purpose of this project is to rehabilitate the 10 penstocks at G.M. Shrum.

Refer to Appendix K – G.M. Shrum Facility Asset Plan for additional information.

Key Drivers:

- Financial
- Safety
- Reliability

Issues Being Addressed:

A number of the penstocks have been assessed as Unsatisfactory and Poor based on the condition of the coating. Due to the compromised coatings, sections of the penstock steel liner, penstock exterior and scroll case show signs of deterioration and metal loss. Failure to address the active corrosion in a timely manner will result in loss of additional metal thickness and could lead to more expensive repairs or eventual penstock replacement.

Discussion of Alternatives:

The following alternatives will be explored in Identification:

i. **Replace** (strip and re-coat) the existing protective coating on all penstocks and key water passage components; and

ii. **Replace (strip and re-coat), refurbish (touch-up) or defer intervention** on a component by component basis. This would focus on high priority items in the short-term, and consider deferring lower priority items into the future.

Project Impacts and Benefits:

- Extend the life of the penstocks.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

Investment Planning ID: G000252	**Project Name:** Revelstoke - U1 - U4 Stator Replacement	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Future	**Filing Reference:** New	

Description: The purpose of this project is to address reliability risks associated with the Units 1 to 4 generator stator cores, stator windings and frames. Refer to Appendix K – Revelstoke Facility Asset Plan for additional information.
Key Drivers: • Reliability
Issues Being Addressed: The Unit 2 to 4 generators are in Poor condition. The main issues leading to a Poor Equipment Health Rating include poor condition of the stator windings, stator core, and rotor windings, as confirmed by poor electrical test results and visible signs of deterioration and deformation. The generator stator issues have been managed with interventions, operating restrictions and monitoring since 2007. Unit 1 is currently rated as being in Fair condition; however, considering the long lead time associated with this project and the fact that all units are the same age and design, intervention on Unit 1 will be considered within the project alternatives.
Discussion of Alternatives: Planning stage alternatives that have been identified include: i. **Replace** stator components for Units 1 to 4 ii. **Replace, Refurbish or defer** intervention on a unit-by-unit basis. Refurbishment would re-wind, as opposed to replace, the stator core
Project Impacts and Benefits: • Address reliability risks associated with Units 1 to 4 generators at Revelstoke

Project Implementation Phase Risk	**Risk Treatment**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

<tr><td colspan="3">Description:
The purpose of this project is to remove a portion of the 138kV lines that currently supply the communities of Taylor and Fort St. John to accommodate construction of the Site C 500 kV transmission lines. To continue to supply Taylor and Fort St. John, this project will construct a new 138kV switchyard, including two 500/138 kV transformers, within the future Site C 500 kV substation. The project will also construct six kilometres of new 138 kV transmission line to supply Taylor and Fort St John from the new Site C substation.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
Two 138 kV transmission lines currently occupy the transmission right-of-way reserved for the Site C 500 kV transmission lines and supply the communities of Taylor and Fort St. John from G.M. Shrum Generating Station (GMS). There is insufficient right-of-way available to retain the existing 138 kV lines and construct the new 500 kV lines.
Removal of the 138 kV lines to accommodate construction of the Site C 500 kV transmission lines will result in a 250 MW load supply shortfall in the Fort St. John-Taylor area, therefore the lines are being re-terminated at the new Site C Substation.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
Partially remove the 138 kV lines to enable construction of the new Site C 500 kV transmission lines and re-connect the 138 kV lines to an expanded Site C Substation. This was selected as the preferred alternative as it avoids a load supply shortfall to the Fort St John – Taylor area.</td></tr>
<tr><td colspan="3">Project Impacts and Benefits:
• Line losses will be reduced by removing the 138 kV lines and serving Fort St John and Taylor from an expanded Site C substation which is closer to the load centre.
• Operating and maintenance cost savings.
• Transmission reliability to Fort St John and Taylor will be improved by feeding these communities from a 500 kV substation.
• Future transmission system capacity will be enabled in the North Peace Region by providing capability in the Site C substation to connect additional 500 kV, 230 kV and 138 kV transmission lines.</td></tr>
<tr><td colspan="2">Project Implementation Phase Risk:
This project currently does not have any identified Zone 3 (high) Implementation Phase risks.</td><td>Risk Treatment: N/A</td></tr>

Additional Information:
N/A

Investment Planning ID: 900219	**Project Name:** DVES: West End Substation - Property Purchase	
Forecast Capital Cost: $80.7 million	**Forecast In-Service Date:**[1] Fiscal 2021	**Start Date of Construction:**[2] Fiscal 2019
Development Phase: Implementation	**Filing Reference:** [redacted]	

Description:

The purpose of this project is to acquire property rights to allow construction of a new substation in the West End of downtown Vancouver to replace the existing Dal Grauer substation.

Refer to Appendix K – Downtown Vancouver Electric Supply Plan for additional information.

Key Drivers:

- Reliability

Issues Being Addressed:

Vancouver's downtown peninsula is currently supplied by three substations; Murrin (**MUR**), Dal Grauer (**DGR**), and Cathedral Square (**CSQ**). All three are approaching their firm capacity, with DGR and MUR approaching end-of-life as they date to 1953 and 1947, respectively. DGR is too physically constrained to allow for expansion or redevelopment while serving load, with no practical means of transferring the load to nearby stations. In addition, DGR is radially supplied by four 69 kV underground circuits fed by two 230/69 kV transformers located at MUR. These circuits and transformers are vulnerable to severe earthquake damage. For these reasons, a replacement station for DGR in a new location is required.

This project secures the property rights to allow the replacement of DGR (195 MVA capacity) with a new substation in the West End (ultimate 400 MVA capacity).

The scope of this project is to acquire property rights to site the new West End Substation, including required transmission and distribution rights-of-ways. Underground property rights for the substation were acquired in August 2018 from the Vancouver School Board at the location presently occupied by the existing Lord Roberts Annex school at 1150 Nelson Street. The acquisition of the remaining required property rights, including distribution and transmission statutory rights-of-way through Nelson Park, is ongoing and is expected to be complete by early fiscal 2021.

A separate project to design and construct the new substation will be initiated later in fiscal 2019 now that the location and attributes of the acquired property are defined.

Discussion of Alternatives:

Eleven potential downtown sites were investigated for the new West End Substation. These were shortlisted to four sites, and eventually BC Hydro made conditional offers on two sites: an underground parcel sited by the existing Lord Roberts Annex, and a private property several blocks to the west. The private property was more expensive than the forecasted property rights at the Lord Roberts Annex, but allowed for the construction of a less expensive above-ground indoor substation when compared to an underground station required at Lord Roberts Annex. With the additional transmission and distribution connectivity costs for the private property factored in, the overall cost of the new West End Substation including all required property rights was estimated to be similar at both sites.

BC Hydro determined that the parcel at Lord Roberts Annex was the preferred alternative given all the benefits that this alternative will provide to the Vancouver School Board and the residents of downtown Vancouver. The avoidance of uncertainty and delay in the acquisition of property rights, and the fact that

[1] Forecast In-Service Date refers to date when required rights of way through Nelson Park are secured.
[2] Start Date of Construction refers to the approval date to acquire the property.

<table>
<tr><td colspan="2">Lord Roberts Annex is closer to DGR which will result in a more efficient transfer of load and de-energization of DGR, were also significant advantages.
The property rights secured at Lord Roberts Annex include an underground parcel on a fee-simple basis which avoids the future expenditure and risk of a long-term leasehold arrangement.</td></tr>
<tr><td colspan="2">Project Impacts and Benefits:
The project will allow the replacement of DGR, and thereby improve security of supply to the downtown peninsula.</td></tr>
<tr><td>Project Implementation Phase Risk:
Rights-of-way on an adjacent property must still be secured - the timing and cost may vary from current expectations.</td><td>Risk Treatment:
Negotiate with property owner, after the stakeholder consultation process, to find a suitable compromise for all parties.</td></tr>
<tr><td colspan="2">Additional Information:
This project will be followed by a project developed under Planning ID 900598 to design and build a substation on this site.</td></tr>
</table>

Investment Planning ID: **92216**	**Project Name:** **Peace Region Electric Supply (PRES)**	
Forecast Capital Cost: $348 million to $197 million	**Forecast In-Service Date:** Fiscal 2022	**Start Date of Construction:**[1] Fiscal 2019
Development Phase: Definition	**Filing Reference:** Amended F12-F14 RRA: • Application: Amended Appendix I, page 17; Amended Appendix J, page 99 • BCUC IRs 1.204.1 Attachment 1, 1.250 series • AMPC IR 1.46.1 • ESVI IRs 1.4 series Dawson Creek/Chetwynd Area Transmission CPCN Application: • BCUC Order Nos. G-144-12 and C-5-13 F2014 Annual Report to the BCUC: • Appendix I, line 48; • Appendix J, page 65. F17-F19 RRA: • Appendix I, line 10, Appendix J, page 47 • BCUC IRs 1.70.3, 1.102.1 – 1.102.8, 2.249.8, 2.260.4, BCOAPO IR 1.36.1, AMPC IRs 1.17.1 to 1.17.6	

Description:

The purpose of this project is to construct two 58 km long 230 kV transmission lines between South Bank substation and Shell Groundbirch substation in the Peace Region. The project also involves constructing a new 230 kV switchyard at South Bank substation including transformation and expanding Shell Groundbirch substation to terminate the new transmission lines in the station.

Key Drivers:

- Reliability
- Reputational

Issues Being Addressed:

The Peace Region is supplied by a network of 138 kV and 230 kV transmission lines originating at the G.M. Shrum Generating Station. According to the May 2016 South Peace Load Forecast – December 2017 update, the load growth in the Peace Region (particularly in the Dawson Creek and Groundbirch areas) is expected to increase by 500 MW by 2028 such that the ability of the transmission system to maintain supply to all customers during system events will be exceeded. In addition to this, based on customer commitments, the ability of the system to supply the growing load under normal conditions is expected to be exceeded by fall 2021. At this point, no further load can be connected in the area without system reinforcement.

In August 2017, the provincial government's Mandate Letter also identified "advancing government's climate action strategies including through fuel switching and electrification initiatives in the transportation, oil and gas, and other sectors" as a key responsibility for BC Hydro. This mandate places an expectation that BC Hydro is in a position to meet the electrification needs of customers in the Peace Region.

---

1 Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:	
The following seven alternatives were assessed in the Identification Phase: i. **Do nothing**; ii. **Construct a new transmission line** from G.M. Shrum Generating Station to Sundance Substation via Sukunka Substation; iii. **Construct a new transmission line** from G.M. Shrum Generating Station to Sundance Substation via Dokie Terminal Substation; iv. **Construct a new transmission line from New Dokie Ridge Substation to Sundance Substation**; v. **Construct a new transmission line from New Pine Valley Substation to Sundance Substation**; vi. **Construct a new transmission line from the Planned South Bank Substation (A 230 kV Switchyard At The Site C Substation) to Shell Groundbirch Substation**;and vii. **Non-wire alternatives:** Non-wire alternatives, such as demand side management and temporary generation were considered for short term needs. Alternative vi, Construct a new transmission line from the planned South Bank Substation, was selected as the preferred alternative because it is the most cost effective solution that addresses the project needs.	
Project Impacts and Benefits:	
• Provide reliable service (N-1) to new and existing customers at the earliest possible in-service date. • Enable electrification of the upstream natural gas industry in the Peace region providing an opportunity to reduce provincial greenhouse gas emissions.	
Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.
Additional Information:	
Order In Council (**OIC**) 101 adds as prescribed undertakings for the purpose of section 18 of the Clean Energy Act investments in infrastructure in Northeast British Columbia that primarily serve natural gas producers and processors (section 4(2) of the Greenhouse Gas Reduction (Clean Energy) Regulation). This includes the Peace Region Electricity Supply (PRES) Project and accordingly, BC Hydro will not be filing an application under section 45(5) of the *Utilities Commission Act* for a Certificate of Public Convenience and Necessity for the PRES Project.

</table>

Investment Planning ID: 92423	**Project Name:** Bridge River Transmission Project	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** New	

Description:

The purpose of this project is to reinforce the transmission system to ensure generation can be delivered at all times of the year from the Bridge River Area to South Interior West via 2L90, without requiring curtailment of Bridge River 1 and 2 Generation.

Key Drivers:

- Reliability
- Environment
- Financial Loss
- Reputational

Issues Being Addressed:

The capacity of the Bridge River transmission system is insufficient to accommodate the Bridge River generation at all times of the year. Currently, when the ambient temperature in the area and regional generation are high, 2L90 may overload. The current mitigation for the 2L90 overload is to curtail the output of Bridge River 1 and 2 Generation, which may increase the likelihood and magnitude of spills from Terzaghi Dam to the Lower Bridge River beyond the Water Use Plan Order (**WUP Order**) targets for annual average flows. BC Hydro has been, and currently is, operating under a variance to our Water Use Plan order, approved by the Comptroller of Water rights (February 16, 2017). With the reduction in generating capacity and the loss of storage due to the drawdown of the Downton Reservoir, effective water management in the system is hindered, and is therefore an important driver for reducing the need to curtail Bridge River generation.

Discussion of Alternatives:

Three alternatives will be evaluated during Identification Phase:

i. **Do nothing:** continue to restrict Bridge River generation in order to prevent overload on 2L90;

ii. **Restore thermal rating** of 2L90 to 55°C operation and upgrade it to 90°C operation to provide sufficient capacity; and

iii. **Upgrade Rosedale (ROS) substation** to add a 360/230 kV transformer.

Project Impacts and Benefits:

- Increase transmission capacity in the Bridge River area to meet the higher generation demands of the system.
- Reduce financial losses associated with generation curtailment.
- Provide reliable water conveyance capacity within the Bridge River system.
- Reduce the likelihood and magnitude of spills from Terzaghi Dam to Lower Bridge River, in order to minimize potential effects on fish, riparian habitat, and First Nations values.
- Maintain BC Hydro’s relationship with the St’at’imc Nation.
- Reduce potential reputational impact due to spill events.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: This project will be timed in order to meet the higher generation demands associated with another project, Bridge River 1 Replace Units 1 to 4 Generators / Governors (G000776). The Bridge River System lies within the traditional territory of the St'át'imc Nation. BC Hydro and St'át'imc have a set of Agreements (signed in 2011) that settle all past, present and future claims related to the Bridge River facilities and provide legal certainty around continued operations of the Bridge River facilities and inform ongoing relationship development. BC Hydro is engaging the St'át'imc Nation in a manner consistent with our Agreements and continues to work with the St'át'imc to address issues and concerns around this project.

<tr><td colspan="3">Description:
West Kelowna Transmission Project:
The purpose of the West Kelowna Transmission Project is to build a new secondary 138 kV transmission line to strengthen the transmission network delivering electricity to the City of West Kelowna and the District of Peachland.
Westbank Substation Upgrade Project:
The purpose of the Westbank Substation Upgrade Project is to increase station firm capacity and replace end of life assets on an expanded footprint.</td></tr>
<tr><td colspan="3">Key Drivers:
West Kelowna Transmission Project:
• Reliability
Westbank Substation Upgrade Project:
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
West Kelowna Transmission Project
Since 1994 there have been three sustained forced outages; one in 1994 caused by lightning resulting in a six-hour outage; one in October 2007 caused by lightning resulting in a seven-hour outage; and the October 2014 pole-top fire related outage resulting in a nine-hour outage. The single outage in 2014 resulted in significant customer hours lost (CHL) (180,000) for West Kelowna. The CHL consequence due to an outage in the area is significant and indicated that BC Hydro should address this risk. Other factors that contribute to the challenge of restoring power include the length of the existing transmission line, its location in rugged and remote terrain, and it’s susceptibility to forest fires and landslides.
While the existing line is considered to be reliable, adding a new, second transmission line (or cable) will provide redundancy to the system, ensuring continued, reliable power in the event of an outage on the existing line.
Westbank Substation Upgrade Project
The peak summer load at Westbank Substation (WBK) exceeds the firm summer capacity of the station. Several components of the substation are also reaching end of life. This includes one 138 kV oil circuit breaker and one 25 kV oil circuit breaker, two circuit switchers and one voltage transformer.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

West Kelowna Transmission Project

Three alternatives were evaluated during Identification Phase for the West Kelowna Transmission Project:

i. **Build a new transmission line to Vernon Terminal Substation** on the west side of Okanagan Lake, connecting Westbank Substation to Vernon Terminal Substation;

ii. **Build a new transmission line to Nicola Substation** connecting Westbank Substation to Nicola Substation using primarily a different route than the existing line; and

iii. **Build a new transmission line to FortisBC** including a submarine cable across Okanagan Lake, connecting Westbank Substation to the FortisBC system.

Alternative ii, Build a new transmission line to Nicola Substation connecting Westbank Substation to Nicola Substation, was selected as the leading alternative as it is more favorable from an overall safety, environmental, socio-economic, cost, geotechnical and wildfire risk perspective compared to the other alternatives.

Westbank Substation Upgrade Project

Three alternatives were evaluated during Identification Phase for the Westbank Substation Upgrade Project:

i. **Upgrade Westbank Substation** to increase firm transformation capacity, replace end of life assets and add space provision to interconnect the new transmission line;

ii. **Build a new substation** to accommodate load growth in the West Kelowna area,; and

iii. **Do nothing:** continue as usual, with curtailment of customer load during transformer contingency.

Alternative i, Upgrade Westbank Substation, is the only viable alternative for the project.

Project Impacts and Benefits:

West Kelowna Transmission Project:

- Improve reliability in West Kelowna by providing redundancy to the system.

Westbank Substation Upgrade Project:

- Increase firm transformation capacity to meet demand.
- Replace end of life assets on an expanded footprint.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

In the BCUC's Decision on our Previous Application, BC Hydro was directed to file a Certificate of Public Convenience and Necessity application for both the West Kelowna Transmission Project and Westbank Substation Upgrade Project. The BCUC also found these two projects to be sufficiently linked that they could be expediently reviewed in one process. The decision provides some flexibility for BC Hydro to have the two projects reviewed in a single process or separately if necessary.

Investment Planning ID: 900266	**Project Name:** East Vancouver - Substation Construction	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Future	**Filing Reference:** New	

Description:

This project will build a new 230/12 kV to 25 kV, 400 MVA (ultimate capacity), station in the Eastside/Strathcona neighbourhood of Downtown Vancouver as part of the second stage of the 30-year Downtown Vancouver Electricity Supply Plan.

Refer to Appendix K – Downtown Vancouver Electric Supply Plan for additional information.

Key Drivers:

- Reliability

Issues Being Addressed:

The Downtown Vancouver area is comprised of the Downtown, West End, Strathcona, and Grandview-Woodland neighbourhoods. The area is supplied by a 230 kV and 69 kV transmission network and three substations:

- Cathedral Square substation (built in 1984);
- Dal Grauer substation (built in 1953); and
- Murrin substation (built in 1947).

There are a number of risks and issues at the ageing Dal Grauer and Murrin substations. More than half of the assets are expected to degrade to poor or very poor condition in the next 10 to 20 years, presenting a reliability risk. Murrin substation is on seismically unstable soil. Approximately half of the 230 kV switchyard, which supplies both Murrin and Dal Grauer loads, is vulnerable to severe earthquake damage from liquefaction and settlement. Physical space constraints at Dal Grauer make redevelopment of the substation in its current location not possible while serving load.

The long term strategy for the area is to mitigate the above reliability and safety risks by replacing Murrin and Dal Grauer substations with new substations. One of these is the new ‘East End Substation’.

Discussion of Alternatives:

The ultimate capacity of the East End substation will be 400 MVA, located in the Strathcona neighbourhood of Vancouver. The project will consider different options for the size of the substation when it is first constructed, given that the 400 MVA capacity may not be required immediately.

Project Impacts and Benefits:

- Improve Eastside/Strathcona Vancouver area reliability.
- Minimize worker safety risks in the area.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when this project reaches Implementation.

Additional Information:

See also Appendix J for the related project:

- Investment Planning ID: 900598; and
- Project Name: West End - Substation Construction and System Reinforcement.

</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives: The ultimate capacity of the underground substation will be 400 MVA, located in the West End neighborhood of Downtown Vancouver. The project will consider different options for the size of the substation when it is first constructed, given that the 400 MVA capacity may not be required immediately.	
Project Impacts and Benefits: • Improve West End Vancouver area reliability. • Minimize worker safety risks in the area.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: See also Appendix Js for the related projects: • Investment Planning ID: 900266; Project Name: East Vancouver - Substation Construction; and • Investment Planning ID: 900219; Project Name: DVES: West End Substation – Property Purchase.	

Investment Planning ID: 90957	**Project Name:** Peace to Kelly Lake Capacitors	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** New	

Description:

The purpose of the project is to reinforce the transmission system between the Peace Region and Kelly Lake substation to ensure transfer capacity is in place for new generation in the Peace Region.

Key Drivers:

- Reliability.

Issues Being Addressed:

The Peace Region is a major generation source for BC Hydro, generating enough power to meet about 36 per cent of the total energy demand in the province. BC Hydro's Network Integration Transmission Services (**NITS**) Base Resource Plan (**BRP**) Rev 06 released on November 25, 2016 identifies a large amount of hydro generation and other intermittent generation being added by 2024 and through until 2034. The Peace Region to Kelly Lake 500 kV transmission system carries power generated in the Peace Region to load centers in the south of the province. The existing transfer demand on the Peace to Kelly Lake transmission section is near 95 per cent of the transfer capacity of the lines. The addition of Site C and other generation in the Peace Region will cause the required power transfer to exceed the available transmission capacity. System studies show that the transfer capacity of the Peace Region to Kelly Lake 500 kV transmission system is limited by thermal, voltage and transient stability and will require significant reinforcements starting in 2024 to deliver the power from the Peace Region to the south of the province without constraints.

Discussion of Alternatives:

Three alternatives were evaluated during Identification Phase:

i. **65 Per Cent Series Compensation via four new capacitor stations** and decommissioning of Kennedy (**KDY**) and McLeese (**MLS**) capacitor stations;

ii. **65 Per Cent Series Compensation via two new capacitor stations** and addition of series compensation at Williston (**WSN**), and decommissioning of KDY capacitor station; and

iii. **65 Per cent Series Compensation via three new capacitor stations** and decommissioning of KDY capacitor station.

Alternative iii, 65 per cent Series Compensation via three new capacitor stations and decommissioning of KDY capacitor station, was selected as the leading alternative as it meets the project objectives, avoids current restrictions between WSN and KLY, and allows some flexibility to respond to changes in load or planning requirements during project development.

Project Impacts and Benefits:

- Improve reliability through reinforcement of the transmission corridor between the Peace Region and Kelly Lake substation so power from new generation in the Peace Region can be moved south.
- Building capacitor stations will help maintain the voltage levels of the transmission lines, maximizing the amount of electricity the existing lines can move.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk	**Risk Treatment**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.
Additional Information: The project will require upgrades to the WSN substation, and will need to coordinate outages with any other planned outages. As the planning level estimate for this project is over $100 million, BC Hydro expects that BCUC approval will be required for this project.	

Investment Planning ID: 900992	**Project Name:** Lower Mainland - Capacitive and Reactive Power Reinforcement	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Future	**Filing Reference:** New	

Description:

Implement sufficient reactive power compensation in the Lower Mainland transmission system to provide voltage support and control to the Lower Mainland transmission system, and to address the Fraser Valley voltage stability constraints.

Refer to Appendix K – Burrard Synchronous Condensers Replacement Study for additional information.

Key Drivers:

- Reliability

Issues Being Addressed:

This project will address the following two issues:

- **Issue 1:** The four Burrard Synchronous Condenser units are reaching end-of-life and are expected to experience reliability issues within the short to medium term. Each unit is rated as -50 MVAr / +100 MVAr. The four units provide capacitive and reactive power to the Lower Mainland transmission system, which allows voltage control and prevents voltage instability during peak load periods.
- **Issue 2:** The 2016 NERC Transmission Planning assessment of the Fraser Valley transmission system identified voltage stability constraints caused by additional reactive power losses within the 10-year planning horizon. The voltage instability would result in voltage collapse and subsequent load loss in the Fraser Valley.

Discussion of Alternatives:

The alternatives being considered include:

i. **Install 230 kV Shunt Capacitor and Shunt Reactor Compensation:** A total of 750 MVAr of capacitive power compensation and a total of 200 MVAr of shunt reactive power compensation would be installed in the Lower Mainland at 230 kV;

ii. **Install 500 kV and 230 kV Shunt Capacitor and Shunt Reactor Compensation:** A total of 750 MVAr of capacitive power compensation would be installed in the Lower Mainland: 250 MVAr at 500 kV, and 500 MVAr at 230 kV. A total of 200 MVAr shunt reactive power compensation would be installed in the Lower Mainland at 230 kV; and

iii. **Restore Burrard Synchronous Condenser Capability and Install Shunt Capacitor Compensation:** Burrard Synchronous Condenser reactive power function would be restored and 500 MVAr of capacitive power compensation would be installed in the Fraser Valley at 230 kV.

Project Impacts and Benefits:

- Maintain BC Hydro’s Lower Mainland bulk transmission system reliability during heavy winter load periods under single contingency conditions.
- Reduce the likelihood of cascading outages to the rest of the WECC system.
- Secure regional Fraser Valley transmission system reliability by compensating for VAr losses during heavy winter load periods under single contingency conditions.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: N/A	

Investment Planning ID: **901251**	**Project Name:** **Interior to Lower Mainland - Remedial Action Schemes Installation**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Future	**Filing Reference:** New	

Description:

This project is to implement a load shedding remedial action scheme (**RAS**) to shed loads at various BC Hydro distribution substations and transmission customer substations in the Lower Mainland and Vancouver Island for certain 500 kV single contingency events during winter heavy load conditions starting as early as 2023. BC Hydro is in the process of developing a new load forecast that will impact the timing for this project.

Key Drivers:

- Reliability

Issues Being Addressed:

Voltage stability constraints would affect the supply reliability of the Interior to Lower Mainland (**ILM**) 500 kV transmission system under certain single contingency events during winter peak load period starting as early as 2023. This timing will be impacted by BC Hydro's new load forecast that is being developed. This is an interim solution and BC Hydro will develop a long-term solution that will be informed by the next IRP.

Discussion of Alternatives:

Alternatives identified for this project include:

i. **Implement a load shedding RAS** to shed loads at various BC Hydro distribution substations and transmission customer substations in the Lower Mainland and Vancouver Island for certain 500 kV single contingency conditions during winter peak load conditions;

ii. **Investigate additional capacity** focused DSM in the Lower Mainland in addition to the current energy focused DSM as an interim solution; and

iii. Do Nothing: This is not considered as BC Hydro will not be able to maintain the system stability in the ILM transmission system during peak load periods under contingency conditions**.**

Project Impacts and Benefits:

- Maintain BC Hydro bulk transmission system reliability.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

N/A

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: **93788**	**Project Name:** **Capilano Substation Upgrade**	
Forecast Capital Cost: $88.0 million to $50.0 million	**Forecast In-Service Date:** Fiscal 2025	**Start Date of Construction:**[1] Fiscal 2020
Development Phase: Definition	**Filing Reference:** Amended F12-F14 RRA: • Application: Amended Appendix I, page 18; • Amended Appendix J, page 125 • BCUC IR 1.204.1 Attachment 1 F2014 Annual Report: • Appendix I, line 113; • Appendix J, page 41. F17-F19 RRA: • Appendix I, line 36, Appendix J, page 63 • BCUC IRs 1.70.3, 2.249.8, 2.253.2, 2.260.4, BCOAPO IR 1.36.1	

Description:

The purpose of this project is to improve the reliability and reduce the safety risks at Capilano Substation (**CAP**).

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

The CAP substation is over 60 years old and most of its major equipment is near end of life and needs immediate replacement. In particular, the 60 kV bulk-oil and 12 kV air-blast circuit breakers are obsolete and pose worker safety and reliability risks. The Asset Health Index on key equipment in the station such as the Protection and Control System, Instrument Transformers and Disconnect Switches is rated as Poor or Very Poor. In addition, the existing feeder section buildings do not meet current seismic standards and the equipment inside one of the buildings does not meet required safe electrical working clearances.

The new CAP substation will provide 25 kV distribution voltage. The existing 12 kV substation will be decommissioned after the surrounding service area has been converted to 25 kV operation which is planned to align with the construction of the new substation.

Discussion of Alternatives:

During Identification Phase the following alternatives were assessed:

i. **Do Nothing**;
ii. **Upgrade** existing CAP substation;
iii. **Replace** CAP substation on new property; and
iv. **Defer** project beyond fiscal 2022.

Alternative ii, Upgrade existing CAP substation, was selected as the preferred alternative as it meets the project objectives and has fewer issues than the replacement alternative.

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">Project Impacts and Benefits:
• Improve reliability for the North Vancouver area through addressing aging equipment concerns.

<tr><td colspan="3">Description:
The purpose of this project is to upgrade the Mount Lehman (MLE) substation to enable decommissioning of the Sumas Way (SMW) substation and serve load in the Abbotsford area.</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Safety</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Abbotsford area is currently supplied by the Clayburn (CBN), Gloucester (GLT), MLE and SMW substations. At present, the total capacity of these four stations is 360 MVA. MLE is a 230/25 kV substation and was placed in service in 2007, with a total transformation capacity of 100 MVA.
Expansion of the MLE substation is required to enable decommissioning of the SMW substation. SMW has increased reliability risks due to degrading asset condition and has elevated safety risks due to the non-arc resistant metalclad design of the 25 kV feeder section. The expansion of MLE substation will also enable safety improvements to be undertaken at CBN substation and ensure that load in the Abbotsford area continues to be served over time.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
This project was identified as a result of a 30-year study carried out for the Abbotsford area in 2013 to mitigate safety issues at SMW and CBN substations and address capacity shortage in the Abbotsford area. The area study resulted in three alternative solutions being identified and reviewed. The alternative comparison was a comparison of different implementation strategies to determine not only what should be done, but also timing. Alternatives were re-evaluated during the Identification Phase of this project. A leading alternative was accepted that includes three phases of upgrades and four major projects:
First Phase:
i. MLE Substation Expansion to 170 MVA (ultimate 200 MVA) (this project);
Second Phase:
ii. CBN Substation reinforce to 200 MVA (Investment Planning ID: 92910);
iii. SMW Substation Decommissioning (Project release after fiscal 2023); and
Third Phase:
iv. CBN Substation reinforce to 300 MVA (future project).
The Mount Lehman Substation Upgrade project comprises the first phase of upgrades.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits:	
• Increase capacity in the Abbotsford area to ensure that BC Hydro can continue to reliably meet the needs of existing and future customers for the next 10 years or more. • Enable safety improvements at CBN substation. • Improve safety by enabling the decommissioning of SMW substation.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: N/A	

Investment Planning ID: 92910	**Project Name:** Clayburn Substation Upgrade	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** F17-F19 RRA: • Appendix I, line 37 • BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1	

Description:

The purpose of the Clayburn Substation Upgrade project is to reduce safety risks, and restore and upgrade the substation's 25 kV feeder capacity to 200 MVA.

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

The Abbotsford area is currently supplied by the Mount Lehman (**MLE**), Clayburn (**CBN**), Sumas Way (**SMW**) and Gloucester (**GLT**) substations. At present, the total capacity of these four stations is 360 MVA.

The general strategy for the area is to expand the MLE substation, address safety issues at the CBN substation, and decommission the SMW substation.

At CBN substation, the existing 25 kV feeder sections are outdoor compact air insulated switchgear with inadequate clearances to energized equipment. These require extended outages for routine operation and maintenance. However, opportunities to take the required outages at CBN substation have been very limited, due to the unacceptable impact on customers. As a result of the safety issues associated with performing work, coupled with the challenges with finding appropriate outage times, maintenance on the CBN substation feeder sections has been postponed indefinitely.

Discussion of Alternatives:

This project was identified as a result of a 30-year study carried out for the Abbotsford area in 2013 to mitigate safety issues at SMW and CBN substations and address capacity shortage in the Abbotsford area. The area study resulted in three alternative solutions being identified and reviewed. The alternative comparison was a comparison of different implementation strategies to determine not only what should be done, but also their timing. These were re-evaluated during the Identification Phase of the Mount Lehman Substation Upgrade project. A leading alternative was accepted that includes three phases of upgrades and four major projects:

First Phase:

i. MLE Substation Expansion to 170 MVA (ultimate 200 MVA) (Investment Planning ID: 92907);

Second Phase:

ii. CBN Substation reinforce to 200 MVA (this project);

iii. SMW Substation Decommissioning (Project release after fiscal 2023); and

Third Phase:

iv. CBN Substation reinforce to 300 MVA (future project).

The Clayburn Substation Upgrade project is the first project in the second phase of upgrades. It is considered the only viable alternative since no other alternative will meet the objectives of the accepted overall solution for the Abbotsford area.

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">Project Impacts & Benefits:
Improve reliability in the Abbotsford area by restoring the capacity of CBN substation to 200 MVA.

[1] Start Date of Construction is the Implementation Approval Date.

[redacted]

Investment Planning ID: 900816	**Project Name:** Pemberton - Substation Upgrade	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Future	**Filing Reference:** New	

Description:

This project will address reliability risks associated with the load exceeding the firm capacity of the Pemberton (**PEM**) Substation, as well as end-of-life and polychlorinated biphenyl (**PCB**) contaminated equipment.

Key Drivers:

- Reliability
- Safety
- Environmental

Issues Being Addressed:

The current load at the PEM Substation exceeds the station's current firm capacity of 22 MVA. This capacity shortfall will be exacerbated in the future, as there are several load interconnection requests from customers.

There are also a number of reliability and safety risks associated with some of the equipment, namely:

- The poor condition of the 230 kV and 25 kV wood pole structures;
- Two 25 kV bulk oil circuit breakers are in poor condition and contain PCB levels above the allowable amounts, requiring phase out by the end of 2025; and
- Limited space between equipment poses safety risks for workers due to limited clearance between energized equipment and ground and lengthy outages are required to safely perform work.

Discussion of Alternatives:

The alternatives being considered include:

i. **Build a new station and decommission existing PEM station:** This alternative will build a new station at a new site, and decommission the existing substation;
ii. **Rebuild the station** at the existing site: This alternative will rebuild the station at the existing site and decommission some of the ageing assets;
iii. **Install a modular substation** This alternative will address growth needs. This alternative would also replace end-of-life and PCB contaminated equipment at the existing site; and
iv. Do nothing.

Project Impacts and Benefits:

- Increase reliability in the area served by PEM station.
- Increase the firm capacity of PEM station.
- Remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline.
- Address safety concerns at PEM station.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

[1] Start Date of Construction is the Implementation Approval Date.

The purpose of this project is to improve the reliability at Sperling Substation (SPG).</td></tr>
<tr><td colspan="3">Key Drivers:
• Reliability
• Safety</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The 60 series feeder section consists of 12 kV bulk oil breakers and a lattice steel structure built for 4 kV prior to 1950. The 60 series feeder section and the bulk oil breakers in the 70/80 series feeder section are at end of life. One breaker in the feeder section has failed, and more breaker failures are expected in the near future. The 60 series feeder section also has insufficient Limits of Approach to protect worker safety. The existing lattice structure does not meet current seismic requirements and is at end-of-life due to aging and corrosion.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
Five alternatives were considered during the Needs stage including:
i. Do nothing and defer the work;
ii. Replace only the bulk oil breakers in the 60 series feeder section;
iii. Replace the existing 60 series feeder section, the bulk oil breaker in the 70/80 series feeder section and four end-of-life electromagnetic protection relays in the substation: the non-arc resistant metalclad switchgears would be replaced with new arc-resistant switchgears;
iv. Decommission SPG and transfer load to other stations; and
v. Replace SPG with a new substation.
Alternative iii, Replace the existing 60 series feeder section, the bulk oil breaker in the 70/80 series feeder section and four end-of-life electromagnetic protection relays in the substation, was selected as the preferred alternative. The non-arc resistant metalclad switchgears will be replaced with new arc-resistant switchgears. This was considered to be the only viable alternative to address the reliability and safety issues at SPG.</td></tr>
<tr><td colspan="3">Project Impacts & Benefits:
• Replacement of the 60 series feeder section with indoor switchgear improves reliability
• Addresses the Limits of Approach (Safety) by using a smaller footprint than other options, resulting in fewer space constraints at SPG.</td></tr>

Development Phase: Identification	**Filing Reference:** New	

Description:

The purpose of this project is to improve the reliability, and reduce the environmental and safety risks associated with transformer T3 and the 12 kV assets at Bridge River 1 Generating Station (**BR1**) and T4 Transformers at Bridge River Terminal (**BRT**).

Key Drivers:

- Reliability
- Environmental
- Safety

Issues Being Addressed:

Reliability risks due to transformer health:

- Phases A, B and spare of transformer T4 at BRT substation are all approaching end of life. Asset health indicators for phases A and B are 'poor'. A significant failure of these phases could cause an extended reduction in the ability to transmit power from the Bridge River system; and
- Transformer T3 at BR1 substation has an asset health indicator of 'very poor' indicating the unit is near end of life.

Environmental risks: A significant failure of transformer T3 may result in an oil release to Seton Lake with environmental impacts.

Other asset reliability and safety issues: The 12 kV system at BR1 requires redevelopment because of aging equipment, limits of approach violations and other safety concerns.

Discussion of Alternatives:

For the BRT – T4 system, three alternatives will be evaluated during the Identification Phase:

i. **Remove phase A** and replace it with a refurbished Phase D, obtain a new spare single phase transformer, add oil containment and passive fire protection;
ii. **Replace phase A & phase B** with new single phase transformers, refurbish phase D for use as a spare transformer, add oil containment and passive fire protection; and
iii. **Replace all three phases of T4** with a new three-phase transformer, obtain an additional new three-phase transformer for use as a spare, add oil containment and passive fire protection.

For the BR1 – T3 the following four alternatives will be evaluated during Identification Phase:

i. Replacement;
ii. Do Nothing;
iii. Deferral; and
iv. Decommissioning.

For the 12 kV system, the following three alternatives will be evaluated during Identification Phase:

i. Replacement;
ii. Do Nothing; and
iii. Deferral.

[1] Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits: • Improve reliability of T4 at BRT, as well as transformer T3 and the 12 kV assets at BR1. • Reduce potential environmental risks associated with transformer T3. • Reduce potential safety risks associated with the 12 kV system.	
Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when project reaches Implementation.
Additional Information: The Bridge River System lies within the traditional territory of the St’át’imc Nation. BC Hydro and St’át’imc have a set of Agreements (signed in 2011) that settle all past, present and future claims related to the Bridge River facilities and provide legal certainty around continued operations of the Bridge River facilities and inform ongoing relationship development. BC Hydro is engaging the St’át’imc Nation in a manner consistent with our Agreements and continues to work with the St’át’imc to address issues and concerns around this project	

Investment Planning ID: 93731	**Project Name:** JOR T1 & T2 Replacement	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** New	

Description:

The purpose of the project is to improve the reliability, and reduce the safety and environmental risks at the Jordan River (**JOR**) substation.

Key Drivers:

- Reliability
- Safety
- Environmental

Issues Being Addressed:

Transformers T1 and T2 are 48 years-old and have numerous deficiencies, including the lack of monitoring gauges, lack of effective cooling, leaking bushings and significant oil leakage from the main tanks with no oil containment. T2 is being closely monitored due to elevated levels of combustible gasses which caused an outage in 2015. T1 and T2 are unique transformers with no system spares.

The transformers are in close proximity to each other and other equipment, and there is insufficient clearance between the equipment to allow access for maintenance and fire protection.

The facility was constructed with no fire barriers or oil containment which would reduce collateral or environmental damage in the event of a catastrophic failure. This exposes both units to risk of a single event, such as a failure of either unit or a circuit breaker, reducing both worker safety and expected reliability. Elimination of this risk is a project objective.

Circuit breakers, disconnect switches, instrument transformers and voltage regulators at JOR are in a deteriorated state. The switchyard does not meet current safety, environmental and seismic standards.

Discussion of Alternatives:

Five alternatives were evaluated during Identification phase:

i. **Like for like replacement** of end of life equipment (was considered not viable);
ii. **Transformer replacement with separate distribution transformers** (was considered not viable);
iii. **Transformer replacement and switchyard expansion**;
iv. **Single-phase step-up transformers**; and
v. **Transformer replacement and switchyard expansion and pad mount distribution transformers**. The two step-up transformers will be replaced, and a portion of the switchyard will be rebuilt. Distribution voltage connection would be through two new pad mounted transformers.

Alternative v, Transformer replacement and switchyard expansion and new pad mount distribution transformers, was selected as the leading alternative because it was the lowest cost viable alternative that addressed the reliability and safety risks.

Project Impacts and Benefits:

- Reduce reliability, environmental and safety risks by reconfiguring the substation, expanding the switchyard and replacing the aging equipment.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.
Additional Information: Construction on the JOR Upgrade Governor & PRV Controls project (G000158) is likely to occur during the same period. The JOR Upgrade Governor & PRV Controls project requires an outage from March to early September 2021. The substation work will coordinate outages with the JOR Upgrade Governor & PRV Controls project.

</table>

Description:

The purpose of this project is to improve the safety, environmental and reliability issues at Mainwaring Substation.

Key Drivers:

- Reliability
- Safety
- Environmental

Issues Being Addressed:

Transformers T1 and T3 are approximately 60-years old and nearing end of life, resulting in increased reliability risk. Both transformers have no on-load tap changers (**OLTC**) resulting in the need for 40 voltage regulators on the feeder positions. The majority of the voltage regulators are in poor condition.

The feeder sections are nearing end of life resulting in increased reliability and safety risk. Many of the circuit breakers and voltage regulators contain oil with PCB concentrations above the federal PCB regulation threshold and are required to be removed by 2025. The feeder section has clearance issues and poses safety risks for workers.

Discussion of Alternatives:

For transformers T1 and T3, three alternatives were evaluated during Identification Phase:

i. **Ongoing sustainment** of individual assets as they fail or reach end of life;

ii. **Extend and upgrade the existing substation** to replace the T1 and T3 transformers; and

iii. **Build a new substation** in the Metrotown area.

Alternative ii, Extend and upgrade the existing substation, was selected as the leading alternative because it is expected to cost less, have fewer stakeholder issues, and can be completed six years earlier than Alternative iii.

For the 50/60 Series Feeder Section, two alternatives will be evaluated during Identification Phase:

i. **Add** a new indoor gas insulated (**GIS**) feeder section; and

ii. **Refurbish** the existing 50/60 series feeder section.

Project Impacts and Benefits:

- Reduce reliability, environmental and safety risks by extending and upgrading the substation.

[1] Start Date of Construction is the Implementation Approval Date.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.
Additional Information:

Investment Planning ID: 900152	**Project Name:** Natal Sub – NTL 60-138 kV Rebuild	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** New	

Description:

The purpose of the project is to improve the reliability and reduce environmental risks at Natal (**NTL**) substation.

Key Drivers:

- Reliability
- Environmental

Issues Being Addressed:

Originally built in 1946, NTL is a transmission substation in southeast B.C. region. NTL is a point of intertie with the Alberta transmission system. NTL is also connected to several other BC Hydro substations at 60 kV, 138 kV, and 230 kV as well as multiple transmission voltage customers.

The main issues and risks at NTL are:

- Reliability: The power transformers, voltage regulators, circuit breakers, disconnect switches, instrument transformers, control building and many protection relays in the 60 kV to 138 kV switchyard are in poor condition; and
- Environmental: Two circuit breakers contain PCB contaminated oil. Current Federal PCB Regulations require the phase out of electrical equipment containing PCB levels of 50 ppm or more by 2025.

Discussion of Alternatives:

Four alternatives were evaluated during Identification Phase:

i. **Within the existing site, replace the NTL 60 kV to 138 kV switchyard,** end of life equipment, and the control building;
ii. **On a new property, replace the NTL 60 kV to 138 kV switchyard,** end of life equipment, and the control building;
iii. **Replace the NTL 60 kV to 138 kV switchyard considering 138 kV to 230 kV transformation** and new, smaller 60 kV switchyard; and
iv. **Do nothing or deferral.**

Alternative i, Within the existing site, replace the NTL 60 kV to 138 kV switchyard, end of life equipment, and the control building, was selected as the leading alternative. This alternative will address the current health and condition of the existing 60 kV to 138 kV station, which poses unacceptable reliability risks. Consideration was given to ensure sufficient space is available on the existing property and the acquisition of new property is not required. This alternative maintains power supply to customers during the construction period.

Project Impacts and Benefits:

- Reduce reliability risks by replacing the NTL Substation 60 kV to 138 kV switchyard, and associated control building.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

<tr><td colspan="4">Description, Objectives and Scope of Program of Projects:
This program of projects was defined to replace ageing 500 kV shunt reactors from the Peace Region to Kelly Lake Substation. A Program Delivery Strategy will be developed during the Identification phase of Phase 1 of the program. This delivery strategy will focus on identifying the most efficient and cost effective model to deliver the subsequent projects within the program.
The objective of this project is to replace 2 reactors as part of a larger program addressing end-of-life units at G.M. Shrum (5RX1, 5RX2), Williston (5RX2, 5RX3, 5RX4, 5RX5, 5RX7) and Kelly Lake (5RX1, 5RX3) according to a ranked priority that is based on the condition assessment. Most of the reactors are single phase units with the exception of Williston 5RX7.
These reactors are required for the operation of the 500 kV bulk transmission system from the Peace Generation system. Failure of any one of the reactors will result in unacceptably high voltage in the 500 kV system, and affect the continued operation of the 500 kV system.</td></tr>
<tr><td colspan="4">Schedule of Program of Projects:
The program strategy will consider replacement of these reactors over a period of 11 years.</td></tr>
<tr><td colspan="4">Risks and Mitigation Strategies:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.
The risk mitigation will be determined when the project reaches Definition phase.</td></tr>
<tr><td colspan="4">Additional Information:
This is an Appendix J for a Program of Projects as outlined in the Revised Proposal, Appendix B, item 6 (k), filed with the BCUC on June 13, 2018.</td></tr>

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: **901034**	**Project Name:** **Norgate - Substation Upgrade**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Future	**Filing Reference:** New	

Description:

This project will address end of life equipment and remove polychlorinated biphenyl (PCB) contaminated equipment at Norgate (**NOR**) substation.

Refer to the following Appendix Ks for additional information: Integrated Planning Report for Capilano and Lynn Valley Substations and Distribution Area, and Asset Management Strategy – Section 2.2.2: Circuit Breakers for additional information.

Key Drivers:

- Reliability
- Environmental

Issues Being Addressed:

The following are the main issues at the Norgate substation that will be addressed as part of this project:

- The poor condition of three power transformers which are subject to oil leaks;
- The poor condition of the voltage regulators in the feeder section which contain polychlorinated biphenyl (**PCB**) at levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline;
- The poor condition of a significant portion of the circuit breakers, reactors, protection and control assets, and disconnect switches; and
- Safety issues related to limited clearance between energized equipment and ground in the feeder section.

Discussion of Alternatives:

Alternatives to be considered include:

i. **Do nothing**;
ii. **Address** environmental compliance requirements only;
iii. Replace/Refurbish the transformers and 12 kV feeder section; and
iv. **Transfer** the load to the neighboring stations and decommission the transformers and the feeder section.

Project Impacts and Benefits:

- Address reliability risks at NOR substation.
- Comply with Federal PCB Regulations.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: Multiple	**Program Name:** NERC CIPv5 Compliance	
Forecast Capital Cost:[1] $40.1 million	**Forecast In-Service Date:**[2] In Compliance of NERC CIP v5 requirements by October 2018. In-Service date of fiscal 2023 for non-regulated enhancements.	**Start Date of Construction:**[3] Fiscal 2017
Development Phase: Multiple (In-service and Implementation)	**Filing Reference:** F17-F19 RRA: • Appendix I, line 47, Appendix J, page 73, • BCUC IRs 1.70.3, 1.111.1 to 1.111.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1	

Description:

BC Hydro achieved compliance with NERC CIP Version 5 by October 1, 2018.

The NERC CIP v5 Compliance initiative consists of five projects and work packages covering five business groups (Technology, Physical Security, Generation Stations, Transmission Stations, and Grid Operations) focused on compliance efforts as indicated below:

1. Transmission Stations – addresses Transmission based Cyber Assets;
2. Generation Stations – addresses Generation based Cyber Assets;
3. Grid Operations – addresses Grid based Cyber Assets;
4. Technology – addresses IT and Physical Security Cyber Assets; and
5. Physical Key Management Work Package– addresses physical spaces containing Cyber Assets.

The purpose of the initiative is to upgrade electronic and physical security for computer/electronic equipment used to control and monitor the Bulk Electric System (**BES**) to meet the standard defined by the North American Electric Reliability Corporation (**NERC**).

The Generation, Grid Operations, and Technology projects and related Physical Key Management work are now in-service; with no remaining capital spend in fiscal 2020 or later.

The Transmission Stations project is continuing in Implementation, in order to extend use of the Station Gateway System and automate a number of manual compliance processes to facilitate on-going sustainment. This effort will exceed NERC CIPv5 compliance requirements, and is expected to complete in fiscal 2023.

Key Drivers:

- Reliability
- Reputational
- Financial Loss

---

1 Forecast Capital Cost was $40.1 million at December 31, 2018.

2 There are multiple in-service dates within the program, the latest of which is for the automation of processes at Medium Impact T&D Stations in fiscal 2023. All requirements under NERC CIPv5 under this program were met by October 1, 2018.

3 There are multiple Start Dates of Construction (Implementation Approval Dates) the earliest of which was for the Technology NERC CIP v5 project, having Start Date of Construction in fiscal 2017.

<table>
<tr><td colspan="2">Issues Being Addressed:
NERC Critical Infrastructure Protection (CIP) Reliability Standard Version 5 was adopted in B.C. by the Commission in July 2015. Through Commission Order No. R-38-15, BC Hydro reached compliance with Version 5 of the standard by October 2018, which has been met</td></tr>
<tr><td colspan="2">Discussion of Alternatives:
None.</td></tr>
<tr><td colspan="2">Project Impacts and Benefits:
• Meet regulatory (NERC CIP Version 5) requirements.
• Improve overall cyber security of BES Cyber Assets.
• Mitigate risk of financial penalties for non-compliance.</td></tr>
<tr><td>Project Implementation Phase Risk:
The ongoing Transmission Stations project currently does not have any identified Zone 3 (high) Implementation Phase risks.</td><td>Risk Treatment:
N/A</td></tr>
<tr><td colspan="2">Additional Information:
Forecast Program capital cost information is provided as of December 31, 2018 in order to present a recent, consolidated forecast of program costs, reflecting the in-service status of the majority of NERC CIP v5 projects and work packages. The forecast cost of the Transmission Stations portion of the program cost is $31.2 million to $17.7 million as provided in Appendix I.</td></tr>
</table>

<table>
<tr><td>Investment Planning ID:
92183</td><td colspan="2">Project Name:
Vancouver Island Microwave Radio System</td></tr>
<tr><td>Forecast Capital Cost:
$32.5 million</td><td>Forecast In-Service Date:
Fiscal 2021</td><td>Start Date of Construction:[1]
Fiscal 2018</td></tr>
<tr><td>Development Phase:
Implementation</td><td colspan="2">Filing Reference:
New</td></tr>
</table>

Description:

The purpose of this project is to replace discontinued microwave radios and multiplexing equipment and incorporate Multi Protocol Label Switching (**MPLS**) at 31 existing sites on Vancouver Island.

The system will be extended to Gold River Substation (**GLD**) and will replace aging Power Line Carrier (**PLC**) systems, increase the communications bandwidth in this area, and allow for high-speed connectivity into Strathcona (**STR**) and Ladore (**LDR**) generating stations.

Key Drivers:

- Reliability

Issues Being Addressed:

The issues and risks associated with the BC Hydro Telecommunication system on Vancouver Island include:

- Equipment reliability and repair issues due to aging equipment that is no longer manufactured or supported by the manufacturer; and
- Lack of communications capacity in the existing telecommunication system to support the increasing communication needs for the existing plants and the new capital projects in progress and planned on Vancouver Island.

Discussion of Alternatives:

Three alternatives were considered in Identification Phase:

i. **Replace** equipment that will not be supported after 2018 **and extend** the Microwave network to GLD;

ii. **Replace** equipment that will not be supported after 2018; and

iii. **Do nothing:** Continue to use the existing microwave radio, multiplexing, and grooming equipment.

Alternative i' Replace equipment that will not be supported after 2018 and extend the Microwave network to GLD, is the preferred alternative as it will improve system reliability and ensure sufficient capacity on the Vancouver Island Power Line Carrier system. MPLS is a network technology that increases the efficiency of transporting Telemetry and Control (**SCADA**), Corporate LAN, voice, and operational traffic.

Project Impacts and Benefits:

- Improve reliability of the microwave radio system.
- Improve operating capacity of the microwave radio system.
- Improve the capacity of the powerline carrier to GLD by replacing it with a microwave system

Project Implementation Phase Risk:	**Risk Treatment:**
This project currently does not have any identified Zone 3 (high) Implementation Phase risks	N/A

Additional Information:

N/A

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: **92768**	**Project Name:** **Various Sites - Microwave System Project Telecom MPLS and DACS Upgrade**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Future	**Filing Reference:** New	

Description:

This project will implement a new smaller Digital Access and Cross-connect System (**DACS**) for teleprotection to address end of life issues with the existing DACS equipment, and Multi-Protocol Label Switching (**MPLS**) equipment that will allow for more efficient use of telecom capacity.

Refer to Appendix K – Asset Management Strategy – Section 2.4.1 and 2.4.2: Fibre Optic & Microwave Equipment for additional information.

Key Drivers:

- Reliability
- Safety

Issues Being Addressed:

Key components of the telecommunications system that directly support the reliability and safety of the Transmission system are at end of life, no longer available for replacement, and no longer supported by the vendor. This project will upgrade these components. The project will also ensure that the telecommunications system continues to meet NERC reliability standards.

Discussion of Alternatives:

Alternatives considered for the project include:

i. **Do nothing:** Run until failure. In time, teleprotection, grid control, and remedial action schemes will not operate effectively so the transmission system will not be safe or reliable. This alternative is rejected;

ii. **Defer:** Defer the upgrade of the DACS by five years. Refurbishing and sourcing used products from the reseller market is becoming increasingly difficult. This alternative would allow for the vendor market to evolve the MPLS or other technology solutions to meet the needs of teleprotection and potentially simplify the solution being implemented; and

iii. Upgrade: Implement a new smaller DACS for teleprotection and MPLS equipment.

Project Impacts and Benefits:

- Increase the reliability of the telecommunications supporting the bulk electric system.
- Add telecommunications services (such as corporate LAN) to BC Hydro sites which do not currently have corporate services.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

Additional Information:

N/A

[1] Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: 901002	Project Name: 2L146 - Cable Replacement	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** New	

Description:

The purpose of this project is to address reliability and environmental risks associated with the poor asset health of 2L146 cable.

Key Drivers:

- Reliability
- Environmental

Issues Being Addressed:

Circuit 2L146 is a 230 kV direct buried oil-filled cable that runs 7.1 km between Horsey substation (**HSY**) and Goward substation (**GOW**) in Victoria. It has been in service since 1976 and has a history of leaks. The cable is in proximity to environmentally sensitive areas, fish habitat and salmonid spawning grounds. Continued oil leaks could have ecological impact on such sensitive areas, and impact community base restoration efforts targeted to improve the habitat value. In recent years, there have been at least seven leaks on the circuit, including one which resulted in oil contaminating Colquitz Creek. Many of the circuit's joints were also gassing thus requiring replacement; more replacements are expected to be required in the future.

In addition, 2L146 was identified as being at high risk for failure during an earthquake in the recent seismic review. Currently, the circuit has an asset health index grade of Very Poor. Failure of this cable would mean that Goward, Horsey, or Esquimalt substations would be reliant on a single circuit and would be at risk of total station outages for six weeks to one year if a concurrent outage occurred on any one of the other circuits supplying this area (2L143, 2L144 or 2L145). This represents up to 375 MVA of load in the Victoria area at risk in the event of a concurrent outage on any of the other circuits.

Based on load forecasts for the Southern Vancouver Island region and a desire to prevent overloads on existing circuits, the existing 2L146 cable will not provide sufficient capacity to meet the local load following a single contingency event after fiscal 2025. This would result in load shedding in the Victoria area and a violation of NERC planning standards.

Discussion of Alternatives:

Three alternatives were evaluated during Identification Phase:

i. **Do nothing / deferral:** This option would defer the replacement of the cable for five years, which may lead to a reactive replacement and increased system risk. This increased risk of circuit failure would leave Horsey and other Victoria substations with diminished reliability for extended periods;

ii. **Replace:** Replace the existing cable with a new cable with the existing rating. It would be installed in a new duct bank and use solid dielectric insulation. However, it would not address the overload issues expected in the future; and

iii. **Upgrade:** Upgrade by replacing the existing cable with a new cable capable of meeting load growth in the future. It would be installed in a new duct bank to improve maintainability and would have solid dielectric insulation to eliminate the risk of oil leaks.

Alternative iii, Upgrade the cable, was selected as the only viable alternative for the project that will meet future load growth.

[1] Start Date of Construction is the Implementation Approval Date.

<table>
<tr><td colspan="2">Project Impacts & Benefits:
• Ensure that future load growth can be met.
• Improve reliability associated with Very Poor asset health.
• Reduce environmental risks associated with the 2L146 cable.</td></tr>
<tr><td>Project Implementation Phase Risk:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.</td><td>Risk Treatment:

</table>

1 Start Date of Construction is the Implementation Approval Date.

Investment Planning ID: **94035**	**Project Name:** **5L63 Telkwa Relocation**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** F17-F19 RRA: • Appendix I, line 45, Appendix J, page 71 • BCUC IRs 1.70.3, 2.249.8, 2.260.4, BCOAPO IR 1.36.1	

Description:

The purpose of the project is to continue reliable transmission of electricity on 5L63 by relocating the line segment currently situated in an active landslide area.

Key Drivers:

- Safety
- Reliability

Issues Being Addressed:

Northwest British Columbia, including the communities of Prince Rupert, Terrace, Kitimat and Smithers are interconnected by a series of 500 kV transmission lines: 5L61, 5L62 and 5L63. Circuit 5L63, built in 1973 / 74 is a 500 kV radial transmission system between Telkwa Substation (**TKW**) and Skeena Substation (**SKA**). As a radial feed, the reliability of this line is essential for this large region of the province.

A section of transmission line 5L63 crosses the landslide area known as the “bulbous toe”. One tower is located in the geotechnically unstable area which has been gradually sliding downhill for approximately 35 years resulting in the tower moving approximately 0.3 metres per year. The continued movement of the tower is leading to a growing risk of catastrophic failure.

The movement is also creating a safety risk to crews performing maintenance on this tower as they are running out of margin to safely adjust guy wires and insulator strings on the tower. There is also a risk that a sudden landslide would destroy the tower and sever the line resulting in an extended outage in the area.

Discussion of Alternatives:

Four alternatives were evaluated during Identification Phase:

i. **Do nothing,** continue to maintain;
ii. **Defer** risk mitigation;
iii. **Do nothing but acquire spares** and pre-plan an emergency response; and
iv. **Relocate** 5L63 away from landslide area.

Alternative iv, Relocate 5L63 away from landslide area, was selected as the only viable alternative for the project, as the other alternatives would not reduce the reliability and safety risks.

Project Impacts and Benefits:

- Improve the reliability of 5L63 and the large region of the province that it serves.
- Address safety risks associated with the section of 5L63 in a landslide area.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation.

[1] Start Date of Construction is the Implementation Approval Date.

Additional Information:
BC Hydro is targeting completion of the project for March 2021 to accommodate customer load interconnection requirements.

Program of Projects Name: H-Frame Elimination - Chinatown		
Appendix I Reference: Distribution, page 7, line 21.		
Investment Planning ID: **900557**	**Project Name:** **H-Frame Elimination – Chinatown**	
Forecast Capital Cost: $48.4 million	**Forecast In-Service Date:** Fiscal 2020	**Start Date of Construction:**[1] Fiscal 2016
Development Phase: Implementation	**Filing Reference:** F17-F19 RRA: • BCUC IRs 1.77.2, 2.307.3	

Description, Objectives and Scope of Program of Projects:

This Program of Projects will eliminate the safety hazards associated with the distribution lines built on H-Frame structures located in back lanes in the Chinatown area of Downtown Vancouver by constructing new underground feeders and relocating overhead feeders and services to the new underground system. Approximately 110 H-Frame structures have primary conductors that do not meet current safety clearances relative to the existing buildings. This close proximity to fire escapes and windows in the back lanes of buildings poses a significant safety risk to the public. In many of the narrow back lanes, it is not possible to bring the H-Frame system into compliance with current safety clearance codes and standards. The objective of the project is to reduce the risk of public contact incidents from these H-Frames.

The scope of the Program of Projects includes:

- Relocating electrical equipment underground in new civil infrastructure to reduce the potential public electrical contact hazard. This will also mitigate the risk of vandalism as well as improve the visual aesthetics of the area; and
- Aligning the work with the Downtown Vancouver Electric Supply Plan.

Schedule of Program of Projects:

The planned in-service dates for the various projects within the program are summarized as follows:

- Primary System Projects – October 31, 2019
  - Columbia & Pender;
  - Main & Powell;
  - Gore & Pender; and
  - Main & Georgia;
- Secondary System Projects – March 31, 2020:
  - Columbia;
  - Main & Powell;
  - Gore & Pender; and
  - Main & Georgia;
- Automation/Fibre Project – October 31, 2019; and
- Dismantling/Removal Project – March 31, 2020.

[1] Start Date of Construction is the Implementation Approval Date.

Risks and Mitigation Strategies:

Risks include:

- The timely development of new or enhanced equipment standards (e.g., to interconnect in-building switchgear to the primary open loop system) and the procurement of long lead time underground equipment (vaults, submersible transformers and switchgear). Any delays in finalizing standards or procuring equipment may delay construction schedules. This risk is being mitigated by identifying any potential deficiencies or risks in early design phases and by placing early pre-orders of long lead time equipment;
- Identifying acceptable locations for underground vault and above ground control enclosures with the City of Vancouver and impacted stakeholders. This is a challenge due to the congested underground infrastructure in Downtown Vancouver. This risk is being mitigated through regular interactions with the City of Vancouver and impacted stakeholders during the design phase;
- There are challenges with negotiating upgrades to customer-owned secondary electrical infrastructure due to a lack of interest or responsiveness from some customers, or difficulty identifying or contacting building owners (e.g., owners may reside outside B.C. or Canada or the building may be owned by a numbered company). This risk is being mitigated through BC Hydro's Community Engagement team involvement in working with the design team and Key Account Managers to help identify building owners, communicate the project objectives, identify the required building modifications and work to obtain signed new Electric Service Agreements; and
- Other construction challenges include limited resources to perform civil work, management of vehicle and pedestrian traffic, congestion with other underground utilities, and limited working hours for construction. These risks are being mitigated by early and frequent engagement with the City of Vancouver and the local Business Improvement Association.

Additional Information:

- This is an Appendix J for a Program of Projects as outlined in the Revised Proposal, Appendix B, item 6 (k), filed with the BCUC on June 13, 2018 as part of the Capital Expenditures and Projects Review. Individual projects within this Program of Projects do not meet the criteria for inclusion in Appendix I.

Investment Planning ID: **900556**	**Project Name:** **Various Sites - LED Street Light Conversion**	
Forecast Capital Cost: TBD	**Forecast In-Service Date:** TBD	**Start Date of Construction:**[1] TBD
Development Phase: Identification	**Filing Reference:** New	

Description:

This project involves the mass conversion of high pressure sodium (**HPS**) street lights to LED street lights.

For additional information, refer to Appendix K – Asset Management Strategy – Section 3.1.8 Street Lighting.

Key Drivers:

- Reputation
- Environmental

Issues Being Addressed:

This Project will address the following:

- Compliance with federal polychlorinated biphenyl (**PCB**) Regulations,
- Mitigation of increasing support and maintenance costs,
- Improvement of customer service and experience,
- Increased data and billing accuracy.

Discussion of Alternatives:

Four alternatives were considered:

i. **Status quo:** Reactive replacement of failed HPS street lights with new bulbs or fixtures. This alternative was rejected;

ii. **Reactive replacement:** Replacement of failed HPS street lights or HPS street lights containing PCBs in a concentration of 50ppm or more with new HPS street lights;

iii. **Reactive Upgrade:** Conversion of failed (or as they fail) HPS street lights to LED street lights; and

iv. **Proactive Replacement:** Mass conversion of all HPS street lights to LED street lights.

Alternative iv, was selected as the leading alternative. It addresses the four key issues identified above; it meets the regulatory requirement, has the lowest lifecycle costs, provides the best customer service and experience, and is technically superior. It also meets the environmental and safety objectives. The other alternatives considered are less efficient and more costly, and do not necessarily meet regulatory compliance and/or improve customer experience and service.

Project Impacts & Benefits:

The expected outcome of this investment is to convert all existing Rate Schedule 1701 Street Lights and Rate Schedule 1755 Private Outdoor Lights from older less efficient High Pressure Sodium (**HPS**) and Mercury Vapour (**MV**) lights to Light Emitting Diode (**LED**) technology.

Project Implementation Phase Risk: Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	**Risk Treatment:** To be determined when the project reaches Implementation.

Additional Information:

<tr><td colspan="3">Description:
The Supply Chain Applications project involves the design and implementation of new business processes and information technology to support the acquisition of materials and services from third parties.</td></tr>
<tr><td colspan="3">Key Drivers:
• Increased operational efficiency,
• Reduced material and service costs,
• Risk reduction.</td></tr>
<tr><td colspan="3">Issues Being Addressed:
In 2013, BC Hydro approved a new Supply Chain Business Model. An assessment of BC Hydro’s current capability against requirements for the new model identified 13 capability gaps requiring technology and process changes. The SupplyChain Applications Project is intended to address these capability gaps and achieve operational efficiencies, reduced material and service costs and an overall reduction in risk.
In the Phase One Decision the BCUC found that, given the capability gap issues raised, the current supply chain system employed by BC Hydro is inadequate considering the size and complexity of BC Hydro and determined that there is a need to address this.</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

Discussion of Alternatives:

BC Hydro employs SAP as the information technology platform for its enterprise resource planning functions and system of record. BC Hydro performed an evaluation comparing a SAP-based technology solution to one based on the existing Ventyx PassPort-based technology. The evaluation indicated that an SAP-based technology solution better supports the Supply Chain Business Model and is expected to provide greater overall net benefits to BC Hydro. Details of BC Hydro's evaluation were provided in Chapter 3 of the Phase One Application filed with the Utilities Commission December 21, 2016.

In the Phase One Decision, the BCUC determined that the work BC Hydro has done to identify and evaluate alternative supply chain applications is reasonable and the selection of an SAP-based system was justified.

Project Impacts & Benefits:

The annual recurring quantifiable benefits of the SCA Project at stabilization are expected to be $34.8 million, with $23 million of this amount monetized. Effort reduction benefits that are quantified but not monetized also have significant value. By redeploying saved time toward other higher-value activities, these effort reduction benefits can help manage increasing workload which may otherwise result in increasing headcount. Additionally there are significant non-quantified benefits, including the ability to close the capability gaps in BC Hydro's Supply Chain function and reduce the current risk profile. Further information on the project benefits and net present value analysis are included in Chapter 3 of the Phase Two Application.

Project Implementation Phase Risk:	**Risk Treatment:**
Scale of business process changes is too large to be absorbed successfully by BC Hydro	• Detailed change management plan. • Extended stabilization period and onboarding plan for implementation and benefits realization. • Strong governance and project management. • Detailed benefit realization plans.
Poor project management	• External quality assurance advisor. • Strong project governance. • Strong project management procedures from the System Integrator.
Poor quality of delivery by systems integrator	• Establish a strong contract with incentives for good quality delivery. • Strong project and contract management. • Robust quality management plan.
Low data quality and or data not being ready according to Project Schedule	• Continue detailed assessment and planning of data conversion requirements in early realization. • Alignment of the data conversion tasks with business transition and resource plans.

Additional Information:

The Phase Two Application relating to the Supply Chain Applications Project was filed with the Utilities Commission on October 12, 2018. The Phase Two Application included a Forecast Capital Cost of $68.0 million based on a Total Expected Capital Cost Estimate of $61.1 million and a Total Capital Project Reserve of $6.9 million. The Authorized Cost estimate (Authorized Cost) is $79.3 million, including capital and operating costs.

<tr><td colspan="3">Description:
This project involves the redevelopment of a regional field office located in Chilliwack.</td></tr>
<tr><td colspan="3">Key Drivers:
• Operational Requirements
• Safety
• Reliability</td></tr>
<tr><td colspan="3">Issues Being Addressed:
BC Hydro operations in the Chilliwack area are based at two locations, Chilliwack and Atchelitz. The existing Chilliwack facility is a leased property within a multi-tenanted facility, consisting of approximately 12,000 ft2 of office and warehouse space at 44550 South Sumas Road. The Atchelitz facility is owned by BC Hydro and was built approximately 40 years ago, and comprises about 5,500 ft2 of office space. It is located at 6155 Lickman Rd in Chilliwack, within the Atchelitz substation property boundaries. A total of approximately 35 staff are based at these two sites.
There is a long-term need for a suitable field office to provide post-disaster recovery and emergency operational support and to meet the needs of the almost 100,000 residents served in Chilliwack and the surrounding areas of Atchelitz, Cultus Lake, Sardis, Promontory Heights, Vedder, Yarrow, and Greendale. This includes appropriate outage response, planning and execution of the electric system to support local/regional development, and maintenance and upgrades to infrastructure to ensure ongoing system reliability in the region. The facilities must remain operational to support 24/7 emergency response in the worst weather conditions and in the event of a natural disaster. The Eastern Fraser Valley is continuing to grow at a fast pace. The population of Chilliwack increased 8.6 per cent between 2011 and 2016, and is expected to continue to grow at a similar rate over the next five to 10 years.
The existing facilities have been prioritized for redevelopment due to: the lack of adequate space for current and projected business operations; the inability to expand either the Chilliwack facility, as it is leased, or the Atchelitz location, as it is in close proximity to a substation; as well as the condition and associated seismic concerns of the existing buildings. The key issues are that the facilities:
• Have inadequate space for existing staff and materials, requiring some staff to work out of the Abbotsford facility, approximately 35 km away, and requiring the Abbotsford office to store a large volume of materials, including poles and transformers, for the Chilliwack/Atchelitz operations. This can delay response time, especially in the winter or during emergencies;
• Are inadequate for working, maneuvering and loading line trucks. The location of the Atchelitz office on the same site as a substation prevents office expansion and puts a strain on the safe and efficient use of yard space. It is also difficult to safely move and load line vehicles in the multi-tenanted Chilliwack office complex;
• Are both located in a high seismic region and do not meet requirements for a facility that is expected</td></tr>
</table>

[1] Start Date of Construction is the Implementation Approval Date.

to be fully functional in a post-disaster situation;

- Have inadequate fire suppression and sprinklers, contain hazardous materials; lack an emergency generator; require the replacement of the Atchelitz end of life roof; and
- Have inadequate office space to support the current and future demands.

Discussion of Alternatives:

The following six alternatives were considered in the Identification phase:

i. **Do nothing:** continue with existing facilities;
ii. **Lease** additional space in the existing Chilliwack facility;
iii. **Renovate and expand** the existing Atchelitz facility, or build new, and maintain the leased Chilliwack facility;
iv. **Construct** a new facility at a new BC Hydro owned location;
v. **Acquire** a new site and construct a new facility; and
vi. **Lease** a new larger facility, long-term.

Alternative v, Acquire a new site and construct a new facility, was selected as the recommended alternative as it best meets the current and anticipated future needs for servicing the Chilliwack region.

Project Impacts and Benefits:

- Project will result in new facility that meets current and anticipated functional and operational needs.
- The new facility will meet all current building codes including post-disaster standards.

Project Implementation Phase Risk:	Risk Treatment:
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase.	To be determined when the project reaches Implementation

Additional Information:

The Chilliwack Field Building was identified in the Previous Application as one of the high priority sites requiring work during the test period. At the time of the Previous Application, the scope of the project was under development.

Investment Planning ID: P201704	**Project Name:** Material Classification Facility Building Redevelopment	
Forecast Capital Cost: $42.4 million	**Forecast In-Service Date:** Fiscal 2022	**Start Date of Construction:**[1] Fiscal 2019
Development Phase: Definition	**Filing Reference:** F17-F19 RRA: • Appendix I, line 11, Appendix J, pages 82-83 • BCUC IRs 1.70.3, 1.117.1, 1.117.2, 1.117.3, 1.117.4, 1.117.5, 1.117.6, 2.249.8, 2.260.4, 2.270.1, 2.271.1, 2.271.2, BCOAPO IRs 1.36.1, 1.64.5, 2.77.1, CECBC IR 1.72.3.2	

Description:

This project involves the redevelopment of the Material Classification Facility located in Surrey.

Key Drivers:

- Environmental
- Operational Requirements
- Safety

Issues Being Addressed:

The Material Classification Facility is located at 12345 88th Avenue in Surrey, BC on the BC Hydro Surrey campus. The facility comprises the Transformer Shop and Hazardous Waste Operations including salvage and disposal operations and occupies an area of 19,766 ft2 of building area and 8.6 acres of yard space. The buildings were constructed throughout the 1970's and 1980's as business needs required. Approximately 27 employees work out of this facility.

The facility receives recovered electrical equipment and hazardous wastes from BC Hydro's facilities from across the entire province, making it critical in supporting other business units' waste needs. The products are received, drained of any oils, sorted, stored, and packaged or re-packaged prior to being transported offsite for recycling, treatment, or disposal at authorized hazardous waste management facilities.

The Material Classification Facility has been identified as a priority for redevelopment due to the environmental regulation requirements, zoning non-compliance, operational challenges, building conditions, and code compliance.

The key issues are that the facilities:

- Will need to meet the Ministry of Environment's requirements that BC Hydro will implement further environmental protection measures to prevent the release of contaminants of concern and prevent pollution;
- Contravene existing zoning regulations from the City of Surrey;
- Do not provide sufficient enclosed areas to sort and store materials;
- Cannot support current business requirements of oil storage and Paper Insulated Lead Covered cable sampling;
- Do not meet current building code standards, including being located in a high seismic region and meeting less than 50 per cent of the BC Building Code minimum requirements for normal buildings being able to withstand a seismic event; and
- Have numerous building components (building envelope, mechanical and electrical systems) at the end of their useful life and needing replacement.

The environmental regulations, functional limitations, and code issues negatively impact the ability of

[1] Start Date of Construction is the Implementation Approval Date.

staff to perform their duties and support BC Hydro operations from the Material Classification Facility.

Discussion of Alternatives:

The following five alternatives were considered in the Identification phase:

i. **Do nothing:** continue with existing facilities;

ii. **Apply for rezoning and, if approved, renovate** and expand the existing facilities to meet current building code, safety and program requirements;

iii. **Apply for rezoning and, if approved, construct** a new facility on the existing site and demolish the existing building;

iv. **Construct** a new facility at a new location on Surrey campus; and

v. **Acquire** a new site off the Surrey campus and construct a new facility.

Alternative iv, Construct a new facility at a new location on Surrey campus, was selected as the recommended alternative as it is the most cost effective alternative that meets the environmental, operational, and zoning requirements.

Project Impacts and Benefits:

- Project will result in a new facility being compliant with Ministry of Environment's Hazardous Waste Regulations.
- Project will reduce the risk of the release of contaminants of concern and prevent pollution.
- Project will result in a new facility being compliant with City of Surrey zoning regulations.
- Project will result in a new facility that meets operational needs and current building codes.

Project Implementation Phase Risk:	**Risk Treatment:**
Risks are identified starting in the Identification Phase and finalized in the Implementation Phase	To be determined when the project reaches Implementation

Additional Information:

The Materials Classification Facility was identified in the Previous Application as one of the high priority sites requiring work during the test period. At the time of the Previous Application, the scope of the project was under development.

The Fiscal 2017 to Fiscal 2019 Revenue Requirements Application identified a possible linkage between this project and the Construction Services/Lower Mainland Transmission Building Redevelopment project. At the time, we had anticipated submitting a section 44.2 application for the two projects, given their combined capital cost. Subsequently, the Construction Services/Lower Mainland Transmission Building Redevelopment project was deferred due to funding constraints, which is discussed further in Chapter 6, section 6.6.4. A project or projects to address the requirements for the Construction Services group and the Lower Mainland Transmission group will be revisited at a future date after the current test period. As a result, the Materials Classification Facility project is proceeding without any direct linkage to the project(s) to address the Construction Services and Lower Mainland Transmission requirements, and therefore a section 44.2 application for the Materials Classification Facility is not contemplated, as the capital cost for this individual project is anticipated to be below the $50 million threshold where BC Hydro would file a building project application.

TBD</td><td>Start Date of Construction:[1]
TBD</td></tr>
<tr><td>Development Phase:
Future</td><td colspan="2">Filing Reference:
New</td></tr>
<tr><td colspan="3">Description:
This project involves the redevelopment of the high criticality large regional field office located in Kamloops.</td></tr>
<tr><td colspan="3">Key Drivers:
• Operational Requirements,
• Safety</td></tr>
<tr><td colspan="3">Issues Being Addressed:
The Kamloops District Office is located at 1155 McGill Road in Kamloops and was constructed in 1981. The District Office is approximately 34,000 ft2 in size and serves BC Hydro customers in Kamloops and the surrounding areas. The facility currently accommodates approximately 130 staff.
There is a long-term need for a suitable field office to provide post disaster recovery and emergency operational support and to meet the needs of more than 100,000 customers in the surrounding area that spans east to Chase, west to Savona, north to Barierre, and south to Lac Le Jeune. This support includes outage response, planning and execution of the electric system to support local/regional development, and maintenance and upgrades to infrastructure to ensure ongoing system reliability in the region. The facilities must remain operational to support 24/7 emergency response in the worst weather conditions and in the event of a natural disaster.
The existing facility has been prioritized for redevelopment due to a lack of adequate space for current and projected business operations, requirement for seismic and safety upgrades, and to address building condition and code compliance. The key issues are that the facility:
• Does not meet current functional and operational needs, with no room for potential growth, i.e. does not provide sufficient space to accommodate all current staff; does not provide adequate truck bays for truck storage or for Fleet’s current needs; and does not provide sufficient yard space for vehicles and materials;
• Is almost 40-years old, and does not meet current building code standards, including being less than 50 per cent of the BC Building Code minimum requirements for a post disaster resistance building;
• Has inadequate fire protection and accessibility, including non-conforming fire separation between the garage and offices;
• Has inadequate office space to support the current and future demands; and
• Has numerous building components (mechanical, electrical, HVAC, interiors) requiring replacement.</td></tr>
<tr><td colspan="3">Discussion of Alternatives:
Alternatives to be considered in the Identification Phase will include: renovate and expand the existing facility, construct a new facility on the existing site, and build a new facility on a new purchased or leased site.</td></tr>
<tr><td colspan="3">Project Impacts and Benefits:
To be determined when project reaches Definition Phase.</td></tr>

Description:

Site C will be a third dam and hydroelectric generating station on the Peace River approximately seven kilometres southwest of Fort St. John. It will be capable of producing approximately 5,100 gigawatt-hours of electricity annually and 1,100 megawatts of capacity.

Key Drivers:

Generation Growth

Issues Being Addressed:

As the third project on one river system, Site C will gain significant efficiencies by taking advantage of water already stored in the Williston Reservoir. This means that Site C will generate approximately 35 per cent of the energy produced at W.A.C. Bennett Dam, with only 5 per cent of the reservoir area.

Discussion of Alternatives:

- Compared to other resource alternatives, Site C is an attractive resource option from the perspective of reliability and cost.
- Site C will be a clean and renewable source of firm electricity for over 100 years.
- Site C will produce among the lowest GHG emissions per GWh, when compared to other forms of electricity generation.

1 Start Date of Construction is the Implementation Approval Date.

Project Impacts and Benefits:

Project Benefits

New resources are required to meet long-term electricity needs in B.C. BC Hydro's long-term energy planning process has found that Site C provides the best combination of financial, technical, environmental and economic development attributes, compared to other electricity-generation options.

The Site C Project will provide key benefits for B.C., including energy, dependable capacity and flexibility, regional economic development, job creation, and benefits for communities and Aboriginal groups.

Project Attributes

- Site C will provide 1,100 megawatts of capacity, and produce about 5,100 gigawatt hours of electricity each year – enough energy to power the equivalent of about 450,000 homes per year in B.C.
- It will be a source of clean and renewable electricity for more than 100 years.
- Site C will have among the lowest GHG emissions, per gigawatt hour, compared to other resource options.
- As the third project on the Peace River, Site C will rely on the existing Williston Reservoir for water storage. This means Site C will generate approximately 35 per cent of the energy produced at the W.A.C. Bennett Dam, with only 5 per cent of the reservoir area.
- Site C will be among the most cost-effective resource options for BC Hydro ratepayers.
- Site C will create approximately 13,000 person-years of direct employment during construction.
- Construction will also provide significant opportunities for businesses of all sizes.
- Construction will contribute $3.2 billion to provincial GDP, including approximately $130 million to regional GDP.
- During construction, Site C will result in a total of $40 million in tax revenues to local governments and, once in operation, $2 million in revenue from grants-in-lieu and school taxes.
- Site C will be a source of affordable power to meet B.C.'s future electricity needs.

Environmental Assessment Process

The Site C Project received environmental approval from the federal and provincial governments in October 2014.

The approval of the project followed a cooperative federal-provincial environmental assessment process by the Canadian Environmental Assessment Agency (**CEA Agency**) and the British Columbia Environmental Assessment Office (**BCEAO**). The process started in August 2011 and took approximately three years to complete.

The environmental assessment process for Site C was thorough and independent and included multiple opportunities for timely and meaningful participation by the public, Aboriginal groups, all levels of government, and other interested stakeholders.

As part of the environmental assessment, BC Hydro undertook multi-year studies to identify and assess potential project effects and proposed comprehensive mitigation measures. All of this information was documented in more than 29,000 pages in the Site C Environmental Impact Statement (**EIS**) and associated documentation. The extensive review process included two months of public hearings in several regional and Aboriginal communities under an independent Joint Review Panel.

Community Benefits and Mitigation Measures

To date, BC Hydro has reached a regional legacy benefits agreement with the Peace River Regional District and community agreements with:

- District of Chetwynd
- District of Taylor
- City of Fort St. John
- District of Hudson's Hope

Among the benefits to local communities from the Site C Project are a regional legacy benefits agreement, infrastructure improvements, recreation and tourism opportunities, and affordable housing.

Project Implementation Phase Risk, Impact & Response Plan

Risk Category(s)	Risk Description	Impact and Response Plan Summary
Geotechnical Construction Execution	On the left bank diversion tunnels: Risk that contractor productivity does not meet plan and/or differing geotechnical conditions.	**Impact:** Potential schedule delay and increased cost. **Response:** Contractor has increased tunnel construction labour and equipment; contractor has improved work methods and/or additional subcontractors; BC Hydro has provided production incentives through settlement agreement with contractor.
Construction Execution	Risk that productivity for roller-compacted concrete is lower than planned.	**Impact:** Project schedule not achieved; potential interface issues may arise with other contractors. **Response:** Physical progress is captured and reported on a weekly basis for key work fronts. Key interface milestones are monitored and discussed on a regular basis. Meetings are held with the contractor on a regular basis.
Risk Category(s)	**Risk Description**	**Impact and Response Plan Summary**
Construction Cost – Labour	Risk that contractor labour rate increases in excess of budgeted amount.	**Impact:** BC Hydro has included provisions in the major contracts that allows for labour escalation to a prescribed amount, as well as a cost / savings sharing formula based on general industry rates above / below the prescribed amount. Increased pressure on the labour market would likely drive labour wage rates higher, potentially resulting in general industry increases beyond the prescribed amounts **Response:** BC Hydro has defined contract labour escalation formulas in all major contracts.
Safety	Risk of a safety incident resulting in fatality or disabling injury.	**Impact:** Serious worker injury or fatality; project delays and associated costs. **Response:** Implemented senior-level safety steering committee with all prime contractors to address shared safety issues and opportunities, hired permanent senior field safety manager, and holding regular on-site safety conferences.
Geotechnical Construction Execution	For work fronts other than the left bank diversion tunnel: Risk of differing geotechnical conditions.	**Impact:** Potential schedule delay and increased cost. **Response:** Completed detailed geotechnical investigations prior to construction; close monitoring and quick intervention to manage construction risk if geotechnical issues arise.
Litigation Indigenous Relations	Risk that Indigenous Nations do not support the project.	**Impact:** Indigenous Nation's file legal challenges (e.g., Injunction Applications) or engage in protest actions that could delay or stop the project work and/or increase costs. **Response:** Project team to fully support the development of legal response documents; follow court order requirements, if applicable; continue to negotiate Impact Benefit Agreements.

Construction Execution	Risk that reservoir clearing not completed for diversion.	**Impact:** Reservoir not cleared causing diversion delay; Outstanding 2018/19 seasonal work moved into next season (2019/20) using up float and increased cost to expedite. **Response:** Award Contracts at start of clearing season (November 2018); carry remaining work into 2019/20 season; hire additional contractors/resources for each clearing season.
Construction Execution	Risk that Highway 29 not completed on time for inundation.	**Impact:** Highway incomplete impacting inundation schedule; additional costs. Response: Increase design resources in peak periods; utilize schedule float; proactively respond to geotechnical issues; proponents to secure steel supply contracts during bid; use Ministry of Transportation Infrastructure specifications; support First Nations contractors to work with qualified builders.
Risk Category(s)	**Risk Description**	**Impact and Response Plan Summary**
Labour Relations and Stability	Risk that project cannot attract and retain sufficient skilled workers.	**Impact:** Contractors may not be able to adequately source, supply, attract, and retain sufficient project labour due to workforce demographics, increased competition for labour from other major projects, and the requirement for specialized workers. This may result in potential impacts to schedule, safety, productivity and cost. **Response:** Contractors provide labour sourcing and supply plans, provide advance notice of foreign workers, and participate in local job fairs. BC Hydro will encourage and facilitate capacity-building initiatives, monitor employee turnover rates and other projects labour conditions.
Foreign Exchange Rate, Interest and Taxes	Risk that BC Hydro's borrowing costs for project are higher than budgeted.	**Impact:** Rising interest rates increase the project's interest costs above the amount budgeted. Response: BC Hydro has hedged interest rates on approximately 50 per cent of future debt placements through fiscal 2024, to reduce the potential impact. The need for additional interest rates hedges is being assessed.

Additional Information:

The Site C Project received environmental approvals from the federal and provincial governments in October 2014. In December 2014, the project received approval from the provincial government to proceed to construction. In December 2017, the government decided to proceed with the Site C Project.

Project components include:

- Access roads and a temporary construction access bridge across the river at the dam site;
- A worker accommodation camp at the dam site;
- Upgrades to roads and realignment of segments of Highway 29;
- Two new 500 kV transmission lines connecting Site C to the existing Peace Canyon Substation, along an existing right-of-way;
- Shoreline protection at Hudson's Hope;
- An 800-metre roller-compacted concrete buttress to improve foundation stability and seismic protection;
- An earthfill dam, approximately 1,050 metres long and 60 metres high above the riverbed;

- A generating station with six 183 MW generating units, and spillways; and
- An 83-kilometre-long reservoir that would be, on average, two to three times the width of the current river.

*Total capital forecast cost presented excludes the Project Reserve of $708 million (established by Government to account for events outside of BC Hydro's control that could occur during construction) which is held by the Treasury Board. The approved total project costs (including Project Reserve, and Regulatory and Operating expenditures) is $10.7 billion

**Planned in-service date for the final unit. This timeline is subject to change based on reviews of the construction schedule.

Fiscal 2020 to Fiscal 2021
Revenue Requirements Application

Appendix K

Summaries of Capital Project Strategies
Plans and Studies

Table of Contents

1 Introduction

This appendix includes summaries of Power System strategies, plans or studies that are linked to specific projects included in Appendix I[1]. Where applicable, the strategy, plan or study linked to a specific project has been identified in column W of Appendix I.

The summaries in this Appendix are consistent with the template provided in Appendix E of Exhibit B-7, filed by BC Hydro as part of the Review of the Regulatory Oversight of Capital Expenditures and Projects proceeding.

This appendix is organized as follows:

- Section 2 provides an overview of the current state of BC Hydro's Power System;
- Section 3 explains BC Hydro's strategic planning process and the types of documents that are included in this appendix; and
- Attachment 1 provides summaries of 54 Power System strategies, plans and studies.

2 BC Hydro's Power System

2.1 Overall System

As described in Chapter 6, BC Hydro's generation, transmission and distribution systems form the Power System, generating electricity and delivering it to our customers throughout B.C. In December 2018, the Auditor General of British Columbia reviewed "whether BC Hydro is managing its assets well through appropriate information, practices, processes and systems. [The Auditor General]

[1] A Technology Strategy and Five-Year Plan is included as Appendix L. Specific strategies are not developed for the Properties, Fleet or Business Support/Other asset categories.

found that it is. BC Hydro has good asset management practices, not by accident, but as a result of a decade-long plan and associated efforts."

Through BC Hydro's capital investments over the last decade, system capacity has been increased, the effective life of several of the critical assets in the system has improved and many of the most critical Dam Safety risks have been mitigated.

BC Hydro continues to provide reliable, affordable, clean electricity throughout B.C. as a result of our asset management and capital investment strategies. As shown in section 6.3.2, BC Hydro's customer reliability, as measured by two industry-standard metrics, System Average Interruption Duration Index (**SAIDI**) and System Average Interruption Frequency Index (**SAIFI**), has performed consistently and BC Hydro's Customer Satisfaction Index indicate that customers continue to be satisfied with the level of reliability they are receiving.

Over time, the condition and performance of existing assets degrade, regulatory and safety requirements change and new assets are required to address load growth and connect new customers. Together, these factors create new issues, risks and opportunities to be addressed through continued maintenance and capital investment.

The following sections provide an overview of the current state of BC Hydro's Power System, with remaining issues, risks and opportunities highlighted. More detailed descriptions of the risks, issues and opportunities are discussed through the summaries of strategies, plans or studies in Attachment 1 of this appendix.

2.2 The Generation System

BC Hydro's generation assets include 83 generating units at 31 hydroelectric generating facilities as well as 81 dams located at generating stations and at additional locations to provide water storage and water diversion functions. Generation assets also include two storage dams, three gas-fired units at

BC Hydro's two thermal generating stations, and four synchronous condenser units at a dedicated synchronous condenser station. These facilities are categorized as "Key", "Strategic" or "Available" according to the significance of the facility to BC Hydro's system. BC Hydro has adopted life cycle asset management practices as its approach to managing generating assets. The objective is to maximize the economic return on physical assets over their life by achieving desired performance outcomes, while effectively managing the risks inherent in owning, managing and operating a large asset base.

2.2.1 Key Facilities

BC Hydro's seven "Key" generating facilities represent the largest hydroelectric facilities on the BC Hydro system and produce approximately 90 per cent of BC Hydro's average annual energy supply. In the past decade BC Hydro completed the installation of Unit 5 at Revelstoke and Units 5 and 6 at Mica generation stations which have added a total of 1500 MW of clean energy to the Power System. In addition, BC Hydro completed a number of sustaining investments to address end of life condition and reliability risks associated with critical equipment, including turbine overhauls and stator /exciter/ runner replacements.

In the coming years, BC Hydro will continue to focus on preserving reliability at the Key facilities, by directing investments towards mitigating the risks associated with the major equipment at these facilities currently rated as Poor and Unsatisfactory. Under this strategy, within 10 years all major equipment at Key facilities will have been, or will have work underway to be, restored to Good or Fair condition. The result of this is that, in aggregate, the reliability of Key facilities will be maintained at or slightly above the average of similar facilities, as reported by the Canadian Electricity Association.

The Bridge River facility contains 30 per cent of all Key facility equipment currently rated as Poor and Unsatisfactory. A number of capital projects are underway at

Bridge River, including the replacement of two of the eight generating units, which are anticipated to be in service in fiscal 2019. This will result in an improvement of asset condition at Key facilities.

The current state of the Key facility assets is also heavily influenced by a number of transformers at GM Shrum (**GMS**) that have been assessed as Poor, and issues with the stators at the Revelstoke facility (500 MW units). Plans are in place to address the deficiencies with the GMS transformers, and the risks with the Revelstoke stators are being addressed, with interim mitigating operating and maintenance strategies prior to proposed capital intervention.

2.2.2 Strategic Facilities

BC Hydro's 18 "Strategic" facilities represent all generating stations on Vancouver Island, all stations located on cascading systems, all thermal generation stations, and generating stations required to provide voltage support to the transmission network. These facilities produce approximately 9 per cent of BC Hydro's average annual energy and provide significant additional value to BC Hydro due to their geographic location and system support services.

In recent years there have been considerable investments in Strategic facilities. Overall, under BC Hydro's Capital Plan, the condition of Strategic hydroelectric facilities has improved. BC Hydro redeveloped the Ruskin and John Hart facilities, which went into service in fiscal 2018 and fiscal 2019, respectively. BC Hydro is restoring the health of the Cheakamus facility through investments in the generating equipment. With the completion of the generator replacement at Cheakamus expected shortly, this facility will see an improvement in its effective life.

Looking out over the next 10 years, equipment in Poor or Unsatisfactory condition at Strategic facilities will either be refurbished or replaced, will have work underway to be refurbished or replaced, or will have a long-term plan developed to mitigate the risk of equipment failure. Discrete investments are being made at Strategic facilities (including thermal generating facilities) to address the highest risks. However, a number of the smaller strategic facilities (e.g., Clowhom and Ash River) will receive limited investment and may experience extended forced outages, or be forced out of service prior to reinvestment. This strategy means that, in aggregate, the reliability of Strategic facilities will be maintained at or restored to the average of similar facilities, as reported by the Canadian Electricity Association.

2.2.3 Available Facilities

BC Hydro's seven "Available" facilities represent those facilities that are of lower strategic importance and produce less than 1 per cent of BC Hydro's average annual energy. 24 per cent of the assets at Available facilities (excluding Elko which is currently out of service) are rated as Poor and Unsatisfactory. The worst assets are located at the four smallest and oldest of these facilities (Shuswap, Elko, Falls River and Spillimacheen). The Elko facility (12 MW) and one of the units at Shuswap (3 MW) are out of service. Based on the current plan, these facilities will not be restored in the next 10 years. BC Hydro expects to continue to provide reliable electricity service to customers with these small facilities out of service.

Overall, Available facilities will receive minimal capital investment and will be taken out of service when they are no longer able to safely generate electricity. BC Hydro will perform regular maintenance and inspection on these assets to keep them safe and inform investment and operating decisions. Options to re-furbish, redevelop or decommission Available facilities that have been taken out of service will be developed as required. There is a high likelihood that a number of these facilities will experience long outages, or be forced out of service over the next 10 years. Over time, this strategy may result in a gradual reduction of the energy produced by Available facilities. However, in the long term this strategy will be revisited if the energy and capacity from these facilities is required, in light of their small contribution.

2.2.4 Dam Safety

BC Hydro operates 81 dams at 43 different sites. Safe operation of a dam considers more than just the physical structure that retains water within the reservoir; it also considers:

- The structures and devices that control and convey water over, through or around the dam leading up to or around the generating station, e.g., spillways, tunnels, penstocks, and gates and valves;
- The natural structures, slopes and barriers that support the dam and surround the reservoir; and
- The supporting infrastructure and instrumentation required to monitor and maintain these various constructed and natural features.

In managing its dams BC Hydro monitors, maintains and, as necessary and practicable, upgrades all of these structures and devices, natural features and supporting infrastructure. A recent audit of BC Hydro’s Dam Safety Program found that “BC Hydro has a well-established Dam Safety Program that is in line with international practices with some aspects operating at best practice levels” and that “BC Hydro continues to be a leader in risk assessment in the international dam safety community with a transparent, systematic and robust risk assessment process.”

BC Hydro’s dams are diverse in character. They range in size from a few very small dams that are upstream of no or only a few persons, to some of the largest dams in the world with that are upstream of several thousands of persons. These dams are classified by the potential consequences of their failure in accordance with the BC Dam Safety Regulation. Of BC Hydro’s 81 regulated dams:

- 28 are classified as being of Extreme consequence;
- Eight are classified as being of Very High Consequence;
- 15 are classified as being of High Consequence;
- 21 are classified as being of Significant Consequence; and
- Nine are classified as being of Low Consequence.

BC Hydro's dams vary in age from just over 10 years old to over 100 years old, with most being between 40 and 70 years old. The dams are situated in a demanding environment, frequently being stressed by extremes in temperature and high inflows. This leads to continuing and expected deterioration of the structures, in particular the spillways requiring ongoing maintenance and occasional capital investments to extend their service lives.

The dams' age also contributes to a state where some equipment is at its end-of-life or where design approaches in use at the time of their construction are no longer considered to be adequate. This is particularly true when it comes to the operational reliability of spillway gates and other flow control equipment, which presents a risk of malfunction that could lead to gates or valves failing to open when needed to route flood inflows or misoperation that could cause sudden changes in downstream flows and endanger the public. BC Hydro actively manages this risk through its continuing program to upgrade and rehabilitate its spillway gates systems.

BC Hydro's dams are located in a part of the world that is subject to natural hazards such as earthquakes and landslides. In response, BC Hydro has developed an industry-leading model to calculate seismic hazards at its dam sites and inform the needs and criteria for seismic upgrades. BC Hydro also maintains a program to monitor the slopes along its reservoirs, which includes instrumentation and drainage infrastructure in some slopes of key interest. Investments are regularly required to replace or remediate this instrumentation and drainage as it ages and loses effectiveness.

BC Hydro has made significant investments in safety upgrades to its dams since 2005, including:

- Approximately $400 million on upgrades to spillway gates systems at various dams;
- Over $200 million in upgrades to Ruskin Dam to address seismic and seepage deficiencies, to increase its flood discharge capacity and to replace its spillway gates systems;
- $120 million to replace the deteriorated rip rap on the upstream face of W.A.C. Bennett Dam;
- $65 million to rebuild Coquitlam Dam; and
- $55 million to perform upgrades to the spillway structure at W.A.C. Bennett Dam and stabilize the rock slope above it.

These investments were prioritized to address the biggest identified risks related to BC Hydro’s dams. Many other, smaller-scale investments in upgrades to the dams and their infrastructure, such as monitoring instrumentation, have also been made in recent years.

Overall, BC Hydro aims to improve or at least maintain the current level of risk across its entire fleet of dams, which we believe is well within the limits of what is considered to be tolerable. Our strategy considers the availability of the necessary expert engineering services (both internal and external) and experienced construction services, as well as our capacity to oversee this work. Our planned level of investment in dam upgrades is primarily driven by our ability to execute these upgrades effectively. On this basis, required investments in upgrades to

BC Hydro's dams have been prioritized over the coming decade and beyond. In the coming years, major investments in BC Hydro's dams will target the biggest current contributors to risk and will be made in the following areas:

- Major upgrades to improve seismic resistance, reservoir discharge capability and spillway gate reliability at the three main dams in the Campbell River system, namely John Hart Dam, Ladore Dam and Strathcona Dam;
- Continued upgrades to W.A.C. Bennett Dam to improve the operating reliability of its spillway gates systems, to decommission disused and deteriorating low level outlets and sluice gates—eliminating two potential weaknesses in the dam's water barrier—and the dam's network of monitoring instrumentation; and
- Improvements in the seismic resistance and operating reliability of the spillways and gates at and Mica Dam and Revelstoke Dam.

We are also just beginning to investigate conceptual alternatives to address deficiencies at La Joie Dam regarding its seismic resistance and excessive seepage that have led to an extended drawdown of its reservoir. Another notable, but smaller, project is being launched to remediate the rockfall hazard in the Terzaghi Dam spillway and provide for safe entry for inspections and repairs to that structure. Smaller investments will also be made to improve or replace dam infrastructure such as reservoir booms and miscellaneous instrumentation.

2.3 The Transmission and Distribution System

The overarching strategy for the Transmission and Distribution system is to maximize the long-term value of the system while minimizing the total life cycle costs of assets and ensuring safety and maintaining reliability. The strategy is accomplished by finding the optimal balance between efficiency, performance, cost, risk, security, regulatory requirements, and environmental and social aspects.

2.3.1 Transmission System

BC Hydro's bulk transmission system includes the 500 kV transmission system, parts of the 230 kV system, the transmission connections to Vancouver Island, and interconnections with other utilities through transmission interties. These lines connect the large remote generating stations in the Peace River and Columbia River areas with the major load centres of the Lower Mainland and Vancouver Island, which together represent over 70 per cent of the BC Hydro load.

Four regional transmission systems transfer energy within four specific geographic areas of the province: the Lower Mainland, Vancouver Island, Northern and the Southern Interior regions. The regional systems generally consist of 230 kV, 138 kV, and 60 kV transmission networks that connect local generation and deliver power to distribution utilities or transmission customers located within the region.

Long-term planning related to bulk and regional transmission needs are typically associated with moving energy over long distances. Long-term planning considers a wide range of supply-side and demand-side options, resulting in an integrated system plan. BC Hydro conducts assessments to evaluate the transfer capability of the system while still meeting North American Electric Reliability Corporation Transmission System Planning Performance and Western Electricity Coordinating Council requirements at all voltage levels. Investments are identified that are necessary to fund transmission system capacity additions.

2.3.1.1 Lower Mainland and Vancouver Island

In the last decade BC Hydro has made significant investments to increase the capacity of the bulk transmission system including the Interior to Lower Mainland and Vancouver Island Transmission Reinforcement projects. These investments have enhanced BC Hydro's ability to continue to serve the electricity needs of our customers in the highest density areas of the province.

With the completion of the Interior to Lower Mainland transmission line, installation of Mica Units 5 and 6 and the third transformer at the Meridian substation, the natural gas fired, peak generation capability from the Burrard Generating Station is no longer required to meet critical loads in the Lower Mainland. Accordingly, Burrard is instead being operated to provide voltage support for the transmission system in the Lower Mainland, using its capability to operate in synchronous condense mode. The four Burrard Synchronous Condenser units are now reaching end of life and are expected to experience reliability issues within the short to medium term. The near term focus of capital investment in the Lower Mainland transmission system will be to maintain BC Hydro's Lower Mainland bulk transmission system reliability during heavy winter load periods under single contingency conditions.

Ensuring the reliability of service in the region also requires addressing reliability risks associated with the end of life condition of 230 kV high voltage cables in the short term. These include the cable between Horsey substation (**HSY**) and Goward substation (**GOW**) in Victoria, as well as the segment of 138kV cable that supplies the Gulf Islands from Vancouver Island.

2.3.1.2 Northern Region

In recent years, BC Hydro has made significant investments in the northern region of the province, with projects such as the 230 kV Dawson Creek Area Transmission line and the 287 kV Northwest Transmission Lines projects, which provide regional transmission reinforcement to serve the growing regional load requirements.

In the next decade, BC Hydro will continue to invest in the Northern transmission system to address load and system growth requirements driven primarily by the development in the Oil and Gas sector in the Peace and North Coast regions. Investments will include completing the 230 kV Peace Region Electric Supply project, reinforcing the 500 kV Peace to Kelly Lake corridor to increase its transfer capability to the Lower Mainland, and interconnecting major industrial customer loads in this region.

Due to the continued economic activities expected in the Liquefied Natural Gas and Oil and Gas sectors, there are potentially significant additional upgrades to the transmission system in the North Coast and Peace region that may be required in the short to medium term which are not included in BC Hydro's Capital Plan. BC Hydro will work with customers in the area to define the need and scope of future projects. Projects will proceed once there is a formal commitment from potential customers. Expanding the capacity of the electricity supply in this region of the province will enable BC Hydro to supply reliable power to our industrial customers and help reduce greenhouse gas emissions by enabling customers to use clean electricity rather than fossil fuels to power their operations.

BC Hydro will also be investing to improve customer reliability in the region through investments such as the 5L63 Telkwa Relocation project, which will relocate a segment of the radial line that serves customers on the north coast and is currently situated in an active landslide area.

2.3.1.3 Southern Interior Region

BC Hydro recently completed the Merritt Area Transmission project to meet the increased demand for power in the Merritt area. BC Hydro is continuing to invest in the transmission system in the Southern Interior region of the province to provide reliable service to our customers. However, we are not expecting any major investments to serve load growth in the medium to long term as there is sufficient capacity to meet the load forecast in this region.

2.3.2 The Regional Substation and Distribution System

BC Hydro has four regional systems (the Lower Mainland; the Northern Interior; the Southern Interior; and Vancouver Island) which connect the transmission system to the local distribution systems. The substation and distribution network are made up of over 300 stations and 68,000 kilometres of distribution circuits in order to serve customers throughout the province.

In the past decade, BC Hydro has built 28 new substations within these regions, including 12 distribution substations enabling BC Hydro to supply more than 900 MVA additional load at distribution voltages. The most significant investments have been in the Lower Mainland and on Vancouver Island. Projects have included building an indoor 230/12 kV substation in the Mt. Pleasant area of Vancouver and two new underground 230 kV transmission lines connecting the new substation, as well as two new substations in the Courtenay and Nanaimo areas of Vancouver Island. In addition to the increased capacity, these new substations have improved the operational flexibility of the system. In some cases, the addition of new substations has facilitated the load transfer from other substations that were reaching end of life or ultimate capacity. This approach helps BC Hydro minimize the total cost of capital investment and maintenance over the life cycle of the substations.

We have also completed the Smart Metering and Infrastructure Program, which included the installation of 1.9 million smart meters in homes and businesses across the province. This provides an advanced telecommunications infrastructure to support electricity system management and customer applications, and information technology to support customer billing, load forecasting and outage management systems.

Our investments in the regional systems mean that BC Hydro's capacity to reliably serve the forecast load growth in many areas of the province has enhanced. Load growth in certain areas of the province, particularly the Fraser Valley, will require continued investment in new substation and distribution infrastructure to reliably supply customers.

BC Hydro will continue to mitigate end-of-life, safety and environmental risks by investing in new substations, such as the new West End Substation in downtown Vancouver. This new substation will enable the load transfer from Dal Graur (**DGR**) and Murrin (**MUR**) substations, which have reached end of life, and have many risks including safety and seismic. For other existing stations, such as Mainwaring in South Vancouver, our current strategy is to replace assets on a component by component basis as needed, considering factors such as condition, rate of deterioration, the operating environment, and criticality. One of the key considerations in determining the timing and strategy of investments is the requirement to replace equipment with polychlorinated biphenyl (**PCB**) levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline.

3 BC Hydro's Strategies, Plans and Studies

As part of its planning practices, BC Hydro identifies investments required on the Power System by evaluating the issues, risks and opportunities related to Power System assets. Long term planning information is captured in planning documents such as strategies, plans and studies. For the Power System, documents such as these help BC Hydro to assess system needs and develop solutions based on a region or area, river system, a facility or group of facilities, and asset classes. These planning documents provide context with respect to the rationale for investments that are either underway, or planned to start in the future. However, changing underlying factors, such as adjustments to load growth forecasts, resource or financial constraints, and new information and priorities can change the original scope of projects or solutions proposed in these planning documents. This means that while the planning documents capture the essence of the approach, the plans and investments proposed may change in response to new information. These changes will be reflected in the planning documents during the next update of the strategy, plan or study.

The process through which Power System strategies, plans and studies are developed is explained in detail as part of the bottom-up planning process descriptions included in section 6.4.2 (Generation) and section 6.4.4 (Transmission & Distribution).

Where applicable the strategy, plan, or study for the investments listed in Appendix I has been identified in column W. Not all projects in the Capital Plan may be related to an underlying strategy, plan or study. A summary of the identified strategies, plans and studies are provided in this appendix, following the example provided in Appendix E of Exhibit B-7. These documents can cover a period of up to 30 years or longer in some cases. Within each of the summaries in this appendix, the following principles were applied for identifying investments within the Short, Medium and Long Term time frames:

- **Short-Term:** Investments with expenditures within the fiscal 2020 to fiscal 2021 test period are defined in the Short-Term Solution;
- **Medium-Term:** Investments with expenditures anticipated to start within the next 10 years, but after the fiscal 2020 to fiscal 2021 test period are outlined in the Medium-Term Solution; and
- **Long-Term:** Investments with potential expenditures beyond the next 10 years are summarized in the Long-Term Solution.

The summaries within this appendix generally belong to one of the following five categories:

1. **Generation Facility Asset Plans:** Generation facility asset plans summarize the issues, risks and opportunities faced by a specific facility and outline the proposed long-term investment strategy that is believed to offer the best value at a specific time. Facility Asset Plans are key inputs to the fleet planning process. The investment strategies that are proposed in discrete facility asset

plans are reviewed collectively, and prioritized to provide the most appropriate suite of investments across the fleet given resource and financial constraints, outage planning, and other considerations;

2. **Dam Safety System Studies:** These studies are initiated to identify options that would permit the optimal risk management and investment strategy for the system using a Systems Engineering approach. A Systems Engineering approach provides a framework to manage complexities within the constraints of the river system to ensure technical coordination across a broad range of disciplines;

3. **Transmission and Distribution Asset Strategies:** BC Hydro has documented Asset Strategies for most of its Transmission and Distribution asset classes. These Asset Strategies provide a fleet approach to the management of each asset class across the entire system, and over their entire asset lifecycle;

4. **Transmission and Distribution Substation Asset Plans:** These plans are developed when a substation requires major investments to address end-of-life and other sustaining needs. The longer term capacity needed at the substation is also integrated in Substation Asset Plans; or

5. **Transmission and Distribution Area Studies:** These area plans are typically prepared, or updated, when capacity additions are required in an area, which is defined by interoperability of the area assets. Other known needs in the area, including sustaining issues at the area's substations, are integrated in the Area Studies.

Name of Capital Strategy, Plan or Study:
Campbell River Systems Engineering Assessment

Summarize Issue:

The Campbell River hydroelectric system on Vancouver Island consists of three reservoirs and dams (Strathcona, Ladore and John Hart) which are close-coupled and in series on the Campbell River. All three facilities are categorized as Extreme Consequence per the BC Dam Safety Regulation. The Campbell River system is an important water resource that makes a major contribution to power generation on Vancouver Island, supports valuable fish habitats and spawning grounds and provides a wide range of community and recreational services in the area. The objective of the Campbell River System study was to identify the preferred risk management strategy for the Campbell River System in view of the potential for future redevelopment.

Previous investigations into dam safety deficiencies in the Campbell River system identified that:

- John Hart Dam and Strathcona Dam have wide-ranging seismic deficiencies. At Strathcona Dam these deficiencies are compounded by the seismically deficient powerhouse and generation water passage that runs beneath the dam;
- The spillway gates system at Ladore Dam has insufficient resistance to seismic loads; and
- The spillway gates systems at all three dams have operational reliability deficiencies.

Owing to their common period of original design and construction, the seismic deficiencies at these dams make all of them vulnerable to failure in an earthquake of intensity expected to occur, on average, once every 500 to 1000 years. Given that these are all Extreme consequence dams, current expectations – as outlined in the Canadian Dam Association's Dam Safety Guidelines – are that they should be able to withstand an earthquake of intensity expected to occur once every 10,000 years.

In 2009, knowing that significant reliability and dam safety investments on this system were going to be required, BC Hydro initiated a top-down Systems Engineering assessment that investigated the full range of options for the development of the river system in order to identify how investments should be prioritized to deliver safe and sustainable long-term management of the river system assets. The range of configurations was bounded at one end by full or partial decommissioning and at the other end by a complete re-configuration and redevelopment of the entire system.

Conceptual solutions included the following considerations:

- Least total risk (to people, property and the environment) configuration;
- Maximum peak demand availability; and
- Maximum total energy output per year.

The Campbell River Systems Engineering Assessment concluded that the river system should not be substantially reconfigured and confirmed that redevelopment of the generating capability at John Hart would be appropriate. It further concluded that improvements in seismic withstand and operational reliability of the flood discharge systems at all three main dams are required and, finally, that protection against flooding is best achieved through adequate storage upstream of Stathcona Dam.

Summarize Solution:

The Campbell River System Study (completed in 2012) prioritized and recommended sequencing of the capital projects by reviewing the relative costs of the projects vs the anticipated risk reductions. A preferred strategy for sequencing of the risk reductions was refined during development of the capital plan, considering technical resource availability along with our understanding of the precedent project timelines and numerous site and project timing and schedule requirements.

One of the projects considered within this strategy, the John Hart Generating Station Replacement, is now in service.

Short-Term:

A number of projects dealing with the highest priority dam safety issues and risks are already underway. These projects will address the inadequate seismic withstand of various components of John Hart and Ladore Dams and establish a deep drawdown capability at Strathcona Dam for post-earthquake response. These projects will also address reliability deficiencies in the three dams' spillway gates

systems. They are: • John Hart - Dam Seismic Upgrade; • Ladore - Spillway Seismic Upgrade; and • Strathcona - Upgrade Discharge.
Medium-Term: In the medium term, risks posed to Strathcona Dam by the inadequate seismic withstand of the generating station water passage under the dam and of the dam itself will be addressed in turn by decommissioning and redeveloping the existing generating station—including the water passage—and upgrading the dam. The Strathcona – Upgrade Discharge project must be completed before implementation of the following can commence. • Strathcona - Dam Improvements – New Powerhouse; and • Strathcona - Dam Improvements – Embankment Dam.

Name of Capital Strategy, Plan or Study:
Alouette Facility Asset Plan

Summarize Issue:

The single unit, 9 MW Alouette facility is located in the Fraser Valley and was commissioned in 1928. It forms part of the Stave River system, with Stave Falls and Ruskin facilities located downstream. It consists of the Alouette Lake Reservoir, Alouette Dam, Power Tunnel from Alouette Reservoir to Stave Lake Reservoir, and Alouette Generating Station. Alouette is a Strategic facility for asset management purposes and Alouette Dam is an Extreme consequence dam per the BC Dam Safety Regulation. The original dam was replaced in 1983 when the current earthfill dam was constructed immediately downstream of the original dam. Alouette Generating Station has been out of service since 2010, due to condition and reliability issues with the majority of the generating equipment; however, the water conveyance components of the facility remain an important mechanism for conveying water to the Stave Falls and Ruskin facilities.

Although Alouette Generating Station is currently out of service, investments are being made to ensure safety, water conveyance, and environmental risks are mitigated. BC Hydro has invested over $5 million over the past 10 years. These investments include safety upgrades, and operating gate and trashrack replacements. The most significant remaining issues and risks associated with the Alouette facility include:

- Dam Safety:
  - Potential damage to the dam’s spillway in a major earthquake expected to occur once every 1,000 to 2,500 years that would render it unsafe for spills or drawdowns after the earthquake;
  - Potential failure of the dam’s right abutment foundation in a major earthquake expected to occur once every 2,500 years, which would lead to the eventual failure of the concrete weir structures that regulate flow over the spillway;
  - Expected failure of the power tunnel’s headworks and surge tower structures and ancillary equipment in an earthquake expected to occur once every 100 to 200 years, which could block the post-earthquake discharge of water from Alouette Reservoir to Stave Lake Reservoir; and
  - Potential rupture in a major earthquake of the seismically deficient low level outlet conduit (having unquantifiable withstand) that runs under the dam and provides environmental flows into the Alouette River downstream of the dam, which introduces the risk of internal erosion damage to the dam.

Summarize Solution:

The Alouette Facility Asset Plan presents short and long term investment strategies to mitigate risks related to dam safety, water conveyance, and the environment. In the short term, investments at Alouette will focus on addressing deficiencies related to post-earthquake discharge of the reservoir and associated risks posed to the dam by ensuring post-earthquake operability of the power tunnel leading from Alouette Lake Reservoir to Stave Lake Reservoir, and by constructing a new passage for passing environmental flows past the dam and down the Alouette River. The medium to longer-term focus will be to preserve the operational capability and infrastructure and, when appropriate, restore generation.

Short & Medium-Term:

- Dam Safety:
  - Headworks and Surge Tower Seismic Stability Improvement; and
  - Environmental Flow Discharge Upgrade and Low Level Outlet Sealing.

Long-Term:

- Generating Equipment:
  - Powerhouse Redevelopment.

The following are retained risks that are intended to be managed by completion of the Headworks and Surge Tower Seismic Stability Improvement project that is presently underway. These include:

- Seismic deficiency of the dam’s right abutment foundation and spillway weir; and

- Seismic deficiency of the dam's spillway.

On completion, this project will provide post-earthquake reservoir discharge into Stave Lake Reservoir via the power tunnel, thereby protecting these potentially damaged dam and spillway assets. Prior to the project's completion, Alouette Lake Reservoir will be operated in a manner that provides sufficient time to provide emergency response following a major earthquake.

Name of Capital Strategy, Plan or Study:
Ash River Facility Asset Plan

Summarize Issue:

The single unit, 28 MW Ash River facility is located on Vancouver Island and was commissioned in 1959. It consists of Elsie Lake Reservoir, Elsie Main Dam, four Saddle Dams, Elsie Spillway Dam, and Ash River Generating Station. Ash River is classified as a Strategic facility for asset management purposes and the dams are classified per BC Dam Safety Regulation as follows:

- Elsie Main Dam – Extreme consequence;
- Saddle Dam 1 – Extreme consequence;
- Saddle Dam 2 – Very High consequence;
- Saddle Dam 3 – Significant consequence;
- Saddle Dam 4 – Significant consequence; and
- Elsie Spillway Dam – High consequence.

Investments totaling over $5 million have been made to address safety and reliability concerns at the facility over the past 10 years. Completed capital investments have included upgrading the fire protection system, extending the life of the pressure regulating valve, improving security at Elsie Dam and upgrading the powerhouse crane.

The most significant remaining issues and risks associated with the Ash River facility include:

- Generating Equipment:
  - Unsatisfactory condition of the generator, elevating the reliability risks associated with the single unit and increasing the likelihood that the facility may experience an extended forced outage; and
  - Obsolete and deteriorating protection and controls and metering systems pose a reliability risk and could result in misoperation, equipment damage, and forced outages.
- Dam Safety:
  - The coatings on the steel penstock have failed which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to re-coat the assets before a much more extensive replacement / refurbishment is required; and
  - The ongoing deterioration and accelerated decay of the woodstave penstock is reducing its ability to continue to safely convey water which may prematurely impact ongoing generation from the facility.

Summarize Solution:

The Ash River Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality.

In the short term, activities to address the risks with the steel penstock, generator, and protection and control and metering systems will be undertaken in order to address reliability and power supply risks. In the medium-term, risks with the woodstave penstock will be mitigated. In the longer-term, work on other major unit components will be undertaken in order to mitigate reliability risks.

Short-Term:

- Generating Equipment:
  - Generator upgrade; and
  - Protection and control and metering systems upgrade.
- Dam Safety:
  - Steel penstock re-coat.

Medium-Term:

- Dam Safety:
  - Woodstave penstock replacement.

Long-Term:

- Generating Equipment:
  - Turbine overhaul;
  - Governor replacement.

Name of Capital Strategy, Plan or Study:
Bridge River Facility Asset Plan

Summarize Issue:

The eight-unit, 500 MW Bridge River facility is located approximately 60 km west of Lillooet and forms part of the Bridge River system with the La Joie facility and the Seton facility located upstream and downstream, respectively. The facility consists of:

- Carpenter Lake Reservoir;
- Terzaghi Dam, which was completed in 1960;
- The four-unit, 200 MW Bridge River 1 Generating Station, which was commissioned in 1954; and
- The four-unit, 300 MW Bridge River 2 Generating Station, which was commissioned in 1960.

The Bridge River facility is classified as a Key facility for asset management purposes and Terzaghi Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation.

BC Hydro has made a number of investments in the Bridge River facility over the past 10 years, totaling over $100 million. Investments in the generating equipment have included: Bridge River 1 (**BR1**) Transformer replacements, BR1 Switchgear Replacement, BR1 Penstock Leak Detection, BR1 Powerhouse Piping Replacement, Bridge River 2 (**BR2**) Unit 7 and 8 Unit Circuit Breaker replacement and BR2 Penstock Inlet Valve Hydraulic Control Upgrade. Other key investments have included: the Bridge River Town Site redevelopment and reliability upgrades of the Terzaghi Dam Spillway Gates.

The overriding concern in the Bridge River System is that of water management and operating in accordance with the water licenses that have been issued to BC Hydro. The system is heavily constrained with limited allowable flows past Terzaghi Dam into the lower Bridge River. At present, the generating capacities of all four units at Bridge River 2 have been de-rated due to degrading equipment condition, reducing the flow of water that can be routed through that generating station and hindering BC Hydro’s ability to prevent excessive flows in the lower Bridge River. This is compounded by the fact that Downton Reservoir behind La Joie Dam at the upstream end of the system has been drawn down to manage dam safety risks at that facility, removing a portion of the system’s available storage buffer and flexibility. Restoring reliable generation to historic levels, at both the Bridge River 1 and Bridge River 2 generating stations, will enable more effective water management throughout the system, and also mitigate reliability risks associated with lost generation.

The most significant remaining issues and risks associated with the Bridge River facility include:

- Generating Equipment:
  - Poor and Unsatisfactory condition of the Bridge River 1 and Bridge River 2 generators, elevating the reliability and water management risks associated with the generating units and increasing the likelihood that the facility may experience an extended forced outage;
  - Poor condition of three Bridge River 2 circuit breakers, elevating the risk of forced outages;
  - Poor condition of two Bridge River 2 exciters and obsolescence of the Bridge River 1 exciters, elevating the risk of forced outages;
  - Poor condition of six of the Bridge River 1 and 2 Governors, elevating the risk of forced outages; and
  - Poor condition of two Bridge River 2 turbines, elevating the risk of forced outages.
- Dam Safety:
  - Failed coatings on the steel penstocks which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstocks. A finite window of opportunity exists to re-coat the assets before a much more extensive replacement or refurbishment is required.
  - Deficiencies in the seismic withstand and operational reliability of the low level outlet gates at Terzaghi Dam, which could result in their failure to open as needed in a flood event or following an earthquake, for which the risk is managed in part by regular testing and maintenance of the gate system;

- Deficiencies in the seismic withstand of the two intake towers on Carpenter Reservoir, which would likely be damaged in an earthquake somewhat smaller than that expected to occur once every 500 years, limiting or disrupting their ability to direct water to the Bridge River 1 and Bridge River 2 powerhouses for generation and managing the reservoir level;
- Stability of the Bridge River 1 penstock slope and powerhouse foundation, especially during an earthquake, comprising a risk that slope or powerhouse movement could cause a penstock rupture. Slope stability is a retained risk that is managed at the powerhouse with wells and sensors to control and monitor groundwater pressures and a leak/rupture detection system on the Bridge River 1 penstocks; and
- Rock fall hazard in the Terzaghi Dam spillway chute, due to which the spillway chute cannot be safely entered without significant preparatory work such as rock scaling and installation of protective structures. Lack of safe access to the spillway chute impedes the inspection, maintenance and assurance of safe condition of the spillway.

Summarize Solution:

The Bridge River Facility Asset Plan presents a strategy to replace assets on a component by component basis considering factors such as condition, rate of deterioration, the operating environment and criticality.

Investments requiring outages have been consolidated to reduce the impact on water management in the system. In the short term, the focus will be on higher priority investments required for water management and safe and reliable generation. The medium to longer-term activities will focus on the low level outlets at Terzaghi Dam and the penstocks at Bridge River 1.

Short-Term:

- Generating Equipment:
  - The units at Bridge River 2 are in relatively worse condition, and will be addressed first:
    - Units 5 & 6 require the most urgent attention – the project will address issues with the generators, governors, circuit breakers and exciters (the forecast in service date is fiscal 2020); and
    - Units 7 & 8 will be addressed next – the project will mitigate issues with the generators, circuit breakers and turbines.
  - Once the highest priority units have been addressed at the Bridge River 2 generating station, attention will turn to remediating risks with the remaining four units at Bridge River 1:
    - The project will address the issues with generators, exciters and governors on the four units. The worst of these is Unit 4, which will be prioritized first.
  - Completion of this work at the Bridge River 1 and Bridge River 2 generating stations will mean that the units are reliable, can run at historic levels and can be used as a reliable mechanism for conveying water.
- Dam Safety:
  - Bridge River 2 interior penstock recoating;
  - Bridge River 1 interior penstock recoating;
  - Bridge River 1 slope stability improvement;
  - Terzaghi Dam spillway chute safe access improvements; and
  - Bridge River 1 Mitigate Surge Spill Hazard.

Medium-Term:

- Dam Safety:
  - Bridge River 1 exterior penstock recoating; and
  - Terzaghi Dam low level outlet reliability improvements.

Long-Term:

- Generating Equipment:
  - Bridge River 1 and 2 major valve replacements.
- Dam Safety:
  - Bridge River 1 and 2 intake seismic stability improvements.

Name of Capital Strategy, Plan or Study:
Cheakamus Facility Asset Plan

Summarize Issue:

The two unit, 158 MW Cheakamus facility is located near Squamish and was commissioned in 1957. It consists of Daisy Lake Reservoir, Cheakamus Dam and Cheakamus Generating Station. Cheakamus is classified as a Strategic facility for asset management purposes and Cheakamus Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation.

BC Hydro has made substantial progress restoring the health of this generating facility over the past 10 years through a number of investments totaling over $100 million. Investments in the generating equipment have included the turbine runner upgrades, powerhouse crane refurbishment, sump controls upgrade, and an improvement of the plant's fire protection and security. Dam Safety investments have included spillway gate reliability improvements.

The most significant remaining issues and risks associated with the Cheakamus facility include:

- Generating Equipment:
  - Poor condition of the Unit 1 and Unit 2 generators which increases the reliability risk of the generating units and could result in an extended forced outage;
  - Failed interior and exterior coatings on Unit 1 and Unit 2 penstocks, which will lead to corrosion and metal loss of the underlying material thereby reducing the life of the penstock; and
  - Unsatisfactory condition of the Unit 1 and Unit 2 Turbine Inlet Valves which increases the operational risks associated with the generating units;
- Dam Safety:
  - Seepage and potential internal erosion of the dam at high reservoir levels which is currently mitigated by maintaining a reduced maximum reservoir elevation;
  - Insufficient resistance to seismic loads that may lead to failure of the dam, spillway, spillway gates and/or penstock pedestals in a major earthquake occurring, on average, about once every 1,000 years or more;
  - Residual deficiencies in the reliability of the upgraded spillway gates system, notably the lack of "black start" capability of the system's uninterruptible power supply (**UPS**) that would restore electrical power to the gates in the event of a local blackout. The risk of the gates failing to operate as required in such events is currently mitigated by maintaining and testing back-up diesel generators on site; and
  - Potential for a landslide at the Barrier and 4th Lobe slopes to impact the dam and downstream channel.

Summarize Solution:

The Cheakamus Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. In the short-term, the focus will be on higher priority investments required for safe and reliable generation that are sequenced to minimize outages. The medium to longer-term activities will focus on the dam and spillway facilities.

Short-Term:

- Generating Equipment:
  - Units 1 and 2 generator replacement (planned In Service Date fiscal 2019);
  - Units 1 and 2 penstocks recoat (interior and exterior); and
  - Units 1 and 2 turbine inlet valves replacement.

Medium- and Long-Term:

- Dam Safety
  - Spillway seismic upgrade;
  - Dam seepage and seismic upgrade.
  - Penstock pedestals and slope improvement; and
  - Spillway gates reliability improvement.

The retained risk associated with a landslide at the Barrier and 4th Lobe slopes is managed by ongoing inspection and monitoring of the slopes.

Name of Capital Strategy, Plan or Study:
Duncan Dam Facility Asset Plan

Summarize Issue:

Duncan Dam is located immediately upstream of the confluence of the Duncan and Lardeau Rivers, and approximately 10 kilometers upstream of the North Arm of Kootenay Lake. Duncan Dam was commissioned in 1967 under the terms of the Columbia River Treaty to provide storage for flood control and to maximize hydro generation in both the United States and Canada. The facility includes Duncan Lake Reservoir and Duncan Dam. There is no generating station at this facility. Duncan Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation.

BC Hydro has made progress in restoring the health of this facility over the past 10 years through a number of Dam Safety investments totaling over $35 million, including the refurbishment of the low level outlet gates, targeted spillway gate system upgrades (not including the gates themselves), upgrades to dam instrumentation to measure seepage through the dam and foundations, and the installation of a steel sheet pile cutoff wall to upwardly extend a portion of the dam's core that was discovered to be 6 feet to 8 feet below its design elevation.

The most significant remaining Dam Safety issues and risks associated with the Duncan Dam facility include:

- Poor structural condition of the spillway gate bodies;
- Potential liquefaction of the dam's foundation in a major earthquake that would be expected to occur, on average, once every 3000 years, which could lead to large enough deformations for the dam to be overtopped;
- Deficiencies in the operational reliability of the reservoir discharge (spillway and low level outlets) systems that could result in their failure to open as needed during high inflows, for which the risk is managed by regular testing and maintenance of these systems; and
- Poor condition of the riprap on the dam's upstream face which could allow erosion of the dam's shell and a consequential failure of the dam's upstream slope, for which the risk is currently managed by semi-annual inspections and provision for localized repairs as need arises.

Summarize Solution:

The Duncan Dam Facility Asset Plan presents a strategy to mitigate risks related to safe storage and reliable passage of water under normal and unusual (e.g., flood and earthquake) conditions.

Short-Term:

- Spillway gates replacement.

Medium-Term:

- Seismic stability improvement; and
- Riprap replacement.

Long-Term:

- Discharge facilities reliability upgrade.

Name of Capital Strategy, Plan or Study:
G.M. Shrum Facility Asset Plan

Summarize Issue:

The 10-unit, 2,917 MW G.M. Shrum facility is located 23 km upstream of Peace Canyon Dam and approximately 160 km from the Alberta border. It was commissioned in stages from 1968 through 1980. It is comprised of the Williston Reservoir, W.A.C. Bennett Dam and the G.M. Shrum Generating Station. G.M. Shrum is classified as a Key facility for asset management purposes and W.A.C. Bennett Dam is classified as an Extreme consequence dam per the B.C Dam Safety Regulation.

BC Hydro has made substantial progress in maintaining and improving the health of this generating facility over the past ten years through a number of investments totaling about $750 million. Investments in the generating equipment have included replacement/refurbishment of many of the original key components, including units 1 to 5 turbine upgrade, units 1 to 4 stator replacement, increased capacity of units 6 to 8, three of four phases of transformer replacements, and station service replacement. Significant Dam Safety investments have included: stabilization of the rock slope above the dam's spillway, resurfacing and other upgrades to the concrete lining of the spillway chute, upgrades to the rip rap on the upstream face of the dam, and upgrades to the dam's core including rehabilitation of instrumentation wells.

The most significant remaining issues and risks associated with the G.M. Shrum facility include:

- Generating Equipment:
  - Poor condition of eight of the 30-unit transformers, combined with emerging deficiencies on some of the unit transformers, poses an operational reliability risk;
  - Poor condition of the unit 5 generator, elevating the reliability risks associated with the unit and increasing the likelihood of an extended forced outage;
  - Failed coatings of the intake operating gates and intake maintenance gates, which could lead to corrosion and metal loss of the underlying material, thereby reducing the life of the gates;
  - Deficiencies in the hydraulic systems of the intake operating gates that could result in operational reliability risks; and
  - Degrading condition of various coatings in the water passages, including penstocks, scroll case, and coupling chamber, which could lead to corrosion and metal loss of the underlying material, thereby reducing the life of the assets.
- Dam Safety:
  - Deficiencies in the operational reliability of the spillway gates that could result in their failure to operate as needed during high inflows, the risk of which is currently managed by regular testing and maintenance of the gates system;
  - Unknown but presumably deteriorating condition of now-disused low level outlets situated within the construction-period diversion tunnels, failure of which would lead to uncontrolled release of Williston Reservoir;
  - Deteriorating, non-functioning and disused sluice gates below the spillway gates, failure of which would lead to uncontrolled release of Williston Reservoir;
  - Continued erosion of the rock face above the spillway approach channel which is beginning to undermine the storage location of the spillway's maintenance stoplogs, the risk of which is managed by ongoing surveillance of the slope and progression of erosion; and
  - Presumed seismic deficiency of the spillway's structures and electrical and mechanical equipment (presently the subject of a Dam Safety Investigation).

Summarize Solution:

The G.M. Shrum Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality. In the short-term, projects are staged to prioritize investments in key generating equipment and high risk dam safety components. In the medium to long-term, projects are staged to address the next highest risks in the generating equipment, including upgrade of units 9 and 10, and improve reliability and seismic performance of the flood discharge system.

Short-Term:

- Generating Station:
  - Unit 5 stator replacement;
  - Unit 9 and Unit 10 circuit breaker replacement;
  - Transformer replacement (phase 4);
  - Pauwels transformer life extension;
  - Intake operating gate and intake maintenance gate refurbishment;
  - Intake operating gate hydraulic upgrade; and
  - Water passage refurbishment.
- Dam Safety:
  - Spillway gate reliability upgrade;
  - Sealing of the low level outlets; and
  - Recommissioning or sealing the spillway sluice gates.

Medium-Term:

- Generating Station:
  - Unit 9 and Unit 10 turbine overhaul; and
  - Unit 9 rewind stator.
- Dam Safety:
  - Spillway seismic upgrade; and
  - Spillway approach channel upgrade.

Long-Term:

- Generating Station:
  - Unit 7 and Unit 8 Stator Replacements.
- Dam Safety:
  - Spillway Gate Electrical and Mechanical Improvements.

Name of Capital Strategy, Plan or Study:
Hugh Keenleyside Facility Asset Plan

Summarize Issue:

The Hugh Keenleyside facility is located on the Columbia River, about 8 km upstream of Castlegar. Hugh Keenleyside Dam was commissioned in 1968 under the terms of the Columbia River Treaty to provide storage for flood control and to maximize hydro generation in both the United States and Canada. The major components of the Hugh Keenleyside facility include the Arrow Lakes Reservoir, Hugh Keenleyside Dam comprising an earthfill dam and a concrete gravity dam with spillway and low level outlets, and a Navigation Lock to provide a passage for commercial and recreational marine traffic through the dam. The Hugh Keenleyside facility does not have a generating station, but a power canal on the left abutment diverts water from the Arrow Lakes Reservoir to the Arrow Lakes Generating Station owned by Columbia Power and the Columbia Basin Trust. Hugh Keenleyside Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation.

BC Hydro has made substantial progress restoring the health of this facility over the past 10 years through a number of investments totaling over $100 million, including an upgrade of the navigation lock controls, a major spillway gate reliability upgrade, replacement of the debris boom, dam instrumentation improvements, and facility security system upgrade.

The most significant remaining issues and risks associated with the Hugh Keenleyside facility include:

- Dam Safety:
  - Spillway and low level outlet concrete erosion which, if not addressed, could impact the operation of the facility and the maintenance and inspection of the gates. There is also a risk that the eroded zones could grow in size during high water discharges, resulting in an extended outage of the spillway. These risks are currently managed by having implemented modified discharge operating procedures to slow the damage and by periodic underwater inspections;
  - Degrading condition of the foundation drains and instrumentation, where non-functioning drains would reduce the stability of the dam. This risk is managed by continuous monitoring of the uplift pressures under the dam and the condition of the instruments;
  - Potential post-earthquake deformation of the concrete spillway piers, which would render the Low Level Outlet Gates inoperable and limit the post-earthquake reservoir discharge capability; and
  - Moderately deficient seismic withstand of the earthfill dam relative to its Extreme consequence classification, estimated to be equivalent to an earthquake expected to occur once every 8,000 years.
- Facility Equipment:
  - Degrading condition of the coatings on the navigation lock gates, which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the asset; and
  - Deterioration of the service water piping.

Summarize Solution:

The Hugh Keenleyside Facility Asset Plan presents a strategy to mitigate risks related to safe storage and reliable passage of water under normal and unusual (e.g., flood and earthquake) conditions. The short-term investments include upgrading the concrete discharge structures to ensure continued safe and reliable water discharge, and preserving the critical navigation lock infrastructure. The medium term investments focus on addressing the seismic withstand deficiencies of the concrete dam (i.e., deformation of the spillway piers), upgrading the instrumentation and monitoring of water pressures under the dam, and enhancing the operability of the select components of the discharge system. The long-term investment focuses on addressing the seismic withstand deficiencies of the earthfill dam.

Short-Term:

- Dam Safety:

  Spillway and low level outlet concrete upgrade.

- Facility Equipment:
  - Service water piping replacement (planned In-service Date fiscal 2020); and
  - Navigation lock gates recoating.

Medium-Term:

- Dam Safety:
  - Concrete dam seismic stability upgrade;
  - Dam foundation drains and instrumentation replacement; and
  - Spillway and low level outlet stoplogs recoat.

Long-Term:

- Dam Safety:
  - Earthfill dam seismic stability upgrade.

Name of Capital Strategy, Plan or Study:
John Hart Facility Asset Plan

Summarize Issue:

The three unit, 135 MW John Hart facility is located on Vancouver Island and was originally constructed in 1947. John Hart forms part of the Campbell River system, with Ladore and Strathcona facilities located upstream. The facility includes the John Hart Reservoir, John Hart Dam, and the John Hart New Generating Station. The original John Hart Generating Station was developed in 1947 and permanently ceased operation when the John Hart New Generating Station was placed into service in 2018. John Hart is classified as a Strategic generating facility for asset management purposes and the John Hart Dam is classified as an Extreme consequence dam per BC Dam Safety Regulation.

The John Hart facility has received a significant level of investment in the last 10 years, with over $1 billion of investments made to construct a new power intake, power tunnel, underground generating station, and environmental flow bypass, as well as provide interim upgrades for the most pressing dam safety issues.

Prior to making this investment, in 2009, BC Hydro initiated the top-down Campbell River Systems Engineering Assessment. This study investigated the full range of options for the development of the river system to prioritize investments to safely and sustainably manage and operate the river system assets, with a particular focus on the risks associated with the system's seismic fragility and flow control deficiencies.

The most significant remaining issues and risks at the John Hart facility include:

- Dam Safety:
  - Susceptibility of the dam to fail in an earthquake expected to occur, on average, once every 500 years;
  - Deficiencies in the operational reliability and seismic withstand of the spillway gates system, for which the risk is currently managed by regular testing and maintenance of the system;
  - Potential for flow imbalance due to interruption of generation at John Hart while generation continues at Ladore Generating Station upstream, for which the risk has been partially addressed by improvements implemented within the generating station redevelopment with the residual risk being managed through controls to automatically shut down generation at Ladore in the event of a shutdown at John Hart; and
  - Unreliable water level gauges downstream of John Hart Dam.

Summarize Solution:

Following the recent redevelopment of the generating station, this facility's investment strategy exclusively targets the existing Dam Safety risks identified above. Capital upgrade projects are currently underway or scheduled to commence in the short-term to address these risks.

Short-Term:

- Dam Safety:
  - Upgrades to the John Hart Dam to address seismic, flow imbalance and spillway gate reliability issues; and
  - Upgrades to the Campbell River water level monitoring system.

Name of Capital Strategy, Plan or Study: **Jordan River Facility Asset Plan**

Summarize Issue:
The single unit, 167 MW Jordan River facility is located on the southern part of Vancouver island, approximately 40 km west of Sooke at the end of a radial transmission line. The facility was redeveloped in 1971. It consists of:
• Bear Creek Reservoir,
• Jordan Diversion Reservoir,
• Elliot Headpond,
• Bear Creek Dam,
• Jordan Diversion Dam,
• Elliot Dam, and
• Jordan River Generating Station.
Jordan River is classified as a Strategic facility for asset management purposes and the dams are classified per BC Dam Safety Regulation as follows:
• Elliott Dam- Very High consequence;
• Jordan Diversion Dam - Very High consequence;
• Bear Creek Dam - Low consequence.
In the past 10 years, Jordan River has benefited from a number of capital investments totaling approximately $25 million. Recent equipment investments have included: mitigating known safety and reliability risks related to the 13 kV circuit breakers, fire protection system upgrades and recoating the majority of the penstock. Other recent investments have included the acquisition of properties downstream of Jordan River. These acquisitions are part of the effort to reduce public exposure in downstream areas that could be in inundated in the event of a major earthquake.
The most significant remaining issues and risks associated with the Jordan River facility include:
• Generating Equipment:
  - Governor and pressure reducing valve obsolescence leading to system reliability and maintainability issues; and
  - Deteriorating condition of the powerhouse fire protection system which could lead to localized damage of the piping and a subsequent failure to operate normally when required.
• Dam Safety:
  - The coatings on a number of sections of the penstock have failed which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to re-coat the assets before a much more extensive replacement or refurbishment is required;
  - Safety risks associated with members of the public accessing the out-of-commission intake tower at Bear Creek Dam for recreational swimming activities;
  - Susceptibility of the Low consequence Bear Creek Dam to failure in a small to moderate earthquake;
  - Obstruction of the Bear Creek Spillway that can cause outflows to back up against the downstream “toe” of the dam and cause potential damage; and
  - Susceptibility of Jordan Diversion Dam and Elliott Dam to failure in an earthquake expected to occur, on average, approximately once in every 500 years, for which the risk is currently being managed as described above.

Summarize Solution:

The Jordan River Facility Asset Plan proposes a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality.

In the short term, activities to address the risks with the governor, fire protection system, and the Bear Creek intake tower structure will be undertaken. In the medium to long term, activities will be started to address Bear Creek Dam and spillway pending the recommendations from a forthcoming strategic review of these assets. In the longer term, investments in the aging generating equipment as well as refurbishment of the Jordan Diversion Dam low level outlets may be required.

Short-Term:

- Generating Equipment:
  - Upgrade of the governor and pressure reducing valve system; and
  - Upgrades to the powerhouse fire protection system;
- Dam Safety:
  - Penstock recoating; and
  - Bear Creek Dam intake tower decommissioning.

Medium-Term:

- Dam Safety:
  - Potential upgrades to the Bear Creek spillway.

Long-Term:

- Generating Equipment:
  - Turbine overhaul;
  - Generator overhaul; and
  - Exciter upgrade.
- Dam Safety:
  - Jordan Diversion Dam low level outlets refurbishment; and
  - Potential seismic upgrade at Bear Creek Dam.

Name of Capital Strategy, Plan or Study:
Kootenay Canal Facility Asset Plan

Summarize Issue:

The four unit, 580 MW Kootenay Canal facility is located on the Kootenay River approximately 20 kilometers upstream of its confluence with the Columbia River near the city of Castlegar. The facility was commissioned in 1975 and consists of Kootenay Canal, which diverts water from the Kootenay River into a concrete lined forebay, Kootenay Canal Dam and Kootenay Canal Generating Station. Kootenay Canal is classified as a Key facility for asset management purposes and Kootenay Canal Dam is classified as a Very High consequence dam per the BC Dam Safety Regulation.

BC Hydro has made effective progress restoring the health of several components of this generating facility over the past 10 years through investments totaling over $40 million. Investments in the facility equipment have included upgrades to the intake gantry crane and replacement of the station service transformer. Dam Safety investments have included the installation of a membrane liner within the forebay to seal off leakage through joints between the concrete slabs. The most significant remaining issues and risks associated with the Kootenay Canal facility include:

- Generating Equipment:
  - Poor condition of all four generators and one governor that could impact the reliability of the generating equipment and result in loss of generation;
  - Failed coatings on the penstocks and intake operating gates that will lead to corrosion and metal loss and reduce the life of the penstocks and the gates;
  - Deficiencies in the existing fire protection system that have increased the risk of system failure due to accelerated corrosion and potential rupture of the piping;
- Dam Safety:
  - Failing and leaking joints between the canal's concrete slabs—upstream of the remediated forebay—that could eventually allow seepage to undermine the slabs. This risk is currently managed by regular visual inspections of the canal's concrete liner and embankments and by measurements of seepage through collection weirs.

Summarize Solution:

The Kootenay Canal Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality.

In the short term, investments to address the risks associated with the protection and control equipment as well as the powerhouse crane will be undertaken. In the medium to long term, investments are proposed to address risks with anticipated degradation of major generating equipment, auxiliary equipment and water passage infrastructure.

Short-Term:

- Generating Equipment:
  - Unit 1 to 4 protection upgrade;
  - Powerhouse crane upgrade; and
  - Unit 1 to 4 controls modernization.

Medium-Term:

- Generating Equipment:
  - Unit 1 to 4 generator refurbishment;
  - Fire detection and alarm system replacement;
  - Unit 1 to 4 penstocks recoat;
  - Unit 1 to 4 intake operating gate refurbishment.
  - AC station service upgrade; and
  - Unit 1 to 4 cooling water piping replacement.

- Dam Safety:
    - Canal concrete liner slab joints upgrade;

Long-Term:

- Generating Equipment:
    - Unit 1 to 4 turbine overhaul;
    - Unit 1 to 2 transformer replacement; and
    - Fire protection piping replacement.

Name of Capital Strategy, Plan or Study:
Ladore Facility Asset Plan

Summarize Issue:

The two unit, 47 MW Ladore facility is located on Vancouver Island and was commissioned in 1958. It was built as part of the Campbell River development and forms part of the Campbell River system with the Strathcona facility and John Hart facility located upstream and downstream, respectively. The facility consists of the Lower Campbell Lake Reservoir, the Ladore Dam, the Loveland Bay Saddle Dam, the Big Slide and McIvor Bay Natural Barriers and the Ladore Generating Station. The facility is classified as a Strategic facility for asset management purposes and the dams are classified per the BC Dam Safety Regulation as follows:

- Ladore Dam - Extreme consequence;
- Loveland Bay Saddle Dam - Significant consequence; and
- Big Slide Saddle Dam - Significant consequence.

In 2009 BC Hydro initiated the top-down Campbell River Systems Engineering Assessment and investigated the full range of options for the development of the river system in order to identify how investment should be prioritized to deliver safe and sustainable long-term management of the river system assets.

In recent years, a number of capital investments totaling $25 million have been made at the Ladore facility. Recent investments have included the replacement of the intake gates, upgrade of the oil containment and replacement of the powerhouse and tailrace cranes.

The most significant remaining issues and risks at the Ladore facility include:

- Generating Equipment:
  - The protection and controls equipment is over 55-years old, with deteriorated electro-mechanical relays with no failure detection system which pose a risk of misoperation leading to increased equipment damage and extended outage;
  - Poor condition of the Unit 1 and Unit 2 generators, turbines and transformers increases the reliability risks of both generating units and could result in an extended forced outage; and
  - The degraded condition of the mechanical auxiliary equipment which increases the potential for forced outages of the main generating equipment.
- Dam Safety:
  - Inadequate seismic withstand of the spillway gates and hoist structures which, following a major earthquake expected to occur, on average, once every 1200 years, could result in a loss of control of the reservoir; and
  - Deficiencies in the operational reliability of the spillway gates that could result in their failure to open as needed in a flood event.

Summarize Solution:

The Ladore Facility Asset Plan presents a unit-by-unit redevelopment strategy to address the identified risks and overall condition of the facility while considering factors such as condition, rate of deterioration, the operating environment, and criticality.

In the short term, activities to address the risks with the spillway gates, protection and control systems and the condition of Unit 1 will be started to mitigate reliability and power supply risks. In the medium to longer term, redevelopment of Unit 2 is expected to be started in order to mitigate reliability and power supply risks associated with Unit 2.

Short-Term:

- Generating Equipment:
  - Address protection and control issues; and
  - Unit 1 redevelopment.

- Dam Safety:
  - Seismic and reliability upgrades of Ladore Dam spillway gate systems.

Medium-Term:

- Generating Equipment:
  - Unit 2 redevelopment; and
  - Mechanical auxiliary equipment upgrades.

Name of Capital Strategy, Plan or Study:
Coquitlam-Buntzen Facility Asset Plan

Summarize Issue:

The single unit, 60 MW Lake Buntzen facility is located in Metro Vancouver and was commissioned in 1951. It is part of the Coquitlam-Buntzen system, which consists of Coquitlam Reservoir and Dam, Coquitlam diversion tunnel, Buntzen Lake Reservoir and Dam, and Lake Buntzen 1 and 2 Generating Stations. Lake Buntzen is classified as a Strategic facility for asset management purposes. Coquitlam Dam is an Extreme consequence dam and Lake Buntzen Dam is a Significant consequence dam per the BC Dam Safety Regulation.

The original Lake Buntzen 1 Generating Station first went into service in 1903. In 1951 the original generating units were replaced with a single 60 MW unit that continues to operate today. The three unit Lake Buntzen 2 Generating Station was built in 1913, and permanently ceased operation 2013. The original Coquitlam Dam, constructed in 1905, was replaced by a second dam in 1914. This second dam was found to be severely deficient under earthquake loading, and a new embankment dam was constructed on the downstream toe of the second dam in 2008. The second dam remains in place, but is not relied upon to retain the reservoir.

BC Hydro improved the health of the Coquitlam-Buntzen system through a number of investments in recent years totaling over $90 million. Investments in generating equipment have included a turbine upgrade. Dam Safety investments have included the construction of a new Coquitlam Dam, upgrades to the Coquitlam Dam low level outlet gates, and an upgrade to the Lake Buntzen spillway.

The most significant remaining issues and risks associated with the Coquitlam-Buntzen system include:

- Generating Equipment:
  - Poor condition of the Coquitlam tunnel gates, a failure of which would result in the loss of control of the transfer of water from Coquitlam Reservoir to Buntzen Lake Reservoir;
  - Poor condition of the Lake Buntzen 1 powerhouse crane, which decreases crane reliability and increases worker safety risks;
  - Failed interior and exterior coatings on the Lake Buntzen 1 penstock which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to re-coat the asset before a much more extensive refurbishment or replacement is required; and
  - Poor condition of the Lake Buntzen 1 generator, which elevates the reliability risks associated with the single generating unit and increasing the likelihood that the facility may experience an extended forced outage.
- Dam Safety:
  - Potential failure of the Coquitlam tunnel's inlet and outlet portals during an earthquake expected to occur, on average, once every 100 to 200 years;
  - Potential failure of the Coquitlam Low Level Outlet structure in an earthquake expected to occur, on average, once every 3,500 to 5,000 years; and
  - Insufficient capacity of the Lake Buntzen 1 spillway that increases the risk of overtopping Buntzen Dam and flooding Lake Buntzen 1 Generating Station, a risk that BC Hydro is currently accepting but managing through increased surveillance when reservoir elevations are high.

Summarize Solution:

The Coquitlam-Buntzen Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as asset condition, rate of deterioration, the operating environment, and criticality.

In the short term, the focus will be on risks associated with the ability to transfer water between Coquitlam Reservoir and Lake Buntzen Reservoir, as well as reliability of the Lake Buntzen 1 penstock and generating unit. In the medium to longer term, investments will continue to address the risks associated with the penstock as well as addressing the seismic withstand capability of the Coquitlam tunnel inlet portal and the flood discharge capability of Lake Buntzen 1 generating station.

Short-Term:

- Generating Equipment
  - Lake Buntzen 1 Powerhouse Crane Upgrade;
  - Coquitlam Tunnel Gates Refurbishment;
  - Lake Buntzen 1 Exterior Penstock Recoat; and
  - Lake Buntzen 1 Generator Replacement.

Medium- and Long-Term:

- Generating Equipment
  - Lake Buntzen 1 Interior Penstock Recoat;
  - Coquitlam Tunnel Inlet Portal Seismic Upgrade; and
  - Lake Buntzen 1 Flood Discharge Capability Improvement.

The risks associated with the low seismic withstand of the Coquitlam Tunnel outlet portal, and the Coquitlam Dam Low Level Outlet structure are monitored and will be retained as the consequences are expected to be low.

Name of Capital Strategy, Plan or Study: **Mica Facility Asset Plan**
Summarize Issue: The six unit, 2780 MW Mica facility is located on the Columbia River north of the town of Revelstoke. It was constructed under the terms of the Columbia River Treaty. The dam was completed in 1973, two generating units were installed and commissioned in 1976, two more in 1977 and the final two in 2015. The facility includes Kinbasket Lake Reservoir, Mica Dam and Mica Generating Station. Mica is classified as a Key facility for asset management purposes and Mica Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation. Approximately $700 million has been invested at Mica over the past ten years, $600 million of which was to upgrade the gas insulated switchgear system and commission the fifth and sixth generating units. Investments in the generating equipment have also included a Unit 1 transformer replacement and battery and charger replacement. Dam Safety investments within this period have generally been limited to instrumentation improvements. The most significant remaining issues and risks associated with the Mica facility include: • Generating Equipment; - Poor condition of the original unit transformers, line reactors and Unit 1 and 2 turbines increases the reliability risk and may result in forced outages; - Obsolescence of the original Unit 1 to 4 circuit breakers, exciter controls and governor controls increases the reliability risk and may lead to forced outages; - Deterioration of the water passage protective coatings will lead to corrosion and metal loss of the underlying material thereby reducing the life of the penstock; - Poor condition of the powerhouse cranes and limited capacity of the crane rails may impact the ability to lift loads associated with unit refurbishment work; - Poor condition of the Heating, Ventilation and Air Conditioning (**HVAC**) systems increases the safety risk in the underground powerhouse as these systems are relied upon to move air through the facility in emergency situations; and - Poor condition of the Unit 1 and 2 cooling water piping increases the risk of piping failure resulting in damage to the facility or equipment. • Dam Safety: - Inadequate seismic withstand of the flood discharge systems (spillway and outlet works) which, following a major earthquake expected to occur, on average, once every 2000 to 3000 years, could result in a loss of control of the reservoir; - Deficiencies in the operational reliability of the spillway gates that could result in their failure to open as needed in a flood event, for which the risk is currently managed by regular testing and maintenance of the existing systems; and - Potential failure of the nearby Dutchman's Ridge and Little Chief Slide into Kinbasket Reservoir under unusual loads (e.g., earthquake or extreme precipitation), which could lead to overtopping of the dam. This risk is managed through a sustained program of slope surveillance and monitoring.
Summarize Solution: With the recent construction of Units 5 and 6, Mica is continuing a period of planned refurbishment of the original four units that were installed and commissioned in the 1970s. The Facility Asset Plan proposes a component by component replacement strategy to sustain operation at the Mica Facility by mitigating the risk of failure of individual assets on an as needed basis (e.g., condition, rate of deterioration, operating environment, and criticality). Investments in the short-term will focus on the highest priority safety and reliability risks in the powerhouse that can be mitigated without an extended outage and on addressing high consequence risks associated with current spillway and outlet works deficiencies. Work in the medium to long-term will be undertaken with continued focus on equipment that is in poor

condition but requires longer duration outages, as well as works to maintain or improve the stability of Dutchman's Ridge and Little Chief Slide.

Short-Term:

- Generating Equipment:
  - Powerhouse cranes and crane rails upgrade (planned In-service Date fiscal 2020);
  - Unit 1 to 4 unit transformer replacements;
  - Unit 1 to 4 exciter controls, governor controls and unit protection replacement;
  - HVAC system upgrades; and
  - 600 V switchgear and essential electrical bus upgrades.
- Dam Safety
  - Flood discharge facilities seismic and reliability upgrades.

Medium-Term:

- Generating Equipment
  - Unit 1 and 2 turbine overhauls;
  - Unit 1-4 circuit breaker and iso-phase bus replacement;
  - 500 kV line reactor replacement;
  - Unit 1 and 2 cooling water piping; and
  - Water passage coatings restoration.
- Dam Safety
  - Little Chief slope inclinometer installation.

Long-Term:

- Generating Equipment
  - Unit 3 and 4 turbine overhauls; and
  - Unit 3 and 4 cooling water replacement.
- Dam Safety
  - Dutchman's Ridge and Little Chief Slide: slope stability improvements or measures to mitigate impacts of failure.

Name of Capital Strategy, Plan or Study:
Mica Townsite Facility Asset Plan

Summarize Issue:

The Mica facility is in a remote location, approximately 130 km north of the town of Revelstoke. The Mica Townsite, owned by BC Hydro, consists of a number of permanent buildings for staff accommodation and recreation. The buildings were originally built in the 1960s, and house approximately 50 staff who maintain and operate the plant on an on-going basis.

Additionally, in 2011, a temporary construction camp was built at the townsite to accommodate up to 400 temporary additional staff working on large capital projects at the Mica facility. The construction camp was scheduled to be removed in 2015 after the completion of the installation of Units 5 and 6 at Mica. However, with the timing of current and planned capital projects at Mica, there is a need to modify and extend the life of the camp to accommodate project related staff over the next 10 to 15 years.

BC Hydro has preserved the townsite infrastructure over the past 10 years through investments totaling roughly $3 million. These investments included refurbishing several of the highest risk building roofs and an upgrade of the fire protection system in one of the buildings.

The most significant remaining issues and risks associated with the Mica townsite include:

- Temporary nature of the existing construction camp is insufficient to meet requirements for the next 15 to 20 years;
- Deficiencies in the roofs of many of the key buildings increase the safety risk posed by snow loads as well as the comfort of occupants due to water ingress;
- Deterioration of items such as windows, flooring and furnishings in the permanent accommodations used to house plant operations staff increases the risk of negative impacts to the well-being of the workers and increases the risk of employee turnover; and
- Deficiencies in the Townsite sanitary sewage system increase the risk of system failure which may have environmental, safety and financial risks.

Summarize Solution:

The Mica Townsite is in a period of planned refurbishment to maintain the infrastructure for both permanent staff supporting operations and maintenance and project related staff supporting the delivery of capital projects.

The proposed strategy for Mica Townsite is to convert portions of the temporary accommodations into permanent facilities, expand the kitchen and dining areas, and address the deteriorating condition of the permanent structures and infrastructure, to ensure continued availability and reliability of the Townsite.

Short-Term:

- Permanent accommodation capacity augmentation through conversion of temporary facilities essential for planned capital projects (planned In-service Date fiscal 2020);
- Building roof refurbishments to address the most significant roof issues;
- Staff accommodations refurbishment; and
- Townsite sanitary sewage system refurbishment.

Name of Capital Strategy, Plan or Study:
Peace Canyon Facility Asset Plan

Summarize Issue:

The four-unit, 700 MW Peace Canyon facility is located 6 km upstream of Hudson's Hope and 23 km downstream of the G.M. Shrum Generating Station on the Peace River. It was placed into service in 1980 and is comprised of the Dinosaur Lake Reservoir, the Peace Canyon Dam, and the Peace Canyon Generating Station. Peace Canyon is classified as a Key generating facility for asset management purposes and Peace Canyon Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation.

BC Hydro has actively maintained the health of this important generating facility over the past 10 years though a number of investments totaling over $100 million. Investments in the generating equipment include replacement of the generator stators and turbine overhauls.

The most significant remaining issues and risks associated with the Peace Canyon facility include:

- Generating Equipment:
  - Failed exterior coatings of the penstock and scroll case which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to re-coat the asset before a much more extensive refurbishment or replacement would be required;
  - Increased risk of water leakages from poor condition of the high and low pressure piping systems that may cause damage to critical and sensitive equipment; and
  - Poor condition of Unit 1 to 4 Exciters.
- Dam Safety:
  - Deficiencies in the operational reliability of the spillway gates that could result in their failure to open as needed in a flood event, the risk of which is currently managed by regular gate testing and maintenance as required;
  - Continuing erosion of rock at the rim of the plunge pool downstream of the spillway structure that could eventually progress upstream to the toe of the spillway and threaten that structure's stability, currently managed by the performance of underwater inspections following spills;
  - Potential failure of the dam in a major earthquake expected to occur, on average, once every 2,500 years; and
  - Diminishing efficiency of the dam's foundation drainage systems that could eventually result in insufficient stability of the dam structure, which is currently managed by continuous monitoring of uplift pressures and drain cleaning as required.

Summarize Solution:

The Peace Canyon Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. Capital upgrade projects are carefully planned in coordination with G.M. Shrum as operations at G.M. Shrum can be restricted when Peace Canyon units are out of service. In the short-term, projects are staged to prioritize reliability investments in key generating equipment. In the medium to long term, projects are staged to restore water passage coatings, improve the reliability of the flood discharge system and improve the seismic withstand of the Peace Canyon Dam.

Short-Term:

- Generating Equipment:
  - Unit 1 to 4 Exciter Replacement; and
  - High and Low Pressure Piping Replacement.
- Dam Safety:
  - Re-drilling of the dam's foundation drains.

Medium-Term:

- Generating Equipment:
  - External Penstock Recoating.
- Dam Safety:
  - Spillway gates control upgrade;
  - Peace Canyon Dam seismic upgrade; and
  - Dam foundation drain rehabilitation.

Long-Term:

- Dam Safety:
  - Spillway gates electrical and mechanical upgrades.

The risk that the spillway plunge pool may continue to erode during major spill events is currently being managed by monitoring the progression of the eroded area. Capital investment is not planned at this time; however, future work may be required to ensure that the spillway structure does not become undermined.

Name of Capital Strategy, Plan or Study:
Generation Asset Management Strategy - Penstock Recoating

Summarize Issue:

There are 67 penstocks supplying 79 units at BC Hydro's hydroelectric generating stations. Penstocks are high-value assets that convey water to a generating unit's turbine. Generally, the exterior and interior surfaces of the steel penstocks are coated to protect the underlying material from abrasion, corrosion, and ultimately material loss and a reduction in structural strength.

Over time, the coatings wear, degrade and fail, leading to corrosion of the underlying penstock material. Recoating of the penstock ensures that its life can be preserved, however, if the window of opportunity to recoat the penstock is missed, the underlying material will continue to corrode over time, and eventually, the penstock can no longer be used to safely convey water to the generating facility.

If the corrosion is too severe, it may not be possible to re-coat the penstock, resulting in a number of issues and risks:

- Financial - A much more expensive penstock replacement and significantly longer generating unit outage would be required;
- Reliability - the asset can no longer safely convey water to the turbine forcing the generator to be taken out of service; and
- Safety and Environmental –severe corrosion and metal loss can result in sudden and large uncontrolled releases of water. BC Hydro mitigates this risk by monitoring the condition of its penstocks over time and would pro-actively remove an asset from service if degradation became too severe.

Currently, approximately 13 penstocks are between 50 and 60 years old, and 23 are more than 60-years old (of which three are no longer in service). Age is one factor but operating environment and water pressure, the quality of the coating and design factors have a larger effect on the asset health. Approximately 32 (48 per cent) of the penstocks have been assessed as Poor or Unsatisfactory, primarily due to issues with the coatings, indicating there is an increased likelihood of loss of structural strength if not addressed in a timely manner.

Summarize Solution:

BC Hydro has undertaken a number of activities to better understand the condition of the penstocks and coatings. Work was undertaken to assess the health of all of its penstocks to establish a baseline of condition and risks. An enhanced penstock asset health methodology was developed to assess both the condition of the penstocks and its coatings. The information has been used to identify the poorest condition penstock coatings and to estimate the window of time remaining to re-coat the penstock before a replacement of the asset would be required.

As a result of this work, a number of capital projects have been identified to remediate the risks associated with the higher risk penstocks with a focus on penstock coatings. The planned scope and timing of these investments has considered factors such as:

- The need to re-coat both the exterior and exterior, or whether one surface is a higher priority;
- The need to recoat an entire penstock or whether only localized coating refurbishment would be sufficient;
- The opportunity to co-ordinate the investment with similar duration unit outages; and
- The operating pressure of the penstock with higher pressure penstocks generally given higher priority for re-coating.

Given the coating condition of a large number of penstocks, consideration was given to a project delivery strategy that minimizes costs, reduces quality risks and more efficiently delivers the recoating projects.

Short-Term:

The condition of assets is reviewed on a regular basis considering such factors as recurring test results, visual inspections, and detailed engineering assessments. This information is used to assess the condition of each penstock to help prepare a consolidated list across the fleet to identify the most appropriate time to address the risks while best coordinating other planned generating unit outages. Below is a list of those penstocks with higher priority requiring investment in the short-term:

- Ash River steel penstock (external recoating);
- Bridge River 1 penstocks 1 to 4 (internal recoating;
- Bridge River 2 penstock 2 (internal recoating);
- Cheakamus penstocks 1 and 2 (internal and external recoating);
- Jordan River penstock (external recoating);
- Lake Buntzen 1 penstock (external recoating);
- Puntledge steel penstock (internal and external recoating); and
- Wahleach penstock (internal and external recoating).

Medium-Term:

There are a number of penstock coating refurbishment projects that will need to be initiated in the medium term. The strategy and prioritization will be adjusted over time to respond to new information becoming available from penstock condition assessments. Currently, the following locations have been identified as higher risk:

- Bridge River 1 penstocks 1 to 4 (external recoating);
- Kootenay Canal penstocks 1 to 4 (internal recoating);
- Lake Buntzen 1 penstock (internal recoating);
- Peace Canyon penstocks 1 to 4 (external recoating);
- Walter Hardman penstock (exterior recoating);
- Mica Creek penstocks 1 to 6 (targeted recoating);
- La Joie south penstock (interior recoating);
- Seton penstock (interior recoating); and
- GM Shrum penstocks 1 to 10 (interior recoating).

Long-Term:

Over the next 10 years, a number of penstock coatings will continue to degrade. Remediation of the risks associated with these assets will be required in the long-term, applying similar assessment and prioritization techniques to those outlined above.

Name of Capital Strategy, Plan or Study:
Puntledge Facility Asset Plan

Summarize Issue:

The single unit, 24 MW Puntledge facility is located near the City of Courtenay on Vancouver Island. The facility is comprised of the Comox Lake Reservoir, Comox Dam, Puntledge Diversion Dam and the Puntledge Generating Station. Both dams were constructed in 1912 and the generating station was constructed in 1955. Puntledge is classified as a Strategic generating facility for asset management purposes. The Dams are classified as follows per BC Dam Safety Regulation:

- Comox Dam - Extreme consequence; and
- Puntledge Diversion Dam - Very High consequence

Over the past 10 years, a small number of capital investments totaling over $5 million have been undertaken at Puntledge in order to mitigate known public safety risks associated with the water level gauges, public warning system, and flow control system and to address penstock reliability issues.

The most significant remaining issues and risks associated with the Puntledge facility include:

- Generating Equipment:
  - The intake operating gates and pressure release valves are subject to a number of issues which can impact their reliable operation resulting in an elevated public safety risk due to unexpected changes in downstream water releases;
  - Poor condition of the generator which increases the reliability risk and increases the likelihood that the facility may experience an extended forced outage;
  - The ongoing deterioration and accelerated decay of the woodstave penstock increases the risk that the asset will no longer be able to safely convey water; and
  - The coating of the steel penstock has failed along the majority of its length leading to corrosion and metal loss of the underlying material thereby reducing the life of the penstock. A finite window of opportunity exists to re-coat the asset before a much more extensive rehabilitation or replacement is required.
- Dam Safety:
  - The spillway operating gates at Comox Dam have deficiencies in reliability that could render them inoperative when needed during high inflows and could lead to overtopping of the dam and abutments, the risk of which is being managed by frequent repairs to deteriorating components;
  - The Comox and Puntledge Diversion Dams have seismic deficiencies that, in the event of an earthquake expected to occur, on average, once every 1000 years, could lead to their failure and consequent downstream impacts;
  - The right abutment of Comox Dam is susceptible to erosion during low probability flood conditions which could result in a breach and uncontrolled release of Comox Lake Reservoir; and
  - Potential overtopping of Comox Dam in the event of the extreme design flood expected to occur, on average, once every 1000 years.

Summarize Solution:

The Puntledge Facility Asset Plan proposes a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality.

In the short term, activities to address the issues with the steel penstock and flow control and water level monitoring systems will be undertaken as these have been identified as being higher priority public safety risks. In the medium-term, activities will be started to address the condition of the generating unit and the seismic withstand of the Puntledge Diversion Dam in order to mitigate reliability and dam safety risks respectively. In the longer-term, seismic withstand of the Comox Dam will be addressed along with the condition of the wood stave penstock.

Short-Term:

- Generating Equipment:
  - Steel penstock recoating.
- Dam Safety:
  - Flow control improvements; and
  - Upgrades to the water level monitoring and public safety warning systems.

Medium-Term:

- Generating Equipment:
  - Generator refurbishment; and
  - Turbine refurbishment.
- Dam Safety:
  - Puntledge Diversion Dam structure seismic upgrade.

Long-Term:

- Dam Safety:
  - Wood stave penstock replacement; and
  - Comox Dam seismic upgrades.

At this time, no investment is proposed to address the overtopping risk of Comox Dam structure due to measures within ongoing and planned projects to mitigate the downstream safety risk.

Name of Capital Strategy, Plan or Study:
Revelstoke Facility Asset Plan

Summarize Issue:

The five-unit, 2391 MW Revelstoke facility was built in 1984 and is located on the main stem of the Columbia River near the town of Revelstoke. The facility includes the Revelstoke Reservoir, the Revelstoke Dam and the Revelstoke Generating Station. The first four generating units went into service in 1984, the fifth unit went into service in 2011, and there is space for a sixth unit. Revelstoke is classified as a Key facility for asset management purposes and Revelstoke Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation.

BC Hydro has made substantial progress in maintaining the health and increasing the capacity of this generating facility over the past 10 years through a number of investments totaling over $230 million. Investments in the generating equipment have included the installation of generating Unit 5, upgrades to the powerhouse crane and facility security upgrades.

The most significant remaining issues and risks associated with the Revelstoke facility include:

- Generating Equipment;
  - Poor condition of the Unit 2 to 4 generators increases the reliability risk and may result in long unit outages;
  - Configuration and expected deterioration of the iso-phase bus increases the reliability risk associated with unit outages;
  - Obsolescence of the Unit 1 to 4 exciter and governor controls increases the reliability risk and may result in unit outages; and
  - Poor condition of six of the twelve Unit 1 to 4 transformers increases the reliability risk and may result in long unit outages.
- Dam Safety:
  - The potential for Downie Slide, a slow-moving land mass on the Revelstoke Reservoir, to slide into and block the Columbia River, which is managed under the terms of the water license by maintaining an extensive network of drainage throughout the extent of the slide and by continuously monitoring the slide's movements and pore water pressures;
  - Potential failure of portions of the rock slope at the dam's left abutment that could impact the penstocks and powerhouse or damage the rock anchors that stabilize larger masses of rock on the slope, which is currently managed by monitoring and surveillance;
  - High hydraulic gradients around the earthfill dam's vertical movement gauge casings could drive water flows around these casings and lead to internal erosion of the earthfill materials, the risk of which is currently managed by continuous monitoring of water pressures in the dam core and water levels in the casings; and
  - Inadequate reliability and seismic withstand of the flood discharge (spillway) system that may impact our ability to manage water in a controlled manner during high inflow events or in the aftermath of an earthquake, for which the risk is currently managed by regular gate testing and maintenance.

Summarize Solution:

The Revelstoke Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. Implementing the investment strategy at Revelstoke facility is at the early stages which include refurbishing the original equipment and infrastructure. Adding the sixth generating unit is also planned in order to meet the long-term system capacity requirements.

In the short-term, projects are staged to prioritize investments required for safe and reliable generation and also to leverage facility growth potential to support meeting system capacity needs. Timing of the addition of the sixth unit and coordination with other Revelstoke projects creates risk due to limited physical space in the powerhouse constraining the ability to carry out several major projects at once.

Investments to monitor and manage risks related to landslides are ongoing and proposed to continue through the medium-term.

Short-Term:

- Generating Equipment:
  - Unit 1 to 4 generator stator replacements;
  - 600 V switchgear replacement; and
  - Addition of the sixth generating unit.
- Dam Safety:
  - Left Bank slope stability improvements to reduce the risk of rockfall and protect the rock anchors in the slope from damage;
  - Downie Slide instrumentation replacements to ensure continued monitoring of water pressures and deformations in the slope in accordance with the dam's water license; and
  - Rehabilitation or decommissioning of the earthfill dam's vertical movement gauges.

Medium-Term:

- Generating Equipment:
  - Addition of the third section of gas insulated switchgear bus;
  - Unit 1 to 4 transformer replacements;
  - Unit 1 to 4 exciter and governor controls replacement; and
  - Databus system replacement.
- Dam Safety:
  - Flood discharge (spillway) system reliability improvements; and
  - Remediation of the slope drainage system at Downie Slide in the timeframe when it's effectiveness is expected to diminish, in accordance with the dam's water license.

Long-Term:

- Generating Equipment:
  - Unit 1 to 4 water passage coating restoration; and
  - Unit 1 to 4 turbine overhauls.

Name of Capital Strategy, Plan or Study:
Seton Facility Asset Plan

Summarize Issue:

The single unit, 44 MW Seton facility is located near Lillooet and was commissioned in 1956. It consists of:

- Seton Lake;
- Seton Dam;
- Left Bank Dyke;
- Cayoosh Diversion Tunnel;
- Seton Canal; and
- Seton Generating Station.

Seton is classified as a Strategic facility for asset management purposes and Seton Dam is classified as a High consequence dam per the BC Dam Safety Regulation.

BC Hydro has made a number of investments over the past 10 years totaling more than $35 million. The most significant investments have included the refurbishment of the power canal lining and upgrades to the spillway gates.

The most significant remaining issue and risks associate with Seton facility include:

- Generating Equipment:
  - Poor condition of the generator with increasing risk of a failure that would result in a loss of generation and high flows in the Seton River;
  - Governor reliability concerns. The original governor is no longer supported by Original Equipment Manufacturers and due to wear is more difficult to maintain and calibrate. Failure to control the unit could lead to outages or in worst case a cause an over speed situation resulting in significant damage to the unit;
  - Unit Protection concerns. The original electro-mechanical protection and control systems are no longer supported. Unreliable protection could lead to extended outages if it fails to operate;
  - Poor condition of the turbine with wear, cracking and excessive leakage through the wicket gates increase reliability risk and may result in a forced outage; and
  - Penstock coating failure. A finite window of opportunity exists to re-coat the asset before a much more extensive rehabilitation or replacement is required.
- Dam Safety:
  - Cracks and leaks in the concrete lined canal could lead to a failure of the lining and breach of the canal, the risk of which is being managed by regular inspections and repairs to slow deterioration of the canal lining's overall condition;
  - Inability to close the headworks gates and shut off flow in the event of a canal failure, with current risk management as per the preceding item; and
  - Uncertainty and expected deficiency of the seismic resistance of various civil assets (headworks operating gates, forebay, dam, left dyke, aqueduct, canal). These structures are estimated to be capable of withstanding an earthquake expected to occur once every 1500 to 5000 years, depending on the asset.

Summarize Solution:

The Seton Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The ability to take outages at the facility can be limited, in light of the important role that the unit plays with respect to water conveyance. The timing of investments that require unit outages have been coordinated, to minimize the impact on water management.

In the short-term, the focus will be on higher priority investments that are required for water management as well as safe and reliable generation. Investments are sequenced to minimize the number and duration of outages required. The medium to longer-term activities will focus on the canal and headworks gates and seismic issues.

Short-Term:

- Generating Equipment:
    - Governor system replacement;
    - Unit protection upgrade;
    - Turbine overhaul;
    - Penstock recoating; and
    - Generator replacement.

Medium-Term:

- Dam Safety:
    - Upgrade headworks gates;
    - Canal refurbishment; and
    - Left Bank Dyke seismic upgrades.

Long-Term:

- Dam Safety:
    - Dam seismic upgrades; and
    - Canal and aqueduct seismic upgrades.

A Dam Safety Investigation is planned to assess and obtain a better understanding of the seismic performance of various civil assets at the facility relative to the criteria for a High consequence dam.

Name of Capital Strategy, Plan or Study:
Seven Mile Facility Asset Plan

Summarize Issue:

The four-unit, 814 MW Seven Mile facility is located on the Pend d'Oreille River in southern British Columbia, upstream of Waneta Dam and downstream of Boundary Dam which is owned by Seattle City Light. The facility includes the Seven Mile Reservoir, the Seven Mile Dam, and the Seven Mile Generating Station. The first unit at Seven Mile Generating Station went into service in 1979, with two additional units installed in 1980 and the fourth unit installed in 2003. Seven Mile is classified as a Key facility for asset management purposes and Seven Mile Dam is classified as an Extreme consequence dam per the BC Dam Safety Regulation.

BC Hydro has invested over $20 million in this facility over the past ten years. Investments in the generating equipment have included the excitation system replacement, Units 1 to 3 stator re-wedging, Units 1 to 4 partial discharge monitoring and Units 1 to 3 protection upgrades. Dam Safety investments have included reservoir slopes instrumentation upgrades and general dam safety improvements.

The most significant remaining issues and risks associated with the Seven Mile facility include:

- Generating Equipment:
  - Poor condition of some of the generating equipment including unit controls, exciter transformers and unit transformers could impact the reliability of the generating equipment and result in loss of generation;
  - Unit 1 to 3 turbines are 37 to 38 years old and have never undergone a major intervention. The latest engineering inspection identified excessive band seal erosion and runner cavitation on these units. Furthermore, due to lack of wicket gate friction devices on these turbines, there is a risk of an undetected shear pin failure event which would result in damage to the wicket gates and unit outages;
  - Failed coatings on the Intake Operating Gates, Intake Maintenance and Draft Tube Maintenance Gates that will lead to corrosion and metal loss and reduce the life of the gates;
  - Poor condition of the powerhouse, tailrace gantry and intake gantry cranes that could impact the reliability of the cranes and their lifting capabilities;
  - Poor condition of the cooling water piping that has increased the risk of piping failure; and
  - Deficiencies in the existing fire alarm and fire protection systems that have increased the risk of system failure due to accelerated corrosion and potential rupture of the piping.
- Dam safety:
  - Deficiencies in the reliability of the flood discharge (spillway) facilities that could lead to a failure of the system to operate on demand during high inflows (a flood or spurious release from Boundary Dam upstream) and result in significant damages to the dam and powerhouse, the risk for which is currently managed through regular gate testing and maintenance; and
  - Deteriorating performance of the dam's drainage system that is continually monitored but, if not remediated, would eventually compromise the dam's stability.

Summarize Solution:

The Seven Mile Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed) considering factors such as condition, rate of deterioration, the operating environment and criticality.

In the short term, the focus will be on higher priority investments required for safe and reliable generation that are sequenced to minimize outages. Medium term activities include those related to maintaining reliable operation of the flood discharge systems. In the long term, activities will continue to focus on investments required to address safety risks and reliability risks for equipment in poor condition.

Short-Term:

- Generating Equipment:
  - Unit 1 to 4 exciter transformer replacement;
  - Powerhouse crane upgrade;
  - Unit 1 to 3 turbine replacement;
  - Fire alarm system replacement;
  - Unit 1 to 4 controls replacement; and
  - Unit 1 transformer replacement.

Medium-Term:

- Generating Equipment:
  - Unit 1 to 3 cooling water piping replacement.
- Dam Safety:
  - Flood Discharge Systems Reliability Improvements; and
  - Foundation drains replacement.

Long-Term:

- Generating Equipment:
  - Unit 2 to 3 transformers replacement;
  - Fire protection piping replacement;
  - Unit 1 to 3 generators replacement;
  - Intake operating gate refurbishment; and
  - Intake gantry crane upgrade.

Name of Capital Strategy, Plan or Study: **Stave Falls New Facility Asset Plan**
Summarize Issue: The two unit, 90 MW Stave Falls New facility is located in the Lower Mainland and was constructed in 1999. It forms part of the Stave River system, with the Alouette facility and Ruskin facility located upstream and downstream, respectively. It consists of the Stave Lake Reservoir, Stave Falls Dam, Blind Slough Dam, and Stave Falls New Generating Station. Stave Falls New is classified as a Strategic facility for asset management purposes. Stave Falls Dam and Blind Slough Dam are rated as Extreme consequence dams per the BC Dam Safety Regulation. The original Stave Falls Generating Station was developed in 1911, and permanently ceased operation when Stave Falls New Generating Station was placed into service. BC Hydro has made a number of investments over the past 10 years totaling over $50 million. Investments in the generating equipment have included site grounding upgrade and a tailrace gantry crane upgrade. Dam Safety investments have included upgrades to Blind Slough Dam's spillway gates and gantry crane. The most significant remaining issues and risks associated with the Stave Falls New facility include: • Generating Equipment: - A design deficiency with the Unit 1 and Unit 2 turbines that could impact the reliability of the generating units and result in loss of generation; and - Potential equipment reliability risks due to expected obsolescence with the unique digital controls systems that could result in loss of generation due to limited spare parts and manufacturer support.
Summarize Solution: The Stave Falls New Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. In the short-term, the focus will be addressing risks associated with the generating units. The medium to longer-term activities will focus on risks associated with the generating unit control systems. **Short-Term:** • Generating Equipment: - Units 1 and 2 Turbine Pitch Assemblies Improvement. **Medium- and Long-Term:** • Generating Equipment: - Unit 1 Controls Upgrade; and - Unit 2 Controls Upgrade.

Name of Capital Strategy, Plan or Study:
Strathcona Facility Asset Plan

Summarize Issue:

The two unit 64 MW Strathcona facility is located on Vancouver Island and was constructed in 1958 (Unit 1) and 1968 (Unit 2). Strathcona forms part of the Campbell River system, with Ladore and John Hart facilities located downstream. The facility includes the Upper Campbell Reservoir, the Strathcona Dam, Crest Creek Diversion Dike, and the Strathcona Generating Station. Strathcona is classified as a Strategic facility for asset management purposes. Per the BC Dam Safety Regulation:

- Strathcona Dam is rated an Extreme consequence dam; and
- Crest Creek Diversion Dike is rated a Significant consequence dam.

In 2009 BC Hydro initiated the Campbell River Systems Engineering Assessment and investigated the full range of options for the development of the river system in order to identify how investment should be prioritized to deliver safe and sustainable long-term management of the river system assets. Remediation of seismic concerns may mean that the generating facility cannot continue to operate in its current location. This still requires extensive investigation; however, the level of investment in the generating equipment has been limited, while the overall strategy is clarified. Over the past 10 years, $25 million of the total $35 million in investments made at the facility have been to implement seismic upgrades with the remaining investments made on essential activities on generating equipment such as the intake gates, one of the generators, and turbine inlet valves (**TIVs**).

The most significant remaining issues and risks associated with the Strathcona facility include:

- Generating Equipment:
  - Poor condition of the Unit 1 generator increases the reliability risk and could result in an extended forced outage resulting in a loss of generation and inability to maintain necessary water conveyance past the facility.
- Dam Safety:
  - Expectedly poor post-seismic performance of the embankment dam after an earthquake occurring, on average, about once every 500 years;
  - Insufficient seismic withstand of the intake tower and the water conduit and penstock that pass under the dam to the powerhouse, raising concerns for their failure in an earthquake occurring, on average, about once every 500 to 1,000 years, resulting in seepage through the dam fills and potential dam failure;
  - Deficiencies in the operational reliability of the spillway gates that could result in their failure to open as needed in a flood event;
  - Insufficient seismic withstand of the spillway gates and hoist structures that, in an earthquake occurring, on average, about once every 1,000 years, could fail and result in a loss of containment and/or control of the reservoir; and
  - Inability to draw down the reservoir to a sufficiently low elevation following a major earthquake, as required by the expectedly poor post-seismic performance of the dam (described above).

Summarize Solution:

The Strathcona Facility Asset Plan presents a strategy that initially focuses on addressing the highest priority water conveyance and dam safety items. The strategy to be taken for upgrades to the dam and ancillary flow control structures is described within the Campbell River Systems Engineering Assessment which is referenced above and has its own summary within Appendix K. Limited investments in the existing generating equipment will be considered on a component by component basis (i.e., undertake discrete investments, as needed), considering factors such as condition, rate of deterioration, the operating environment and criticality.

In the short term, activities will address the identified risks and issues associated with the reservoir discharge capability and generating units, in order to address immediate high priority dam safety and reliability risks, respectively. In the medium term, the focus will remain on water conveyance and addressing the seismic withstand risks associated with the dam. It is possible that the solution required to remediate the seismic issues associated with the dam may result in an inability to continue generation within the existing powerhouse. If this is the case, in the long-term, opportunities to redevelop the generating station will be investigated.

Short-Term:

- Generating Equipment:
    - Generator (G1) refurbishment.
- Dam Safety:
    - Upgrade of the reservoir discharge facilities to provide sufficient operational reliability, required seismic withstand, post-earthquake drawdown capability, and capability to provide compensatory flows in the event of lost or discontinued generation.

Medium-Term:

- Dam Safety:
    - Embankment dam seismic upgrades; and
    - Possible decommissioning of the intake tower, water conduit and penstock under the dam and concomitant decommissioning of the generating station or reducing the Generating Station to a non-operational station.

Long-Term:

- Generating Equipment:
    - Potential redevelopment of the Strathcona generating station.

Name of Capital Strategy, Plan or Study:
Wahleach Facility Asset Plan

Summarize Issue:

The single unit, 61 MW Wahleach facility is located in the Lower Mainland and was commissioned in 1952. It consists of the Jones Lake Reservoir, Wahleach Dam, Boulder Creek Diversion Dyke, Jones Lake Intake structure, and a water conveyance tunnel and penstock leading to the Wahleach Generating Station. Wahleach is classified as a Strategic facility for asset management purposes and Wahleach Dam is classified as a Very High consequence dam per the BC Dam Safety Regulation.

BC Hydro has maintained the health of the Wahleach facility through a number of investments over the past 10 years totaling over $20 million. Investments have been focused on generating equipment, which included penstock inlet valve, governor, exciter, protection and control, transformer, switchgear, and cooling water replacements.

The most significant remaining issues and risks associated with the Wahleach facility include:

- Generating Equipment:
  - Poor condition of the generator, elevating the reliability risks associated with the single unit and increasing the likelihood that the facility may experience an extended forced outage;
  - The coatings on the penstock and tunnel steel liner have failed which will lead to corrosion and metal loss of the underlying material, thereby reducing the life of the penstock. A finite window of opportunity exists to re-coat the assets before a much more extensive refurbishment or replacement is required; and
  - There is an increased risk of failure associated with the fire protection system due to accelerated corrosion which could lead to potential rupture of the piping and flooding of the powerhouse.
- Dam Safety:
  - Potential defects in the seepage control sheet piles at Wahleach Dam that could lead to erosion of dam or foundation materials and risk of dam failure. This risk is being managed by monitoring seepage through instrumentation and weekly inspections, and a response plan is in place in the event that any sign of significant seepage through the dam is observed;
  - Potential failure of the intake gates at Jones Lake during a major earthquake occurring, on average, about once every 4,800 years, which would prevent the closure of the water passage and cessation of flows to what would likely be a damaged generating station and could result in the inundation of adjacent utility and transportation corridors; and
  - Potential slope failure at Four Brothers Mountain that could result in the loss of the Wahleach facility and impact adjacent utility and transportation corridors.

Summarize Solution:

The Wahleach Facility Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. In the short-term, the focus will be on higher-priority investments required for safe and reliable generation that are sequenced to minimize outages. The medium to longer-term activities will focus sustaining safe reservoir containment at Wahleach.

Short-Term:

- Generating Equipment:
  - Generator refurbishment;
  - Penstock and tunnel liner coatings replacement; and
  - Fire protection system upgrade.

Medium- and Long-Term:

- Dam Safety:
    - Intake Tower and Gates seismic upgrade; and
    - Dam foundation seepage control upgrade.

The potential for a slope failure at Four Brothers Mountain is a retained risk, with no practicable means available to reduce or eliminate it. BC Hydro has implemented an ongoing surveillance program to identify changes in the slope's behaviour and to provide warning of impending instability.

Name of Capital Strategy, Plan or Study:
Abbotsford Area Study

Summarize Issue:

The Abbotsford area is supplied by a 230 kV and 60 kV transmission system and the following four substations:

- Mount Lehman has a capacity of 100 MVA, and was built in 2007;
- Gloucester has a capacity of 25 MVA, and was built in 2002;
- Clayburn has a capacity of 180 MVA, and was built in 1984; and
- Sumas Way has a capacity of 55 MVA, and was built in 1977.

The four substations supply the entire load in the study area which extends from about 248 St in Langley to Sumas Prairie east of the City of Abbotsford, and from the Fraser River to the Canada/USA border. The Abbotsford area has approximately 60,000 customers and a peak load of 306 MVA in fiscal 2017. The present area firm capacity is 360 MVA.

The City of Abbotsford, the largest municipality in this area, has a population of over 130,000. It is the largest municipality in the Fraser Valley Regional District and the fifth largest municipality in British Columbia.

A number of investments have been made in this area in the last 20 years totaling over $65 million. The recent investments have included the construction of two substations: Mount Lehman Substation and Gloucester Substation, together with the decommissioning of the old Abbotsford substation.

The most significant issues and risks remaining in the Abbotsford area include:

- Clayburn substation has feeder sections that were designed to be compact in size and now present safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs, however, workers are unable to safely and efficiently work on the equipment without taking extended customer outages. As a result, some maintenance work at the substation cannot be completed;
- At the Sumas Way substation, all of the equipment in the 25 kV switchyard is in poor condition. Both metalclad feeder sections have arc-flash hazards. Due to this safety concern, workers are restricted from entering the feeder section buildings while the equipment is energized; and
- In the last 10 years, the load has grown by approximately 1 per cent each year. In fiscal 2017, the actual demand was approximately 306 MVA.

Summarize Solution:

The strategy for this area is to mitigate the above reliability and safety risks while continuing to provide a reliable supply to the customers. BC Hydro has developed alternatives that upgrade the area supply in coordination with the need to retire major equipment approaching their end-of-life, and to address existing safety risks at Clayburn and Sumas Way substations. The coordination will avoid stranded investments in asset replacement projects to sustain the existing system. The solution alternatives consider a number of factors, including:

- The present capacity and future load growth in the area;
- The health of the assets at area substations, and their expected degradation over time;
- Opportunities to utilize capacity at neighboring substations;
- The timing of required projects at area substations combined with the need to retain adequate overall area capacity; and
- The need to develop the sequencing of projects in a way that minimizes/ avoids stranded investments that address issues in the existing substations.

For the Abbotsford area, the following strategy is being implemented:

Short- and Medium-Term:

- Expand Mount Lehman capacity from 100 MVA to 170 MVA;

- Address the safety risks associated with Clayburn by replacing the feeder section;
- The completion of the above will allow the transfer of load between stations:
  - Offload Clayburn load to Mount Lehman; and
  - Offload Sumas Way load to Clayburn; and
- Decommission Sumas Way.

Upon completion, there will have been a significant improvement in the overall equipment condition and reliability, the safety risks will have been mitigated, and the area will have sufficient capacity to accommodate future load growth in the area.

Long-Term:

In the longer-term, it is anticipated that a component by component replacement strategy will be undertaken at the different substations, to address risks with discrete assets as they degrade over time. In addition, growth in the area will continue to be monitored, to determine whether additional capacity is required.

Name of Capital Strategy, Plan or Study:
Barnard Asset Plan

Summarize Issue:

The 191 MVA Barnard substation is a transmission and distribution substation serving North Burnaby and portions of West Coquitlam and Port Moody. First commissioned in 1954, the substation consists of:

- Three switchyards: 230 kV, 69 kV, and 12 kV;
- Two power transformers; and
- Three feeder sections.

Barnard is an important substation given its dual role as both a transmission station and a distribution station. The station serves over 35,000 customers, and has the seventh largest peak load (133 MVA) in the Lower Mainland Metro region. Barnard provides one of the two transmission supplies to Lougheed substation and to six transmission voltage customer substations including Simon Fraser University.

Since commissioning in 1954, the substation has been expanded over time and there have been a number of investments in the past 20 years totalling over $15 million. Recent investments have included the addition of a new feeder section in 2008 and a project that is underway to replace all the circuit breakers in the 69 kV switchyard.

The most significant remaining issues and risks associated with Barnard substation include:

- One of the older feeder sections was designed to be compact in size and poses safety risks for workers due to limited clearance between energized equipment and ground. The risk is currently partially mitigated through physical barriers and warning signs;
- There are elevated reliability risks associated with the above-mentioned older feeder section due to the poor condition of 67 per cent of the 18 circuit breakers and 96 per cent of the 56 disconnect switches. The oil-filled circuit breakers in this feeder section also contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline;
- There are elevated reliability risks associated with a second older feeder section and with the 230 kV switchyard, due to obsolescence issues with the original mechanical protection and control relays; and
- There are elevated reliability risks associated with the two relay buildings in the 69 kV switchyard. The buildings are in poor condition with cracking, leaking and seismic issues.

Summarize Solution:

The Barnard Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the feeder sections of compact size will be addressed concurrently with equipment replacement projects. In the short and medium term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out PCBs by the end of 2025. The longer-term activities are anticipated to focus on the remaining feeder sections and the transformers.

Short- and Medium-Term:

- Address the safety and reliability risks associated with the older feeder section that has high risk by replacing it with a new indoor feeder section;
- Address the reliability risks associated with protection and control equipment for the other older feeder section and the 230 kV switchyard by replacing the associated protection and control panels;
- Remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline; and
- Replace the two relay buildings in the 69 kV switchyard as part of the 69 kV circuit breaker replacement project which is now underway.

Long-Term:

The equipment at the Barnard substation will continue to degrade over time, and a level of investment is anticipated in the longer term to preserve the reliability of the substation, and address emerging risks. Expected investments are required to address the risks associated with the remaining older feeder section as well as the transformers.

Name of Capital Strategy, Plan or Study:
Bridge River Transmission System Upgrade – Network Integrated Transmission Service Study

Summarize Issue:

The Bridge River area is located north of Pemberton. Generation in the Bridge River area is currently restricted as the Bridge River generating units have been de-rated due to degrading equipment condition. As BC Hydro invests in the generating units, transmission capacity may be exceeded creating system constraints during the summer period (June to July). With the increase in generation from the addition of IPPs and in concert with the existing BC Hydro facilities, there is a need to increase the capacity of the Bridge River regional transmission system to allow the delivery of full power during the summer months.

The main issues and risks include:

- Increase transmission capacity in the Bridge River area to meet the generation demands of the system;
- Reduce economic losses associated with generation curtailment;
- Provide reliable water conveyance capacity within the Bridge River system;
- Reduce the likelihood and magnitude of spills from Terzaghi Dam to Lower Bridge River; and
- Maintain BC Hydro's relationship with the St'at'imc Nation.

Summarize Solution:

The strategy is to provide sufficient transmission capacity to avoid the need for generation curtailment during summer months.

Short- and Medium-Term:

Alternatives that are being considered to deliver on this strategy include:

- Upgrading the 230 kV transmission line (2L90) between Bridge River Terminal and Kelly Lake;
- Expanding Rosedale substation; and
- Curtailing local generation.

Name of Capital Strategy, Plan or Study:
Asset Management Strategy - Section 2.2.2: Circuit Breakers

Summarize Issue:

There are 3,974 circuit breakers operating at voltages from 2.5 kV to 500 kV in BC Hydro's substations. A circuit breaker fulfills two roles: first, it acts as an automatically operated switch to protect an electric circuit from damage caused by high currents; second, circuit breakers are used by system operators to disconnect or connect different components of the electric system. Circuit breakers contain high pressure air, oil, vacuum or sulphur hexafluoride (**SF6**).

The general issues and risks associated with the failure of circuit breakers include:

- Reliability:
  - Elevated reliability risk if the circuit breaker does not operate as intended causing damage to other equipment in the circuit; and
  - Elevated reliability risk due to the sudden release of energy or fire impacting adjacent equipment.
- Environment:
  - Elevated risk of oil spills in the population of over 670 oil filled circuit breakers;
  - Elevated environmental and safety risk associated with SF6 leakage from the population of over 1,500 SF6 filled circuit breakers; and
  - Approximately 240 circuit breakers contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline.
- Safety:
  - Elevated safety risk due to the sudden release of energy or fire; and
  - Elevated safety risk should a circuit remain live when it should otherwise be de-energized.

Over the last 10 years, BC Hydro has installed over 1,500 circuit breakers with two thirds being installed in the distribution substations and the balance on the transmission system.

Over 795 circuit breakers are currently over 40 years old, and approximately 622 (~16 per cent), of the circuit breakers have been assessed as Poor or Very Poor, indicating that there is an increased likelihood of failure.

Summarize Solution:

BC Hydro has developed a long term replacement strategy for circuit breakers to address the large number of aging circuit breakers and their associated risks. Historically the majority of work has focused on replacing circuit breakers on the 500 kV, 360 kV and 230 kV system. More recently the focus has shifted towards the lower voltage circuit breakers operating at 138 kV, 69 kV and lower. To address the issues and risks identified above, a number of approaches are taken, including:

- The replacement of circuit breakers will be included in the scope of work in a number of discrete capital projects. These projects will often address multiple issues at a substation, of which the circuit breakers are one element;
- Circuit breaker replacement programs will focus on remediating the risks associated with the highest priority circuit breakers at a large number of substations;
- A spares strategy will continue to be implemented to ensure that adequate spare breakers and parts are available to minimize the impact of failures; and
- Consideration has been given to opportunities to decommission assets where replacement is not necessary.

Short-Term:

Asset condition is reviewed on a regular basis considering factors such as recurring test results, visual inspections, and, detailed engineering assessments. This information is used to assess the risks related to each circuit breaker and to update a consolidated list with the intended timing of replacement investments.

Replacement projects that will occur in the short-term are described in the table below.

Upon completion of the work outlined in the table below, approximately 33 per cent of the 240 circuit breakers containing PCBs will have been removed from service. The replacement of theremaining 67 per cent will start and be completed in the medium-term ahead of the December 31, 2025 Federal deadline.

	Circuit breaker will be addressed as part of a larger project	**Projects where the circuit breaker is the primary driver**
Replacement projects that are underway and will be completed in the short-term	N/A	• Kelly Lake (1 x 500 kV) • Peace Canyon (1 x 500 kV)
Replacement projects that will start and will be completed in the short-term	N/A	• Atchelitz (7 x 69 kV) • Arnott (3 x 69 kV) • Babine Lake (1x 25 kV) • Barriere (1 x 25 kV) • Boston Bar (2 x 25 kV) • Cranbrook (6 x 69 kV) • Comox (1 x 25 kV) • Chetwynd (5 x 25 kV) • Dawson Creek (3 x 25 kV) • Dease Lake (1 x 25 kV) • Douglas Street (6 x 25 kV) • Fort St. John (3 x 25 kV) • Hundred Mile House (6 x 25 kV) • Horne Payne (4 x 12 kV) • Horne Payne (4 x 69 kV) • Horseshoe Bay (7 x 12 kV) • Horsey (20 x 12 kV) • Ingledow (2 x 12 kV) • Kent (6 x 12 kV) • Kidd No. 1 (7 x 12 kV) • Keating (1 x 25 kV) • Ladysmith (2 x 25 kV) • Minette (6 x 25 kV) • Newell (12 x 12 kV) • Suncor Energy (4 x 69 kV) • Port Kells (4 x 25 kV) • Puntledge (9 x 25 kV) • Parksville (5 x 25 kV) • Revelstoke (2 x 12 kV) • Skeena (1 x 12 kV) • Seton (3 x 69 kV)

		• Smithers (2 x 25 kV) • Steveston (3 x 25 kV) • Stewart (2 x 25 kV) • Tsawwassen (3 x 25 kV) • Vernon (3 x 25 kV) • Wahleach (2 x 69 kV) • Williams Lake (4 x 69 kV) • White Rock (5 x 25 kV)
Replacement projects that are underway and will continue into the medium-term	• Barnard (18 x 12 kV) • Mainwaring (18 x 12 kV) • Sperling (18 x 12 kV)	N/A
Replacement projects that will start in the short-term, and continue into the medium-term	• Kidd No. 1 (11 x 69 kV)	• Norgate (3 x 69 kV)

Medium- and Long-Term:

Considering the age and condition of the overall population of almost 4,000 assets, it is anticipated that a continued level of investment will be required. Replacement of the 12 kV, 25 kV and 69 kV circuit breakers will continue through the annual circuit breaker replacement programs. In addition, a number of discrete capital projects will address risks with the higher voltage circuit breakers, as part of their broader scope of work.

The goal is to manage the highest reliability, environmental and safety risks associated with circuit breakers. Approximately 20 per cent of the population is over 40 years old and will require remediation in the medium to long term as the assets move through their lifecycle. To pace these investments over time, approximately 100 units will need to be replaced on an annual basis, considering the design life of 35 to 40 years for circuit breakers. Factors such as age, condition and criticality will continue to be used for identifying the high priority units for replacement.

Name of Capital Strategy, Plan or Study:
Downtown Vancouver Electric Supply Plan

Summarize Issue:

The Downtown Vancouver study area is comprised of the Downtown, West End, Strathcona, and Grandview-Woodland neighborhoods. The area is supplied by a 230 kV and 69 kV transmission network and three substations:

- Cathedral Square substation which has a capacity of 302 MVA was built in 1984;
- Dal Grauer substation which has a capacity of 195 MVA was built in 1953; and
- Murrin substation which has a capacity of 200 MVA was built in 1947.

The study area contains the largest commercial center in Vancouver and has the highest load density in B.C. The area has approximately 95,000 customers and had a peak load of 411 MVA in fiscal 2017. The present area firm capacity is 697 MVA.

A number of investments have been made in this area in the past 20 years totaling over $300 million. Recent investments include the addition of a transformer and a feeder section at Cathedral Square in 2009 and the construction of a new 230 kV transmission cable circuit from Mount Pleasant to Cathedral Square in 2014.

The most significant issues and risks remaining in the Downtown Vancouver area include:

- There are elevated reliability risks at Dal Grauer and Murrin substation where more than half of the substation assets are expected to be in Poor or Very Poor condition within the next 10 to 20 years;
- Seven of the 11 transmission cable circuits supplying the three stations are expected to be in Poor or Very Poor condition within 20 years;
- More than half of the distribution cables at Dal Grauer and Murrin are expected to be in Poor or Very Poor condition within 20 years;
- The 12 kV equipment at Dal Grauer and Murrin substations exposes workers to safety risks due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs;
- The indoor circuit breakers and exposed bus at Dal Grauer and Murrin substations expose workers to safety risks from potential arc flashes in the event of insulation failures; and
- Murrin substation is on seismically unstable soil. Approximately half of the 230 kV switchyard, which supplies both Murrin and Dal Grauer loads, is vulnerable to severe earthquake damage from liquefaction and settlement. All load being served from Dal Grauer and Murrin substations may experience a prolonged outage after a seismic event.

Summarize Solution:

The long term strategy for the area is to mitigate the above reliability and safety risks by replacing Murrin and Dal Grauer substations with new substations. The addition of the new substations will be timed to precede the need to retire major existing equipment as the assets approach their end-of-life. This means that new capabilities will need to be created, while older assets are still in-service, in anticipation of the decline in condition of a large population of assets. The sequencing of activities will need to be carefully planned and staged over the long-term, to minimize or avoid stranded investments in assets that may not be required in the long-term. The Downtown Vancouver Electricity Supply Plan examined three alternatives, each of which considered:

- The need to reduce seismic risk exposure;
- The health of each substation’s assets, and their expected degradation over time;
- The present area capacity and future load growth;
- Opportunities to transfer load to neighboring substations outside the study area;
- Opportunities to permanently decommission substations;
- The feasible timing of required work and the need to maintain sufficient area capacity;

- The costs of the different solutions;
- Performance and reliability requirements in the downtown area;
- Local stakeholder support; and
- Environmental impacts.

In light of the sizeable and complex issues noted above, the criticality of load in the downtown area, and the lead time required to build new substations in the Downtown Vancouver Area, it was particularly important to consider a long term planning horizon.

For the Downtown Vancouver Area the following strategy is being implemented:

Short- and Medium-Term:

- West End Substation:
  - Build a new underground 230/12-25 kV substation in the West End neighbourhood. This substation will have an ultimate capacity of 400 MVA; and
  - Build new 230 kV cable circuits to connect the new substation to the existing system.
- East Vancouver Substation:
  - Build a new indoor 230/12-25 kV, substation in the Strathcona neighbourhood. This substation will also have an ultimate capacity of 400 MVA.

Both of the substations above represent important infrastructure in critical locations that are anticipated to be in place for more than 50 years. The ultimate 800 MVA capacity of the two substations will not be installed immediately, but provides flexibility for growth over time, as the need for the load materializes.

Long-Term:

The activities outlined above have a relatively long lead time, and will enable a number of activities in the long-term:

- Offload the Dal Grauer substation to the West End substation;
- Offload the Murrin substation to the East Vancouver substation;
- Decommission the Dal Grauer and Murrin substations, as well as the 69 kV circuits;
- Replace the 230 kV cables that are in poor condition as required; and
- Add new 230 kV transmission circuits as required to meet future load growth.

Name of Capital Strategy, Plan or Study:
Kidd 1 Asset Plan

Summarize Issue:

The 100 MVA Kidd 1 substation is a transmission and distribution substation that serves Vancouver South. First commissioned in 1951, the substation consists of:

- Three switchyards: 69 kV, 12 kV and 4 kV;
- Four power transformers;
- Three feeder sections; and
- One 230 kV cable terminal.

Kidd 1 is an important substation given its dual role as both a transmission station and a distribution station. The station serves over 15,000 customers, and has the fifteenth largest peak load (69 MVA) in the Lower Mainland Metro region. Kidd 1 provides the primary transmission source for Big Bend substation and provides the only source of supply to the 69 kV switchyard at Sperling substation which in turn supplies the University of British Columbia. In addition, Kidd 1 supplies six transmission voltage customers and the distribution is adjoined by Sperling providing some flexibility to transfer load between the two substations.

Since commissioning in 1951, the substation has been expanded over time and there have been a number of investments in the past 20 years totaling over $35 million. Recent investments have included the replacement of two transformers and addition of a feeder section in 2014.

The most significant remaining issues and risks associated with Kidd 1 substation include:

- One power transformer is in Very Poor condition and has severe leaks;
- The two older feeder sections were designed to be compact in size and pose safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs;
- There are elevated reliability risks associated with the two older feeder sections, due to the poor condition of 86 per cent of the 28 circuit breakers, 100 per cent of the seven voltage regulators, 84 per cent of the 25 current limiting reactors and 92 per cent of the 103 disconnect switches. The oil-filled voltage regulators in these feeder sections also contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline;
- There are elevated reliability risks associated with the 69 kV switchyard, due to the poor condition of 92 per cent of the 12 circuit breakers and 95 per cent of the 37 disconnect switches. The oil-filled circuit breakers also contain PCBs at levels above the allowable amounts, requiring phase out by the end of 2025; and
- There are elevated reliability and safety risks associated with the control building, due to the poor condition of 51 per cent of the 65 protection and control relays, the low seismic withstand capability of the building, and the presence of asbestos.

Summarize Solution:

The Kidd 1 Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the compact sections of the substation will be addressed concurrently with the equipment replacement projects or by the decommissioning of the equipment. In the short and medium-term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out PCBs by the end of 2025.

Short- and Medium-Term:

- Address reliability risk with the power transformers and one of the feeder sections by decommissioning the 4 kV switchyard and power transformers;
- Address reliability and safety risks associated with the other feeder section that poses the highest risk

and remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline;

- Address reliability risks associated with the 69 kV switchyard and remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline; and
- Address reliability risks associated with the control building.

Long-Term:

The equipment at the Kidd 1 substation will continue to degrade over time, and a level of investment is anticipated in the longer-term to preserve the reliability of the substation, and address emerging risks. Expected investments are required to address those risks associated with the remaining outdoor feeder section and the 69 kV switchyard that are not resolved in the short or medium term.

Name of Capital Strategy, Plan or Study: **Burrard Synchronous Condensers Replacement Study**
Summarize Issue: Burrard Thermal was a natural gas fired generating station with six 150 MW thermal generating units that were first put into operation in 1962. Since 2016, the Burrard facility has only operated as a synchronous condenser station. As a synchronous condenser station, Burrard is a major reactive power source in the Lower Mainland and is used to regulate system voltage under various system operating conditions. The facility is over 55 years old and approaching end of life which poses system reliability, environmental, and safety risks. The main issues and risks include: • The Burrard Synchronous Condensers (**BSY**) are at or approaching end of life. The four synchronous condenser units provide capacitive and reactive power to the transmission system. The capacitive and reactive power provides voltage control and prevents voltage instability during peak load periods; and • An assessment of the Fraser Valley transmission system has identified voltage stability constraints caused by reactive power losses.
Summarize Solution: BC Hydro is evaluating alternatives to address both issues summarized above. **Medium and Long-Term:** To ensure the capability currently provided by BSY is preserved, the alternatives listed below will be reviewed: • BSY reactive power function would be restored and additional capacitive power compensation would be installed in the Fraser Valley transmission system; or • Retire the BSY facility and add capacitive and reactive power requirements elsewhere in the BC Hydro Lower Mainland transmission system.

Name of Capital Strategy, Plan or Study:
Mainwaring Asset Plan

Summarize Issue:

The 211 MVA Mainwaring substation is a transmission and distribution substation serving Vancouver South. First commissioned in 1964, the substation consists of:

- Two switchyards: 230 kV and 12 kV;
- Three power transformers; and
- Two feeder sections.

Mainwaring is an important substation given its dual role as both a transmission station and a distribution station. The station serves over 60,000 customers, and has the fourth largest peak load (169 MVA) in the Lower Mainland Metro region. Mainwaring provides one of the two transmission supplies to Camosun substation. There is also flexibility to transfer the distribution load between the adjoining Newell and Mount Pleasant substations.

Since commissioning in 1964, the substation has been expanded over time and there have been a number of investments in the past 20 years totaling $25 million. Recent investments have included the addition of a new transformer in 2006 and replacement of the 230 kV circuit breakers in 2007 and 2011.

The most significant remaining issues and risks associated with Mainwaring substation include:

- One of the power transformers is in poor condition and is gassing. One other transformer has severe oil leaks. These do not have on-load tap changers, therefore voltage regulators in the feeder section are required to regulate the voltage;
- Both feeder sections were designed to be compact in size and pose safety risks for workers due to limited clearance between energized equipment and ground. The risk is currently partially mitigated through physical barriers and warning signs; and
- There are elevated reliability risks associated with both feeder sections, due to the poor condition of 39 per cent of the 46 circuit breakers, 80 per cent of the 38 voltage regulators, 51 per cent of the 41 current limiting reactors and 80 per cent of the 153 disconnects. The oil-filled voltage regulators and circuit breakers in these feeder sections also contain polychlorinated biphenyl (**PCB**) levels above the allowable amounts, requiring phase out by the end of 2025.

Summarize Solution:

The Mainwaring Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the compact sections of the substation will be addressed concurrently with equipment replacement projects. In the short and medium term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out PCBs by the end of 2025. The longer-term activities are anticipated to focus on the remaining equipment and the control building.

Short- and Medium-Term:

- Address reliability risk associated with two of the power transformers; and
- Address the safety and reliability risks associated with the two feeder sections and remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline.

Long Term:

The equipment at the Mainwaring substation will continue to degrade over time, and a level of investment is anticipated in the longer term to preserve the reliability of the substation and address emerging risks, including those associated with the control building.

Name of Capital Strategy, Plan or Study: **Metro North Transmission Planning Report**
Summarize Issue: The Metro Vancouver (**Metro**) region includes BC Hydro's service areas in Vancouver, Burnaby, New Westminster, Richmond, and Coquitlam/Tri Cities. As a result of load growth in this region, a shortfall of supply capacity is anticipated within the next five years in the Metro North Transmission System which is part of the interconnected 230 kV transmission network that supplies the Metro region. This shortfall of transmission supply capacity would mean BC Hydro would not be able to supply the full demand of the Metro region during system normal winter peak load periods. Consequently, some load will need to be curtailed during winter peak load periods to avoid overloading and potentially damaging transmission equipment. The amount of required curtailment is anticipated to be up to 100 MW (equivalent to approximately 15 per cent of Downtown Vancouver). BC Hydro initiated the Metro North Transmission Project in 2013 to resolve the above shortfall of capacity with a planned October 2022 in-service date. The project has been put on hold while BC Hydro develops an updated load forecast which will confirm the timing of the constraints and the required project in-service date.
Summarize Solution: To address the above issue and avoid load curtailment, the following approaches have been identified: **Short-Term:** • Interim operational measures have been identified to resolve the transmission constraints. These measures are effective until fiscal 2025 and include: - Modifying the system configuration in real-time to divert the flow of electric power to alternative paths thereby reducing the amount of power flowing through the constrained circuits; and - Utilizing the overload capabilities/emergency ratings of transmission circuits, for a specified limited number of hours per year based on engineering studies. **Medium- and Long-Term:** • Construct a new 230 kV circuit between Meridian (**MDN**) and Horne Payne (**HPN**) substations, and extend an existing 230 kV circuit from HPN to Mount Pleasant Substation (**MPT**).

Name of Capital Strategy, Plan or Study:
Newell Asset Plan

Summarize Issue:

The 234 MVA Newell substation is a transmission and distribution substation that serves South Burnaby. First commissioned in 1955, the substation consists of:

- Three switchyards: 230 kV, 60 kV and 12 kV;
- Five power transformers; and
- Four feeder sections.

Newell is an important substation given its dual role as both a transmission station and a distribution station. The station serves over 50,000 customers, and has the third largest peak load (186 MVA) in the Lower Mainland Metro region. There is flexibility to transfer the distribution load between the adjoining Big Bend and Mainwaring substations.

Since commissioning in 1955, the substation has been expanded over time and there have been a number of investments in the past 20 years totalling over $25 million. Recent investments have included addition of a new feeder section in 2003 and replacement of the 230 kV circuit breakers in 2011.

The most significant remaining issues and risks associated with Newell substation include:

- One power transformer is in Poor condition, has severe oil leaks and contains polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline;
- Three of the feeder sections were designed to be compact in size and pose safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs; and
- There are additional elevated reliability risks associated with two of the feeder sections, due to the poor condition of 62 per cent of the 29 circuit breakers, 95 per cent of the 37 voltage regulators and more than 60 per cent of the 220 disconnect switches. The oil-filled voltage regulators in these feeder sections also contain PCBs at levels above the allowable amounts, requiring phase out by the end of 2025.

Summarize Solution:

The Newell Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the compact sections of the substation will be addressed concurrently with equipment replacement projects. In the short-term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out PCBs by the end of 2025. The medium- to longer-term activities are anticipated to focus on the remaining feeder sections, substation security and the control building.

Short-Term:

- Address reliability risk with the power transformer and remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline.

Medium-Term:

- Address the safety and reliability risks associated with the two feeder sections that pose the highest risks.

Long-Term:

- The equipment at the Newell substation will continue to degrade over time, and a level of investment is anticipated in the longer-term to preserve the reliability of the substation, and address emerging risks. Expected investments are required to address the risks associated with the two remaining feeder sections, to enhance the security of the substation, and also address risks associated with the degrading control building.

Name of Capital Strategy, Plan or Study:
Natal Asset Plan

Summarize Issue:

Natal substation is a transmission substation located in the Southern Interior region, near Sparwood, that consists of:

- Three switchyards: 230 kV, 138 kV and 60 kV; and
- Four power transformers.

The 60 kV and 138 kV switchyards were commissioned in 1968 and the 230 kV switchyard was commissioned in 1972. Natal is an important transmission substation given its role both as a bulk transmission substation and a source of supply for industrial customers. The station serves 10 industrial customers, providing over $20 million of revenue annually. Natal is also a point of intertie with the Alberta transmission system.

Since commissioning in 1968 the station has expanded over time and there have been a limited number of investments in the past 20 years totaling over $5 million. Recent investments have included replacement of surge arrestors in the 60 kV yard and circuit breakers in the 138 kV and 230 kV yards.

The most significant remaining issues and risks associated with Natal substation include:

- There are elevated reliability risks, due to the poor condition of 50 per cent of the four power transformers, both of the voltage regulators, 35 per cent of the 14 circuit breakers, 49 per cent of the 44 instrument transformers, as well as a significant proportion of the protection and control systems supporting the 60 kV and 138 kV switch yard;
- Many of the circuit breakers contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline; and
- The 60 kV and 138 kV switchyards were designed and built to electrical clearance at the time, and pose safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs.

Summarize Solution:

The Natal Asset Plan presents a strategy to replace the 60 kV and 138 kV equipment. The safety issues associated with the substation will be addressed concurrently with the equipment replacement projects or by the decommissioning of the equipment. In the short-term, the focus will be on higher priority investments required for safe and reliable transmission of energy and to meet the requirements to phase out PCBs by the end of 2025.The medium to longer-term activities are anticipated to focus on sustain activities of the remaining equipment.

Short- and Medium-Term:

- A replacement of the 60 kV and 138 kV switchyards may be required to address the reliability, environment and safety risks of the 60 kV and 138 kV equipment. The scope of this work will include the power transformers, circuit breakers, instrument transformers, and protection and control systems. Consideration will also be given to the control building that houses the protection and control systems.

Long-Term:

- The equipment at the Natal substation will continue to degrade over time, and a level of investment is anticipated in the longer-term to preserve the reliability of the substation, and address emerging risks. Expected investments are required to address the risks associated with the 230 kV switchyard as it approaches poor asset health.

Name of Capital Strategy, Plan or Study:

Asset Management Strategy - Section 2.2.8: Oil Spill Containment

Summarize Issue:

Oil spill containment is an engineered asset, typically consisting of oil/water separators, tanks or pits, built in conjunction with oil containing equipment such as transformers, reactors or voltage regulators. These are used to collect oil that is accidently released from equipment and prevent contamination of the surrounding environment.

The general issues and risks associated with failure to contain an oil spill include:

- Environmental:
  - Contamination of land and water resources, and plant and animal species which can have long recovery times;
- Financial:
  - Costs associated with cleaning up areas affected by oil spills; and
  - Fines may be issued in the event of environmental damage; and
- Reputational:
  - Spills that threaten the environmental quality of water, land or air must be reported to the regulatory agencies and may damage BC Hydro's reputation with government and the public.

BC Hydro has over 1,000 pieces of oil-filled substation equipment which each contain more than 4,000 litres of oil. Approximately 60 per cent of these items do not have adequate oil spill containment.

Positive progress has been made to remediate these risks and over 400 oil containing pieces of equipment have new or upgraded oil containment.

Summarize Solution:

A risk assessment has been done at each of the substations containing those equipment items. Factors considered in the risk assessment include the quantity of oil on site, proximity to: aquatic resources, wildlife, species at risk, habitats, parkland, and First Nations land. The risk assessment also considers the water use in the area and the likelihood of a spill.

To address the issues and risks identified above, two approaches are used:

- Capital projects which install large oil containing equipment will also have oil containment installed; and
- An oil containment program which prioritizes upgrades of legacy substations that do not meet the current standard. This will address risks which are not otherwise addressed through a capital project.

Our strategies address these assets in two ways. First, we initiate projects that address multiple asset issues within a specific facility. When work is done as part of a project, the total duration of the project may exceed the two year test period. Second, we target specific oil containment issues as stand-alone items when this is the primary area of focus in a facility.

Short-Term:

Activities that will occur in the short-term are described in the table below.

	Oil spill containment that will be addressed as part of a larger project	Projects where oil spill containment is the primary driver
Containment activities that will be completed in the short-term	N/A	N/A
Containment activities that are underway, and will continue into the medium-term	• Bridge River 1 • Bridge River Terminal • Capilano • Hundred Mile House • Jordan River • Natal • Newell	• Atchelitz • Meridian
Containment activities that will start in the short-term, and continue into the medium-term	• Kelly Lake • Norgate • Patricia • Rosedale • Spillamacheen • Williston	N/A

Medium-Term:

The investments outlined above address the most pressing risks associated with oil spill containment. Many of the investments initiated in the short-term will continue to have capital expenditures and will go into service in the medium-term. The following substations are expected to have work initiated in the medium term:

- Nelway;
- Gold River;
- Balfour;
- Dal Grauer;
- Loughheed;
- Nakusp;
- Quesnel;
- Richmond;
- Scott Road;
- Sumas Way; and
- Surrey.

In the short- and medium-term this approach will reduce the risks associated with oil containment of another 10 per cent of equipment. This is an addition to the 40 per cent that already have adequate oil spill containment.

Long-Term:

In the long-term, work will continue to improve oil spill containment at a rate similar to the short and medium term and will be risk assessed and prioritized as outlined above.

Name of Capital Strategy, Plan or Study:
Patricia Asset Plan

Summarize Issue:

The 87 MVA Patricia substation is a distribution substation that serves Prince George. First commissioned in 1964, the substation consists of:

- Two switchyards: 60 kV and 12 kV;
- Three power transformers; and
- One feeder section.

Patricia is an important substation as it is the only distribution station supplying load to the downtown area of Prince George. The station serves over 14,000 customers making it the second largest substation by customer count in the Northern Interior region. The Patricia load cannot be served from the surrounding stations due to different distribution voltages (12 kV vs 25 kV).

Since being commissioned in 1964 the substation has been expanded over time and there have been a limited number of investments in the past 20 years totaling over $2 million. Investments have included replacements of a number circuit breakers and surge arresters in the 12 kV and 60 kV switchyards.

The most significant remaining issues and risks associated with Patricia substation include:

- The three power transformers were manufactured in the 1960s and do not have on-load tap changers, therefore voltage regulators are required to regulate the voltage. One of the power transformers is in poor condition;
- All 12 kV voltage regulators are in poor condition and contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline;
- The 12 kV feeder section was designed to be compact in size and poses safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs; and
- Fourteen 12 kV bulk oil circuit breakers are in poor condition and contain PCB levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline.

Summarize Solution:

The Patricia Asset Plan presents a strategy to replace assets on a component by component basis (i.e. undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the compact section of the substation will be addressed concurrently with equipment replacement projects. In the short-term, the focus will be on higher priority investments required for safe and reliable distribution of energy and to meet the requirements to phase out PCBs by the end of 2025. The medium- to longer-term activities are anticipated to focus on the remaining feeder section issues and the control building.

Short- and Medium-Term:

- Replace the existing transformers. These will have on-load tap changers, enabling the removal of the voltage regulators in the feeder section;
- Remove all the voltage regulators containing PCBs; and
- Retrofit the 12 kV feeder section, replace all circuit breakers, disconnect switches, surge arresters and mitigate the electrical clearance issues.

Long-Term:

- The equipment at the Patricia substation will continue to degrade over time, and a level of investment is anticipated in the longer term to preserve the reliability of the substation, and address emerging risks. Expected investments are required to address the risks associated with the two station service transformers, and also address risks associated with the degrading control building.

Name of Capital Strategy, Plan or Study:
Peace to Kelly Lake 500 kV Transmission Reinforcement Study

Summarize Issue:

The Peace Region to Kelly Lake 500 kV system is used to transfer power from the Peace Region to the load centers. The capacity of the Peace to Kelly transmission system is limited by the voltage stability, transient stability, and the rating of the existing series capacitors. The Peace to Kelly transmission system is near capacity and generation additions in the Peace area (including Site C and future IPPs) will result in the transfer demand exceeding the transmission capacity.

The risk associated with the existing transmission system condition after 2024 is unable to transmit full generation capacity in the Peace Region to the load center during system normal and contingency conditions.

Summarize Solution:

To accommodate new generation in the Peace Region, transmission reinforcement is needed to continue reliable power delivery to the load centers. Increasing series compensation levels on the existing 500 kV transmission lines will increase transmission capability.

Short- and Medium-Term:

- Increase transmission capability to deliver the power generated in the Peace Region to the load centers by improving the utilization of the existing transmission assets, through a combination of reconfiguration of the existing series capacitor stations and building new series capacitor stations; and
- If load continues to grow in the Peace and North Coast regions, power flow south of Williston substation to the load center would decline. As a result, the scope of proposed reinforcements (south of Williston substation) would be scaled back by reducing the capacitor size of a new station and eliminating the reconfiguration of an existing capacitor station.

Name of Capital Strategy, Plan or Study:

Asset Management Strategy - Section 2.2.10: Shunt Reactors

Summarize Issue:

BC Hydro has 142 shunt reactors in its substations, the majority of which are 500 kV units. Shunt reactors are oil-filled and similar in construction to transformers. They are expensive substation assets with long lead times to acquire and replace. The majority of shunt reactors were installed from the 1960s to 1980s when most of the 500 kV transmission lines were built. Shunt reactors have two main purposes: firstly, they are used to help control the voltage on the transmission system under certain operating conditions and secondly they are used to protect the transmission cables from potential damage due to overvoltages.

The general issues and risks associated with the failure of shunt reactors include:

- Reliability:
  - Reduced transfer capability and increased network risks associated with the transmission system; and
  - Elevated transmission system voltages which can damage the transmission cables;
- Environmental:
  - Elevated risk of oil spills, particularly in locations with less robust spill containment and more sensitive environments; and
- Safety & Financial:
  - The increased likelihood of a fire poses a safety risk to workers, and may cause damage to surrounding assets.

Over the last 20 years, nine shunt reactors have been installed at eight substations. BC Hydro has also developed and implemented a spares strategy, and has purchased four reactors for 230 kV and 500 kV spares to minimize impacts of a failure. The total value of these investments was over $5 million.

Approximately 33 shunt reactors are between 40 and 50-years old and seven are more than 50-years old. Of the 142 shunt reactors, 41 (29 per cent) have been assessed as being in Poor or Very Poor asset health, indicating that they have an increased likelihood of failure.

Summarize Solution:

To address the issues and risks identified above, two general approaches are identified:

- Capital projects have been identified to remediate the risks associated with shunt reactors with the highest risk of failure. New units will be installed with oil spill containment; and
- A spares strategy will continue to ensure that critical spares are available to minimize the impact of shunt reactor failures.

Short-Term:

Condition of assets is reviewed on a regular basis considering such factors as recurring test results, visual inspections, and, where required, detailed engineering assessments. This information is used to assess the risk of failure of each reactor and to prepare a consolidated list across the system. The risk based list is used to identify the appropriate timing to replace individual reactors. Below is the list of those reactors with a highest priority for replacement.

Investments are recommended in the short term to replace these units:

- G.M. Shrum (six reactors).

Medium-Term:

The investments outlined above address the most pressing risks associated with the shunt reactors. A number of additional reactors will need to be addressed by future projects in the medium-term. The strategy and prioritization of risk reductions will be continually monitored over time as other shunt reactors degrade and the risk assessments are updated.

In the medium term, the following reactors have been identified as presenting higher risks:

- Williston (16 reactors); and

- Kelly Lake (six reactors).

Long-Term:

There are currently 33 shunt reactors between 40 to 50-years of age. Over the next 10 years, it is likely that a portion of these will degrade to poor or very poor condition. The risks associated with falling health of these assets will need to be addressed in the long term, following similar assessment and prioritization techniques to those outlined above.

Name of Capital Strategy, Plan or Study:

Integrated Planning Report for Capilano and Lynn Valley Substations and Distribution Area (2010) / Norgate Asset Plan

Summarize Issue:

North Vancouver is comprised of two municipalities, the City of North Vancouver and the District of North Vancouver. The area is bounded by the Capilano River to the west, the North Shore mountains to the north, Burrard Inlet to the south and Indian Arm to the east. There are approximately 60,000 customers in this area. The total load in 2017 was 203 MVA.

The City and District of North Vancouver and surrounding areas are supplied by five main substations, which together have a capacity of 331 MVA:

- North Vancouver has a capacity of 67 MVA and was built in 1950s;
- Lynn Valley has a capacity of 100 MVA and was built in the 1980s;
- Norgate has a capacity of 53 MVA and was built in the 1960s;
- Capilano has a capacity of 56 MVA and was built in the 1950s; and
- John Lawson has a capacity of 55 MVA and was built in the1950s.

Over the past 10 years there have been a number of investments undertaken to maintain and upgrade three of these stations, including, the addition of a new feeder section at Lynn Valley in 2013, a complete 12 kV rebuild of the North Vancouver substation in 2012, cable upgrades, additional feeder positions and a number of circuit breaker replacements at John Lawson between 2009 and 2016. At Capilano and Norgate substations, most of the assets are at the end of life and there are also some safety and other issues which need resolution.

The Capilano substation serves over 12,000 customers, and consists of:

- A 60 kV and a 12 kV switchyard;
- Two power transformers; and
- One feeder section.

The most significant issues and risks at the Capilano substation include:

- A significant portion of the equipment is in poor condition, including both of the 60 kV circuit breakers, 85 per cent of the 27 protection and control assets, 88 per cent of the 56 disconnect switches, and 50 per cent of the 42 the instrument transformers;
- A number of the circuit breakers are obsolete, unreliable and contain oil with polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline; and
- The existing feeder section building does not meet current seismic standards and equipment has limited clearance between energized equipment and ground. The risk is currently partially mitigated through physical barriers and warning signs.

The Norgate substation serves over 5,000 customers, and consists of :

- A 60 kV and a 12 kV switchyard;
- Three power transformers; and
- One feeder section.

The most significant remaining main issues and risks at Norgate substation include:

- All three power transformers are in poor condition and subject to oil leaks;
- All of the voltage regulators in the feeder section are in poor condition and contain PCBs at levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline;
- The majority of the remaining substation assets are also in poor condition including: 42 per cent of the 17 circuit breakers, 64 per cent of the 11 reactors, 94 per cent of the 31 protection and control assets, and 87 per cent of the 52 disconnect switches; and

- The feeder section has worker safety issues related to limited clearance between energized equipment and ground. The risk is currently partially mitigated through physical barriers and warning signs which create access restrictions during maintenance and operations.

Summarize Solution:

Performing work at these substations is complex. Space is often limited, meaning that workers have to work in close proximity to the energized equipment when the major construction needs to be done to replace/add the equipment. To continue to supply the load to the customers during construction, the new equipment and infrastructure has to be added before it is possible to take existing equipment out of service since there is a limited capacity to transfer the load elsewhere to the neighboring stations. Creating space within the substations is sometimes challenging and at times requires expansion of the substation footprint.

The strategy for the area is intended to sequence work in such a way that the issues and risks outlined above are mitigated, while continuing to provide reliable supply to customers. The development of a strategy for the area will consider a number of factors, including:

- The current capacity and projected growth for the area;
- The condition of the assets at different area substations, and their expected degradation over time;
- The sequencing and timing of required sustainment work at area substations combined with the need to manage overall area capacity;
- Minimize/ avoid stranded investment in the area substations by optimizing the planning and the staging of work; and
- Opportunities to utilize capacity at neighboring substations.

Short- and Medium-Term:

- The Capilano substation will be completely rebuilt with a capacity of 100 MVA.
  - A new substation will be built within the footprint of the existing substation fence;
  - The load from the existing 56 MVA substation will be transferred to the new substation; and
  - The existing 56 MVA substation will be decommissioned.
- For Norgate substation, alternatives are being examined to address the ageing assets, safety risks and other specific issues outlined above. The alternatives will include:
  - Replace or refurbish the transformers and 12 kV feeder section; and
  - Transfer the load to the neighboring stations and decommission the transformers and the feeder section.

When all the above investments are completed there will be significant improvements in the overall equipment condition and reliability. The safety and seismic risks will be mitigated and PCBs will have been removed ahead of the end of 2025 Federal deadline. The area will have the necessary capacity to accommodate the future growth in the area.

Long-Term:

In the longer-term, it is anticipated that a component by component replacement strategy will be undertaken at the different substations to address risks with discrete assets as they degrade over time.

Name of Capital Strategy, Plan or Study:
Sperling Asset Plan

Summarize Issue:

The 214 MVA Sperling substation is a transmission and distribution substation that serves Vancouver West. First commissioned in the 1940s, the substation consists of:

- Three switchyards: 230 kV, 69 kV and 12 kV;
- Two power transformers; and
- Four feeder sections.

Sperling is an important substation given its dual role as both a transmission station and a distribution station. The station serves over 55,000 customers, and has the fifth largest peak load (166 MVA) in the Lower Mainland Metro region. Sperling substation is the only source of supply to the University of British Columbia and one of the two supplies to Camosun substation. There is also flexibility to transfer the distribution load between the adjoining Camosun, Mount Pleasant and Kidd 1 substations.

Since commissioning in the 1940s, the substation has been expanded over time and there have been a number of investments in the past 20 years totaling over $30-million. Recent investments have included the addition of a new indoor feeder section in 2009 and the replacement of the circuit breakers in an older indoor feeder section in 2012.

The most significant remaining issues and risks associated with Sperling substation include:

- The two outdoor feeder sections were designed to be compact in size and pose safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs;
- There are elevated reliability risks associated with one of the outdoor feeder sections and transformer circuit breakers, due to the poor condition of 90 per cent of the 10 circuit breakers, and 93 per cent of the 56 disconnect switches. The oil-filled circuit breakers in these feeder sections also contain polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline;
- All eight indoor transformer circuit breakers pose safety risks for workers due to the potential for arc flash hazards in the event of failures; and
- There are elevated reliability risks associated with the 69 kV switchyard due to the poor condition of 92 per cent of the 13 disconnect switches, and obsolescence issues with the original mechanical protection and control relays.

Summarize Solution:

The Sperling Asset Plan presents a strategy to replace assets on a component by component basis (i.e., undertake discrete investments as needed), considering factors such as condition, rate of deterioration, the operating environment, and criticality. The safety issues associated with the two feeder sections of compact size will be addressed concurrently with other equipment replacement projects. In the short- and medium-term, the focus will be on higher priority investments required for safe and reliable transmission and distribution of energy and to meet the requirements to phase out PCBs by the end of 2025.

Short- and Medium-Term:

- Address the safety and reliability risks associated with one of the outdoor feeder sections and the bus breakers by replacing them with a new indoor feeder section in a new building;
- Remove equipment with PCB levels at or above 50 ppm by the December 31, 2025 Federal Regulation deadline; and
- Address the reliability risk associated with the 69 kV switchyard by decommissioning the switchyard and control building at Sperling after transferring the load to the adjoining Camosun substation.

Long-Term:

The equipment at the Sperling substation will continue to degrade over time, and a level of investment is anticipated in the longer term to preserve the reliability of the substation, and address emerging risks. Expected investments are required to address the risks associate with the remaining outdoor feeder section and transformers that were installed in the 1970s.

[redacted]

[redacted]

Name of Capital Strategy, Plan or Study:
Asset Management Strategy - Section 2.2.15: Synchronous Condensers

Summarize Issue:

There are eight synchronous condensers on the BC Hydro system all of which are over 40-years old. Four are located at Burrard Synchronous Condenser Station, three are at Vancouver Island Terminal and one is at Kelly Lake Substation. They are expensive assets with long lead times to acquire and replace. Synchronous condensers are rotating machines that are similar to generators. Each machine has a number of supporting systems, including a gas handling system, an excitation system, and a protection & control system. These assets are used to provide system voltage control and contribute to the system stability.

This strategy focuses on the four synchronous condensers at Vancouver Island Terminal and Kelly Lake substation as the future use of synchronous condensers at Burrard is presently under review.

The main issues and risks with the synchronous condensers are:

- Safety - There are fire risks associated with leaks in the hydrogen gas handling systems; and
- Reliability - The excitation and the protection and control systems are aging, with increased likelihood of failure. There are obsolescence issues and spare parts can be challenging to source given that manufacturer support is limited. These issues can result in long downtimes if a unit is forced out of service.

Over the last 10 years, refurbishment of the windings and internal components of each of the four machines has been completed. BC Hydro also developed and implemented a spares strategy, and made additional investments in spare parts to minimize outage time in the event of failures. To help with troubleshooting, BC Hydro increased the use of on-board diagnostics and implemented a knowledge transfer process to enhance its repair capability in the field. The total value of these investments was over $26 million.

As a result of this work, the overall condition of the assets at Vancouver Island Terminal and Kelly Lake has been improved. However, reliability and safety risks remain with specific supporting systems, such as gas handling, excitation and protection and control.

Summarize Solution:

To address these issues and risks, the following approaches will be taken:

- Capital projects will upgrade the gas handling, excitation, and the protection and control subsystems of each unit;
- A spares strategy will ensure that critical parts are available to facilitate breakdown repairs and shorter outages; and
- Increased use of on-board diagnostics to shorten outages.

Short-Term:

Investments will begin in the short-term with projects for each of the four synchronous condensers to focus on addressing the remaining risks in the support systems, namely the gas handling system, excitation system, and the protection and control system.

Medium- and Long-Term:

Given that the assets at Vancouver Island Terminal and Kelly Lake are over 40-years old, a level of ongoing work will be required as the assets progress through their lifecycle and risks associated with falling health of these assets will need to be addressed.

Name of Capital Strategy, Plan or Study: **Transmission Planning Study for the Peace Region Electric Supply Project**
Summarize Issue: The Peace region is experiencing significant load growth especially in the Dawson Creek and Groundbirch areas, mainly driven by the gas industry. The regional transmission system has already exceeded its supply capability to reliably serve the community of Dawson Creek and existing industrial customers in the region. The regional transmission system has also reached its normal system supply limit, and as a result no new industrial customers can be interconnected to BC Hydro's system. The Dawson Creek / Chetwynd Area Transmission (**DCAT**) project, which went into service in late 2015, resolved the initial constraints in the transmission system supplying the area, but a second project, the Peace Region Electricity Supply (**PRES**) project, is required to supply (firm supply) the forecasted load over the next 30 years. A load shedding scheme was implemented which will automatically interrupt power service to industrial load customers in the event of a transmission outage until PRES is implemented. The risks associated with the current system condition are: • New Loads: Not being able to supply any new industrial loads in Dawson Creek and Groundbirch areas; and • Exiting Loads: Not being able to supply the existing load under single contingency on the system.
Summarize Solution: The PRES project is required at the earliest in service date to ensure the availability of capacity on the transmission system to serve new customers in the region. Seven alternatives were identified to resolve the supply constraints within the Peace region system. The leading alternative (construct a new double circuit 230 kV line from Southbank switching station (**SBK**) to Shell Groundbirch substation (**SGB**)) was selected by evaluating factors such as load supply capability, system reliability, capital costs of construction, operating and maintenance costs and transmission system losses. **Short-Term:** • Provide reliable supply for the existing loads (transmission and distribution); • Avoid load shedding; • Avoid dispatching of the customer owned generators to minimize operating costs; and • Serve new customers in the region. **Medium-Term:** • Electrify new or existing oil and gas loads (gas compression) in the Peace region; and • Reduce greenhouse gas emissions by electrification of industrial loads and reducing customer owned generation. **Long-Term:** • Provide supply capability for future load growth (transmission and distribution).

Name of Capital Strategy, Plan or Study:
Asset Management Strategy - Section 2.1.2: Conductors

Summarize Issue:

BC Hydro has approximately 19,300 circuit-km of overhead transmission conductors. The average age of conductors on the transmission system is 45 years. The objective of the conductor strategy is to achieve a life of 80 years for transmission circuits while operating at design load capacity.

Overall, conductor condition is determined by regular inspections and failure analysis. Systematic sampling is also used for analytical condition assessments, by removing short segments of conductor for laboratory testing. When defects are identified, capital projects are initiated considering an integrated approach, and factoring in the nature of the defect, site conditions, overall condition of the line and system needs.

Overhead transmission line conductors can be classified in two main types: aluminum conductor steel-reinforced (**ACSR**), which is the industry standard and comprises the majority of installed conductors; and copper (**Cu**), which is obsolete for use as conductor. There are some exceptions where other types of conductor are used on the transmission system: for example all-aluminum conductor (**AAC**), all-steel conductor (**ASC**), and aluminum conductor - carbon fibre core (**ACCC**).

Copper conductors have largely been replaced with ACSR; approximately 300 circuit km of copper conductor remain in the BC Hydro Transmission system. Since fiscal 2010, approximately 150 km of copper conductor has been replaced, including recent projects for circuits 60L02, 60L03, 60L18, and 60L19.

The risks and issues associated with overhead conductors include:

- Condition – Degradation can occur from age and stresses such as wind, ice, lightning, thermal loading, corrosion, mechanical damage and air pollution;
- Safety & Reliability – Failures due to degradation can create public and worker hazards and result in forced outages with long restoration times; and
- Capacity – Degradation of the conductor can lead to de-rating of the circuit.

Summarize Solution:

To address the above issues and risks, the following staging of investments is recommended:

Short-Term:

- Continue to maintain and prioritize conductor replacements and upratings based on condition;
- Manage operation overload limits to avoid conductor damage;
- Continue with the Copper conductor replacements planned for circuits 60L004, 60L011, and 60L054 on the south side of Burrard Inlet around Burnaby Mountain.
- Initiate a conductor sampling program for ACSR conductor; and
- Address the end-of-life conductor issues at Jervis Inlet Crossing.

Medium- and Long-Term:

- Continue Copper Conductor Replacement Program; and
- Continue the ACSR conductor sampling program to identify scope for future overhead conductor replacement capital program.

Name of Capital Strategy, Plan or Study:
Asset Management Strategy - Section 2.1.10: Transmission Cables

Summarize Issue:

The major objective of the strategy is to achieve a life of 55 years for transmission cable systems, which is 15 years longer than the life stated by cable manufacturers, by targeted upgrades and refurbishments. BC Hydro has approximately 350 km of transmission cables, of which 196 km are submarine with the remainder being underground in mostly the Greater Victoria and Metro Vancouver areas. Cables are used to transfer electricity where it would be difficult or impractical to install overhead transmission lines, such as across large bodies of water or through cities where tall buildings or high density make it impossible. A cable system is comprised of a cable, duct banks, manholes, and ancillary equipment (such as pressurization and monitoring systems). There are two broad categories of cables: self-contained fluid-filled (**SCFF**) which uses paper and oil for insulation, and cross-linked polyethylene (**XLPE**), which instead uses a form of plastic and is oil-free.

The main issues and risks associated with transmission cables include:

- Capacity - Historic growth can result in the need to operate existing cables closer to their maximum electrical rating which can result in higher temperatures and reduced life spans;
- Security - Terminal structures where the cables connect to overhead lines are vulnerable to vandalism, particularly by copper thieves;
- Reliability - Cables are essential for service for reliable transfer of electricity. Failed cables leading to forced outages may cause localized load shedding and impact system reliability significantly. Repairs take a long time and leave the system in a vulnerable state; and
- Environmental - Fluid-filled cables can leak oil which can result in adverse environmental impacts. The risk of leaks increases with age as the cable’s outer metallic layer (which acts to contain the oil) fatigues.

Recent projects have included installing temperature monitoring systems on the 230 kV cables in Vancouver to ensure the transmission cables are not overloaded and to gauge overall health. Installation of pressure monitoring systems to provide early warning of any leaks has also been completed. Additional spare cables have been purchased to reduce response times if cables are damaged.

Summarize Solution:

To address the above issues and risks, the following staging of investments is recommended:

Short-Term:

- Continue with maintenance and inspection programs;
- Replace the cable (2L146) between the Goward and Horsey substations;
- Gulf Islands - Transmission Reinforcement Project; and
- Refurbish pumping equipment to maintain and extend service life of fluid-filled cable systems.

Medium-Term:

- Expand use of temperature monitoring systems to measure cable temperature and adopt dynamic rating systems to allow for higher power transfers (by running closer to thermal limits) and defer cable replacements that may be required by growth needs.

Long-Term:

- Consider the replacement of the 138 kV submarine cable that supplies the Gulf Islands and Vancouver Island; and
- Continue practice of installing solid-dielectric insulated cables to eventually phase out use of oil-filled transmission cables to mitigate potential environmental risk.

Name of Capital Strategy, Plan or Study:

Asset Management Strategy – Section 2.4.1 and 2.4.2: Fibre Optic and Microwave Equipment

Summarize Issue:

The BC Hydro fibre optic system has a total of 272 assets connecting 71 substations, and the microwave system has a total of 1388 assets at 152 different locations around the province. The microwave and fibre optic elements of the telecommunications system work together to enable high-speed clearing of transmission system faults, system protection, and Supervisory Control and Data Acquisition (**SCADA**) linking the major stations with the Control Centre. The Telecommunications system also provides a dedicated communications system available in emergencies and is a key element in meeting WECC/NERC reliability standards.

In addition to telecom system growth required to connect new substations, major load customers, and generation interconnections, in the past three years, critical SCADA and Energy Management System traffic has begun to be transferred from the old failing assets onto new network equipment. Replacement models for microwave radios and digital cross connect systems have been identified and accepted for use in the system. Some failing microwave radio equipment has been replaced with new equipment, and a number of failed multiplexors have been replaced.

The main issues and risks associated with the fibre optic and microwave equipment include:

- The main telecommunications equipment components of the system are degrading and are no longer supported by the manufacturer. These include the microwave radios, multiplexors, and digital cross connects;
- Some of the sites have local environmental conditions that affect operation; and
- Growth of the power system requires telecommunication upgrades at certain locations.

Summarize Solution:

Projects are planned for the sustainment of the microwave and fibre optic system by balancing asset condition and criticality.

To address the above issues and risks, the following staging of investments is recommended:

Short-Term:

Specific regional issues exist with some systems where growth has occurred, requirements have changed, environmental and/or situational conditions have lead to short-term project needs.

The projects planned in the short-term include:

- Address icing issue at the Copper Mountain microwave tower and replace the building;
- Upgrade the telecommunications system at Natal substation;
- Replace the telecommunications equipment on Vancouver Island; and
- Replace the Digital Cross Connect System equipment across the province.

Medium-Term:

The microwave radios are degrading and require replacement across the majority of the system. Additionally, the plan addresses some key microwave sites in the Fraser Valley that are dependent on a single physical point of failure.

The projects in the medium term include:

- A replacement of the microwave radios and multiplexors across the province; and
- A project to address single points of failure of the microwave system in the Fraser Valley.

Long-Term:

In the long-term, the microwave system includes sites that are single physical point of failure and projects are planned to address mitigating the risk of significant events such as forest fire or land slides.

Name of Capital Strategy, Plan or Study:
Asset Management Strategy – Section 2.4.4: Protection and Control Equipment

Summarize Issue:

Protection and Control (**P&C**) assets include a wide range of electrical devices that protect transmission equipment from damage, ensure reliability and stability of the transmission system, and provide local and remote operational visibility and control of transmission lines, station equipment, and the BC Hydro power system as a whole. P&C equipment includes devices such as protective relays, control modules, alarm systems, electrical meters, and local and remote supervisory control and data acquisition system remote terminal units (**SCADA RTUs**).

Protection assets and systems are used to detect abnormal voltage and current conditions and automatically make response decisions about de-energizing and isolating a piece of equipment or portion of the system. These systems are also subject to evolving Mandatory Reliability Standards as defined by North American Electric Reliability Corporation (**NERC**) and regulated by the BCUC.

Over the past five years a considerable amount of work has been undertaken to address the issues with P&C assets:

- Complete station P&C upgrades have been completed at: Arnott, Atchelitz, Barnard, Cambie, Campbell River, Como Lake, Camosun, Douglas, Lake Cowichan, McLellan, Newell, Northfield, Nicomekl, Port Hardy, Port McNeill, Sooke, Strawberry Hill, Steveston and White Rock;
- Digital Fault Recorders (**DFRs**) have been replaced at: Ashton Creek, Cranbrook, G.M. Shrum, Ingledow, Kootenay Canal, Kelly Lake and Nicola;
- SCADA RTUs have been replaced at American Creek, Armstrong, Babine Lake, Balfour, Barriere, Buckley Bay, Bridge River Terminal, Beaverley, Cranbrook, Cheekye, Coquitlam, Cathedral Square, Chevron, Fort St. John, Fernie, Forest View, George Dickie, Joeseph Creek, Kalum, Kenedy, Kicking Horse, Meridian, Malaspina, Portage Pass, Pineview, Rosedale, Rupert, Ruby Creek, Richmond, Selkirk, Shell Groundbirch, Skeena, Sundance Lakes, Surrey, and Sorrento;
- Programmable Logic Controllers have been replaced at Ingledow and Meridian;
- Full station controls modernization upgrades are underway at Williston and G.M. Shrum; and
- A portion of the protection relays have been replaced at Clayburn, Kidd 2, Lougheed, Sperling, Gloucester, Silverdale, Salmon Arm, Long Beach, Mission, Meridian, Murrin and Williams Lake.

The main issues and risks associated with P&C equipment include:

- DFRs and certain models of SCADA RTUs across the system are at end of life and no longer supported by the vendors;
- NERC Critical Infrastructure Protection (**CIP**) five mandatory reliability standards are an immediate requirement where BC Hydro was required to achieve initial compliance by October 1, 2018 and implement systems to maintain that compliance into the future; and
- Control systems are at end-of-life.

Summarize Solution:

Projects are planned for the sustainment of the P&C system assets by considering asset condition and their criticality in meeting the power system reliability and safety. To address the above issues and risk the following staging of investments is recommended:

Short-Term:

- Address the most critical elements of the P&C system including:
  - Replace the SCADA RTUs at the following stations: Walters, Dal Grauer, Texada Island East and West, Texada Island Reactor, Cape Cockburn, Nile Creek, Murrin and Kidd 2; and
  - Replace the DFRs at the following stations: Peace Canyon, Selkirk, Cheekye, Revelstoke, Arnott and Vancouver Island Terminal;
- Specific local issues exist where entire station control assets are at end of life and need to be refreshed. These stations are: Ingledow, Williston, G.M. Shrum, and the American Creek Capacitor

station; and

NERC CIP 5 mandatory reliability standards are also an immediate requirement, and BC Hydro achieved initial compliance October 1, 2018 and needs to implement systems to sustain compliance in the medium impact transmission stations.

Medium- and Long-Term:

- Replacement of end of life P&C assets will continue with a focus on the highest risk assets including legacy models of protection relays, SCADA RTUs, and DFRs. This includes the DFRs at the Dunsmuir and Malaspina stations and the RTUs at Burrard, Savona, Sechelt, Comox and Harewood;
- Comply with the next generation of Mandatory Reliability Standards, particularly NERC CIP 7; and
- In the long-term, the P&C systems will need to be modernized to align with industry advances that bring additional safety, reliability and operational cost benefits.

Name of Capital Strategy, Plan or Study:
Asset Management Strategy - Section 2.2.16: Power Transformers

Summarize Issue:

There are 572 power transformers with a voltage class of 60 kV or greater at BC Hydro substations. Transformers are one of the most critical and expensive assets in a substation, and have long lead times to acquire and replace. Transformers fulfill multiple roles. Firstly, power transformers are used to increase the voltage to a level that can be transmitted over long distances via the transmission network. Secondly, in the transmission network, transformers are used to connect systems that are operated at different voltages. Finally, transformers are used to reduce transmission voltages to a lower level that can be distributed to customers.

The general issues and risks associated with a failure of a power transformer include:

- Reliability:
  - Elevated risk of customer outages at single transformer distribution substations, and a loss of redundancy at multi transformer distribution substations; and
  - Reduced transfer capability and increased network risks associated with the transmission system;
- Environment:
  - Elevated risk of oil spills, particularly in older transformers with less robust oil spill containment; and
- Safety & Financial:
  - The increased likelihood of a fire poses a safety risk to workers, and may cause damage to surrounding assets.

Over the last 10 years, 80 transformers have been installed at 55 substations. BC Hydro has also developed and implemented a spares strategy, and has purchased 10 new spare transformers of different ratings to minimize impacts in the event of a failure. The total value of these investments was over $400 million.

Approximately 87 transformers are between 50 and 60-years old, and 36 are more than 60-years old. Approximately 121 (21 per cent) of the total power transformers have been assessed as Poor or Very Poor, indicating that there is an increased likelihood of failure.

Summarize Solution:

To address the issues and risks identified above, a number of approaches have been taken, including:

- Capital projects have been identified to remediate the risks associated with some of the transformers;
- A spares strategy will continue to be implemented, as necessary, to ensure that critical spares are available to minimize the impacts of a transformer failure; and
- Consideration has been given to opportunities to decommission assets where replacement is not necessary.

Our strategies address these assets in two ways. First, we have initiated projects that address multiple asset issues with a specific facility. When work is done as part of a project, the total duration of the project may exceed the two year test period. Second, we target specific transformers as stand-alone items when this is the primary area of focus in a facility.

Short-Term:

Condition of assets are reviewed on a regular basis considering such factors as recurring test results, visual inspections, and, where required, detailed engineering assessments. This information is used to assess the risk of failure of each transformer to help prepare a consolidated list across the fleet to identify the timing to address the risks.

Activities that will occur in the short-term are described in the table below.

	Transformers that will be addressed as part of a larger project	Projects where the transformer is the primary driver
Activities that will be completed in the short-term	N/A	N/A
Activities that are underway, and will continue into the medium-term	• Capilano (60/12 kV) • Kidd 1 (60/4 kV) • Mainwaring (230/12 kV) • Mount Lehman (230/25 kV) • Natal (138/60 kV) • Newell (230/12 kV)	• Bridge River 1 (60/238 kV) • Bridge River Terminal (345/238 kV) • Hundred Mile House (60/238 kV) • Jordan River (13/25/138 kV)
Activities that will start in the short-term, and continue into the medium term	• Norgate (60/12 kV) • Patricia (60/12 kV) • Pemberton (230/25 kV) • Rosedale (345/238 kV)	N/A

Medium-Term:

The investments outlined above address the most pressing risks associated with the transformers. Many of the investments initiated in the short-term will continue to have capital expenditures and will go into service in the medium-term.

The following is a list of assets that are expected to be initiated in the medium-term. The strategy and prioritization will be continually monitored over time as other assets degrade. In the medium term, transformers at the following substations have been identified as higher risk:

- Balfour (60/12 kV);
- Coquitlam (60/12 kV);
- Dal Grauer (60/12 kV);
- Glenmore (60/4 kV);
- Horne Payne (230/12 kV);
- Loughheed (60/12 kV);
- Nakusp (60/12 kV);
- Quesnel (60/12 kV);
- Richmond (60/12 kV);
- Scott Road (60/12 kV);
- Sumas Way (60/25 kV);
- Surrey (60/12 kV); and
- Wahleach (345/13 kV).

Long-Term:

There are approximately 164 transformers between 40 to 50-years of age. Over the next 10 years, it is likely that a portion of these will degrade to poor or very poor condition. Remediation of the risks associated with these degrading assets will be required in the long-term, applying similar assessment and prioritization techniques to those outlined above.

Name of Capital Strategy, Plan or Study:
West Kelowna Area Study

Summarize Issue:

The 138/25kV Westbank Substation (**WBK**) supplies the West Kelowna area and is connected only to Nicola Substation (**NIC**) by a single 80-km long radial 138 kV transmission line. WBK has no ties to any other substations and there is no local generation to serve the load in the area. Consequently, if the radial transmission line is out of service, the 22,000 customers in the West Kelowna area will experience an outage. The geographic area of the transmission line has been subjected to wildfires in past summers.

In addition, there is a need to increase the station capacity at WBK. The station has three 138 kV/25 kV transformers with a summer firm capacity of 80 MVA (assumes the loss of a transformer). Firm capacity was exceeded by 15 per cent in fiscal 2019 by the summer load demand.

Also, some equipment that has been in-service since the early 1970s is nearing end-of-life and needs replacement.

Summarize Solution

BC Hydro is evaluating alternatives to address the above issues with an integrated approach.

Short- and Medium-Term:

- Two alternatives are being considered to mitigate natural hazard risks to the West Kelowna transmission system:
  - Build a new, secondary transmission line to WBK to improve the reliability of supply and supply future load growth; and
  - Improve the resiliency of the existing transmission line to minimize the risk of outages resulting from forest fires and geotechnical events.
- Westbank Upgrade Project:
  - Increase the WBK summer firm capacity from 80 MVA to 120 MVA by replacing an existing 28 MVA transformer with a 75 MVA unit and replace end-of-life assets; and
  - Provide for the addition of a new feeder section which may be required to accommodate future load growth.

Name of Capital Strategy, Plan or Study:
Wood Pole Substation Strategy

Summarize Issue:

There are 50 substations that have been classified as Wood Pole substations for asset management and planning purposes. Collectively, all of these substations serve approximately 75,000 customers. Their common characteristics generally include:

- Individually, these are small distribution stations, the majority of which have a load of less than 15 MVA and serve less than 3,000 customers;
- Usually located in remote rural locations, often at the end of a radial line;
- A wooden structure which is used to mount electrical equipment such as disconnect switches;
- A single power transformer;
- A small number of feeder positions (usually less than four);
- No control room; and
- Mobile transformers are required in the event of a failure.

The general issues and risks associated with Wood Pole substations include:

- Reliability:
  - The poor condition of the wooden structures represents an elevated reliability risk. The wooden cross members in the wooden box structure can sag over time, physically contacting nearby equipment, and causing customer outages; and
  - The poor condition of equipment such as transformers, disconnect switches and voltage regulators represents an elevated reliability risk. Limited redundancy in these substations means that a failure of any one component has a high likelihood of causing a total outage of the station;
- Safety:
  - The degrading condition of the wooden structure represents a safety hazard to workers inside the substation; and
  - The compact size poses safety risks for workers due to limited clearance between energized equipment and ground. This risk is currently partially mitigated through physical barriers and warning signs;
- Environmental:
  - Much of the oil filled equipment in wood pole substations contains polychlorinated biphenyl (**PCB**) levels at or above 50 ppm which will be proactively replaced by the December 31, 2025 Federal PCB Regulation deadline.

Over the last 20 years, approximately $60 million has been invested in addressing the most pressing risks at 12 of the 50 Wood Pole substations. Work at another three of these is also currently underway. BC Hydro has also invested in mobile transformers to act as emergency replacements in the event of failures at the Wood Pole substations.

Approximately 52 per cent of the 50 Wood Pole substations are over 50-years old, with 10 per cent over 60-years old. Approximately 45 per cent of equipment within the Wood Pole substations has been assessed as Poor or Very Poor, indicating that there is an increased likelihood of failure.

Summarize Solution:

Wood Pole substation investments are prioritized considering factors such as the age and condition of the wood poles, the condition of equipment within the substation, as well as the criticality of the substation. To address the above issues and risks, the following staging of investments is recommended:

- Firstly, a number of capital projects have been identified to remediate the risks associated with the Wood Pole substations. The scope of these will be tailored to suit the specific Wood Pole substation, and the risks, ranging from the component by replacement of targeted assets, to a more complete redevelopment of the substation;
- Secondly, a contingency strategy, utilizing mobile transformers, will continue to be implemented, as

necessary, to ensure mobile transformers are available to minimize the impacts of equipment failure; and

- Finally, consideration has been given to find opportunities to decommission stations where replacement can be avoided by finding other economical solutions.

Short- and Medium-Term:

Condition of assets are reviewed on a regular basis considering such factors as recurring test results, visual inspections, and, where required, detailed engineering assessments. This information is used to assess the risk of failure at each Wood Pole substation to help prepare consolidated list across the fleet and identify the potential timing to address the risks. Below is a list of those substations with a higher priority:

- Britannia;
- Monte Lake;
- Parson;
- Clinton;
- Chase;
- Joseph Creek;
- Sandspit;
- Lumby #2;
- Diana Lake;
- Canal Flats;
- Skookumchuck;
- Woss Lake; and
- Anahim Lake.

Long-Term:

The investments outlined above will address the highest priority risks. However, considering that a number of the Wood Pole substations were constructed in the 1970s and 1980s, additional work is anticipated in the long-term. The strategy and prioritization will continually be monitored over time.

Name of Capital Strategy, Plan or Study:
Asset Management Strategy - Section 2.1.11: Transmission Wood Poles

Summarize Issue:

BC Hydro has approximately 75,000 wood pole structures on the Transmission system. This equates to approximately 110,000 individual wood poles, as some structures are built using multiple wood poles. The average life of a wood pole is approximately 50 years. With the Wood Pole Test & Treat Program (inspection and maintenance), BC Hydro aims to achieve a 70-year life for transmission wood poles. Currently, 47 per cent of transmission wood poles are in the mid-life age class of 30 to 50 years old.

BC Hydro has safely maintained transmission reliability and quality of service through investment in wood pole structure replacements to address critical end-of-life wood poles and crossarms across the province. Over the last five years, an average of 668 structures and 319 crossarm (framing) replacements were completed each year with the majority of replacements in the Lower Mainland area (wetter and prone to biologic decay) and the Southern Interior (dry and prone to damage caused by woodpeckers). This means that over 10 per cent of the asset class (almost 1,000 transmission structures) is getting refreshed with life extension investments each year. This is a sustainable and acceptable rate of replacement based on the population demographics.

The main issues and risks associated with transmission wood poles include:

- Condition – managing the ageing population of poles and overall asset condition that could lead to safety and reliability risks;
- Availability of materials – reduced availability of large size wood poles and timbers that meet performance specifications could limit BC Hydro’s ability to replace end-of-life structures and negatively impact the life expectations for new structures;
- Environmental performance – efficacy of wood preservatives and preservation techniques currently approved in Canada;
- Constructability – difficulty in securing outages for structure replacements and concerns with access to farms and other private property results in delayed replacements; and
- Climate change – increase in extreme events such as storms and forest fires leading to pole damage. Longer and wetter winter cycles accelerate biological decay and all these factors increase the rate of pole replacements.

Summarize Solution:

To continue addressing the known issues and risks, the following staging of investments is recommended:

Short-Term:

- Target inspections of about 10,000 structures with the annual Test & Treat Program as per published standards. This allows wood pole life extension;
- Target replacement of approximately 700 wood pole structures and 300 crossarms with the annual Wood Structure and Framing Replacement Program; and
- Circuit refurbishment of 2L13/2L14.

Medium- and Long-Term:

- Continue the annual Test & Treat Program;
- Continue testing and research on wood pole end-of-life assessment, life extension, work prioritization and alternate structure materials in collaboration with Powertech Labs and international organizations to ensure best value for asset replacements and longer lasting materials for lowest total ownership cost of structures;
- Continue the annual Wood Structure and Framing Replacement Program at current levels; this program addresses end-of-life structures, ensures safety, maintains service levels and if required improves reliability; and
- Continue to develop Circuit Refurbishment Programs. These projects target efficiency where there are relatively large volumes of pole replacements on a single transmission line.

Name of Capital Strategy, Plan or Study:
Distribution Planning Practice - Section 6.1 and 6.4.2: New Feeders & Voltage Conversion

Summarize Issue:

BC Hydro’s distribution system experiences load growth which requires the addition of new feeders and voltage conversion to more effectively serve load over time. In addition, the distribution system technical requirements and customer expectations for reliability evolve over time. The Distribution Planning Practices (**Planning Practices**) establish planning criteria that guide the need for new feeders and voltage conversion. The Planning Practices also support the implementation of distribution system expansion and improvement capital projects which address capacity constraints and anticipated load growth, and maintain and improve distribution system performance including addressing customer reliability, safety risks and regulatory and legal requirements. The Planning Practices document is reviewed and updated regularly to consider factors such as new industry practices, standards, and technologies, along with financial, regulatory, and environmental requirements.

New Feeders (Planning Practice section 6.1)

New feeders are required as new load develops, for example:

- Loads on feeders may grow to the point where the individual feeder capacity is exceeded and a new feeder is needed to serve the additional load;
- A new feeder may be required to ensure faster customer service restoration in case of feeder outages; and
- A large customer may require a dedicated feeder for backup purposes.

New feeder projects recently completed include new feeders in Vancouver, Burnaby, Coquitlam, Maple Ridge, North Vancouver, Richmond, Surrey, Chilliwack, and Colwood. The significant areas of planned new feeder projects include: Abbotsford, Delta, and Kamloops.

Voltage Conversion (Planning Practice section 6.4.2)

Conversion of the primary voltage to a higher level may be required to:

- Increase system capacity to supply distribution customer load growth;
- Increase system flexibility for restoration and operations aligned with substation and transmission plans including the ability to transfer loads between feeders or substations;
- Increase system efficiency by reducing electrical system losses and improving customer service voltages; and
- Reduce congestion in heavily populated corridors.

Voltage conversions recently completed include portions in Vancouver, Burnaby, Coquitlam, North Vancouver, Richmond, Surrey, and Esquimalt. The other areas of planned feeder voltage conversions include: Vancouver, Burnaby, North Vancouver, Richmond and Surrey.

Summarize Solution:

To address the above issues, the following investments have been initiated:

Short-Term:

- Feeder circuit voltage conversions associated with the following substations:
  - Horne Payne, Lougheed, Richmond, George Dickie, and Quesnel;
- New Feeder circuits associated with the following substations:
  - Murrin, West Kamloops, Campbell River, Fleetwood; and
- Feeder extensions associated with the following substations:
  - Douglas Street.

Name of Capital Strategy, Plan or Study: **Asset Management Strategy – Section 3.1.8: Street Lighting**
Summarize Issue: BC Hydro owns and maintains approximately 90,000 street lights mounted on BC Hydro or Joint Use (co-owned with TELUS) poles, and 4,200 leased private outdoor lighting units installed on customer or BC Hydro owned poles located on private property. Most BC Hydro street lights are high pressure sodium technology while most private outdoor lights are mercury vapour technology. BC Hydro provides street lighting service to various customers (mainly municipalities) to: • Support night-time safety for the general public; and • Contribute to reliability by reducing outages due to vehicular accidents. The main issues and risks associated with street lighting include: • Approximately 20 per cent of BC Hydro’s street lights may contain polychlorinated biphenyls (**PCBs**), which must be removed from the system by December 31, 2025 in accordance with Federal PCB Regulations; • Municipalities are increasingly interested in implementing various cost and energy-saving initiatives such as Light Emitting Diode (**LED**) technology lights and adaptive controls; and • Meeting the street lighting outage response target of 10 working days is challenging in certain smaller districts of the province due to lack of dedicated resources.
Summarize Solution: The objective of this strategy is to replace conventional street lighting with LEDs and consider new technology to provide customers with increased flexibility of use. A street light replacement program to convert existing high pressure sodium and mercury vapour technology street lights to LED technology is current being developed with a target to being implementation in mid-2020. **Short-Term:** Work is ongoing to qualify manufacturers of LED street lights and adaptive control systems. Business justification is in progress to recommend a preferred LED solution which may or may not include adaptive controls. Once justification is approved, a rate application will be made to include LED technology as part of existing street light and private outdoor light rates. The current target to begin implementation of the conversion program is mid-2020. **Medium- and Long-Term:** The timeframe for to complete implementation is currently estimated in the range of two to four years after commencement of implementation.

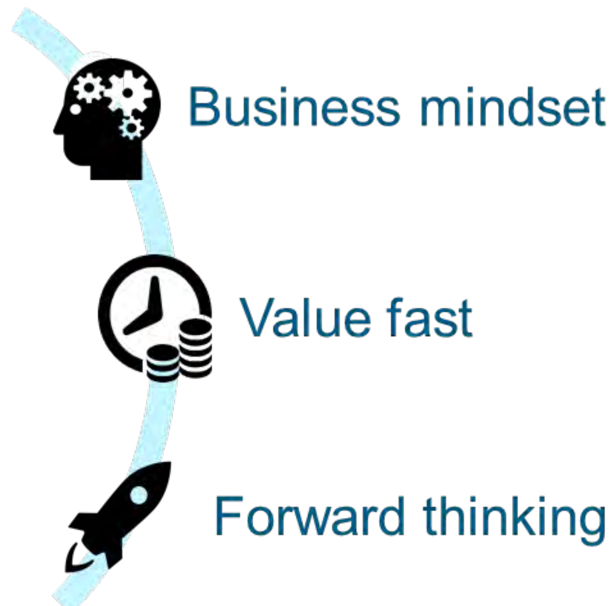
BC Hydro Technology Strategy and 5-Year Plan

BC Hydro
Technology Strategy and 5-Year Plan

Supporting BC Hydro’s Service Plan Objectives



Prepared by the Technology Group

November 2018

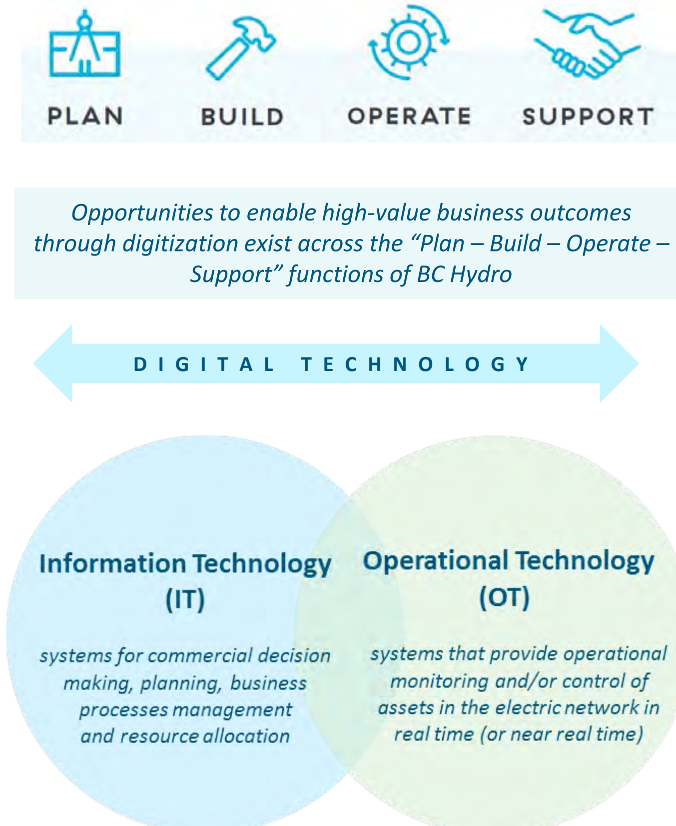
BC Hydro
Power smart

Introduction

Technology plays a critical role in the operation of BC Hydro and is embedded in virtually everything we do; from enterprise business systems, to the monitoring and controlling of field assets, to mobile devices in the hands of workers. Global trends, business competition, and high consumer expectations are driving rapid advances in technology. In the utility industry, the application of digital technology is viewed as essential in meeting future business objectives.

For BC Hydro, investment in technology can help us achieve our service plan objectives to provide reliable and responsive service, maintain affordable rates, continue to support clean, renewable energy and focus on safety above all else.

In this document, "technology" refers to digital technologies encompassing *information technology* (IT) as well as *operational technology* (OT). Traditionally separate domains in the electric utility business, the digital technology environments of IT and OT are now converging as the trend continues towards automation of all aspects of the power systems and the use of grid system data for business decision-making. New capabilities using rapidly evolving digital technologies such as cloud computing, mobility, internet of things, and machine learning, are being implemented as utilities modernize towards a more intelligent grid – this is the digitization of the utility industry.



Introduction

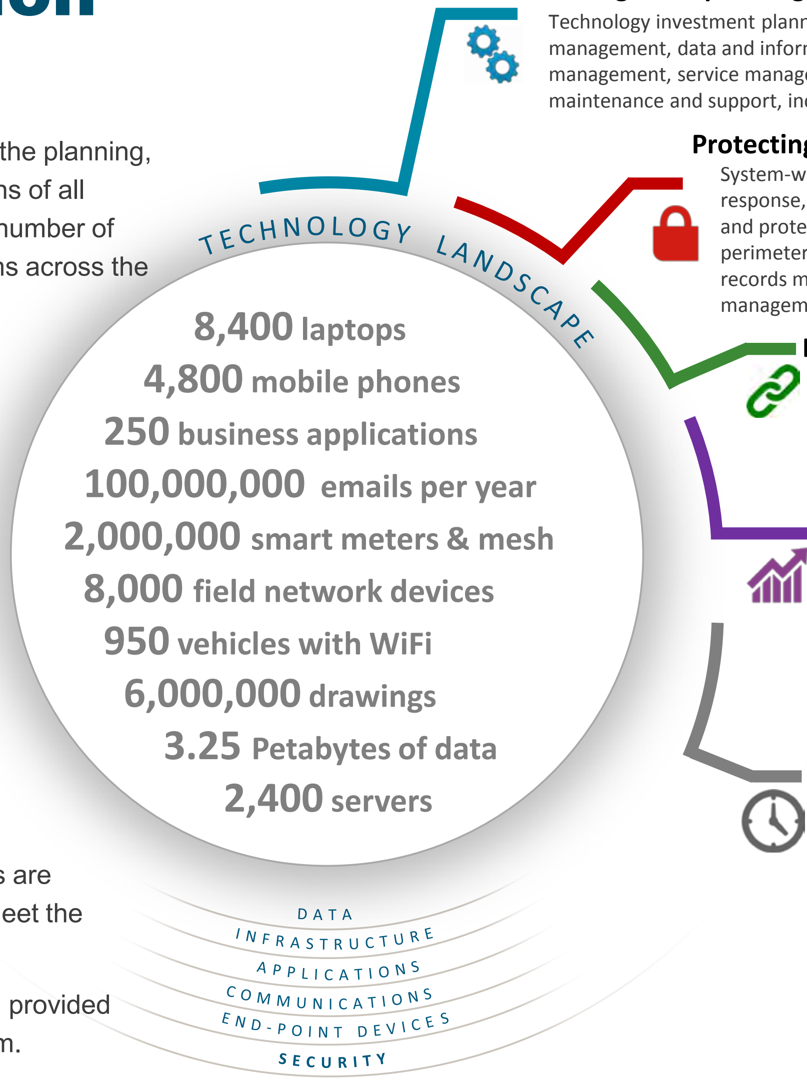
Our role

Technology is responsible for the planning, design, delivery, and operations of all information technology and a number of operational technology systems across the enterprise.

We provide technology leadership and oversight across BC Hydro. We actively collaborate with our organization to understand current and future needs. We are responsible for the enterprise technology architecture, and selection of appropriate technology solutions to deliver strong business outcomes.

Our work ensures our systems are reliable, secure, and able to meet the growing needs of BC Hydro.

Governance of our activities is provided by BC Hydro's Executive Team.



Planning and operating our complex environment

Technology investment planning, architecture and design, performance management, data and information governance, portfolio and resource management, service management, service desk, systems monitoring, maintenance and support, incident response and recovery

Protecting our systems and information

System-wide cybersecurity, system design, monitoring and response, testing, education, policy, compliance, detection and protection tools, vulnerability assessment, securing perimeters, privacy protection, security risk management, records management, information protection, drawings management, library and archive services

Ensuring the resilience of our systems

Service continuity planning and response, disaster recovery, risk management, high-availability architecture, cloud-based services, internal capabilities for critical functions, asset maintenance and health management

Enabling new business capabilities

Engaging with the business to understand their current and future needs, managing our capital investments and on-going sustainment, delivering high value projects on-time, on-scope and on-budget

Improving operational efficiency

Effectively managing vendors and contracts, retiring legacy assets, balancing internal and external resources, modernizing tools and processes, introducing agile methods, use of cloud, out-of-the-box solutions

3

BC Hydro
Power smart

Introduction

About this document

This Technology Strategy and 5-Year Plan is the result of extensive collaboration across BC Hydro. Its primary goal is to provide guidance and direction for future technology investments to meet compliance and security objectives, sustain and modernize our existing operations, and enable new business capabilities.

A clear strategy and plan is essential to inform the direction of future investments, but the approach looking forward must be flexible in order to adapt to, and exploit, the ever-changing technology landscape as well as to address new business opportunities as they arise. Given the rapid advancements in technology, and the continuing evolution of BC Hydro's business needs, the 5-Year Plan will be refreshed annually.

Our investment in technology is aligned with our capital plan over the next five years. The 5-Year plan describes the major investments we anticipate, however each will be supported by its own business case and initiated based on changing priorities, available funds and resources.

The purpose of this document is to:

- ✓ **Articulate BC Hydro's technology investment objectives**
- ✓ **Describe our strategy to meet these objectives**
- ✓ **Communicate the 5-Year Plan to guide investment and inform current and future regulatory submissions**

Context

- Our strategic objective
- Drivers for our strategy
- Digital value streams for electric utilities

BC Hydro
Power smart

Technology Strategy

Our strategic objective

This Technology Strategy and 5-Year Plan is designed to support BC Hydro in achieving its Service Plan Objectives:

- ✓ **Set the standard for reliable and responsive service**
- ✓ **Ensure rates are among the most affordable in North America**
- ✓ **Continue British Columbia's leading commitment to renewable clean power**
- ✓ **Safety above all**

Implementation of technology solutions has the potential to advance each of these objectives, for example:

- By maintaining the health, stability and security of our digital systems we assist in ensuring the reliability and responsiveness of our service.
- Providing tools to streamline workflows, optimize work and asset management, and inform decision making all enable productivity improvements that lead to affordable rates.
- Mobile applications can provide location and job specific information to assist with improving safety outcomes for field workers.

Technology Strategy

Drivers for our strategy

BC Hydro is affected by numerous drivers having a direct impact on the strategy we employ to meet our objective. These drivers affect the type of investments we make, how we prioritize investments and adapt to future trends.

BC HYDRO SERVICE PLAN OBJECTIVES

- Safety above all
- Set the standard for reliable and responsive service
- Ensure rates are among the most affordable in North America
- Continue British Columbia's leading commitment to renewable clean power

GOVERNMENT DIRECTION, REGULATION, AND COMPLIANCE

- BCUC regulation and rates forecast
- Mandatory Reliability Standards (MRS) and NERC CIP (Critical Infrastructure Protection) regulations requirements are increasing

BC HYDRO BUSINESS UNIT OUTCOMES

- Integrated Planning – optimize investments
- Capital Infrastructure Project Delivery – reduce delivery, safety and environment risk
- Operations – improve productivity
- Safety – improve safety outcomes, reduce risk
- Business Support Services – improve productivity and service

UTILITY INDUSTRY DIRECTION

- Increased expectations for digital solutions to improve safety, productivity, and management visibility
- Increasing OT/IT convergence provides opportunities for knowledge and resource sharing
- Security and compliance continues to be a rapidly increasing and growing market, ever changing and demanding
- A growing need to control distributed and customer side sources of energy as well as demand side management and load control
- Increasing electrification of transportation and management of charging infrastructure
- Climate change adaptation and mitigation

Technology Strategy

TECHNOLOGY ASSET HEALTH

- Existing systems are on ageing platforms that cannot be supported or are incompatible with newer operating systems
- Built in product obsolescence leads to regular upgrades to retain product support

TECHNOLOGY MARKET DIRECTION

- Subscription licensing is a major trend within the software industry changing our cost profile away from capital investment and towards operating costs
- Commoditization of technology services can result in lower costs, for example data network transport costs
- Everything as a service or cloud services are becoming the norm, changing our cost profile away from capital investment and towards increased operating costs

TECHNOLOGY TRENDS

- Cloud services are growing rapidly offering scalability, disaster recovery, and mobility enablement
- Mobility offers productivity benefits for field workers
- Internet of things, Edge computing and Digital twin offers opportunities in asset monitoring and performance management
- Artificial intelligence and robotic process automation offer efficiency gains through replacement of manual processes
- Augmented and virtual reality for training, virtual mentoring and maintenance support
- Robotics and drones for inspections and progress reporting
- Blockchain for secure transaction processing

Technology strategy

Digital value streams for electric utilities

Digital technologies are used to enable new and improved capabilities and drive value across all functions of the utility.

PLANNING & DESIGN

High performance computing, cloud solutions, and advanced analytic and drafting tools enable more comprehensive and timely energy and system planning, load forecasting, resource management, engineering and design.

ASSET MANAGEMENT

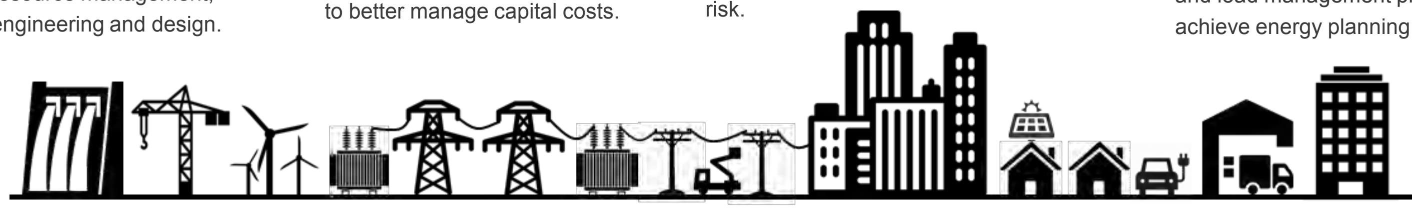
Real-time asset health information enables condition-based maintenance and just-in-time replacement to reduce asset sustainment costs. Asset health also provides for optimized investment planning to better manage capital costs.

MOBILE WORKFORCE

A fully mobile workforce seamlessly completes their field work. Job information is available, inspections are captured, drawings updated, and problems and progress automatically reported. Safety training and support is available on demand. Value is achieved through productivity, efficiency and reduced safety risk.

CUSTOMER ENGAGEMENT

Multi-channel technologies and relationship management tools improve quality and timeliness of customer interactions. Self-service reduces our costs and improves customer experience. Systems to support demand side management and load management programs help achieve energy planning targets.



WORK MANAGEMENT

Productivity, efficiency and risk reduction can be achieved through mobile applications, digital workflows to manage information and record keeping, use of drones to capture progress images, access to real-time data and business intelligence and analytics. Scheduling tools and optimization algorithms make managing work, during both normal and emergency situations, more efficient.

GRID INTELLIGENCE & CONTROL

Smart devices on the grid help optimize power delivery and resilience, and give operators and field service crews visibility into outages, faults, power quality issues, and the status of energized equipment. Digital systems manage distributed energy resources, automate connect and disconnect functions, power distribution and power quality.

SAFETY & SECURITY

Sensors, imaging and internet of things technologies provide visibility to facilities that are remote and/or unmanned. Monitoring and surveillance technologies improve identification and response to safety and security situations. Mobile field tools aid in worker and crew safety. Improved protection of digital information, systems and equipment reduces cyber security risk.

BUSINESS OPERATIONS

All business functions benefit from improvements to work processes, access to analytics, decision making, information management, and knowledge retention tools. Opportunities also exist to improve hiring, development and retention of valuable employees through specialized tools.

BC Hydro
Power smart

Approach

- Principles
- Critical success factors

BC Hydro
Power smart

Technology Strategy

Principles

We will adopt a business mindset, ensuring we work within our constraints to achieve the best outcomes for BC Hydro while maintaining the security and integrity of our information and systems at all times. We will adapt our solutions and processes to exploit short term opportunities and deliver outcomes early and often. We will develop technology roadmaps to ensure alignment on business solutions, leverage new technologies and prepare for technology obsolescence.

Business mindset

Optimize our investment

- ✓ Use a prioritization and selection methodology to achieve optimal outcomes
- ✓ Develop a plan that works within the constraints of costs and resources
- ✓ Use structured decision making in choosing investment alternatives
- ✓ Leverage existing systems
- ✓ Use a risk based approach to sustainment

Value fast

Deliver outcomes early and often

- ✓ Adapt delivery processes to deliver early and often
- ✓ Use a flexible architecture to support early value
- ✓ Leverage our existing systems
- ✓ Use off-the-shelf products
- ✓ Use cloud services

Forward thinking

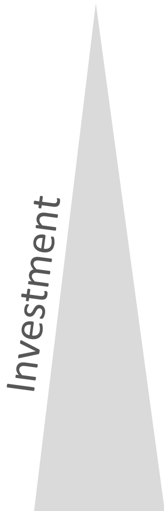
Leverage technology

- ✓ Develop roadmaps for foundation technologies
- ✓ Ensure alignment of short-term business solutions
- ✓ Plan for future obsolescence

Technology Strategy

Principles – Business mindset

- **Justify and prioritize investments.** Investment proposals are selected into the portfolio based on relative value to the organization. Compliance, security, sustainment and risk mitigation solutions receive higher priority followed by those required to enhance business capability. Business cases must identify value and articulate specific benefits. Value (both cashable and non-cashable) from the investment must support the total cost of the investment.



Initiative / Investment	Description
Enhance our Capability	Discretionary activities that provide new or improved business capabilities
Manage our Risk and Sustain Productivity	Critical activities needed to ensure reliable and safe operations and to maintain the current level of productivity for our users
Compliance & Security	Mandatory activities needed to meet government/BCUC/NERC/WECC requirements

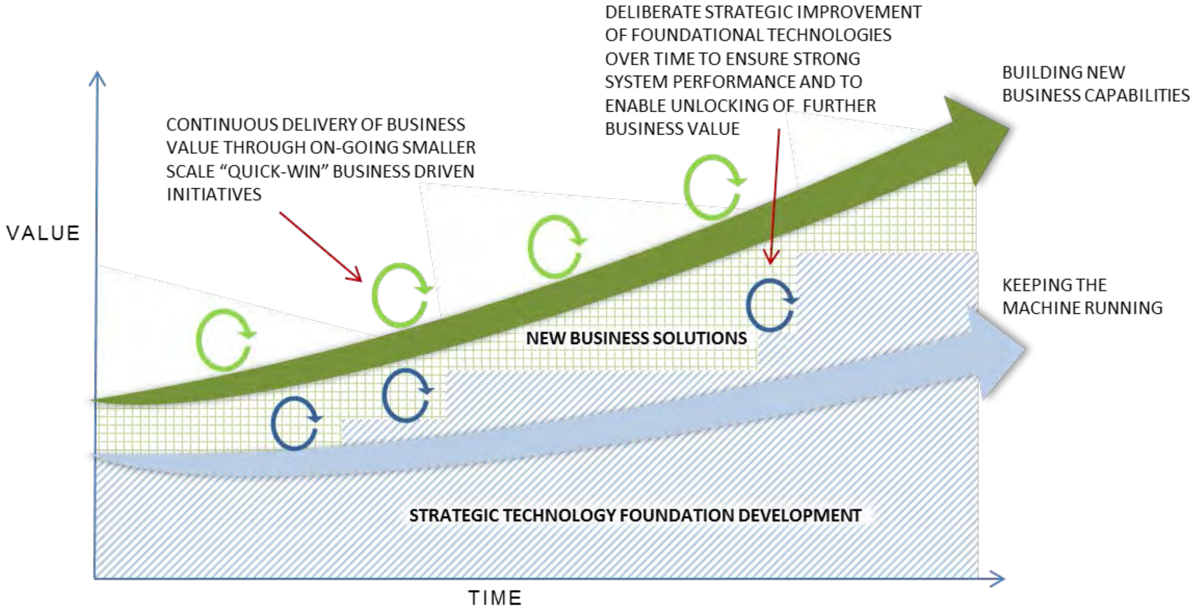
- **Work within our constraints.** Investment decisions are subject to the application of constraints due to funding, resource capacity, available skill sets, and ability of the organization to sustain and absorb change. Choices between investment options are decided through structured decision making.
- **Track the outcomes of investments**. Sponsors of technology-enabled initiatives are required to track benefits throughout implementation and into sustainment.

BC Hydro
Power smart

Technology Strategy

Principles – Value fast

- **Deliver value early and often.** Our approach is to exploit opportunities to deliver value early from interim solutions, even at a cost – provided the value exceeds the cost over the life of the interim solution. We will use "two-speed" or "agile" delivery methods, where appropriate, to expedite implementation of solutions.
- **Ensure architectural flexibility.** We will make investments that advance our delivery of value while still maintaining flexibility in our systems architecture. This allows for incremental and early value delivery, while implementing efficient and sustainable long-term foundation investments.



The diagram shows how we strive to deliver value early and often through incremental improvements (in green) while continuing to invest in our technology foundation for long term strategic business enablement (in blue)

BC Hydro
Power smart

Technology Strategy

Principles – Forward thinking

- **Build for the future.** Technology roadmaps describe how we can invest in our foundation and leverage new technologies to enable our strategic objective. The roadmaps sequence initiatives, identify decision points, and provide unconstrained scheduling of milestones to enable business outcomes. Given the dynamic nature of technology and technology industry changes as well as changes to BC Hydro's environment, our roadmaps will be updated annually. The following summaries describe current guidance for each foundation area however all initiative proposals require individual investment justification.

NETWORK CONNECTIVITY	Sustain existing wide area, field area and local area networks, as well as extend network bandwidth and coverage to our more remote sites. Continue to refresh our network equipment based on end-of-life cadence, meet current and future capacity requirements, and take advantage of software alternatives as they become available. Continue to invest in wireless networks for our facilities and vehicles to enable workforce mobility, asset management, and increased safety and security.
ENTERPRISE APPLICATIONS	Continue to upgrade our enterprise applications based on a cadence to maintain product support. As upgrades are scheduled, take advantage of opportunities to modernize current platforms as per industry direction to remain current and reduce risk of obsolescence. Implement new customer contact centre systems to replace those that are not meeting requirements of availability and reliability, as well as modernizing the stack to extend and enhance current functionality for our customers. For Enterprise Resource Planning (ERP), we have adopted a "Core ERP" approach in which SAP is our single system of record for enterprise data but the systems our users engage with may be "bolt-ons" or cloud service products. Our technology roadmap includes the implementation of supply chain and the potential future adoption (subject to our structured decision making framework) of Enterprise Asset Management and Work Management in SAP, allowing for the decommissioning of Passport. Future migration of SAP to the HANA© platform for in-memory processing, offers improved performance and easier data access.
CLOUD & DATA CENTRE	BC Hydro's approach to cloud is to adopt services on a case-by-case basis. Use cloud services as needed for compute power, specific business functionality, disaster response environment, collaboration and productivity. Continue to refresh our data centre servers, storage and other equipment based on end-of-life cadence. As equipment is replaced, leverage opportunities to consolidate racks as well as review cloud options. Leverage major product upgrades in line with the direction of our product vendors as they move to cloud platforms.

Technology Strategy

Principles – Forward thinking

MOBILITY SERVICES

Extend and improve our mobile services and mobile workforce capabilities. Continue to refresh our user's mobile phones and devices based on recommended refresh cadence, break/fix and device management requirements. Replace our existing mobile application management platform to better support device management, performance and required functionality. To facilitate future development of field worker applications, implement a suite of container services, application program interfaces (APIs) and a mobile work management platform. Strive to extend our device management capability to a broader range of devices.

GIS

Our approach is to use the ESRI platform for applications requiring GIS (Geographic Information System) and defer decisions on our Smallworld GIS applications until a major product replacement or upgrade. Focus on integrating GIS with our CAD (Computer Aided Design) tools, mobile application and ERP capabilities in order to support designers, field workers, asset management and work management. Extend our use of GIS in application development to provide geographic location search to access information, provide operational and emergency situational awareness. Continue to upgrade our GIS platforms based on a cadence to maintain product support.

PERSONAL WORKSPACE

Continue to refresh personal computing devices based on recommended refresh cadence, productivity, break/fix and device management. Upgrade our desktop environment to Windows 10 to improve performance and functionality, implement Microsoft's Office 365 suite of tools to support improved collaboration and productivity, and migrate to Microsoft Exchange Online to optimize storage capacity, ensure product support and align with product vendor direction. Upgrade our information collaboration (Sharepoint) platform and make Sharepoint online available for collaboration in the future. We expect to maintain an "on premise" presence for security and business continuity.

Technology Strategy

Principles – Forward thinking

CYBER SECURITY

BC Hydro uses a risk-based approach to cyber security and information protection. New investments are made based on compliance requirements, emerging threats and retaining our risk posture. Comply with NERC (North American Electric Reliability Corporation) CIP (Critical Infrastructure Protection) versions 5, 6 and 7. Sustain and maintain our information management systems, corporate monitoring tools, firewalls and other protection equipment based on end-of-life cadence, and risk mitigation. Leverage upgrades to modernize our architecture and optimize network segmentation through software as it becomes operationally mature. To improve our overall risk posture, apply information technology (IT) cybersecurity best practices to our operational technology (OT) environments and develop an information protection program to improve security of our systems of record, information sharing and records management platforms.

BUSINESS INTELLIGENCE & ANALYTICS

BC Hydro's direction is to adopt a self-service model for analytics in which users are given access to data and can use their own tools and analysts to meet their needs. In support of this approach, work to broaden access to our smart meter data, implement our SAP Business Warehouse (BW) on HANA© for improved performance and easier data access, and implement a virtual data warehouse to improve ability to share both enterprise and business specific data across business functional areas. In addition, implement a telematics solution for fleet data analytics, fleet asset management and fleet operations, as well as a platform for asset performance management to enable business outcomes such as enhanced condition based maintenance. Continue to leverage the Province of BC and TELUS Strategic Innovation Fund to explore implementation of an enterprise data collection platform (internet-of-things) to support business outcomes related to worker and public safety.

ENERGY MANAGEMENT

BC Hydro's grid modernization work identified opportunities for improving operations, security, safety and visibility to the grid with many of these improvements involving the deployment of digital technologies. Our approach is to take advantage of these opportunities on a case-by-case basis depending on their ability to meet our strategic objectives, the priorities of our organization, the maturity of the technologies and business constraints. Continue to upgrade our Energy Management System and Outage Management System (PowerOn) to maintain product support, and work to extend the use of our smart meter data to support outage management objectives. In the future, we expect to deploy an integrated grid management system including bulk energy system, advanced distribution management (including outage management and switching order management), distributed energy resource management and demand response management to improve performance, meet business outcomes and align with product vendor direction.

Technology Strategy

Critical success factors

Delivery of the strategy demands that we address some non-technical factors that will be critical to success:

1. **Early engagement with our business leaders on strategic direction.** Technology must be recognized as necessary to achieving the goals of the organization. Technology leaders must be invited to work closely with business leaders during their planning to understand the strategic objectives and advise on opportunities for technology enablement.

2. **Streamline our delivery processes to be fit for purpose.** We have a robust IT delivery process (ITDSP) which has served us well in providing strong guidance and oversight of our project delivery function. This process does not scale adequately for our lower risk project activity nor provide the agility needed for user facing capability development. We are developing alternative delivery models (both variants to ITDSP as well as 2-speed or agile models) to meet the needs of modern technology deployment.

3. **Resource availability and reduction in capacity bottlenecks.** Project initiation decisions must consider not only capital investment availability. Equal emphasis is required for the availability of operating funds to support the non-capital project costs and on-going sustainment costs, and availability of resources to deliver and support pre-project and project delivery activities.

4. **Portfolio management prioritization and selection processes.** Capital investment prioritization and selection must be based on a common value framework for the organization and an integrated selection process that allows for trade-offs in non-sustainment investments. Investment decisions are subject to the application of constraints due to funding, resource capacity, available skill sets, sustainment capabilities, and ability of the organization to absorb change.

5. **Funding**. The current funding model based on capital investment for technology does not support future subscription and cloud services investments that typically require operating funds. A new funding model is required to ensure the success of future technology investment and operations.

6. **Governance, risk and compliance.** Continued central governance of systems architecture and project delivery is required to optimize resources and ensure compliance with security, privacy, delivery and architecture standards and policies.

5-Year Plan

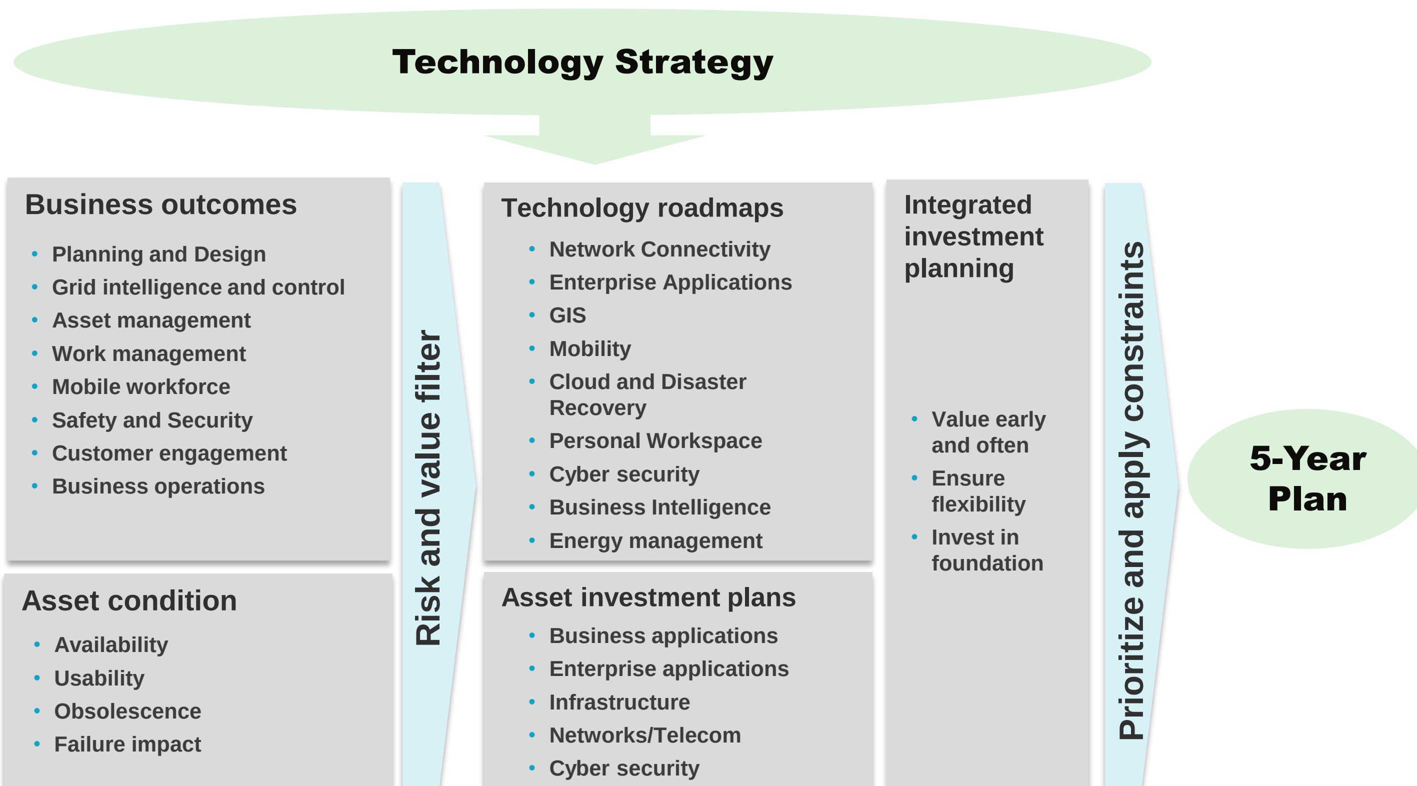
- Developing the plan
- Future business outcomes
- Prioritization and constraints
- Investment summary
- Measuring our success
- Conclusion

BC Hydro
Power smart

5-Year Plan

Developing the plan

Fundamentally, the objective of the Technology group is to enable business outcomes and sustain the availability and security of our existing assets.



BC Hydro
Power smart

5-Year Plan

Developing the plan

Over a period of six months, the Technology group facilitated over twenty workshops with business group leaders to identify desired business outcomes for the next five to ten years. Over two hundred outcomes were articulated, with approximately half of those dependent on a technical solution. These outcomes were assessed for value based on executive and senior management's best judgement on their contribution to meeting our strategic objectives. This information is used to inform our technology roadmap development.

The condition, health and longevity of our assets are assessed annually by our Technology team. Our Business Partner Services team also use their best judgement in how well the business and enterprise applications are meeting the needs of BC Hydro. This information, together with the impact of lost availability, is used to inform our technology asset investment plans.

Integrated investment planning activities bring together the technology roadmap view, the asset investment view, and alignment with business expectations. The result is our aspiration for technology investment. Application of selection and prioritization criteria, as well as funding and resource constraints, leads to the development of the five year plan.

This 5-Year Plan shows the investments currently anticipated based on BC Hydro's capital plan for the next five years. Our technology capital plan is constrained beyond 2020 and this is expected to limit investments to improve business capabilities. In the event that additional resources become available, we will focus on investments that provide opportunities for operational efficiencies.

5-Year Plan

Future business outcomes

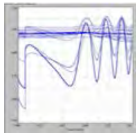
Our Technology team reviewed and aggregated the business outcomes for commonalities and determined the underlying technology investment needed. This is a summary of the aggregated business outcomes.

VALUE STREAMS

BUSINESS OUTCOMES

PLANNING & DESIGN

- Enhanced load forecasting and energy planning
- Enhanced engineering design



GRID INTELLIGENCE & CONTROL

- Distribution grid management
- Demand response management
- Digital substations
- Distributed energy resource management
- Resilient tele-communications networks

ASSET MANAGEMENT

- Integrated and optimized investment planning
- Asset performance management
- Asset intelligence for decision making
- End-to-end asset management

WORK MANAGEMENT

- Operations work planning and scheduling
- Optimized planned outage management
- Real-time monitoring and management of work

MOBILE WORKFORCE

- Ability to complete job on site
- Safety practices integrated into work process on site
- Work site awareness
- Real-time visibility to grid status on site
- Ability to collect quality information from the field

SAFETY AND SECURITY

- Resilient and secure IT and OT systems
- Real-time situation awareness during emergencies
- Physical grid security
- Automated facility security
- Enhanced dam safety systems

CUSTOMER ENGAGEMENT

- Customer inclusion in conservation and electrification programs
- Improved outage and restoration information
- Customer work booking
- Optimized customer service interactions

BUSINESS OPERATIONS

- Optimized supply chain function
- Optimized back office processes
- Enhanced data access and business intelligence
- Improved information, records management, search
- Improved employee experience, productivity and collaboration
- Workforce planning and development

5-Year Plan

Prioritization and Constraints

There are many opportunities for utilizing technology to unlock value in BC Hydro but it is not possible to achieve all outcomes all at once. Therefore, it is necessary to **prioritize** the outcomes and focus on those which we consider most important to the organization. In general, mandatory initiatives needed to address *compliance and security* are the highest priority and critical initiatives that address *risk management and sustainment of productivity* are next.

Initiative / Investment	Description
Enhance our Capability	Discretionary activities that provide new or improved business capabilities
Manage our Risk and Sustain Productivity	Critical activities needed to ensure reliable and safe operations and to maintain the current level of productivity for our users
Compliance & Security	Mandatory activities needed to meet government/BCUC/NERC/WECC requirements

Initiatives that *enhance our capability* are considered discretionary and are third in priority ranking. It should be noted, however, that these initiatives may provide significant benefits and help us in achieving our strategic objectives.

Once prioritized, it is necessary to apply our **constraints** in order to develop a plan that can be delivered with confidence. We apply a number of critical constraints including,

- The Technology team capacity
- Capital and operating funding
- Business capacity for change
- Availability of BC Hydro and contractor support resources
- Technical dependencies
- Technology maturity

5-Year Plan

Investment summary

Under the current constraints, work will continue to complete projects underway however only a limited number of new business value initiatives will be undertaken. The bolded outcomes are those that are wholly or partially addressed by major planned initiatives.

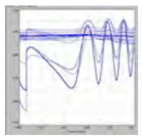
VALUE STREAMS

BUSINESS OUTCOMES

PLANNING & DESIGN

- Enhanced load forecasting and energy planning
- Enhanced engineering design

GRID INTELLIGENCE & CONTROL



- Distribution grid management
- Demand response management
- Digital substations
- Distributed energy resource management
- Resilient tele-communications networks

ASSET MANAGEMENT

- **Integrated and optimized investment planning**
- Asset performance management
- Asset intelligence for decision making
- End-to-end asset management

WORK MANAGEMENT

- **Operations work planning and scheduling**
- **Optimized planned outage management**
- Real-time monitoring and management of work

MOBILE WORKFORCE

- Ability to complete job on site
- **Safety practices integrated into work process on site**
- Work site awareness
- Real-time visibility to grid status on site
- Ability to collect quality information from the field

SAFETY AND SECURITY

- **Resilient and secure IT and OT systems**
- Real-time situation awareness during emergencies
- **Physical grid security**
- Automated facility security
- **Enhanced dam safety systems**

CUSTOMER ENGAGEMENT

- Customer inclusion in conservation and electrification programs
- Improved outage and restoration information
- Customer work booking
- Optimized customer service interactions

BUSINESS OPERATIONS

- **Optimized supply chain function**
- Optimized back office processes
- Enhanced data access and business intelligence
- Improved information, records management, search
- Improved employee experience, productivity and collaboration
- Workforce planning and development

5-Year Plan

Investment summary

With the application of prioritization and constraints, our investments over the next five years will be driven primarily by compliance, security and sustainment. There will be some investment in managing our safety, operations and business risk with limited opportunities to improve business capabilities. Major initiatives are listed here under the appropriate outcome.

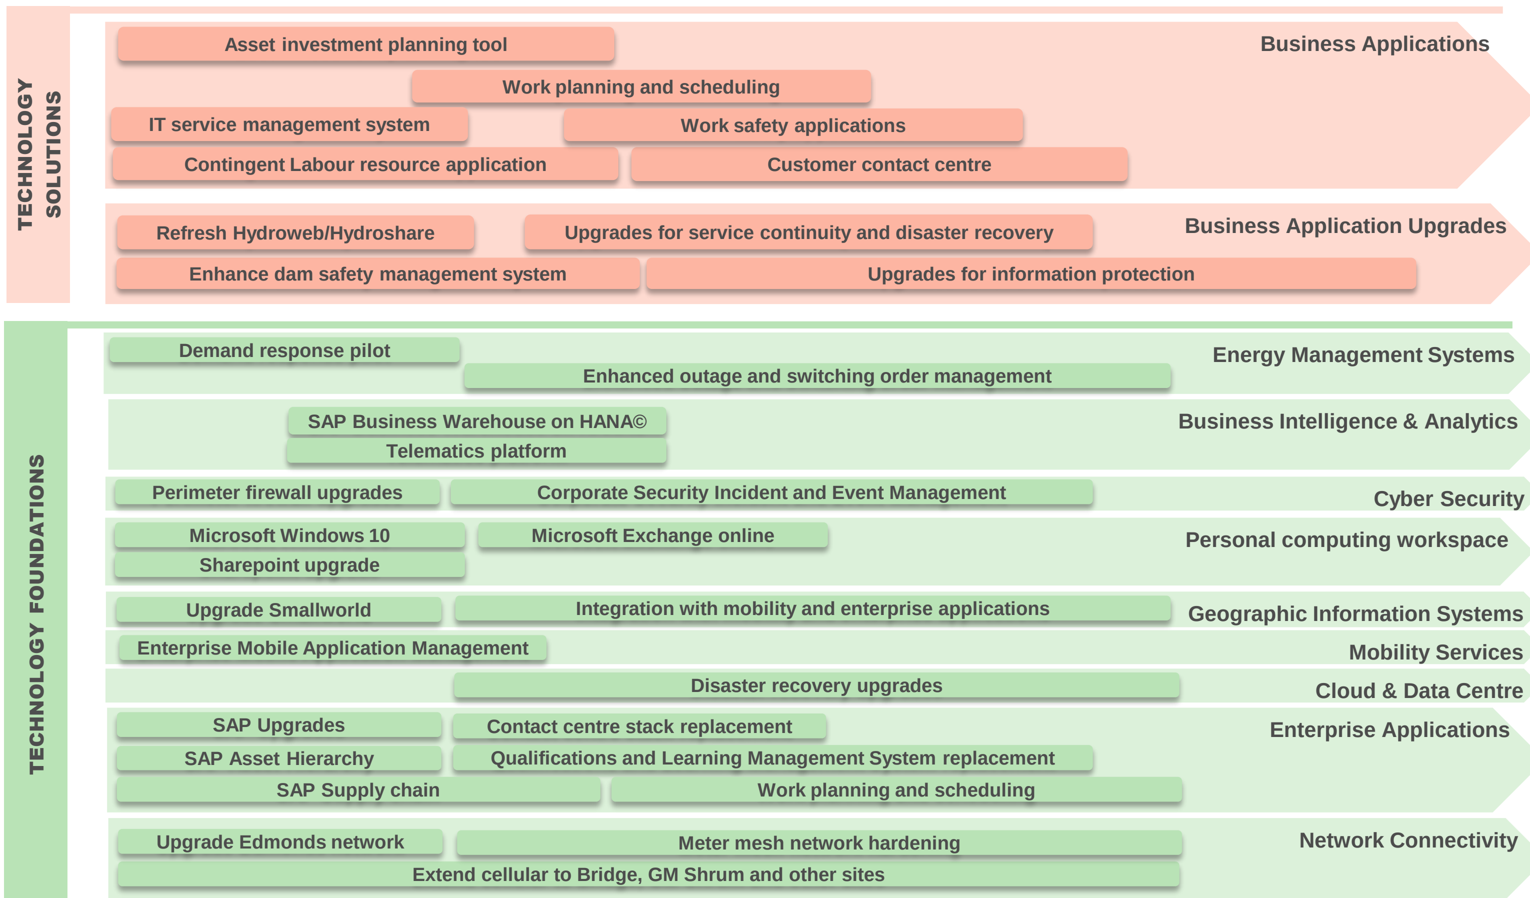
Investment category	Outcome description
Enhance our Capability	**Integrated and optimized investment planning** • Asset investment is integrated and optimized based on enterprise priorities • Information is available for vehicle asset optimization and performance management **Operations planning and work scheduling** • Work is scheduled centrally based on priority, available skillsets and location of resources (partial) **Optimized planned outage management** • Integrate planned outage management across Generation Supply Operations and Grid Operations **Optimized supply chain function** • Optimized process for procuring contingent labour resources • Optimized supply chain processes
Manage our Risk and Sustain Productivity	**Resilient OT and IT systems** • Sustain systems to ensure product support and systems availability • Improve service continuity and disaster recovery capability **Safety practices integrated into work processes on site** • Access to safety information and worker (including contractor) qualifications confirmed on site **Enhanced dam safety systems** • Dam safety engineers have easy access to dam safety information • Sensor and telecommunications networks are extended to increase dam safety visibility
Compliance & Security	**Physical grid security** • Ensure compliance with NERC CIP regulation **Secure OT and IT systems** • Maintain our cyber security risk posture

5-Year Plan

Investment summary

The diagram below shows the sequence of technology investments required to support planned initiatives.

Time



5-Year Plan

Measuring our success

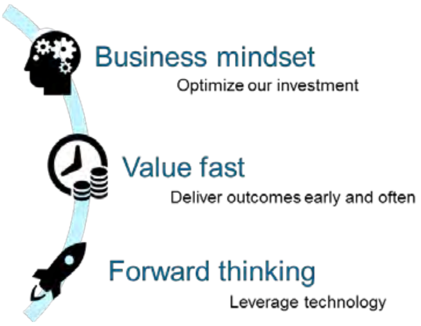
The Technology group has a variety of ways to track and measure the success of our capital investments. These range from the immediate and quantifiable, such as operational and delivery metrics, to the completely qualitative business satisfaction survey. We recently introduced a benefits tracking process for business capability driven initiatives. In this process both quantitative and qualitative assessments are made over a period of time following deployment of a solution.

- **Operational Metrics** – Technology uses a number of metrics to evaluate and track the performance of our systems, services, and vendors.
- **Delivery Metrics** – Technology uses a number of metrics to assess and track the performance of our delivery which include measures on cost, schedule, and quality.
- **Business satisfaction** – Technology conducts an annual satisfaction survey to solicit feedback from across the business of the level of satisfaction with Technology delivery and services.
- **Project Benefits** – Benefits from initiatives undertaken as part of implementing technology solutions will be tracked to assess how well they deliver on the expectations set out in their respective business cases.

Technology Strategy and 5-Year Plan

Conclusion

Our strategy describes BC Hydro's landscape and the drivers that influence our future business and technology decisions; our overall objective is to help BC Hydro achieve its service plan goals through the use of technology. We identify eight value streams across BC Hydro through which technology can unlock significant benefits. Our approach is to operate with a *business mindset*, to deliver *value fast*, and to be *forward thinking* in all we do.



BC Hydro's 5-Year Technology Investment Plan identifies expected business outcomes from across planning, delivery, operations and business support functions. The outcomes are assessed based on their ability to help achieve our service plan objectives. Following prioritization and the application of constraints, the Plan describes the outcomes we expect to achieve in the next five years and the corresponding investments in technology.

We must also sustain and maintain our existing systems. Investments for sustainment include refreshes for infrastructure, personal devices, network, telephony and cyber security assets, as well as upgrades and replacement of business and enterprise applications.

The plan reflects corporate planning activities and uses input from BC Hydro's executive and senior managers as well as the Technology subject matter experts. BC Hydro uses an annual planning cycle to maintain currency of plans and adapt to changes. We expect to update this plan annually.

Appendix M

Asset Health - Generation

Table of Contents

1 Introduction

Equipment health is assessed for Generation, Transmission and Distribution assets. The information is used for the life-cycle management of assets, including supporting the need for capital investments. The methodologies used provide a systematic, objective, repeatable, and transparent assessment of asset health.

In December 2018, the Office of the Auditor General of B.C. released an independent audit of Capital Asset Management in BC Hydro. This audit is included as Appendix F. With regards to BC Hydro's asset health information, the audit stated:

> "Asset information is current and reliable
>
> BC Hydro has collected the information it needs to support good asset management practices. BC Hydro knows the service requirements that its electricity-generating, transmission and distribution capability must meet. This knowledge is informed by information about its assets that is current, comprehensive and routinely updated. Within its asset knowledge base, BC Hydro keeps records of asset condition and monitors asset performance, information that in turn informs decision-making and planning functions.
>
> BC Hydro uses an equipment health rating methodology, which captures in a standardized way the actual performance of equipment, relative to design specifications and operational expectations, as well as maintenance activity and service life estimates. BC Hydro has been working to ensure that these records are all up to date and has put in place monthly inter-unit meetings to discuss emerging equipment issues or unanticipated events that could affect asset performance and trigger needed action."

Summaries of the methodologies and Generation asset health information are provided below.

2 Generation Equipment Health Ratings

Generation periodically evaluates the condition of its major assets (turbines, generators, governors, exciters, transformers, and circuit breakers) based on the latest available maintenance test and inspection data. Health assessments are based primarily on asset condition but also consider safety and environmental issues, reliability, design deficiencies, asset age and industry expected life and availability of spare parts and technical expertise.

Each health assessment results in a rating of Good, Fair, Poor, or Unsatisfactory:

- **Good:** The asset is in as new condition, with no noticeable deterioration or defects;
- **Fair:** There is some normal deterioration of the asset with one or more minor defects; function is not affected;
- **Poor:** There is serious deterioration of the asset or serious defects in at least some portions of the asset; function is affected; and
- **Unsatisfactory:** There is extensive deterioration of the asset and the asset no longer functions as designed.

Assets that have an Equipment Health Rating of Poor or Unsatisfactory are considered to have an increased likelihood of failure. Assets assessed as being in unsatisfactory condition are believed to have the highest likelihood of failure, with capital investment or replacement generally recommended within the next five to seven years. Investments in assets assessed as poor are generally considered with the next 10 to 12 years.

Equipment Health Ratings for Generation assets as of April 2018 are provided below.

Asset Health – Transmission and Distribution

Table of Contents

List of Tables

1 Introduction

Asset Health is assessed on a regular basis for all BC Hydro assets. Transmission and Distribution Asset Management developed a methodology called Asset Health Index to evaluate the health of Transmission and Distribution assets. The information is used for the life-cycle management of assets, including supporting the need for capital investments. The methodology provides a systematic, objective, repeatable, and transparent assessment of asset health.

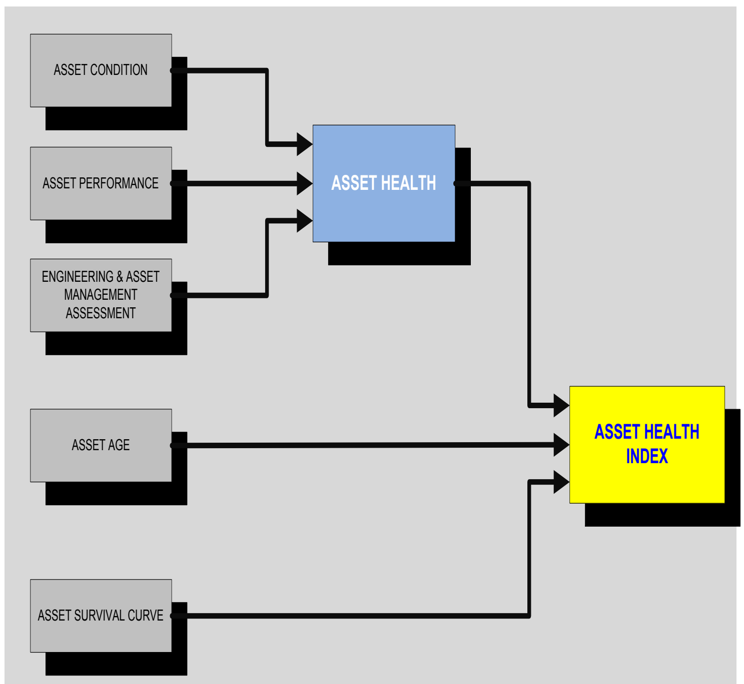
In December 2018, the Office of the Auditor General of B.C. released an independent audit of Capital Asset Management in BC Hydro. This audit is included as Appendix F. With regards to BC Hydro's asset health information, the audit stated:

> "Asset information is current and reliable
>
> BC Hydro has collected the information it needs to support good asset management practices. BC Hydro knows the service requirements that its electricity-generating, transmission and distribution capability must meet. This knowledge is informed by information about its assets that is current, comprehensive and routinely updated. Within its asset knowledge base, BC Hydro keeps records of asset condition and monitors asset performance, information that in turn informs decision-making and planning functions.
>
> BC Hydro uses an equipment health rating methodology, which captures in a standardized way the actual performance of equipment, relative to design specifications and operational expectations, as well as maintenance activity and service life estimates. BC Hydro has been working to ensure that these records are all up to date and has put in place monthly inter-unit meetings to discuss emerging equipment issues or unanticipated events that could affect asset performance and trigger needed action."

Summaries of the methodology and Transmission and Distribution asset health information are provided below.

2 Transmission and Distribution Asset Health Index

Asset Health Index is derived from operating, maintenance and asset management data. The methodology is described below.



The index is used to predict the asset's future performance and investment needs. Asset Health Index ratings and possible investment needs are:

Very Good	Normal maintenance
Good	Normal maintenance
Satisfactory	May require increased diagnostics and component replacement
Poor	Overhaul or replacement may be required within four to ten years
Very Poor	Overhaul or replacement may be required within three years

Asset Health Index can be grouped and analysed by asset class and/or criticality. Below are Asset Health Index charts for Transmission and Distribution asset classes as of April 2018:

Table N-1 Asset Health Index Summary

T&D Assets	Number of Assets (% of Total Assets)	% of Asset Replacement Value
		100 90 80 70 60 50 40 30 20 10
T&D Assets	4,056,320 (100%)	
Transmission	125,474 (3.1%)	
Substation	54,361 (1.3%)	
Distribution	3,876,485 (95.6%)

Executive Summary

This report is a forecast of electricity sales to our customers and total gross system electricity requirements from F2019 to F2024. We developed the October 2018 Load Forecast for the F2020-F2022 Service Plan and the F2020-F2021 Revenue Requirements Application (F20-F21 RRA). This report is supplemental to the October 2018 Load Forecast information presented in chapter three of the F20-F21 RRA. Its purpose is to provide further information on the methodology and drivers underlying the results.

After introducing key concepts, we detail out the methodology and results of the component sector forecasts that make up the October 2018 Load Forecast. Where applicable, these methods and results are presented alongside an alternative forecast based on FortisBC Electric's short-term forecasting approach as applied to BC Hydro's context. We provide this additional analysis in light of the F17-F19 Revenue Requirement Application Decision's observation that other B.C. utilities use different forecast methodologies for the short term.

We begin with component forecasts for our major sectors:

- Residential
- Commercial
- Light Industrial
- Large Industrial

These sector forecasts are followed by details on the anticipated demand from emerging technologies: the cannabis and cryptocurrency industries and demand from electric vehicles. Sections 11 and 12 discuss the October 2018 Load Forecast uncertainties and provide an analysis of the challenges in estimating the electricity savings from codes and standards.

The summary table on the following page contains the results of our October 2018 Load Forecast on a billed sales basis from fiscal 2019 to fiscal 2024. In addition to developing this mid sales forecast, we also develop a total high and a low band around the mid forecast. The high and low bands are prepared using a Monte Carlo uncertainty model. The bands represent a range in future demands for electricity before savings from demand side management (DSM) and demonstrate some of the range of uncertainty.

In summary, our total firm sales forecast is expected to grow by 0.5 per cent per year[1] over the next six years, after adjusting for rate impacts and our DSM plan. Most of this growth is due to increased natural gas sales (in both upstream and downstream facilities) in the Large Industrial Sector. Large Industrial sector sales are forecast to grow by approximately 1.2 per cent per year. We are also forecasting a 1.5 per cent annual sales growth in the light industrial sector, primarily driven by expected growth in the emerging cannabis and cryptocurrency industries. Forecast residential sector sales are expected to experience relatively modest growth at 0.6 per cent per year. In contrast, commercial sector sales are expected to decline by 0.6 per cent annually over the forecast period. This decline is a result of slower projected growth in economic drivers, increases in the efficiency of how commercial customers use electricity, an update to the commercial model's calibration period, as well as the impacts of BC Hydro's DSM savings.

[1] Unless otherwise stated historical values and forecasts of electricity sales are computed on an annual compound basis.

October 2018 Load Forecast (Billed Sales) - After Rate Impacts and after Demand-Side Management[1]												
Fiscal Year	Main Customer Sectors					Other Loads				Low with DSM Total Domestic Sales (GWh)	Mid with DSM Total Domestic Sales (GWh)	High with DSM Total Domestic Sales (GWh

Table notes:

1. All forecast values includes all load reductions for rate impacts, DSM savings, and savings from loss reductions.
2. Light Industrial/Commercial is the sum of the loads in the light industrial sector and commercial sector.
3. Total Domestic Sales is the sum of the loads from the Main Customer Sectors and Other Loads.
4. The forecast for fiscal 2019 reflects six months of actuals billed sales and six months forecast on a billed sales basis.
5. Growth rates are computed on an annual compound growth basis over five years.

Table of Contents

1.0 Introduction

BC Hydro is the third largest utility in Canada and serves 95 per cent of British Columbia's population. BC Hydro's total energy requirements, including losses and sales to other utilities and non-integrated areas (NIAs), were 57,842 GWh in fiscal 2018. Excluding the NIAs, the total integrated system energy requirements were 57,527 GWh.

Load forecasting is central to BC Hydro's long-term planning, medium-term investments, and short-term operational & forecasting activities. BC Hydro's Electric Load Forecast is developed for the purpose of providing decision-making information for electricity rates, as well as where, when, and how much electricity we expect to need from the BC Hydro system. About two thirds of the forecast is based on Statistically Adjusted End Use (SAE) econometric (regression) models that use historical billed sales data combined with economic forecasts and inputs from internal, government and third party sources. The other one third of the forecast is derived from individual forecasts of our large industrial customers.

BC Hydro's load forecasting activities are focused on the preparation of a number of time and location specific forecasts of energy sales requirements in order to provide information for decision makers.

Given the variety of uses, our load forecast consists of a suite of forecasts, each of which fulfills different user requirements. For example, integrated system energy planning considers system losses associated with delivering energy from generation resources to our customers, but not the forecast demand from customers that are not connected to our integrated system (i.e., this is referred to as our total integrated gross system requirements). Revenue forecasting includes all customer demand (i.e., domestic sales, including non-integrated customers, sales to other utilities, and firm exports), but does not consider losses or BC Hydro's own use. In addition, the British Columbia Utilities Commission (BCUC) requires us to separately reflect the impacts associated with future electricity price increases (rate impacts) and demand side management plan (DSM) savings. Rate impacts are load reductions estimated using price elasticity and bill impact projections in real dollars (net of inflation). The projection of bill impacts reflected in the October 2018 Load Forecast is based the last five years of the 2013 Ten-Year Rates Plan.

We develop high and low uncertainty bands which represent ranges around the mid or expected forecasts at certainty levels of statistical confidence. These high and low uncertainty bands are produced because there is uncertainty in the input variables that predict future loads and in the predictive capabilities of the forecasting models themselves.

BC Hydro developed the October 2018 Load Forecast for its annual Fiscal 2020-Fiscal 2022 Service Plan and the Fiscal 2020-Fiscal 2021 Revenue Requirements Application (i.e., F20-F21 RRA). The October 2018 Load Forecast presented in this report is a forecast of electricity sales by customer sector and total gross system electricity requirements from fiscal 2019 to fiscal 2024. The CleanBC Plan, released by government in December 2018, is not reflected in the Load Forecast which was finalized in October 2018. By 2030, the CleanBC Plan could require approximately 4,000 gigawatt-hours of energy over and above currently projected demand growth to electrify key segments of the economy. Some of the implications of this include a further commitment to electric vehicle incentives which may mean more electric vehicle sales and associated loads, increased building load, and increased natural gas sector load. This information will be incorporated in our future forecasts.

Following the BCUC's requirements, we produce three types load forecasts:

- before considering rate impacts, DSM and loss reductions,[2]
- after considering rate impacts, but before DSM and loss reductions, and
- after considering rate impacts, DSM and loss reductions.

[2] Loss reductions were referred in our F2017 to F2019 Revenue Requirements Application as Var and Voltage Optimization (VVO) savings.

The Load Forecast information presented in chapter three of the F20-F21 RRA is our forecast of sales after taking into account rate impacts, incremental DSM savings and savings from our loss reductions program, which account for efficiencies at BC Hydro's distribution substations to minimize line losses. The loss reduction program is separate from our DSM plan.

This report is supplemental to our October 2018 Load Forecast contained in our F20-F21 RRA. BC Hydro develops an electricity sales forecast for each of its main customer sectors including: residential, commercial, light industrial, and large industrial. We also develop a forecast of electricity sales to other utilities and firm exports supplied by BC Hydro. The methods and forecasts for each sector as well those for other utilities and firm exports are the focus of this report. Where vintages of forecasts are compared, the October 2018 Load Forecast is contrasted with the May 2016 Load Forecast – our last 20-year forecast.

This report details the methodology and results of our October 2018 Load Forecast on a billed sales basis as historical billed sales data from our billing system underpins our load forecast methods. Our F20-F21 RRA presents the Load Forecast on an accrued sales basis because accrued sales are used to estimate revenues on a monthly and fiscal year basis. An explanation of the difference between billed and accrued sales forecasts is provided in Section 2.2.3.

The next section provides an overview of the components and steps involved in developing our total gross system requirements forecast. This is followed by a discussion of methodology improvements we have incorporated into the October 2018 Load Forecast. After the methodology discussion, the forecasts for each customer sector are summarized. Where applicable, these methods and results are put alongside an alternative forecast based on FortisBC Electric's short-term forecasting approach as applied to BC Hydro's context. We provide this additional analysis in light of the F17-F19 RRA Decision's observation that other B.C. utilities use different forecast methodologies in the short term. Finally, each sector's risk and uncertainties are discussed.

The customer sector forecasts are followed by details on the anticipated demand from emerging sub-sectors and technologies: the cannabis and cryptocurrency industries, and demand from electric vehicles. This is followed by our forecast uncertainty bands as determined by our Monte Carlo uncertainty model and a discussion on the integration of codes and standards between our forecasting methods and our DSM plan where code and standards are common to both.

Finally, the most detailed information is available in the appendices supplementing each section. They include:

- a comparison between the October 2018 Load Forecast and the May 2016 Load Forecast,
- a general description of the SAE model and equations,
- improvements to the SAE models,
- the summary statistics and regression results of our October 2018 SAE models,
- our temperature normalization procedures for the residential and commercial sectors and residential accounts improvements,
- economic and other drivers of the forecasts, and
- summary tables containing the October 2018 Load Forecast.

2.0 Load Forecast Components

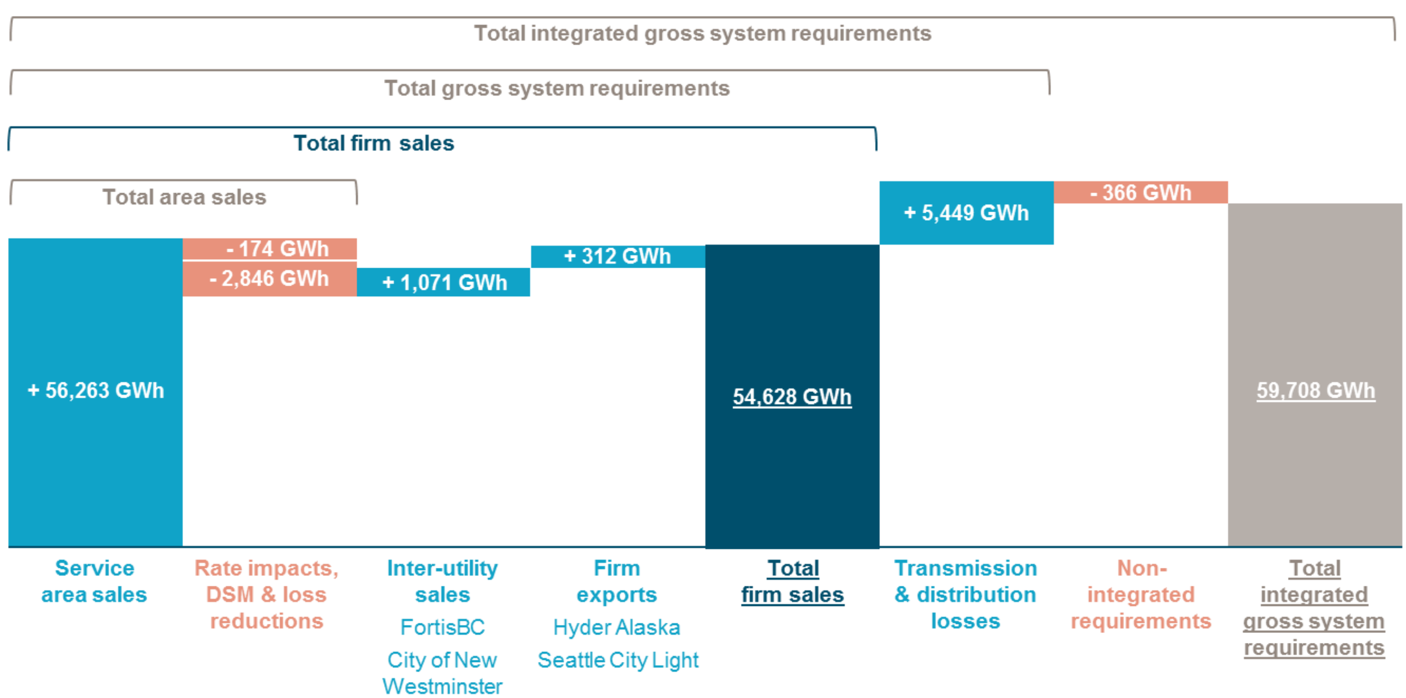
The highest level of our forecast is called the integrated gross system requirements. It is used to optimize operation of our system in the short-term and to plan our system over the long-term. For short-term analysis, the forecast is used by BC Hydro's Generation System Operations business unit in monthly energy studies. The analysis from these studies yields a forecast of the volume of market purchases and costs of market purchase, which is part of the total cost of energy included in our revenue requirements applications.

The forecast of BC Hydro's total gross system requirements is built up from a series of components and steps, including:

- A forecast of electricity sales to all customers in our service area (service area sales). This includes a forecast for our main customer sectors (i.e., residential, commercial, light industrial and large industrial) and other loads including street lighting customers, irrigation customers, and electricity used by BC Hydro assets, such as distribution substations. We refer to this BC Hydro asset-related consumption as BC Hydro own use,
- A forecast of electricity sales to other utilities supplied by BC Hydro under contracts and tariffs. Service area sales plus sales to other utilities results in total firm sales, and
- A forecast of system distribution and transmission losses (i.e., total losses). Total firm sales and total losses results in total gross system requirements.

Figure 2.1 illustrates the build-up of our forecast of total gross system requirements and integrated total gross system requirements based on one of the three forecast types, namely: after taking into account rate impacts and savings associated with our DSM plan and loss reductions program.

Figure 2-1 Build-up of Total Integrated Gross System Requirements Forecast after Rate Impacts, DSM and Loss Reductions for Fiscal 2024



The loads used to develop each of the major components of total integrated gross system requirements are summarized in the following sections.

2.1 TOTAL AREA SALES

The forecast of our service area constitutes most of our main customer sectors (i.e., residential, commercial, light industrial, large industrial, etc.) and involves the most significant aspects of our load forecasting process. Each customer sector is developed using the following steps.

2.1.1 Model projections are used for each main customer sector

Model projections are forecasts for our main customer sectors: residential, commercial, light industrial, and large industrial. These are laid out in the early sections of this document:

- Section 4 outlines our projections of electricity sales to the residential sector,
- Section 5 outlines our projections of electricity sales to the commercial sector,
- Related to the residential and commercial sector model projections:
  - Section 12 describes the adjustment to account for a potential double counting because of an overlap in codes and standards. This overlap occurs because there are energy savings from codes and standards that are reflected in both our DSM plan and the US Energy Information Administration (EIA) assumptions included in the SAE model.
- Section 6 outlines our electricity sales forecast to the light industrial sector, and
- Section 7 outlines our electricity sales forecast for the large industrial sector. The industrial sector forecast is a summation of the individual customer forecasts for about 190 large industrial customers.

2.1.2 Load additions

In addition to our model projections, unique customer segments and technologies are also added in our customer sector forecasts:

- expected loads for the cannabis and cryptocurrency customer segments are included in the light industrial and large industrial sector and described in Section 8,
- a forecast of electric vehicle load, included in our residential and commercial sector forecasts, is outlined in Section 9,
- fuel switching loads based on specific government or BC Hydro programs that incent customers to switch from fossil fuel-based energy to clean electricity are added to the residential, commercial, light industrial and large industrial sectors, and
- construction loads are included in the light industrial sector.

2.1.3 Load reductions

Service area loads are reduced to account for rate impacts, DSM savings and loss reductions.

Load reductions that result from rate impacts are calculated separately for each of our main sectors. Rate impacts are based on:

- an electricity price elasticity of -0.1 applied to the major sectors including residential, light industrial, commercial, and customers that make up the large industrial sector, and
- a projection of real dollar (i.e. net of inflation) bill impacts informed by the last five years of the 2013 Ten-Year Rates Plan.

The incremental savings from our DSM plan and loss reductions program are also computed separately for each customer sector and at the BC Hydro service area level. The forecast of DSM savings reflected in our October 2018 Load Forecast is based on our latest DSM plan, which is included in our F20-F21 RRA. DSM savings from fiscal 2019 to fiscal 2024 are based on incremental activities to the fiscal 2018 base year which was the last year of actual sales.

BC Hydro's DSM plan is comprised of a number of initiatives that have the objective of reducing customers' energy consumption and by doing so, reducing their electricity bills. The main components of BC Hydro's DSM plan are:

- Programs: Programs are available to all customer sectors and deliver a mix of information, access to technology and services, technical assessment and support, and financial assistance to all customer classes to address barriers to cost effective DSM. Programs are designed to capture additional DSM potential that remains beyond that obtained from codes and standards and rate structures.
- Codes & Standards: Codes and standards refer to a range of government policy instruments that influence the use of energy, including product/equipment regulations, building codes, tax measures. BC Hydro supports the development of these codes and standards and also works with communities on municipal zoning/building permitting processes, as well as enhanced approaches for Indigenous and remote communities.
- Rates: Rate structures are changes to the design of electricity rates to provide more economically efficient price signals to customers which encourage conservation. BC Hydro currently has conservation rate structures in place for residential and large industrial (transmission voltage) customers.
- Supporting Initiatives: Supporting initiatives include public engagement and awareness activities and general management and infrastructure.

The forecast of loss reductions are developed for our distribution system and are also incremental to the fiscal 2018 base year. Loss reductions are applied to residential, light industrial and commercial sectors on load share basis.

2.1.4 Other elements of service area

Forecasts for other small loads such as irrigation customers, street light customers and BC Hydro's own use are developed separately and these forecasts are included as part of our total area sales. With the exception of BC Hydro own use, all of these loads are developed with trend analysis.[3] The forecast of BC Hydro own use is developed with trend analysis for the base load and supplemented with additional construction load for the Site C Project. The construction loads are based on estimates provided to BC Hydro from the various contractors involved in the construction of the Site C Project. The details of the trend analysis and forecast results for these other loads are not covered in this report.

2.1.5 Inter-utility sales and firm exports

The next component represented in Figure 2-1 includes sales to the City of New Westminster and FortisBC Electric. Sales to these two utilities make up total inter-utility sales. Sales to Seattle City Light and Hyder, Alaska make up total firm exports. Rate impacts using the same price elasticity and bill impact projections as described above are applied to loads from the City of New Westminster and Hyder, Alaska. Sales to Seattle City Light are determined by a treaty and as such rate impacts are not applied. For sales to FortisBC Electric, rate impacts are built into a methodology that determines the electricity sales. That methodology and the forecasted inter-utilities sales and firm exports are detailed in Section 10. The combined forecast of inter-utilities sales, firm exports, and total area sales is the forecast of total firm sales.

2.1.6 Transmission and distribution losses

Transmission and distribution losses are developed by applying loss factors to the individual loads that make up total firm sales. These loss factors result in a forecast of system wide losses which are close the average of actual system wide losses (i.e., transmission and distribution). The actual transmission & distribution losses are calculated as the difference between actual total system gross system requirements and actual total firm sales.

[3] The forecast is based on historical growth trends. BC Hydro is in the process of approving its business case to replace street lights with LED technology. The potential roll-out of this program will not have a material impact on the total load over the forecast period (expected to be about 20 GWh/year), but will be monitored for impacts to future load forecasts.

With the forecast of transmission and distribution losses in hand, total gross system requirements, as shown in Figure 2-1, is arrived at by adding total firm sales.

2.1.7 Total integrated gross system requirements

Finally, total integrated gross system requirements is calculated by reducing total gross system requirements by the portion of sales and losses from loads in our Non-Integrated Areas (NIA). Section 10 defines NIA and its forecasts.

2.2 TYPES OF LOAD FORECASTS

2.2.1 BCUC required forecasts

Following the BCUC Resource Planning Guidelines, BC Hydro develops three types of forecasts:

- before considering rate impacts, DSM and loss reductions,
- after considering rate impacts, but before DSM and loss reductions, and
- after considering rate impacts, DSM and loss reductions.

These forecast types allow us to identify the specific effects associated with future electricity price (rate) increases and DSM savings. Each type is calculated as a mid (expected) load for each of the forecast components outlined previously in Section 2.1.

For example, we have three forecasts of total firm sales:

- the forecast of total firm sales before rate impacts includes all model projections for main sectors, adjustments, load additions, forecasts for irrigation customers, street lights customers, BC Hydro own use, and sales to inter-utilities and firm exports,
- the forecast of total firm sales after rate impacts is the same, but also includes the effects of rate impacts, and
- the forecast of total firm sales after DSM and loss reductions is the same as total firm sales after rate impacts, but includes load reductions for DSM and loss reductions savings.

This convention for naming the three types of forecasts is used through the rest of the document.

When each of the other forecast components is calculated in the same three ways, they can be combined to make up three types of total gross system requirement and integrated gross system requirements, and the results for these forecasts are summarized in tables contained in Appendix G of this report.

2.2.2 Forecasts to characterize uncertainties

To quantify the various uncertainties in the factors that increase or decrease load, BC Hydro develops a high and a low uncertainty band around our mid forecast after rate impacts. The high and low uncertainty band, for each year of the forecast, comes from our Monte Carlo uncertainty model and a simulation process. The details of our Monte Carlo uncertainty model, the equations of the model, and the results of the model are contained in Section 11 of this report.

2.2.3 Billed and accrued sales forecasts

Total billed domestic[4] sales after load reductions for rate impacts, DSM, and loss reductions savings is the foundation of our electricity sales projections for our revenue requirements with one exception. The forecasts for the residential, light industrial and commercial sectors are developed on an accrued sales basis for our revenue requirements application because accrued sales are used to estimate monthly and fiscal year revenues for these sectors.

[4] Domestic sales are total area sales, excluding BC Hydro own use, and sales to inter–utilities and firm exports.

Page 13 of 170

In general terms, historical billed sales represent what was billed to our customers in a month and over a fiscal year in line with our billing cycle, while historical accrued sales are estimates of actual electricity consumption in a month and over a fiscal year. Our forecasts are based on relationships between load drivers and billed sales. As such, the forecast of future customer loads are in the form of billed sales projections. Revenue projections from these future loads are based on accrued sales which are estimates derived from monthly billed sales. As such, the forecasts of future loads for our customers in our revenue requirements application are in the form of accrued sales.

The electricity sales data contained in this report is different to sales data contained in Chapter 3 of our F20-F21 RRA. These differences occur in the following areas:

First, all of the history and forecasts for the residential, light industrial / commercial, and large industrial sectors contained in this report are on a billed sales basis. All of the history and forecasts for these sectors in our F20-F21 RRA are on an accrued sales basis, with the exception of the large industrial sector where the forecasts for this sector as shown in our F20-F21 RRA is on billed sales basis.

Secondly, all history and forecasts for light industrial and commercial sectors in this report are shown separately on a billed sales basis. Our F20-F21 RRA shows the combined total history and forecasts of the light industrial and commercial sector and it refers to the combined sector as the light industrial / commercial sector.

Finally, the summary tables in Appendix G of this report contain total firm billed sales and total domestic billed sales. Total domestic sales are total area sales, excluding BC Hydro own use, and sales to other utilities and firm exports. BC Hydro own use is not included in our calculation of revenues. Summary tables in our F20-F21 RRA contain total domestic sales on accrued sales basis.

2.2.4 Consideration of an alternative forecast

We developed alternative forecasts for the residential and commercial sectors in response to commentary in the BCUC's F17-F19 RRA Decision. We found that the results based on forecasts using the alternative methodology did not perform better than those derived from our approach. Further details on the comparison between the forecasts developed using the alternative method and the forecasts developed with our approach for the residential and commercial sectors are contained in sections four and five respectively.

In the F17-F19 RRA Decision, the BCUC noted that some utilities in B.C. use a different load forecast methodology in their short term forecast for setting rates. We reviewed the short term load forecast methodologies of Fortis BC Energy Inc. (Gas), FortisBC Electric, Pacific Northern Gas West, and PNG Gas East. We selected FortisBC Electric as a comparable alternative because it is the other major regulated electric utility in B.C. In addition, we found their methodology compatible with our customer data, allowing for a more direct comparison between our methodology and theirs.

The table below compares our current methodology to that of FortisBC Electric.

Table 2-1 Comparison of BC Hydro's and FortisBC Electric's Short-Term Load Forecast Methodologies

Sector	BC Hydro October 2018 Load Forecast methodology	FortisBC Electric short term methodology
Residential	An SAE model is used to forecast average use per residential account in each of BC Hydro's four major service regions. Refer to Section 4.2.3.1 for more information on the residential SAE model. The account growth is based on historical ratio of accounts growth to housing growth and housing growth forecasts, which are provided by the Conference Board of Canada, June 2018 Economic Forecast.	The forecast of average use per account is established with a three year historical trend line of temperature normalized use per account. The time trend is assumed to continue into the future to develop the forecast. The residential account forecast is based on a regression of historical accounts and population statistics which are provided by BC Statistics.

Commercial	SAE models are used to forecast electricity sales for both small commercial customers and large commercial customers in each of BC Hydro's four major service regions. Refer to Section 5.2.1 for more detail on the commercial SAE model.	The commercial sector forecast is based on a regression analysis of load to provincial GDP. The GDP forecast is provided by the Conference Board of Canada.
Large Industrial	BC Hydro has approximately 190 large industrial customers, and forecasts load for this sector is developed for each customer. Forecast load for each account is developed using a probabilistic assessment of future customer sales. This assessment relies on intelligence from external consultants who are industry and/or plant experts, as well as third party market subscription services. The assessment also relies on customer information provided by BC Hydro's key account managers who liaise directly with our customers. Based on the probability weighting for each customer, BC Hydro makes an "in or out" call on the variability of each account for the test period years. The methodology for the large industrial sector is explained in more detail in Section 7.2 of this report.	FortisBC Electric has approximately 50 large industrial customers. Forecast load for these customers is developed based on confidential updates shared by customers through surveys conducted by FortisBC Electric. Where customer information is not available, FortisBC Electric applies GDP growth rates to each of its customers.

We did not develop an alternative large industrial forecast based on the FortisBC Electric method. Both utilities use customer information to develop their respective large industrial sector forecasts, making a direct comparison impossible. In addition, Section 7 shows how our large industrial forecast methodology goes beyond just customer information in our attempts to refine the performance of our large industrial forecast.

3.0 Improvements to the Load Forecast

In this section we address improvements since the May 2016 Load Forecast, which were a product of our continuous improvement efforts, and feedback from a BC Hydro internal audit as well as two BCUC reviews. Significant improvements, which are discussed in Section 3.2, include:

- changes to the Liquefied Natural Gas (LNG) forecast methodology,
- SAE model improvements,
- residential sector accounts forecast, and
- adjustments to price elasticity values.

3.1 EXTERNAL REVIEWS OF THE LOAD FORECAST SINCE THE MAY 2016 FORECAST

An August 2017 audit of our load forecasting function endorsed the overall load forecast methodology, while making some recommendations on how to improve, which have been incorporated into the October 2018 Load Forecast.

The audit of our load forecasting function was completed by BC Hydro Audit Services (Load Forecasting Audit). The objective was to review load forecasting processes to ensure timely and reliable forecasts. A copy of this audit is included as Appendix P in our F20-F21 RRA.

The audit relied on an independent subject matter expertise from GDS Associates Inc. GDS is a U.S. based firm with experience with load forecasting in the electrical utility industry. The principal at GDS who undertook the work has over 30 years of load forecasting experience. His knowledge included preparing load forecasts for utility clients (ranging from day-ahead to annual and long-term time frames), and filing regulatory testimony related to load forecasting and statistical analyses.

GDS's findings, which were adopted by the Load Forecasting Audit, included:

- "Overall, the load forecasting function at BC Hydro compares favorably to industry standards and to other large electric utilities in North America. No critical weaknesses were found."
- "Load forecasting methodologies are consistent with best practices and load forecast outputs are provided to users and stakeholders on a timely basis."
- "The greatest risk of load forecasting inaccuracy falls on the industrial class and is due to the uncertainty of future economic activity and the volatility of many individual customer loads."
- "Areas for improvement identified primarily relate to making adjustments to forecast models and inputs to enhance overall forecast accuracy."

The Load Forecasting Audit included recommendations focused on adjustments to our models and inputs that could improve forecast performance. For example, the audit recommended that we "accelerate internal studies and development on the elasticity coefficients used in the development of the Load Forecast, including price elasticity and statistical adjusted end-use (SAE) model elasticity." As discussed next, we have addressed the audit recommendations.

In addition the Load Forecasting Audit discussed above, two BCUC reviews have occurred since the May 2016 Load Forecast:

- **August 2017, Fiscal 2017 – Fiscal 2019 Revenue Requirements Application Decision:** The BCUC found that BC Hydro's May 2016 Load Forecast was, "reasonable for use for the F2017 to F2019 test period", but acknowledged concerns regarding price elasticity and historical load forecast accuracy.[5]
  - The BCUC acknowledged BC Hydro's observation that electricity rate increases, "were known to industrial customers when BC Hydro's key account managers conducted their forecast surveys. Accordingly, [the BCUC was], "satisfied that the issue of price elasticity for future, unknown price increases [was] not an issue in the test period."[6]
  - The BCUC further noted that some utilities use a, "different load forecast methodology for their short term forecast for setting rates as compared to [their] long-term forecast for resource planning."[7]
- **November 2017, Site C Inquiry Final Report**: The Inquiry focussed on long-term demand as opposed to the short-term forecast for a particular test period. However, the BCUC identified a number of issues related to BC Hydro's Load Forecast, including:
  - The accuracy of the industrial forecast and, in particular that, "BC Hydro had not made a probabilistic assessment of the likelihood of the LNG load materializing."[8]
  - "GDP[9] and disposable income estimates used by BC Hydro in its Current Load Forecast are higher than similar Conference Board of Canada estimates."[10]
  - For price elasticities, "long-run price elasticity used by BC Hydro for all rate classes to be too low in magnitude."[11]

Table 3-1 provides a summary of Load Forecasting Audit and BCUC issues raised and how they have been addressed.

Table 3-1 Summary Consideration Table of Load Forecasting Issues Raised

Issues	BC Hydro's Consideration
BCUC Fiscal 2017 – Fiscal 2019 Revenue Requirements Application Decision	
1) "[BCUC] Panel acknowledges the concerns of AMPC regarding price elasticity use for industrial customers," but is nevertheless "satisfied that the issue of price elasticity for future unknown price increases is not an issue in the test period."[12]	BC Hydro engaged DNV GL Consulting to review price elasticity and recommended increasing elasticity values from (0.05) to (0.1) and applying price elasticity across all customer sectors. Recommendation adopted.
2) "[BCUC] Panel notes there is a need to accurately predict the next three years."[13]	Implemented the following improvements to our forecasting methods: **Industrial**: • Applying binary call to large industrial probability based method for first three years of the load forecast. • Revised LNG forecast method to be consistent with large industrial sector methodology. • Retained third party consultant to support natural gas sector market forecast. **Residential and Commercial Models:** • Work completed with model vendor (ITRON) to update relationships between economic drivers and electricity use as well as temperature and electricity use.
3) "[BCUC] Panel notes that other utilities such as Pacific Northern Gas, FortisBC (natural gas) and FortisBC (electricity) use a different load forecast methodology for their short term forecast for setting rates as compared to its long term forecast for resource planning."14	We compared alternative short term methodologies and have included result based on the FortisBC (electricity) method as an alternative forecast for the residential and commercial sectors.
Load Forecasting Audit Findings	
1) Economic/Industrial Outlooks: Request industrial and economic consultants to provide explanations and/or reasons for the variances between outlooks provided and actual output once actual or estimated data becomes available.	Consultants are now required to provide an explanation of variances to actuals when available.
2) Market Research: Consider conducting residential customer surveys once every three years if the key trends being measured are not changing significantly over time.	Determined there is a need to continue with both residential and commercial end-use survey.

[12] BCUC Decision on BC Hydro's F2017 to F2019 Revenue Requirements, Appendix B, page 6.
[13] BCUC Decision on BC Hydro's F2017 to F2019 Revenue Requirements, Appendix B, page 11.
[14] BCUC Decision on BC Hydro's F2017 to F2019 Revenue Requirements, Appendix B, page 11.

3) Specific Input Assumptions: Accelerate internal studies/development on: • The stock and flow model • Elasticity coefficients updates used in the development of the load forecast; including price elasticity and SAE model elasticity	A stock and flow model (beta version) has been completed and in the process of calibration. DNV GL Consulting reviewed price elasticity and recommended increasing elasticity from (0.05) to (0.1) and applying price elasticity across all customer sectors. Recommendation adopted. Residential and Commercial Models: Work completed on relationship between economic drivers and electricity use.
BCUC Site C Inquiry Final Report	
1) [BCUC] "Panel agrees with several parties who express concern with the fact that BC Hydro has not made a probabilistic assessment of the likelihood of the LNG load materializing"[15]	Revised LNG forecast method to be consistent with large industrial sector methodology.
2) [BCUC} "Panel finds the GDP and disposable income estimates used by BC Hydro in its Current Load Forecast are higher than similar Conference Board of Canada estimates."[16]	As part of BC Hydro's normal competitive procurement practices, the Conference Board of Canada was the successful proponent on an RFP for economic consulting services to provide us with a sub-regional and aggregate economic forecast for the province.
3) [BCUC] "Panel finds that the historical instances of over-forecasts are greater than under-forecasts, especially in the industrial load, and that the accuracy of BC Hydro's historical industrial forecasts looking out three and six years has been considerably below industry benchmarks."[17]	Current five year forecast is made up of a higher percentage of high probability/committed projects compared to previous forecast which included lower probability projects. Implemented the follow improvements to our forecasting methods: • Applying binary call to large industrial probability based method for first three years of the load forecast. • Retained third party consultants to support natural gas sector market forecast

3.2 LOAD FORECAST METHODOLOGY CHANGES

The following sections outline the forecast methodology changes since the May 2016 Load Forecast.

3.2.1 Large industrial sector: using a binary approach instead of probability weighting for early years

An improvement in the October 2018 Load Forecast is to move away from a probability weighted forecast for large industrial customers over the early term of the to a full load or no load binary approach. This means that the probability weighting, which we develop for each customer, is used to inform an "in" or "out" call for each customer in the first three years of the forecast. Customers with a greater than or equal to 50 per cent weighting are included in the forecast at their full anticipated load. Customers falling below that probability are excluded from the forecast for all years of the forecast. For example, a customer with a low probability weighting - say a 25 per cent probability - would not be included.

[15] BCUC Inquiry Respecting Site C – Final Report (November 1, 2017), page 78.
[16] BCUC Inquiry Respecting Site C – Final Report (November 1, 2017), page 78.
[17] BCUC Inquiry Respecting Site C – Final Report (November 1, 2017), page 78.

The binary method results in discrete projection (i.e. in or out) of load and revenues. Given that we have good information to make the binary call, we believe forecasting load in this manner is preferred over the test years rather than having partial load and partial revenue projections. Beyond fiscal 2021, the methodology for the large industrial customers is unchanged from the May 2016 Load Forecast methodology. For further details on the methodologies for the large industrial sector please see Section 7 of this report.

3.2.2 Large industrial sector: LNG forecast methodology

In the May 2016 Load Forecast, we included the load that LNG proponents announced would be supplied by BC Hydro and the dates they expected to require service. These loads were not probability weighted. For the October 2018 Load Forecast, the forecasts for LNG plants is consistent with the methodology applied to all other large industrial customers just described in the previous section. That is, the forecast of LNG plants' loads are now based on a binary call of 'in or out' for the first three years from fiscal 2019 to fiscal 2021 and by a probability assessment from fiscal 2022 and beyond. Further details on the LNG plants' loads included in our October 2018 Load Forecast period is provided in Section 7.

3.2.3 Residential and commercial sectors: SAE model improvements

We updated all of our SAE models for the relationship between load and temperature. This work involved updating the temperatures at which these customers respond to colder temperatures (with heating) and warmer temperature (with cooling). These temperatures vary by region within British Columbia. This work was undertaken using aggregated customer load profiles developed using a load shape model and electricity consumption data from our smart meters. Additional details on the results of this temperature and load analysis are discussed in Appendix C.

The updates to our parameters and load temperature relationships are intended to enhance forecast accuracy because: (i) they reflect the most recent information gathered over the past 10 years ending fiscal 2018 which is our SAE model estimation period; and (ii) they use smart metering infrastructure (SMI) data to improve accuracy rather than a limited number of representative samples from customer hourly metered data we relied on before SMI data was available.

In addition to updating the parameters on the load and temperature relationship, we re-calibrated the relationship between economic variables and load (i.e. economic elasticities) for the various economic variables in our all of SAE models. This work was completed in response to the Load Forecasting Audit recommendations. The revised economic elasticities are summarized in Appendix C of this report. The revised elasticities are relatively small and consistent with our observations of a lower growth in load and higher growth in the economy over recent years.

3.2.4 Residential sector: accounts forecast

BC Hydro has modified its methodology on how we forecast the number residential accounts. Previously, we assumed that there was a one-to-one relationship between housing growth and growth in BC Hydro residential accounts. We used a historical analysis of recent account growth and housing growth and concluded that a more appropriate average ratio is 0.9 new accounts per unit of housing growth. We updated our methodology to reflect this, and the details of that implementation and a comparison to previous account forecasts are in Appendix E of this report.

3.2.5 Main sectors: electricity price elasticity of demand

The need to review and update our price elasticity assumption was a finding from the Load Forecasting Audit, the previous application's proceeding, and the Site C Inquiry. In March 2018, BC Hydro retained DNV GL Consulting to conduct an electricity price elasticity study for each of our customer sectors. DNV GL Consulting is a global quality assurance and risk management company, with a highly regarded energy advisory services division offering institutional, legal and technical expertise on electricity systems, supplies, regulations and standards. The company has global operations in over 100 countries. The results of their price elasticity study are included as Appendix Q (Elasticity Study & GDP Study) of our F20-F21 RRA.

DNV GL Consulting's key findings, which were adopted for this forecast, included:

- "In our survey, the most commonly reported price elasticity for the residential sector is -0.10. While values as low as -0.06 and as high as -0.26 are in use among the utilities we reviewed, the most commonly reported value is a useful indicator of typical consumer response to rate changes. The -0.10 value is also most commonly reported for the two other sectors. Further, this value (-0.10) was recently recommended in an expert testimony to the Manitoba Public Utilities Commission presented in the table above."
- "Values from external sources as well as those determined by BC Hydro from its own and neighbouring utility data, indicate a residential price elasticity value that centres on -0.10 is a reasonable value for BC Hydro's residential customers. Therefore, we recommend that BC Hydro increase the price elasticity in use to assess rate impact and determine load forecast growth for the residential customers. Based on the convergence of values, we find an increase to -0.10 to be reasonable."
- "In general, we find BC Hydro's application of price elasticity to be consistent with that of many of the Canadian and U.S. utilities we reviewed. DNV GL supports the continuation of BC Hydro's approach to load forecasting which involves building up sector specific forecasts, including site-specific large commercial and industrial forecasts, and applying a single price elasticity to account for price changes in the forecast. Given that BC Hydro employs a site by site assessment for industrial facilities which captures price effect for a selection of energy intensive facilities, such as pulp mills; and precedent elsewhere, of applying the same price elasticity across all three sectors, we recommend that BC Hydro continue to use the same price elasticity estimate for all sectors."

The GNV DL Consulting study results, combined with the results of our own evaluation of the residential inclining block rate (fiscal 2013 to fiscal 2017), supports the results of previous internal studies and third party assessments that our price elasticity estimates are consistent with what is commonly reported and on the lower end of the survey data.

BC Hydro has increased the electricity price elasticity value from -0.05 to -0.10.The revised price elasticity is used to determine rate impacts for the main customer sectors which is reflected in the October 2018 Load Forecast.

3.2.6 Oil and gas sector: additional consultant services

Previously we had not relied on external subject matter experts to provide analyses of B.C. shale gas development. However, for this forecast we recognized the shale gas component of the oil and gas sub-sector as the fastest growing area of our sales, and retained the services of an oil and gas consulting company. Their western Canadian expertise served to provide industry intelligence to improve the accuracy of our assumptions, with a focus on:

- Montney shale gas development in B.C. (in light of competition with Alberta),
- oil and gas and gas liquids price forecasting,
- oil sands development (which will consume much of B.C.'s natural gas and gas liquids), and
- assessing the shale gas plants in BC Hydro's forecast based on their well property locations (to improve new plant probability weightings and reduce load forecast uncertainty).

The consulting services delivered on key components of the shale gas model: a Montney gas production forecast, and specific recommendations for model improvements.

4.0 Residential Forecast

The following sections describe the methodologies and results of our account forecast, our average use per account forecast and the alternative forecasts of accounts and use per account for the residential sector. At the end of this section, the Residential Load Forecast is presented in table format for first three years of the forecast covering fiscal 2019 and the test period of the F20-F21 RRA.

4.1 RESIDENTIAL SECTOR DESCRIPTION

At the end of fiscal 2018, there were 1.8 million residential accounts served by BC Hydro and electricity sales were 18,148 GWh. This represents about 35 per cent of BC Hydro's total firm sales on a billed basis. Residential customers use electricity for a variety of what we call "end-uses." These include space heating, cooling, lighting, water heating, cooking, refrigeration, and other plug-in loads which include computer equipment and home entertainment systems. Since space heating and cooling loads are dependent on the outside temperature, residential sales can be affected by temperature. As such, our forecasting process, like most utilities, develops a residential sales forecast based on a historical rolling average of temperatures over the past 10 years, or also referred to as a "temperature normalized basis." More information on temperature normalization is available Appendix E of this report.

BC Hydro has four main service regions. In fiscal 2018 electricity use across these regions as a percentage of total residential sales was:

- Lower Mainland 53 per cent,
- Vancouver Island 25 per cent,
- South Interior 13 per cent, and
- North Region eight per cent.

The North Region includes customers connected to our integrated grid and those in our non-integrated areas.

Historical trends in our residential sector include:

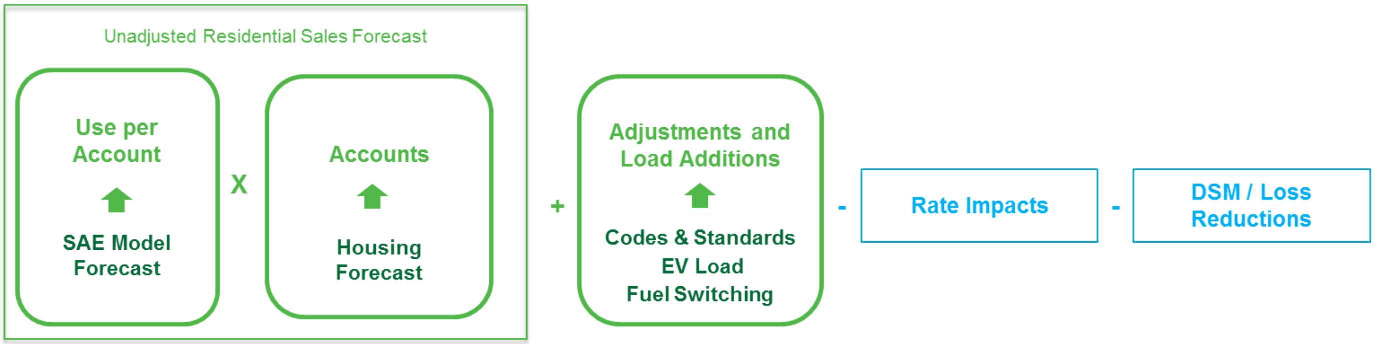
- strong historical growth in accounts which have increased on a year-over-year average of about 23,000 over the past five years ending fiscal 2018,
- a movement to denser multiple housing, and
- a decline in the average use per account.

In fact, over the past five fiscal years ending fiscal 2018, the average residential use per account (annual billed sales divided by the average number of accounts) has declined on both an actual basis and on a temperature normalized basis by 0.9 per cent and 1.1 per cent respectively.

4.2 RESIDENTIAL UNADJUSTED FORECAST MODEL METHODS & COMPARISONS

Figure 5.2.1 below shows our forecasting process and the build-up of the Residential Load Forecast.

Figure 4-1 Residential Forecast Build-up



The equation used to develop the unadjusted[18] residential sales forecast, represented in the first part of the figure, is:

Equation 4.1

$$Unadjusted\ Residential\ Sales\ Forecast = Number\ of\ Residential\ Accounts\ \times\ Intensity\ (average\ use\ per\ account)$$

This equation is applied to develop residential model projections of sales for each of our four service regions. The total residential model projection of sales for our service area is the sum of the regional model projections.

The model projection of average use per account comes from four SAE models (i.e., one model per each major region). The SAE models are calibrated using the past 10 years ending fiscal 2018. The models' inputs include monthly billed data on the average use per account and other load drivers that are specific to the residential sector. The residential account forecast is based housing projections that come from Conference Board of Canada's June 2018 Economic Forecast.

The sum total of model projections, the adjustments, the load additions, and the reductions for rate impacts makes up the residential forecast after rate impacts. The final step in the residential forecasting process includes load reductions for incremental savings from the DSM plan and load reductions for the residential portion of loss reductions. This last step results in the residential load forecast after DSM and loss reductions.

The next two sections discuss the SAE methodology which determines the average use per account and our method of forecasting residential accounts. The alternative method of developing an account and use per account forecast is also described along with the alternative forecast results.

4.2.1 Residential accounts forecast methods and comparisons

4.2.1.1 Comparison of May 2016 to October 2018 residential account forecast method

Our approach to residential accounts forecast for the October 2018 Load Forecast has changed from the methodology used in the May 2016 Load Forecast. The changes were intended to improve the performance of the accounts forecast itself in support of the residential sales forecast.

Table 4-1 below compares the current methodology to the one used in the May 2016 Load Forecast. The main difference between the two approaches is that that growth in accounts in the current method is based on a historical average ratio of growth in accounts to housing growth as opposed to a 1:1 relationship between account growth and housing growth. Appendix E of this report contains a

[18] The terms unadjusted sales forecast and model projections are used interchangeably in this report. Unadjusted sales forecast, within the context of the residential sector, is the product of the average use per account (SAE model projection) and accounts. Unadjusted sales forecast for the commercial sector refers the forecast of sales from the commercial SAE models. Unadjusted sales forecast, within the context of the light industrial sector includes model projections and customer forecasts.

detailed comparison of forecasts under the new and previous method. That analysis indicates that a forecast using our new method is more accurate to a forecast done with previous method.

Table 4-1 Comparison of Residential Current to Previous Account Forecast Methods

Forecast Element	May 2016 Load Forecast Method	October 2018 Load Forecast Method
Internal Inputs based on BC Hydro billing data)	The total number of accounts for single family dwellings / duplex and total number of accounts for all multiple housing types (i.e., row, apartment mobiles) for 15 sub-areas that make up our four major regions.	Same
External Inputs	History and projections of net housing starts (i.e., housing starts less demolitions) for two housing types for 15 sub-areas from Robert Fairholm Economic Consultant, March 2015.	Projection of net housing stock[1] (i.e., growth in housing stock excluding demolition of homes) for the 2 housing types for 15 sub-areas. History of forecast of housing types comes from the Conference Board of Canada, June 2018 Economic Forecast.
Accounts Forecast Method	For Year 1 of the forecast: Number of accounts = base year accounts + net housing starts For Year 2 of the forecast and beyond: Number of accounts = previous year accounts forecast + net housing starts. This is developed for each of the 2 housing types within each of the 15 areas.	For Year 1 of the forecast: Number of accounts for each housing types for the 15 sub-areas is based on a review the current trend in account growth over initial months of fiscal 2019[2] For Year 2 of the forecast and beyond: Number of accounts = previous year forecast of accounts + ratio[3] × net housing stock projection. This is developed for the 2 housing types within each of the 15 sub-areas
Regional Residential Forecast	The forecast for the two housing types for each of the 15 sub-areas is aggregated to develop a total accounts forecast for each of the four service regions.	Same

Table notes:

1. Conference Board of Canada's methodology on developing housing projections for each of the 15 sub-areas by housing type is based on a forecast of net housing stock and gross housing starts. Robert Fairholm Economic Consultant's forecast of housing, which informed the May 2016 Load Forecast of accounts, was based on net housing starts. Both methods account for the impact of demolitions and rebuilds except these impacts are reflected in the net housing stock variable and housing starts variable from the respective economic forecasts.
2. Rather than using the forecast of growth in net housing stock to develop the growth in accounts for the first year of the forecast (i.e., fiscal 2019), the forecast of accounts for that year was based on our analysis of the account growth from our billing statistics from March 2018 to August 2018. Account data from September 2018 was not available in time to inform the account projection of fiscal 2019.
3. The term "ratio" mentioned above is a historical average ratio of account growth to growth in net housing stock for two housing types housing for each of the 15 sub-areas. For each housing type within each of the 15 sub-areas we did a detailed review of the historical ratio of account growth to net housing stock growth to determine an average ratio to be used in the forecast.

4.2.1.2 Comparison of BC Hydro to FortisBC Electric residential account forecast method

In response to comments we received from the BCUC on our May 2016 Load Forecast as stated in Section 3.1, where the, "Panel notes that other utilities such as Pacific Northern Gas, FortisBC [natural gas] and FortisBC [electricity] use a different load forecast methodology for their short term" forecasts, we have developed an alternative forecast based on FortisBC Electric short-term method and compared it against our methodology.

The FortisBC Electric short-term method of developing a residential account forecast is based on a regression of the year-end customer accounts regressed against historical population in the FortisBC Electric service area. A forecast of accounts is developed with the results of the regression and a forecast of population for the FortisBC Electric service area. The history and forecast of population for the FortisBC Electric service area is provided by BC Stats, the provincial government's statistical agency.

To develop an alternative forecast of accounts using FortisBC Electric's method we estimated a regression model of the historical year-end total number of BC Hydro residential accounts and historical population for our BC Hydro service area. We developed a forecast of accounts using the results (i.e., the coefficients) of the regression model and the forecast of population for our service area as per projections from Conference Board of Canada from June 2018. The alternative accounts projection is shown in the last column in Table 4-4 contained in section 4.2.2.2. The statistics and the results of the regression model used to develop the alternative accounts forecast are shown in the table below. The estimate period used in this linear regression model was from fiscal 2014 to fiscal 2018, which is consistent to the number of years that FortisBC Electric uses to estimate their regression model. The regression results indicated that there is a good fit to the historical data (high R-square value) and the coefficients of the regression model are statistically significant (p-values less than 5 per cent).[19]

Table 4-2 Regression Model of Accounts & Population used for Alternative Accounts Forecast

SUMMARY OUTPUT								
Regression Statistics								
Multiple R	0.999							
R Square	0.998							
Adjusted R Square	0.997							
Standard Error	1,893							
Observations	5

	df	*SS*	*MS*	*F*	*Significance F*			
Regression	1	5,680,815,259	5,680,815,259	1,585	0.0%			
Residual	3	10,748,971	3,582,990					
Total	4	5,691,564,230						
	Coefficients	*Standard Error*	*t Stat*	*P-value*	*Lower 95%*	*Upper 95%*	*Lower 95.0%*	*Upper 95.0%*
Intercept	(270,049.71)	50,831.71	(5.3)	1.30%	(431,819)	(108,281)	(431,819)	(108,281)
Population	0.47	0.01	39.8	0.00%	0.43	0.51	0.43	0.51
Durbin-Watson Statistic	2.07							

In contrasting our methodology against this alternative forecast based on FortisBC Electric's approach, two points come to the fore.

First, our accounts forecast is based on the methodology described in Table 4-1 above where the primary driver of our account growth is the forecast of net housing growth provided by the Conference Board of Canada. Given this, our account forecast is a detailed sub-area approach that considers many factors beyond the underlying population and demographic trends across our service area. These factors include items such as interest rates, government policies aimed to cool market as well as housing construction targets aimed for lower incomes.

[19] Descriptions of regression model statistics such as R-squared and p-values are provided in Appendix D

Second, in addition to modelling the underlying demographic demand for housing, the Conference Board of Canada's June 2018 housing forecast also considers the impact of interest rates and government policies such as the provincial government's housing plan and how these factors may impact housing demand. The Conference Board of Canada's modelling of housing growth also considers the impact of large capital investments projects which have secondary impacts on residential housing demands within specific parts of our service area. While we have not reviewed the BC Stats report produced for FortisBC Electric, our understanding is that the population forecast as developed by BC Stats is largely based on demographics factors.

4.2.2 Residential account forecast results and comparison

4.2.2.1 October 2018 residential account forecast results

Table 4-3 outlines the October 2018 Load Forecast's expectations for residential customer accounts out to fiscal 2024.

Table 4-3 October 2018 Residential Accounts Forecast

Fiscal year	Accounts forecast
Actuals	
F2013	1,688,994
F2014	1,709,009
F2015	1,727,945
F2016	1,751,296
F2017	1,776,503
F2018	1,803,752
Forecast	
F2019	1,831,954[1]
F2020	1,861,572
F2021	1,885,943
F2022	1,907,221
F2023	1,927,188
F2024	1,946,489
5 Yr. Actual (F13 to F18)	1.3%

5 Yr. Forecast (F18 to F23)	1.3%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

The account forecast shows an average annual growth of about 24,680 accounts over each of the next five years ending fiscal 2023. This is higher than the historical five year average growth rate which was about 22,952 accounts per year.

The forecast of accounts for fiscal 2019 was based on current year billing data and our assessment of that data as to how accounts would grow over fiscal 2019. Account growth over the first five months of fiscal 2019 was higher than account growth over the previous year after five months. As such, for fiscal 2019 we anticipated continued strong growth in accounts between fiscal 2018 and fiscal 2019.

After fiscal 2019, the account growth is developed for 15 sub-areas (aggregated to 4 service regions then aggregated to a BC Hydro total) with the projections of housing growth and ratios of account growth to housing growth by housing type within these areas. The Conference Board of Canada June 2018 projection of growth in net housing stock anticipates growth between fiscal 2019 and fiscal 2020. This reflects the continued trend of construction in housing which we have seen over the past several years. Beyond fiscal 2020, growth in net housing stock is forecasted to generally decline driven by a projection of lower housing starts. This gradual decline reflects the impact of policy measures introduced to cool housing markets as well as the expectation that interest rates would slowly rise which would also reduce the demand for new housing and new residential accounts.

4.2.2.2 Comparison of BC Hydro to FortisBC Electric residential account forecast results

Table 4-4 below shows the October 2018 accounts forecast versus the alternative accounts forecast developed based on the FortisBC Electric short-term method.

Table 4-4 Accounts Forecast: October 2018 vs FortisBC Electric

Fiscal year	October 2018 Accounts Forecast	Alternative Accounts Forecast based on FortisBC Electric short-term method
Actuals		
F2013	1,688,994	
F2014	1,709,009	
F2015	1,727,945	
F2016	1,751,296	
F2017	1,776,503	
F2018	1,803,752	
Forecast		

F2019	1,831,954[1]	1,827,119[1]
F2020	1,861,572	1,851,419
F2021	1,885,943	1,872,801
F2022	1,907,221	1,894,560
F2023	1,927,188	1,916,691
F2024	1,946,489	1,939,188
5 Yr. Actual (F13 to F18)	1.3%	1.3%
5 Yr. Forecast (F18 to F23)	1.3%	1.2%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

The alternative account forecast predicts that accounts will grow by about 23,367 between fiscal 2018 and fiscal 2019. Our projection is for accounts to grow by about 28,202 over the same time period.

At the end of August 2018, residential accounts had grown by about 11,734 accounts since March 2018. This growth is about 1,600 or 16 per cent more than the growth between March 2017 and August 2017. Given the robust growth in accounts over the past few fiscal years and the fact that account growth seemed to be trending strong through the current fiscal year we believed that our forecast for fiscal 2019 would be more accurate compared to the alternative forecast.

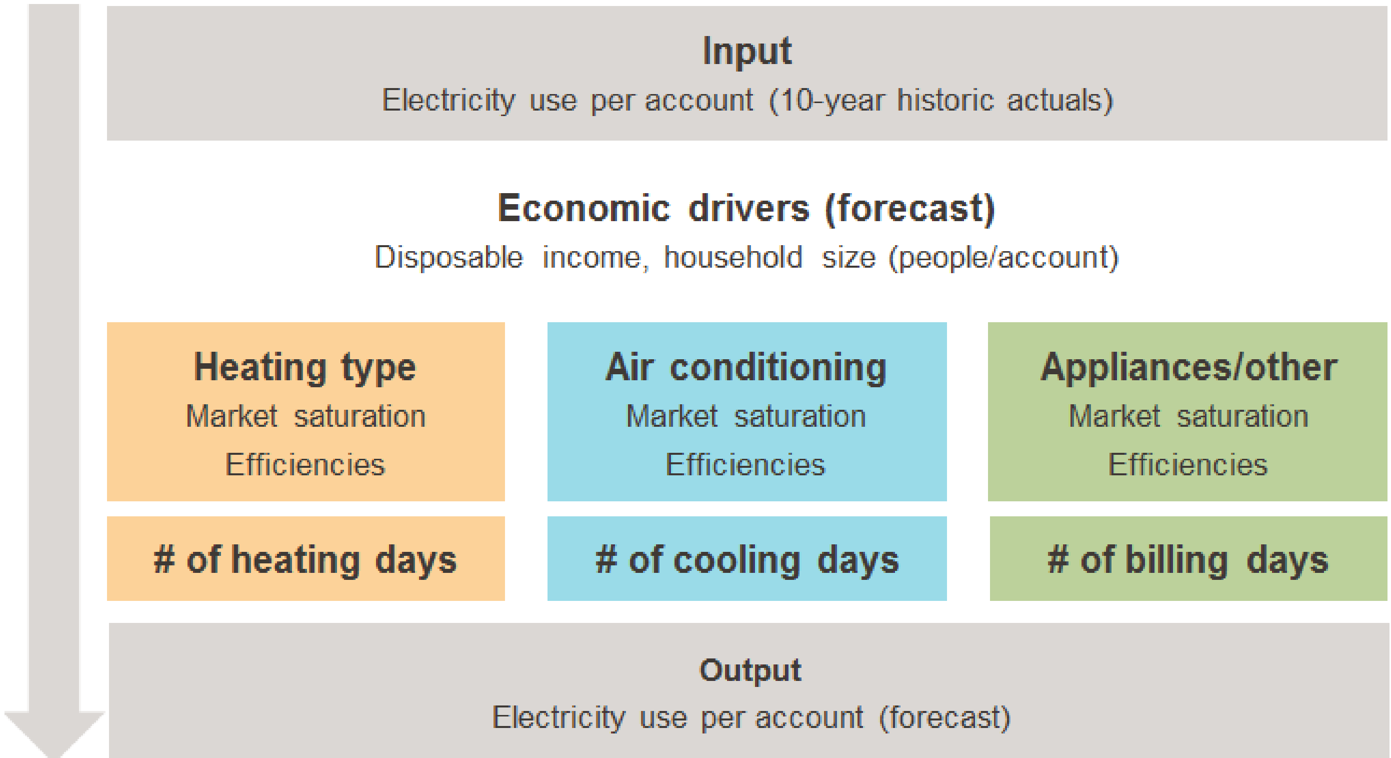
4.2.3 Residential average use per account methods and comparison

4.2.3.1 October 2018 residential average use per account method

BC Hydro uses an industry standard SAE model to estimate the average residential use per account for each of our four main service regions. The SAE approach is used by approximately 60 different utilities and organizations throughout North America. This method has been reviewed in several previous regulatory applications including our F17-F19 RRA.

Figure 4-2 below is a graphical representation of the SAE model while our specific residential SAE models are contained in Appendix D of this report.

Figure 4-2 Residential SAE Model Inputs and Outputs



Our residential SAE models are an end-use regression model which establishes a historical relationship between the average use per account and the historical values for the following variables:

- economic variables including real personal disposable income and household size represented by people per account,
- non-economic variables including the average efficiency of residential end use of electricity, appliance shares (i.e., percentages of customers that have a specific residential electrical appliance), and
- temperature variables represented by heating and cooling degree days.

The forecasts for these variables and the estimated coefficients of our four regional residential SAE regression models determine the model projections of the average use per account over the forecast period for each region.

The SAE model approach has the following main characteristics:

- **A regression element** that develops a historical relationship between heating, cooling, and other major end uses of electricity and the average use per account developed from billing data on residential electricity sales and accounts.
- **An end-use efficiency element** which reflects: (i) future average efficiency projections of residential end uses of electricity for the Pacific region, as developed in 2018 from the U.S. EIA; and (ii) regional BC Hydro data on appliance shares for various end-uses of electricity such as lighting and refrigeration. Regional data on saturation rates come from our historical residential customer end use survey (REUS) while forecasts come from the EIA[20].

  The following examples are provided to illustrate how the model incorporates REUS and EIA elements:

[20] To develop our October 2018 Load Forecast we used the data on from the past 10 residential end use survey including the last survey results complied in 2017.

- Refrigerators: Our latest REUS data indicates that about 99 per cent of our Lower Mainland accounts have a refrigerator with an average efficiency of 582 kWh/year based on data from the EIA. Over the forecast period, market share for refrigerators (99 per cent) is projected to remain unchanged and the EIA data forecasts average refrigerator efficiency to increase to 515 kWh per year.
- Dishwashers: Our REUS data indicates about 78 per cent of our Lower Mainland accounts have a dishwasher and this market share percentage is expected to increase to 83 per cent by the end of the forecast period. From the EIA data, the average efficiency rating is expected to increase from 0.84 (Btu per hour per watt) to 0.91(Btu per hour per watt).

- **An economic element** that reflects future projections of economic variables such as real disposable income and household size represented by people per account. The model also contains elasticities which are estimates of the percentage increase in use per account for a one percentage increase in economic variables. The economic forecasts and elasticities are regional specific for each model. The economic forecasts are based on Conference Board of Canada June 2018 projections.
- **A temperature element** which is measured in heating and cooling degree days. The model is estimated with actual heating and cooling degree days and the forecast is based on a normal temperature which is defined as a ten year rolling average of monthly heating and cooling degree days that are region specific. Using a ten year rolling average will better reflect current trends relative to longer term averaging periods.

Appendix C contains the economic elasticities include in our SAE model. Appendix F contains a summary of the two economic drivers included in our SAE models, EIA end-use efficiency data and regional end-use market saturation data.

4.2.3.2 Comparison of BC Hydro to FortisBC electric account forecast method

In contrast, the alternative forecast of average use per account is developed using a simple regression time trend analysis of the last three years of historical temperature normalized average use per account at the BC Hydro service area.[21]

Table 4-5 below shows the regression model of temperature normalized use per account and a historical time trend. This model is the basis for alternative forecast of average use per account as per FortisBC Electric's short-term method.

[21] To develop the alternative forecast of average use per account we used our historical data on temperature normalized use per account rather than developing a separate historical normalized use per account based on the Fortis BC Electric method of temperature normalization. See Section 19.2 of this report which describes our temperature normalization method for the residential use per account and commercial sales.

Table 4-5 Regression Model Trend in Residential Average use per Account used in Alternative Forecast

SUMMARY OUTPUT								
Regression Statistics								
Multiple R	0.994							
R Square	0.989							
Adjusted R Square	0.977							
Standard Error	23.16							
Observations	3							
ANOVA								
	df	*SS*	*MS*	*F*	*Significance F*			
Regression	1	46,399.70	46,399.70	86.52	6.8%			
Residual	1	536.31	536.31					
Total	2	46,936.01						
	Coefficients	*Standard Error*	*t Stat*	*P-value*	*Lower 95%*	*Upper 95%*	*Lower 95.0%*	*Upper 95.0%*
Intercept	10,500.815	35.375	296.843	0.2%	10,051.3	10,950.3	10,051.3	10,950.3
Trend	(152.315)	16.375	(9.301)	6.8%	(360.38)	55.75	(360.38)	55.75
Durbin-Watson Statistic	3.00							

The Durbin Watson statistic of 3.00 in the table above indicates there could be auto correlation[22] in the estimated error terms which makes it difficult to assess the statistical significance of the individual variables, the forecast's results, and ultimately the statistical robustness of the alternative model. In contrast, our linear regression SAE models of average use per account are statistically robust, have good fits to the historical data, and generally have statistical significant variables with no auto-correlation in the error terms. Appendix D of this report contains the model statistics for each of our residential SAE models.

On the surface, the regression model above indicates a strong goodness of fit (R-squared value) to the historical data. However, the time trend variable - which is the key driver of the forecast - is not statistically significant. That is, its p-value is just above 5 per cent. The auto-correlation, which may be present, could be due to the wrong functional form, missing variables, or the short period for which the regression model is estimated. As such, further investigation into causes of the auto-correlation would be needed. We did not undertake any further analysis as this would take additional effort to determine the underlying cause of the auto-correlation, if present. In addition, we wanted to establish the regression results for the alternative forecasts to be as close as possible to the FortisBC Electric method.

The major differences in the approaches include:

- our method considers more than one variable (i.e., time trend) to explain the historical variation in use per account and determine a forecast in the use per account, and
- we use a longer time period to develop a statically sound relationship between the average use per account and multiple drivers of average use per account.

After comparing the model approaches to developing a projection for average use per account projection, we expect that the SAE approach to perform better than the alternative forecast method because:

- it uses several variables to develop the forecast rather than a single trend,

[22] A Durbin Watson of 2 would indicate no autocorrelation. Auto-correlation means that the error term in the regression model in one period is correlated with error term in a previous period. Regression models do not have auto-correlation are statistically more robust.

- the SAE model is a multi-linear regression approach that is widely accepted through North America as one of the best practices in load forecasting,
- FortisBC Electric method predicts that the average use per account will decline in direct proportion to the number of the years in the forecast period, a modelling assumption we find too drastic for our context,
- our SAE models are performed well against statistical regression evaluation whereas the alternative method was challenged, and
- given the diversity within our regions, we believe our regional forecasting approach is more reliable than developing a single forecast for our entire service area from a linear time trend.

4.2.4 Residential average use per account results and comparison

4.2.4.1 October 2018 residential average use per account results

The Table 4-6 shows is summary of our SAE model projections of the average use per residential account at the total BC Hydro level, which is based on a weighted average of the regional SAE model projections.

Table 4-6 October 2018 Residential Average Use per Accounts Forecast Results

Fiscal year	October 2018 model projections of average use per account BC Hydro service area (kWh/account)
Actual (temperature normalized)	
F2013	10,625
F2014	10,552
F2015	10,459
F2016	10,358
F2017	10,177
F2018	10,053
Forecast	
F2019[1]	9,981[1]
F2020	9,958
F2021	9,977
F2022	9,990
F2023	10,003

F2024	10,010
5 Yr. Actual (F13 to F18)	-1.1%
5 Yr. Forecast (F18 to F23)	-0.1%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

The results indicate that our average use per account is expected to decline over the forecast period which follows the trend in recent history. These results reflect a number of factors that have put downward pressure on the growth in the average use per account over the forecast period. These factors include:

- a 10 year estimation period (calibration period) ending fiscal 2018, where the historical average use per account has been declining over several years,
- the average efficiency projections from the EIA which generally indicate an increase in efficiency of residential end uses of electricity, and
- the economic variable projections are expected to grow slower over the forecast period relative to history.

Table 4-7 below shows the five year average historical and forecast in the number of people per account and real disposable income in the BC Hydro service area. With fewer people living in a residence, as per the forecast, this means, all else equal, a lower electricity consumption; similarly slower growth in disposable income, all else equal, would tend result in lower electricity consumption.

Table 4-7 Residential Economic Drivers History vs. Forecast

Residential Economic Drivers	Historical Average[3] Growth (F2013 to F2018)	Forecast Average[3] Growth (F2018 to F2023)
People per account[1]	-0.2%	-0.3%
Real disposable income[2]	4.1%	2.4%

Table notes:

1. People per account is based on the ratio of population within our service area to the total number of residential accounts. Population history and forecast come from the Conference Board of Canada’s June 2018 economic forecast, and accounts history and forecasts come from BC Hydro.
2. History and forecast of real disposable income comes from the Conference Board of Canada’s June 2018 economic forecast.
3. Averages for disposable income are computed as an average of the year over year annual growth over five years. The percentages for people per account are computed on a compound growth basis over five years.

4.2.4.2 Comparison of BC Hydro to FortisBC Electric residential use per account results

Table 4-8 shows a comparison of our average use per account alongside that of the alternative model projection for the BC Hydro service area.

Table 4-8 Residential Average Use per Accounts SAE Model vs Alternative Model Projections

Fiscal year	October 2018 model projections of average use per account BC Hydro total service area (kWh/account)	Alternative model projections based on FortisBC Electric short-term method (kWh/account)
Actual (temperature normalized)		
F2013	10,625	10,625
F2014	10,552	10,552
F2015	10,459	10,459
F2016	10,358	10,358
F2017	10,177	10,177
F2018	10,053	10,053
Forecast (temperature normalized)		
F2019[1]	9,981	9,892
F2020	9,958	9,739
F2021	9,977	9,587
F2022	9,990	9,435
F2023	10,003	9,282
F2024	10,010	9,130
5 Yr. Actual (F13 to F18)	-1.1%	-1.1%
5 Yr. Forecast (F18 to F23)	-0.1%	-1.6%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

The alternative model projection shows a forecast of declining use per account that is much higher relative to historical trends. This is due to the fact that forecast is primarily driven by the number of years in the forecast.

In summary, both approaches resulted in declining forecasts of the average use per account which is consistent with recent historical trends. The alternative forecast resulted in a faster decline of average use per account over the forecast period relative to history compared to our model projections.

4.3 RESIDENTIAL SALES FORECASTS

4.3.1 Residential sales forecast methods and comparison

Our Residential Load Forecast is an aggregation of model projections, adjustments for overlap in codes and standards, load additions for EVs and fuel switching, and reductions for rate impacts, DSM and loss reduction savings.

In comparison, the alternative Residential Load Forecast is also an aggregation of all of these forecast elements except for adjustments for codes and standards overlap. The alternative average use per account forecast does not explicitly reflect, unlike our method, that the decline in the average use per account could be from codes and standards which are reflected in our model projections and our DSM plan.

4.3.2 Residential sales forecast results and comparison

4.3.2.1 October 2018 residential sales forecast results

Table 4-9 contains our residential sales forecast after rate impacts. This forecast is an aggregation of model projections, load additions for EVs and fuel switching, and reductions for rate impacts.

Table 4-9 October 2018 Residential Sales History and Forecasts After Rate Impacts

Fiscal year	October 2018 Forecast after Rate Impacts (GWh)
Actual (temperature normalized)	
F2013	17,852
F2014	17,928
F2015	17,973
F2016	18,019
F2017	17,952
F2018	17,997
Forecast	

F2019[1]	18,361[1]
F2020	18,679
F2021	19,007
F2022	19,303
F2023	19,605
F2024	19,912
5 Yr. Actual (F13 to F18)	0.2%
5 Yr. Forecast (F18 to F23)	1.7%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

The forecast above after rate impacts shows that residential sales are expected to grow faster than historical trend. This reflects the increase in accounts, estimates of overlap in codes and standards and EV load. The SAE model projection of average use per account is essentially flat as such not a factor of growth.

4.3.2.2 Comparison of BC Hydro to FortisBC Electric residential sales forecast results

This section presents our results of comparing BC Hydro's forecast methodology with an alternative methodology using FortisBC Electric's short term forecast method.

Table 4-10 shows a comparison of our residential sales forecast after rate impacts and the alternative residential sales forecast after rate impacts. Both forecasts include EVs, fuel switching and rate impacts. Our October 2018 residential sales forecast includes adjustments for overlap in codes and standards, while the other alternative does not include these adjustments. The alternative does not include overlap adjustments because the foundation (i.e., starting point) for the alternative forecast of residential sales is product of a simple time trend of use per account and the alternative accounts projection.

Table 4-10 Residential Sales History and Forecasts After Rate Impacts

Fiscal year	October 2018 Forecast after Rate Impacts (GWh)	Alternative FortisBC Electric Short-term Forecast after Rate Impacts (GWh)
Actual (temperature normalized)		
F2013	17,852	17,852

F2014	17,928	17,928
F2015	17,973	17,973
F2016	18,019	18,019
F2017	17,952	17,952
F2018	17,997	17,997
Forecast		
F2019[1]	18,361	18,116
F2020	18,679	18,092
F2021	19,007	18,033
F2022	19,303	17,977
F2023	19,605	17,947
F2024	19,912	17,940
5 Yr. Actual (F13 to F18)	0.2%	0.2%
5 Yr. Forecast (F18 to F23)	1.7%	-0.1%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

Table 4-11 shows a comparison of our residential sales forecast after DSM and loss reduction savings and the alternative residential sales forecast after DSM and loss reduction savings.

Table 4-11 Residential Sales History and Forecasts After Rate Impacts and After DSM

Fiscal year	October 2018 Residential Load Forecast (GWh)[1]	Alternative FortisBC Electric Short-term Forecast after DSM / Loss Reductions (GWh)[1]
Actual (temperature normalized)		
F2013	17,852	17,852
F2014	17,928	17,928

F2015	17,973	17,973
F2016	18,019	18,019
F2017	17,952	17,952
F2018	17,997	17,997
Forecast		
F2019[2]	18,198	17,953
F2020	18,253	17,667
F2021	18,324	17,351
F2022	18,411	17,085
F2023	18,551	16,893
F2024	18,709	16,737
5 Yr. Actual (F13 to F18)	0.2%	0.2%
5 Yr. Actual Forecast (F18 to F23)	0.6%	-1.3%

Table notes:

1. Loss reductions make up a small component of the load forecast, but are included in the alternative forecast for completeness.
2. Forecast for fiscal 2019 does not include any actuals.

In contrast to the alternative forecast, the October 2018 Residential Load Forecast is higher due to a higher accounts forecast and a higher model projection of the average use per account. In addition to the comparison of performance of the accounts forecast and use per account forecast, here are further reasons we believe our forecast will perform better than the alternative forecast:

- As of September 2018, our Residential Load Forecast for fiscal 2019 was lower by 0.2 per cent relative to actuals over the first six months and higher by 0.6 per cent on a temperature normalized basis. The alternative projection of 17,953 GWh for fiscal 2019 was tracking well below normalized sales by 3.6 per cent over the same time period. As such, we were more confident about our results over this time period, and
- Given the size of the of FortisBC Electric service area it would appear that a top down approach (i.e., one forecast for the service area) is reasonable. Unlike our service area, there is likely no need to further divide the FortisBC Electric service area into sub-regions to develop forecasts for the sub-regions (i.e., bottom up approach). Given the size and diversity of our load, economic growth, and monthly temperatures across our service areas, we believe the residential and commercial forecasts will be accurate from our bottom up approach.

A litmus test for comparing the two forecasts is looking at variance from actuals as measure of forecast performance. To do this, we re-developed residential forecasts for fiscal 2016 to fiscal 2018 using the alternative FortisBC Electric method. Based on our analysis, we found that the residential sales variance, after temperature normalization, using the alternative approach for fiscal 2016 to fiscal 2018 were 0.7 per cent, 2.4 per cent, and 3.9 per cent respectively or an average of 2.4 per cent over all years. These variances are higher compared to the residential variance as per the May 2016 Load Forecast which are 0.1 per cent -0.4 per cent and -0.6 per cent or an average of -0.3 per cent over all years on a temperature normalized basis over the same time period.

4.4 RESIDENTIAL SALES FORECAST BUILD-UP F2019 TO F2021

The billed sales forecast with DSM and loss reductions before accruals is the foundation of the Residential Load Forecast contained in our F20-F21 RRA. The detail on the build-up of the billed sales Residential Load Forecast for fiscal 2019 to fiscal 2021 is presented in the tables below. From the billed sales load forecast we also develop a Residential Load Forecast on an accrued sales basis, which is used to develop our revenue forecast.

Table 4-12 Fiscal 2019 Residential Billed Sales Forecast Build-up

Accounts	Use per account (kWh/ account)	Model projection[1] (GWh)	Codes overlap adjustments (GWh)	EV load additions (GWh)	Fuel switching additions (GWh)	Rate impacts[2] (GWh)	DSM (GWh)	Loss reductions (GWh	Residential Load Forecast[3,4] (GWh)
1,831,954	9,981	18,285	33	48	2	(7)	(158)	(5)	18,198

Table notes:

1. A model projection is average use per account times the number of residential accounts which equals model sales. The model projection above is the sum model projections from all four regions.
2. Rate Impacts is an estimation of load reduction based on formula that include our forecast of real electricity rate increases, a price elasticity assumption of -0.1 and the residential model projections, load adjustments, and load additions.
3. The Residential Load Forecast is an aggregation of model projections, adjustments for codes and standards, load additions less rate impacts, less DSM savings, and loss reductions.
4. The forecast of 18,198 GWh for fiscal 2019 does not include any actual billed sales over the current fiscal year. The forecast of 18,184 GWh (found in the Executive Summary of this report) reflects six months actual billed sales over fiscal 2019 and six months forecast. To develop this estimate the Residential Load Forecast of 18,198 GWh is allocated into 12 months using a rolling five year average shape of monthly billed sales at the BC Hydro level. After the Residential Load Forecast is allocated, the first six months of forecast are replaced with actuals sales.

Table 4-13 Fiscal 2020 and F2021 Residential Billed Sales Forecast Build-up

Fiscal year	Accounts	Use Per account (kWh/ account)	Model projection[1] (GWh)	Codes overlap adjustment (GWh)	EV load addition (GWh)	Fuel switching load addition (GWh)	Rate impacts[2] (GWh)	DSM (GWh)	Loss reductions (GWh	Residential Load Forecast[3] (GWh)
F2020	1,861,572	9,958	18,537	81	65	10	(15)	(418)	(7)	18,253
F2021	1,885,943	9,977	18,815	114	89	14	(26)	(673)	(10)	18,324

Table notes:

1. A model projection is the average use per account times the number of residential accounts. The model projections in the table above are the sum model projections from all four regions.
2. Rate impacts is an estimation of load reduction based on formula that include our real rate increase projection, a price elasticity assumption of -0.1 and the residential model projections, load adjustments and load additions.
3. The Residential Load Forecast is an aggregation developed by model projections, adjustments for codes and standards, load additions less rate impacts less savings for DSM and loss reductions.

4.5 RESIDENTIAL SALES FORECASTS UNCERTAINTIES

Variance in actual residential sales compared to forecast can occur due to many factors, listed below.

4.5.1 Number of accounts

Our current approach depends on our projection of accounts starting in fiscal 2019 and housing growth projections from the Conference Board of Canada, June 2018. In developing the forecast of accounts for fiscal 2019, we used the first five months of account growth from fiscal 2019 to inform our expectations for the remainder of year. While more data over fiscal 2019 would likely enhance the very short term forecast we believe the variance in the forecast of accounts will be less than one per cent for fiscal 2019.

Beyond fiscal 2019, housing trends may differ from what the Conference Board of Canada expects. Factors that could impact housing trends in B.C. over the next several years include:

- provincial housing policy on affordable supply via targeted smaller unit construction,
- federal commitments to affordable housing, and
- government policy aimed at reducing demand and rising house prices through taxes & tightening of mortgage rules.

There is uncertainty as to how consumers will react to all of these measures which are occurring simultaneously.

4.5.2 Use per account

The average use per account forecast is based on our SAE model projections which reflect economic factors and changes in average efficiency and saturation of residential appliances. All of these factors have the potential to contribute to the uncertainty in our load projections. In addition, government policies such as further incentives for EVs may contribute to future variances. Other factors that influence use per account in an upward direction include:

- increases in home sizes,
- increases in air conditioning and other cooling devices, and
- increases in real disposable income.

While some of the countervailing forces working to decrease use per account are:

- increases in appliance efficiencies and consumer uptake of efficient end uses of electricity,
- faster movement towards more multiple dwellings, and
- customers becoming more conscious of electricity use.

4.5.3 Temperature

In the short term, temperature can be highly variable relative to our assumption of a rolling 10 year average trend. Therefore, in any one year, there is a risk that weather and associated temperatures may have a significant impact on residential sales. For example, after the

El Niño event of fiscal 2015, sales to the residential sector declined by close to five per cent between fiscal 2014 and fiscal 2015 mainly due to warmer temperatures. Like most utilities, we develop a forecast based on historical temperature average or on a temperature normalized basis. This is standard practice across most utilities rather than developing an electricity sales forecast based on a prediction of future temperatures and weather conditions.

5.0 Commercial Forecast

5.1 COMMERCIAL SECTOR DESCRIPTION

At the end of fiscal 2018, there were 181,651 commercial accounts and commercial billed sales totalled 14,539 GWh. The commercial sector as of fiscal 2018 was about 28 per cent of BC Hydro's total firm sales.[23]

Within the commercial sector we group customers on the basis of the type of service they receive:

- customers with a demand under 35 kW peak demand within a month which includes operations such as small offices, small retail stores, restaurants, and motels, and
- customers with a demand greater than 35 kW peak demand within a month which includes buildings such as large offices, larger retail stores, hospitals and hotels.

In the last five years, the total increase in commercial sales is about 243 GWh or 1.7 per cent or 179 GWh or 1.3 per cent on a temperature normalized basis. There is not a significant difference in the historical growth trend on an actual and temperature normalized basis because the commercial sector is a very diverse sector.

Given the diversity of businesses and type of operations within the commercial sector, commercial electricity sales are not as sensitive to temperatures as the residential sector. However, some commercial customers such as schools, restaurants, and smaller health care facilities are more sensitive to temperature. Even though the total commercial load is not as temperature sensitive compared to the residential load, we still appropriately factor into our commercial forecasting models historical average temperature variables (i.e., heating and cooling degree days) over the forecast period. As such, the commercial forecasts are prepared on a temperature normalized basis and the actual commercial sales are temperature normalized. For details on the temperature normalization process see Appendix E of this report.

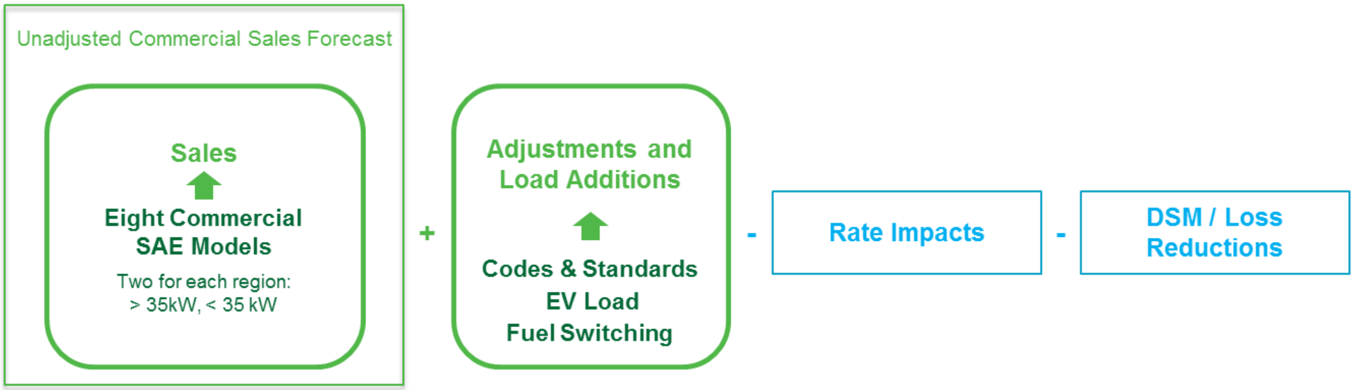
5.2 COMMERCIAL UNADJUSTED FORECAST MODEL METHODS AND COMPARISON

5.2.1 October 2018 commercial forecast methods

Similar to the residential sector, the forecast of commercial sector begins with model projections. Our commercial model projections come from eight SAE models. These eight models correspond to our four major service regions (Lower Mainland, Vancouver Island, South Interior, and North Region) each then divided into the two levels of electrical service mentioned earlier (<35 kW or >35 kW). Most commercial sales are in the Lower Mainland over 35 kW customer group and Vancouver Island over 35 kW customer group. Combined, these two customer groups make up over half of the total commercial sales. Figure 5-1 shows the commercial forecasting process and build-up of the Commercial Load Forecast after DSM and loss reduction savings.

[23] In other BC Hydro annual load forecast documents the commercial sector consisted of electricity sales to commercial customers connected at various distribution levels, two large universities in the Lower Mainland which are connected at the transmission level, street lighting customers, irrigation customers and BC Hydro Own Use. For this report, which supplements our F20-F21 RRA, the commercial sector only consists of the over 35 kW and under 35 kW commercial customers connected to our distribution system.

Figure 5-1 Commercial Load Forecast Build-up



Looking to the left hand portion of Figure 5-1, the starting point in the commercial forecasting process is the commercial SAE model projections. Our commercial SAE model's results and their statistical characteristics are provided in Appendix D of this report.

The general structure of our commercial SAE models is the same as the SAE model diagram shown in the Residential Section (Figure 4-2 of section 4.2.3.1). However, there are with two exceptions. The inputs are different, and model projections for the commercial sector are different, as they are on a sales basis versus average use per account basis.

Each of our eight commercial SAE models is an end use regression model which determines a relationship between historical commercial billed sales and historical values of the two types of variables:

- **economic variables** including employment, retail sales, and commercial GDP, and
- **non-economic variables** including the average efficiency of commercial end uses of electricity and shares of commercial end uses (i.e., the percentages of commercial customers which have a specific commercial end use). The history and forecast of both these variables come from the 2018 dataset developed by the U.S. EIA for the Pacific region. Other non-economic variables include temperature variables represented by heating and cooling degree days.

The forecasts for these variables and the estimated regression coefficients of the eight commercial SAE regression models determine the commercial model projections of electricity sales over the forecast period. Similar to the residential SAE model, our commercial SAE models are estimated over the past 10 fiscal years ending fiscal 2018.

Within our SAE commercial models, one factor determining the projected growth in electricity sales is the anticipated level of future economic activity and its impact. The relationship between the commercial sales and these economic variables are represented as economic elasticities (distinct from price elasticities) in the SAE model. Appendix C of this report describes the updated elasticities that have informed our October 2018 model projections. In addition to reviewing the economic elasticities, we reviewed the relationship between commercial sales and temperature variables. Appendix C of this report also describes the updated temperature variables for each commercial SAE model.

5.2.2 FortisBC Electric alternative commercial forecast method

The FortisBC Electric short-term method involves a model estimated over 15 years. Commercial load is regressed against B.C. real provincial GDP and other binary variables specific to the FortisBC Electric service area.

To prepare the alternative forecast using the FortisBC Electric method we developed several regression models because we had to assess how the FortisBC Electric approach could be applied with our data. As such, we estimated regression models involving our BC Hydro service area, total commercial billed sales and various economic variables such as B.C. provincial real GDP, real GDP at the BC Hydro service area level, employment at the BC Hydro service area level, and real retail sales at the BC Hydro service area level.

All history and forecast of economic data used to estimate the alternative commercial models come from Conference Board of Canada, June 2018 Economic Forecast. Table 5-1 summarizes the statistical results of the alternative regression models we developed.[24]

Table 5-1 Alternative Commercial Forecasting Models

	Model 1	Model 2	Model 3	Model 4	Model 5
Independent Variable	B.C. TOTAL PROVINCIAL REAL GDP	B.C. TOTAL PROVINCIAL REAL GDP	BC Hydro TOTAL REAL GDP	BC Hydro TOTAL EMPLOYMENT	BC Hydro TOTAL REAL RETAIL Sales
Period of Estimation	15 years	10 years	10 years	10 years	10 years
R-squared (Goodness of Fit)[26]	0.65	0.25	0.25	0.34	0.32
Durbin Watson statistic[26]	0.37	2.95	0.25	3.15	3.14
p- value of constant[26]	0.0%	0.0%	0.0%	0.0%	0.0%
p-value of independant variable	0.03%	14.4%	14.5%	7.6%	9.1%
F2018 Temperature Normalized Actual (GWh)	14,513	14,513	14,513	14,513	14,513
F2019 Model Projection (GWh)	14,919	14,513	14,513	14,575	14,556
F2024 Model Projection (GWh)	15,360	14,599	14,600	14,698	14,641

Model 1 in the Table 5-1 comes from a regression model of our total actual commercial sales regressed against real B.C. provincial GDP over the past 15 years ending fiscal 2018[25]. This model was dismissed as an alternative because the forecast from this model after load additions did not track actual sales well over the first six months of fiscal 2019[26]. In addition to this, the Durbin Watson statistic of 0.37 for this model indicated positive auto-correlation in the error terms which could be a result of missing variables or wrong function form.

The other alternative regression models (i.e., models 2 to model 5) in Table 5-1 above involved regressions of our historical temperature normalized commercial sales regressed against the various economic drivers over the past 10 years ending fiscal 2018. All of these regression models have several common statistical features including, having fairly poor statistical fit of the historical data (i.e., low R-squared statistics), the coefficients of independent variables (i.e., the economic variables) were not statistically significant, and most of models indicated no auto-correlation in the error terms.

Model projections for model 2 and model 3 indicated very little growth in sales between fiscal 2018 and fiscal 2019. Unlike model 4 and model 5, these models were dismissed as alternatives because they did not track actual sales data well over the first six months of fiscal 2019. Given the above analysis, we considered model 4 as an alternative regression model because: (i) it had one of the highest R-square values, (ii) it tracked actual sales fairly well over the first 6 months of fiscal 2019,[27] and (iii) the independent variable of employment has historically been a strong variable which we have used in the past to develop commercial SAE model forecasts. Table 5-2 is a full summary of the results of regression model 4.

[24] Definitions of R-squared, Durbin Watson statistic and p-value are described in Appendix D of this document.

[25] We do not have a complete history of commercial temperature normalized sales over the past 15 years with the updated heating and cooling variables included in the October 2018 SAE models.

[26] The assessment of the how the alternative models were tracking to actuals over fiscal 2019 involved developing a load forecast by aggregating the alternative model projections with load additions of EVs and fuel switching and load reductions for rate impacts, DSM savings and savings from loss reductions.

[27] After the first six months of fiscal 2019, the variance of actual sales compared to the alternative forecast (model 4) after DSM and loss reduction savings was 1.66 per cent and the variance in our October 2018 Commercial Load Forecast after DSM and loss reduction savings was 1.10 per cent.

5 Yr. Forecast (F18 to F23)	0.3%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

5.3.2 Commercial unadjusted sales forecast results compared

Table 5-4 contains model projections from the alternative commercial model 4 and our commercial SAE model projections at the BC Hydro service area level. The model projections from both approaches are relatively close to each other for fiscal 2019 and beyond. By fiscal 2024 the alternative model projection is 0.44 per cent lower to the SAE model projections.

Table 5-4 Commercial SAE Model vs Alternative Model Projections

Fiscal year	October 2018 commercial model projections BC Hydro service area (GWh)	Alternative model projections based on FortisBC Electric short-term method (GWh)
Actual (temperature normalized)		
F2013	14,333	14,333
F2014	14,343	14,343
F2015	14,460	14,460
F2016	14,257	14,257

F2020	14,716	14,600
F2021	14,729	14,629
F2022	14,755	14,658
F2023	14,744	14,681
F2024	14,763	14,698
5 Yr. Actual (F13 to F18)	0.2%	0.2%
5 Yr. Forecast (F18 to F23)	0.3%	0.2%

Table notes:

1. Forecast for fiscal 2019 does any actuals.

Our commercial model projections in Table 5-4 are expected to grow slowly and in line with historical sales growth over the forecast period. The variables in our SAE models that contribute to the projection of slow growth include: (i) the updated calibration period reflecting the latest 10 years of historical sales, (ii) the Conference Board of Canada's June 2018, Economic Forecast and (iii) the 2018 EIA projection of average efficiencies for commercial end uses of electricity. The average efficiency forecast for some of the commercial end uses of electricity are projected to increase over the forecast period which puts downward pressure on the model projections of electricity sales. As per the calibration period, both the residential and commercial SAE models are calibrated over the last 10 years of billing data ending fiscal 2018. This calibration period reflects a slower growth of historical sales relative to the previous calibration period used in the May 2016 Load Forecast which was 10 year ending fiscal 2015.

Table 5-5 shows a summary of the historical and forecast of the major commercial economic drivers at the BC Hydro area service level. The forecast of growth in economic drivers, as developed by the Conference Board of Canada Economic Forecast, June 2018 are generally below the historical growth rates which contributes to a slow growth in the SAE models' projections.

Table 5-5 Commercial Economic Drivers History versus Forecast

Commercial Economic Drivers[1]	Historical Growth[2] (F13 to 18)	Forecast Growth[2] (F18 to F23)
Employment	1.7%	1.3%
Real Retail Sales	4.8%	2.4%
Real Commercial GDP	2.9%	2.4%

Table notes:

1. Growth rates are based on data from the Conference Board of Canada, June 2018 Economic Forecast.
2. Averages are computed as an average of the year over year annual growth over five years.

5.4 COMMERCIAL SALES FORECAST RESULTS & COMPARISON

5.4.1 Commercial sales forecast results

Table 5-6 shows the October 2018 commercial sales forecast after rate impacts with history on a temperature normalized basis, and adjacent to that, the October 2018 Commercial Load Forecast after DSM and loss reduction savings. The October 2018 Commercial Load Forecast is an aggregation of all of our SAE model projections, adjustments for code and standards, loads additions, (i.e., EVs and fuel switching) and load reductions (i.e. rate impacts, DSM savings and loss reductions).

Table 5-6 Commercial Sales History and Forecasts After Rate Impacts

Fiscal year	October 2018 Forecast after Rate Impacts (GWh)	October 2018 Commercial Load Forecast (GWh)
Actual		
F2013	14,333	14,333

5 Yr. Forecast (F18 to F23)	0.4%	-0.6%

Table notes:

1. Forecast for fiscal 2019 does include any actuals.

5.4.2 Commercial sales forecast compared

Just like the residential alternative forecast after rate impacts, the alternative commercial forecast with rate impacts does not include an adjustment for overlap in codes and standards. This is because the alternative model projection depends upon one driver of load which is employment.

Table 5-7 compares our forecast (one after rate impacts, the other after DSM and loss reductions) to their corresponding alternative commercial forecast. Next to the forecasts are the temperature normalized actual sales.

Table 5-7 Commercial Sales History and Forecasts After Rate Impacts and After DSM

Fiscal year	October 2018 Forecast after Rate Impacts (GWh)	Alternative FortisBC Electric short-term after Rate Impacts (GWh)	October 2018 Commercial Load Forecast after Rate Impacts after DSM/Loss Reductions (GWh)[1]	Alternative FortisBC Electric short-term after Rate Impacts and after DSM / Loss Reductions (GWh)[1]
Actual

F2017	14,582	14,582	14,582	14,582
F2018	14,513	14,513	14,513	14,513
Forecast				
F2019[2]	14,659	14,578	14,568	14,488
F2020	14,731	14,604	14,484	14,358
F2021	14,767	14,642	14,353	14,227
F2022	14,825	14,685	14,244	14,104
F2023	14,835	14,711	14,113	13,990
F2024	14,880	14,735	14,034	13,902
5 Yr. Actual (F13 to F18)	0.2%	0.2%	0.2%	0.2%
5 Yr. Forecast (F18 to F23)	0.4%	0.3%	-0.6%	-0.7%

Table notes:

1. Savings from loss reductions reflected in the Commercial Load Forecast and the alternative forecast attributed to commercial sector is expected to increase from 4 GWh in fiscal 2019 to 13 GWh in fiscal 2024. As such, DSM savings, in particular savings from codes and standards, are expected to contribute to the decline in sales over the forecast period.
2. Forecast for fiscal 2019 does not include any actuals.

We believe that our October 2018 Commercial Load Forecast compared to the alternative forecast, as shown in the Table 5-7 above, is a more reliable forecast because:

- Our commercial SAE model forecasts are developed using variables besides a single driver of the commercial load. We believe the size and complexity of the commercial sector alone demands we include multiple variables, rather depend upon a single driver,
- In addition, the alternative regression models had a poor fit to our historical data. This supports the assertion that other variables besides one economic variable is need to explain how commercial sales have changed over time,
- Given the size of the of FortisBC Electric service area it would appear that a top down approach (i.e., one forecast for the entire area) is reasonable. Therefore, there is no need to further divided up their service area into sub-regions and then add up forecasts for the sub-regions (i.e., bottom up approach). In contrast, given the size and diversity of our load, economic growth, types of

commercial operations, and temperatures across our service area, we believe the commercial forecast is better represented using our bottom up approach, and

- Looking at variance from actuals as measure of forecast performance shows our methodology yielded better when compared to the alternative method applied to our context. To do this, we re-developed commercial forecasts for fiscal 2016 to fiscal 2018 using the alternative FortisBC Electric method. The commercial sales variance on a temperature normalized basis as per the alternative approach[28] for fiscal 2016 to fiscal 2018 were -1.4 per cent, 1.9 per cent, and 1.8 per cent respectively or 0.8 per cent over all years. These variances are higher compared to the variances based on the commercial load forecast as per our May 2016 Load Forecast which are: -2.3 per cent, 0.7 per cent; and 0.3 per cent on a temperature normalized basis from fiscal 2016 to fiscal 2019 respectively or -0.4 per cent on average over all years.

5.5 COMMERCIAL SALES FORECAST BUILD-UP F2019 TO F2021

The commercial sector is most of the light industrial / commercial sector sales. The billed sales forecast of combined total load forecast for light industrial / commercial sector with DSM and loss reductions before accruals is the foundation for light/commercial load forecast in our F20-F21 RRA. As such, the detail on the build-up of the billed sales Commercial Load Forecast for fiscal 2019 to fiscal 2021 is presented in the tables below.

Table 5-8 Fiscal 2019 Commercial Load Forecast Build-up

Model projection[1] (GWh)	Codes overlap adjustment (GWh)	EV load addition (GWh)	Fuel switching load addition (GWh)	Rate impact[2] (GWh)	DSM (GWh)	Loss reductions (GWh)	Commercial Load Forecast[3] (GWh)
14,652	4	8	0	(6)	(87)	(4)	14,568

Table notes:

1. The model projection is the sum total of all commercial SAE model projections.
2. Rate Impacts is an estimation of load reduction based on a formula that includes our real rate increase projection, a price elasticity assumption of -0.1, the commercial model projection, codes overlap adjustment and all commercial load additions.
3. The Commercial Load Forecast is an aggregation of commercial model projections, adjustments for codes and standards, commercial load additions (i.e., EVs and fuel switching) less rate impacts, less DSM and loss reduction savings.

In Table 5-8 above the forecast of 14,568 GWh for fiscal 2019 does not include any actuals over the current fiscal year. After the first six months of the fiscal year this forecast was 77 GWh or 1.1 per cent below actuals. The forecast of 14,646 GWh, as shown in the executive summary, reflects six months actual billed sales over fiscal 2019 and 6 months forecast. To develop this estimate the Commercial Load Forecast of 14,568 GWh is allocated into 12 months using a rolling five year average shape of monthly billed sales at the BC Hydro service area level. After the annual projection is allocated, the first 6 months of forecast are replaced with actuals sales.

[28] To compute these variances, we developed a regression model of historical temperature normalized sales regressed against employment for a 10 year period ending fiscal 2015. Using the regression model and Robert Fairholm Economic Consultant's March 2015 forecast of employment we developed a model projection that was augmented by including EV load additions and reductions for rate impacts and savings for DSM and loss reductions. The elasticity of -0.05 was used for estimate rate impacts. DSM saving and loss reductions savings were the same amounts used in the May 2016 Forecast.

Table 5-9 Fiscal 2020 and F2021 Commercial Billed Sales Forecast Build-up

Fiscal year	Model projection (GWh)[1]	Codes overlap adjustment (GWh)	EV load addition (GWh)	Fuel switching load addition (GWh)	Rate impacts[2] (GWh)	DSM (GWh)	Loss reductions (GWh)	Commercial Load Forecast[3] (GWh)
F2020	14,716	10	12	5	(11)	(241)	(6)	14,848
F2021	14,729	25	16	17	(20)	(407)	(8)	14,352

Table notes:

1. The model projections are the sum total of all commercial SAE model projections.
2. Rate Impacts is an estimation of load reduction based on formula that includes our real rate increase projection, a price elasticity assumption of -0.1, the commercial model projection, codes overlap adjustment and all commercial load additions.
3. Commercial Load Forecast is an aggregation of commercial model projection, adjustments for codes and standards, commercial load additions (i.e., EVs and fuel switching), less rate impacts less loss reductions and DSM savings.

5.6 COMMERCIAL SALES FORECAST UNCERTAINTIES

The Commercial Load Forecast reflects the combination of several forecasts such as model projections, adjustments for code and standards, load additions, and load reductions.

Our unadjusted sales forecasts come from our SAE models which reduces the risk that our commercial forecasting models are not capturing a proper relationship between historical sales and drivers of commercial loads. In addition, our commercial forecasting models have multiple drivers of load as opposed to a single load driver. This reduces forecast risk in that our model projections are from multiple external forecasts rather than one external forecast of one economic variable. We also develop model projections for individual service regions rather than developing a forecast of total commercial load and allocation it to the regions from the top down. This reduces the risk that we don't recognize the diversity within the commercial segments across our service area.

Our forecasting models reflect several factors that impact commercial load including average efficiency assumption, estimates of overlap of codes and standards, economic forecasts, economic elasticities and normalized temperature conditions captured in our heating and cooling variables. As such there is uncertainty in all of these components that make up the commercial forecast. While some of these uncertainties may offset each other, there could be conditions that could lead to a variance in the forecast where the actuals are higher or lower than forecast. Some of these are listed below.

Conditions that could result in lower than forecast commercial sales include:

- a change in the economic conditions where the economy expands less than anticipated in the forecast,
- improved equipment efficiency beyond the trends anticipated in the forecast,
- a high Canadian dollar lowers tourism and retail sales,
- growth in on line shopping and internet business that could result in less activity and future expansion in commercial stores and therefore reduce demand for electricity sales to the commercial retail sector, and

- summers that are colder than normal (reducing air conditioning loads) and winters that are warmer than normal (reducing heating loads).

Conditions that could lead to higher than forecast commercial sales include:

- stronger than projected economic conditions,
- higher demand for commercial office space,
- expansion of the technology sector in B.C.,
- a lower Canadian dollar which encourages tourism and retail sales, and
- summers that are above normal temperatures (increasing air conditioning loads) and winters that are colder than normal (increasing heating loads).

While many of these conditions are factors outside our control addressing them is part of our continuous improvement approach to load forecasting.

6.0 Light Industrial Forecast

6.1 LIGHT INDUSTRIAL SECTOR DESCRIPTION

The light industrial sector consists of approximately 29,000 customers connected at the distribution level. At the end of fiscal 2018, sales to the light industrial sector were 4,364 GWh or 8.3 per cent of our total firm sales. The light industrial sector is subdivided in the following sub-sectors: coal, forestry, oil and gas, and 'other' industrial loads which include various industrial activities such as agriculture and manufacturing.

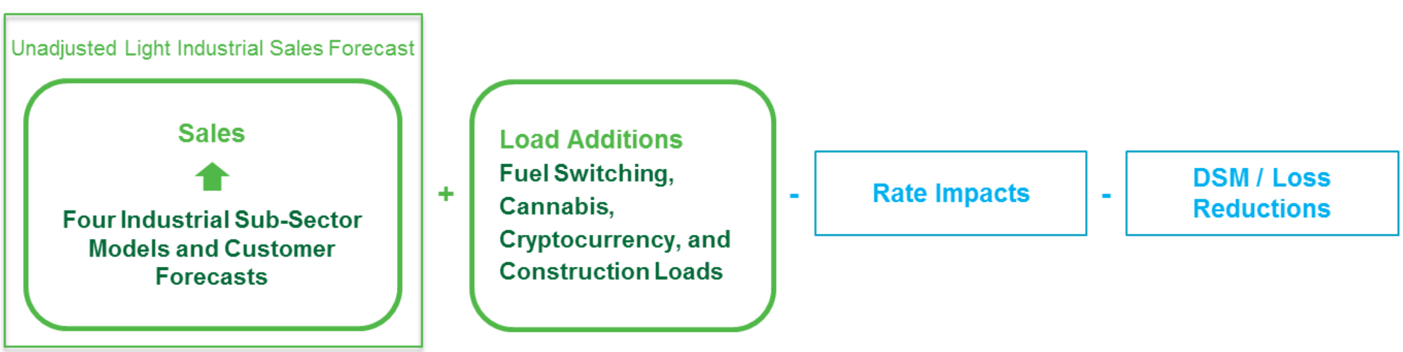
As of October 2018, we have also included the following additional loads to this sector: (i) fuel switching estimates, (ii) incremental cannabis and cryptocurrency loads; and (iii) construction load for LNG plants and other facilities located in northeast B.C. These additional loads are combined with the model projection for the other light industrial loads. While cannabis and cryptocurrency loads are covered in Section 8 of this report, we have included the forecasts for these loads connected at distribution voltages in the tables below to show the total sector load.

Over the past five years, electricity sales across all light industrial customers have grown by 1.8 per cent on average (i.e., five year annual compound growth). This growth has been led by increases in sales in the other light industrial sub-sector and the oil and gas sub-sector. Similar to the large industrial sector, the light industrial sector is not sensitive to temperature variation and is therefore not prepared on a temperature normalized basis.

6.2 LIGHT INDUSTRIAL FORECAST METHODOLOGY

Figure 6-1 shows the process steps to develop the forecast for the light industrial sector. The October 2018 Light Industrial Load Forecast is an aggregation of model projections and customer forecasts from the four main sub-sectors listed above, and load additions for fuel switching, cannabis and cryptocurrency loads, and construction loads. This forecast also includes load reductions for rate impacts, DSM and loss reduction savings. The DSM savings and loss reductions are determined at the total sector level. As such, there are no specific DSM savings and loss reductions for the loads that make up the four main sub-sectors or any of the load additions.

Figure 6-1 Light Industrial Load Forecasting Steps



Each of the sub-sectors uses their own forecast methodology which is described below. Since the light industrial sector is not developed on an end-use basis there is no need for adjustments due to overlaps in codes and standards. In addition, there is no allocation of EV load to this sector.

Customers within the forestry sub-sector (approximately 1,200 GWh per year or 27 per cent of the light industrial sector) encompass sawmills, panel mills and pellet plants. Mill by mill production projections are developed for this sub-sector by the same experts who develop production forecasts for the large industrial wood products segment. The individual mill production forecasts are aggregated together on a regional basis and then multiplied by intensity factors (i.e. kWh/unit of production) to develop regional model projections. These projections are then aggregated to make up the total forestry sub-sector forecast.

Oil and gas customers (approximately 460 GWh or 11 per cent of the total light industrial sector) are involved in production and processing, transportation (pipelines, pump stations, truck terminals) and support services for the oil and gas industry. This sub-sector's forecast is determined on an account by account basis. Account projections are developed with information from BC Hydro Distribution Area planners and Load Interconnections personnel. Probability assessments are carried out on customer requests from natural gas processing plants and natural gas pipeline customers that make up most of the growth in the current forecast.

There are three coal mining customers (approximately 40 GWh or 1 per cent of the total sector sales). This forecast is developed on an account by account basis using a probability weighted approach.

The forecast projections for other industrial distribution loads (2,700 GWh which is approximately 62 per cent of the total light industrial sales) are based on a forecasting model, results of a regression model, and the forecast of real provincial GDP.

Equation 6.1 is the model used to develop the projections for the other light industrial loads. The parameters of this model are informed by coefficients from a regression model of the log of sales per unit of provincial GDP and a time trend. The statistical characteristics and results of the regression model are provided in Table 6-1. These results provide the coefficients for our forecasting model (equation 6.1). The regression model is statistically robust and has a good fit to the historical data, and therefore viewed as a sound model to develop the forecast.

The model used to projections the other industrial loads is the following expression:

Equation 6.1

$$INDD = \left(e^{\propto+\beta T}\right) \times GDP$$

Where:

- INDD is other industrial distribution sales (excluding sales for the sub-sectors of forestry, oil and gas and coal),
- α and β are the regression coefficients from a log regression model of the log of sales per unit of provincial GDP, and a time trend,
- e is exponential base,
- T is a time trend variable, and
- GDP represents the provincial real GDP forecast.

Table 6-1 Log regression model of the log of sales per unit of provincial GDP and a time trend[1]

Variable and Statistics	Result
Constant	2.544 (p-value of 0.0%)
Independent Trend Variable	-0.013 (p-value of 0.0%)
Adjusted R-Square	0.91
Auto-correlation Range (AR)	1-1.34
Durbin-Watson Statistic	1.36
Auto-correlation test result	No Auto-correlation

Table notes:

1. See Appendix D for definitions of p-value, R-Square, Auto-correction Range and Durbin-Watson Statistics.

6.3 LIGHT INDUSTRIAL LOAD FORECAST RESULTS

Table 6-2 shows the forecast for the light industrial sector after rate impacts as the sum of two forecasts:

- the forecast in column A is the sum of model projections and individual customer forecasts for all the sub-sectors (i.e., coal, forestry, oil and gas, and the other light industrial loads) less rate impacts; and
- the forecast in column B is the forecast of total load additions (i.e., incremental cannabis and cryptocurrency loads, fuel switching loads, construction loads for LNG operations, and other facilities) less rate impacts.

Table 6-2 Light Industrial Sales History and Forecasts After Rate Impacts

Fiscal year	A October 2018 model projections / customer forecasts of light industrial sub-sectors after rate impacts (GWh)	B October 2018 total load additions after rate impacts (GWh)[1]	A+B October 2018 light industrials sales after rate impacts (GWh)
Actual			
F2013	3,994		3,994
F2014	4,164		4,164
F2015	4,227		4,227
F2016	4,148		4,148
F2017	4,275		4,275
F2018	4,364		4,364
Forecast			
F2019[2]	4,363	46	4,409
F2020	4,424	113	4,537
F2021	4,437	327	4,764
F2022	4,468	329	4,796
F2023	4,484	346	4,831
F2024	4,518	336	4,855
5 Yr. Actual (F13 to F18)	1.8%		1.8%
5 Yr. Forecast (F18 to F23)	0.5%		2.1%

Table notes:

1. As of fiscal 2018 there were no light industrial customers classified as cannabis and cryptocurrency loads. As such, historical and forecast compound growth rates are not shown. In addition, actual loads for construction were relatively small.
2. Forecast for fiscal 2019 does not include any actuals.

Column A shows the total of the model projections and customer forecasts that make up the four main light industrial sub-sectors less rate impacts. Most of the 155 GWh of growth from fiscal 2019 to fiscal 2024 is attributed to the other light industrial sub-sector and the oil and gas sub-sector. The increase in the other sub-sector is about 81 GWh or 52 per cent of the total growth. This increase is based on the projection of GDP and the regression results in Table 6-1.

Column B shows the total of additional loads from fuel switching, cannabis and cryptocurrency, and construction loads less rate impacts. Most of the increase in the forecast from fiscal 2019 to fiscal 2024 is attributed to incremental sales to cannabis and cryptocurrency loads. In fiscal 2019, the forecast sales to cannabis and cryptocurrency customers are approximately 42 GWh which is expected to increase to about 246 GWh by fiscal 2024. The methodology and further details on the forecasts for the cannabis and cryptocurrency loads are described in Section 8 of this report.

Table 6-3 shows the Light Industrial sales history and forecast after DSM and load reductions.

Table 6-3 Light Industrial Sales History and Forecasts After Rate Impacts and After DSM

Fiscal year	October 2018 Light Industrial Load Forecast (GWh)
Actual	
F2013	3,994
F2014	4,164
F2015	4,227
F2016	4,148
F2017	4,275
F2018	4,364
Forecast	
F2019[1]	4,390
F2020	4,487
F2021	4,683
F2022	4,688
F2023	4,697
F2024	4,697
5 Yr. Actual (F13 to F18)	1.8%

5 Yr. Forecast (F18 to F23)	1.5%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

After accounting for DSM and loss reductions, the total light industrial load growth from fiscal 2019 to fiscal 2024 is about 300 GWh. Most of the growth comes from incremental growth in cannabis and cryptocurrency loads. The forecasted growth for the cannabis and cryptocurrency customers represent customer requested loads that are considered highly probable based on their advanced stage of progress in BC Hydro's interconnection process. In addition, the vast majority of the growth in these emerging sectors comes from new cannabis operations where some of this load includes customers that were already connected to our system but have modified existing operations to become cannabis suppliers in fiscal 2019.

6.4 LIGHT INDUSTRIAL LOAD FORECAST BUILD-UP F2019 TO F2021

The build-up of the Light Industrial Load Forecast for fiscal 2019 and fiscal 2020 to fiscal 2021 is presented in Table 6-4 and Table 6-5, respectively.

Table 6-4 Fiscal 2019 Light Industrial Load Forecast Build-up

Light industrial model projections / customer forecast (GWh[1])	Cannabis/crypto currency load additions (GWh)	Construction load additions (GWh[2])	Fuel switching load additions (GWh)	Rate impacts[3] (GWh)	DSM (GWh)	Loss reductions (GWh)	Light Industrial Load Forecast[4] (GWh)
4,365	42	3	0	(2)	(17)	(1)	4,390

Table notes:

1. The light industrial forecast for the four main sub-sectors.
2. Construction loads included are for future LNG terminals and other facilities.
3. Rate Impacts is an estimation of load reductions based on a formula that includes our real rate increase projection, a price elasticity assumption of -0.1 and the light industrial forecast, including all load additions .
4. The Light Industrial Load Forecast is an aggregation of light industrial model projection, customer forecasts, and load additions (i.e., cannabis and cryptocurrency loads, construction loads, and fuel switching loads), less rate impacts, loss reductions and DSM savings.

The Load Forecast of 4,390 GWh for fiscal 2019 does not include any actuals over the current fiscal year; this forecast was lower than actuals by 25 GWh or 1.2 per cent after the first six months of fiscal 2019. The forecast of 4,415 GWh as shown in the executive summary reflects six months of actual billed sales and six months forecast. To develop this forecast, the 4,390 GWh is allocated into 12 months using a rolling five year average shape of monthly billed sales at the BC Hydro service area level. After the load forecasts are allocated into monthly load forecasts, the first six months of forecast are replaced with actual sales.

Table 6-5 Light Industrial Load Forecast Build-up Fiscal 2020 and F2021

Light industrial model projections (GWh[1])	Cannabis-crypto currency load addition (GWh)	Construction load addition (GWh[2])	Fuel switching load addition (GWh)	Rate impacts[3] (GWh)	DSM (GWh)	Loss reductions (GWh)	Light Industrial Load Forecast (GWh)
4,427	79	34	0	(4)	(48)	(1)	4,487
4,430	242	85	13	(7)	(79)	(2)	4,683

Table notes:

1. The light industrial model projection is the sum of the projections from all four main sub-sectors.
2. Construction loads included are for future LNG terminals and other facilities such as gas pipelines.
3. Rate Impacts is an estimation of load reduction based on formula that include our real rate increase projection, a price elasticity assumption of -0.1 and the model projections and all load additions including in the light industrial sector.

The Light Industrial Load Forecast is an aggregation of the light industrial model projection, adjustments for codes and standards, light industrial load additions (i.e., cannabis and cryptocurrency loads, construction loads, and fuel switching loads), less rate impacts, loss reductions, and DSM savings.

6.5 LIGHT INDUSTRIAL SALES FORECAST UNCERTAINTIES

The total load growth over the forecast period (i.e. fiscal 2019 to fiscal 2024) for the light industrial sector is about 300 GWh. Most of this growth comes from incremental load requests from cannabis and cryptocurrencies. The remainder comes from construction loads and the forecast for each of the four light industrial sub-sectors. Fuel switching loads are not a significant of load growth.

The forecast represents an aggregation of various customers that have requested electricity service for supporting activities for the construction of gas pipelines, LNG projects that have made a final investment decision, and other projects in northeast B.C. We anticipate that these loads will materialize but they could vary over the short term based on construction schedules and when construction will begin to ramp up.

For the light industrial loads related to the 'other' sub-sector, the regression model we have used to develop the sales projection is statistically robust (no autocorrelation) and has a good fit to the historical data (high R-square value). However, since the forecast largely relies upon the GDP forecast, there is a risk that actual GDP growth may vary from forecast.

In addition, the other light industrial sub-sector is composed of manufacturing loads. These loads may respond differently to other factors such as tariffs, exchange rates, technology changes and commodity prices which could impact sales. This also holds true for the oil and gas light industrial sub-sector.

7.0 Large Industrial Forecast

7.1 LARGE INDUSTRIAL SECTOR DESCRIPTION

The large industrial sector is comprised of about 190 customers that account for about 26 per cent of BC Hydro's total firm sales. The individual customers are organized into four main sub-sectors: mining, forestry, oil and gas (including LNG), and other large industrial customers. While light industrial customers are connected at distribution voltages, large industrial customers are connected at transmission voltages. Most of our large industrial customers are involved in extracting, processing and manufacturing resource based commodities, which are largely exported outside B.C. Export volumes can vary significantly from year to year in response to market forces and consequently, electricity sales to this sector can also vary.

7.2 LARGE INDUSTRIAL FORECAST METHODOLOGY

Sales to the large industrial sector are forecast on an individual customer basis. The process that we use to produce the Large Industrial Sector Load Forecast is shown in Figure 7.1.

Figure 7-1 Large Industrial Load Forecast Process

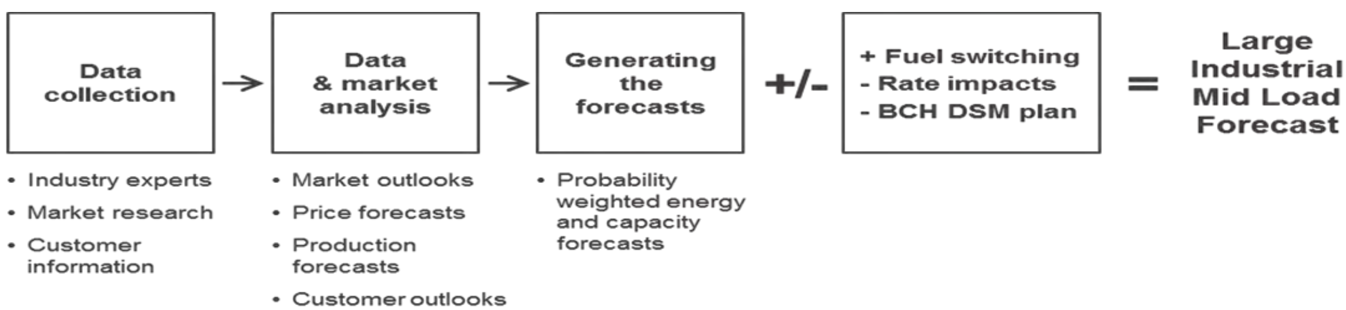


Figure notes:

- Fuel switching amounts are relatively small and are developed on a sub-sector basis.
- Rate impacts are based on an elasticity assumption of -0.1 applied to each sub-sector and real rate increase projections (real dollar bill impacts).
- Forecast of DSM savings are based on our DSM plan.

We develop the Large Industrial Sector Load Forecast using information from several sources. These include:

- **industry experts:** We retain external consultants who develop production and commodity price forecasts and provide both facility and sector-specific market assessments,
- **market research:** We subscribe to services that provide market research and industry analyses in addition to publicly available reports from government agencies, and
- **information from our customers:** Our Key Account Management and Load Interconnections groups who are in contact with our customers gather direct information about those customers' anticipated demand.

Using these sources, we develop probability weightings of expected sales to our current customers. These probability weightings represent a risk assessment of the likelihood of future sales.

For each potential new customer, these same sources of information are used to develop similar probability weightings to forecast if and when new demand may materialize.

Each of these probability weightings represents our professional judgement based on the synthesis of information from our sources as well as factors that are considered when assigning probability weightings, which include:

- how far a customer has passed through our interconnection processes,
- the status of the customer's regulatory/approval permits and project financing,
- BC Hydro's ability to meet the customer's requested in-service date,
- consultant mill, facility and market assessments, where applicable,
- the market outlook for the customer's products,
- the credit and financial viability of the customer,
- the impact of electricity costs on the customer, and
- the likelihood that the customer will take electricity supply from BC Hydro instead of self-supplying their power needs.

Due to commercial sensitivities, individual account assessments are kept confidential. To maintain this confidentiality the large industrial forecast is aggregated by sub-sector.

7.2.1 Additional improvements to large industrial methodology

In addition to modifying the price elasticity assumption described in Section 3, we made improvements to the large industrial load forecast methodology. These improvements specifically address, but also go beyond, issues raised by the BCUC and Load Forecasting Audit. We believe these changes will improve the performance of the forecast.

LNG: We updated our methodology for forecasting sales to LNG customers. In the Site C Final Report, the BCUC observed that "BC Hydro had not made a probabilistic assessment of the likelihood of the LNG load materializing." In this Application, we forecast sales to LNG customers in a manner consistent with other Large Industrial customers: using the probabilistic assessment approach outlined in the Large Industrial Sector Methodology section. For further detail see Section 7.5.2.2.

Probability Weighting: As part of our ongoing internal efforts to improve our load forecast methodology, we changed how we incorporate individual customer probability assessments into the first three years of our large industrial sector load forecast (fiscal 2019 to fiscal 2021). Previously, a customer's load was adjusted by the probability weighting we assigned to it over the forecast period. The probability weightings reflect a number of risk factors, including the likelihood that customers will expand, contract or maintain operations; close operations; or start new operations (e.g., in the case of new customers). A review of our fiscal 2018 variance, as per our May 2016 Load Forecast, showed a significant positive variance (higher actual loads relative to forecast) and negative variance (lower actual loads relative to forecast) for several industrial sub-sectors, notably forestry (positive variances) and oil and gas (negative variances). These variances were determined to be attributed to risk adjustments (i.e., probability weightings) on specific customers that were significantly driven by closure risk considerations (for some existing customers) or start-up likelihood consideration (for new customers). For example, a customer with a 25 per cent probability of closure would have their anticipated load included in a load forecast at 75%. Operationally, the net effect of facility closures or start-ups is that a facility will either be fully operational (i.e., on) or not operating at all (i.e., off). However, the net effect of reflecting those "on/off" risk adjustments in the load forecast results in partial loads. It is the difference between those partial loads reflected in the forecast and actual operations being either "on" or "off" which largely explains the recent industrial sub-sector load forecast variances. To address this BC Hydro has moved to a binary approach for the first three years of the forecast. The binary method results in discrete projection (i.e. in or out) of load and revenues. This approach is applied as follows:

- we continue to undertake probability assessments on an individual customer account basis,

- where the dominant risk factor amongst all others is closure risk, customer loads included in the forecast are reflected at either their full expected load (weighted at 100% probability) or zero load (weighted at 0%) for the period fiscal 2019 to fiscal 2021, depending on whether the closure risk is assessed as being low or high, and
- where the main risk factor is start-up likelihood, only high likelihood projects are included at their full expected load in the period fiscal 2019 to fiscal 2021. For these highly likely projects we also consider project schedule risk as part of the binary assessment. For example, there may be uncertainty on when a project actually comes into service relative to the customer requested in-service date. In these situations we will exercise our professional judgement in deciding whether to reflect the full expected load at a later date than that requested by the customer. If we determine there is a reasonable likelihood the actual in-service date will occur beyond the customer requested in-service date, the full expected load (i.e., weighted at 100%) will be reflected at that later date in the forecast and at zero load (i.e., weighted at 0%) prior to that date.

On an aggregate sector total basis, this binary approach may or may not improve load forecast accuracy over the test period since positive variances in one sub-sector may offset negative variances in another. However, we believe this approach will improve load forecast accuracy for specific segments since it explicitly addresses why the most recent variances occurred. Over the long term, we believe a probabilistic based approach continues to be the best method for developing the large industrial sector forecast on an aggregate basis. Our view is supported by our load forecast audit findings.

In addition to these methodological changes, we retained the services of an oil and gas consulting company to provide additional analysis of shale gas development in B.C., recognizing that the shale gas component of the oil and gas sub-sector is the fastest growing area of our sales. These consultant services are described in section 7.5.2.1.2.

7.3 MINING

As a result of our market outlook and internal information related to service requests from potential new customers, we are expecting minimal growth in the mining sub-sector load between fiscal 2018 and fiscal 2024. The total load in the mining sub-sector in fiscal 2024 is expected to be close to the current level of sales which is 3,900 GWh as of fiscal 2018. A number of uncertainties exist, which are reflected in the high and low forecasts.

7.3.1 Mining sub-sector description

The mining sub-sector accounts for about 29 per cent of sales to the large industrial sector. It is categorized into two segments: metal and metallurgical coal mines. Demand from metal mining makes up 85 per cent of the total sales in the mining sector. Since metal mining represents the vast majority of the mining load for BC Hydro, the drivers of metal mining have the most influence on the total mining load.

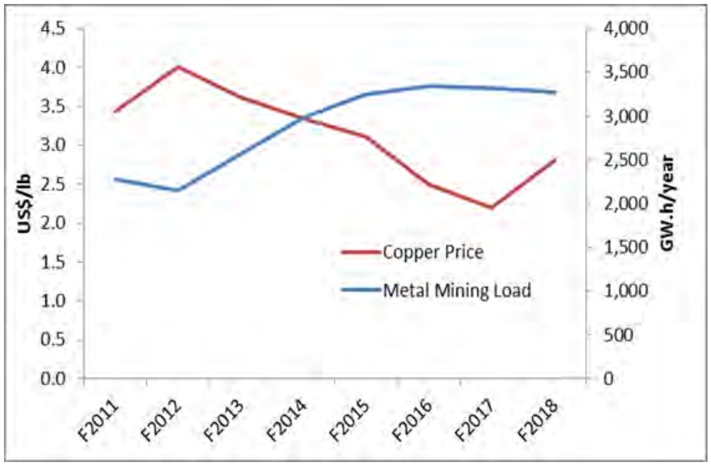
Metal mines typically consume significantly more electricity than coal mines, due to the energy required in the comminution process (crushing and grinding ore to extract the target minerals). Electricity used in metal mining operations typically represents about 10 to 15 per cent of total production costs. The metal mines in B.C. produce predominantly copper with gold, molybdenum, and silver as common secondary products. Two operating mines - Brucejack and New Afton - list gold, as the main product.

Metallurgical coal is an export commodity which is sold worldwide to integrated steel mills for steel-making purposes. Metallurgical coal mines consume less electricity than metal mines, due to the softer sedimentary nature of these deposits. Only crushing is required to break up the rock and energy intensive milling is not required. Electricity used in metallurgical coal operations typically represents about 5 per cent of production costs.

Growth in B.C.'s mining industry is linked to commodity prices, which are driven by economic growth within parts of Asia and the relative global supply/demand balance for copper, metallurgical coal, gold and to a lesser extent molybdenum. China is currently responsible for about 50 per cent of global copper demand. Other factors that impact mining sales and the development of new mines include the availability of financing, regulatory & environmental approvals, and First Nations considerations.

The mining sector is exposed to price volatility and commodity cycles. This is shown in Figure 7-2 below.

Figure 7-2 Metal Mining Load vs. Copper Price



The metals commodity boom between 2009 and 2011 triggered a significant increase in mine development activity. However, this was followed by an economic downturn in 2013-2016, as growth in China slowed down. A recent pick-up in commodities demand as well as supply constraints have caused most metal and coal prices to increase in the last 12 to 18 months, but current global trade tensions are casting a shadow on the price recovery.

Due to long construction periods and additional time to ramp up or ramp down production, electricity sales in the mining sector typically lag commodity prices. Restarts and upgrades at existing operations are generally the fastest response to positive price signals, followed by greenfield additions. Prolonged low price environments may lead to shutdowns, but most closures have also a built-in lag effect as metal miners continue to run the electric intensive mills to process stockpiles months after the shutdown of pit operations.

The recent history of mining load in B.C. is a good example of the lag effect. The commodity price boom in 2009-2011 prompted upgrades at existing operations (e.g., Gibraltar, Endako, Highland Valley) accompanied by brownfield restarts (Copper Mountain, New Afton) and greenfield additions (Mt Milligan, Red Chris and, most recently, Brucejack). This resulted in the metal mining load increasing by approximately 40 per cent between fiscal 2011 – fiscal 2015, despite the commodity market being in a pronounced downturn. The ramp up in mining load after fiscal 2016 was offset by shutdowns at Endako and Huckleberry mines due to low commodity prices and the temporary closure at Mt. Polley due to dam failure. This resulted in a flat profile for mining load between fiscal 2016 and fiscal 2018.

Despite the recovery in copper and metallurgical coal prices over the past year, financing still represents a challenge for miners. Most mining companies scaled back or cancelled exploration activity in recent years and deferred investment decisions. Annual exploration spending in B.C. has decreased from a record $680 million in 2012, to $205 million in 2016 and $246 million in 2017, according to the BC Exploration Survey.[29]

Subsequent to the production of this October 2018 Load Forecast, Imperial Metals announced on January 7, 2019 the suspension of operations at the Mt. Polley mine. In its news release, the company stated the shutdown was due to market conditions, and that the operation will resume, "once the economics of mining at Mt. Polley improve." As a result, we expect reduced sales from Mt. Polley relative to what is included in the mid load forecast from fiscal 2020.

7.3.2 Mining forecast methodology

The mining sector’s sales are forecast on an individual customer account basis, in line with the large industrial sector methodology. There are two independent methods of deriving the forecast of electricity sales for mining customers.

[29] (https://www2.gov.bc.ca/gov/content/industry/mineral-exploration-mining/further-information/statistics/exploration-spending).

The primary method is the product of expected peak demand, load factor, and probability. The load factor is a measure of the utilization rate, or efficiency of electrical energy usage. In case of existing customers, historical consumption information is used as starting point updated with newest information (such as equipment upgrades). The probability weighting, which is informed by the criteria outlined in section 7.2 include factors such as the project's economics, availability of financing, regulatory progress and BC Hydro interconnection status. A mine's economics is analyzed in the context of the global market. The mining forecast includes closure risk for existing customers.

The secondary method uses production, electricity intensity and probability. The production data is informed by the third party subscription and the electricity intensity is derived from our internal sources.

For the current forecast, we rely on the Wood Mackenzie copper mining subscription and Consensus Economics price forecast to support the development of the metal mining forecast. We also use public reports from the Ministry of Energy and Mines, Thompson Reuters, PricewaterhouseCoopers, Deloitte, Genome British Columbia, company public reports and information gather by our Key Account Management and Load Interconnections business units.

In contrast, for the metallurgical coal forecast we rely on Consensus Economics, the Ministry of Energy and Mines, company public reports and internal information.

7.3.3 Mining forecasts results and uncertainties

7.3.3.1 Metal mining segment

7.3.3.1.1 Metal mining segment description

In the long term, electricity sales to metal mines are tied to price expectations for copper and gold and to a lesser extent, molybdenum and silver. The prices of these commodities are influenced by global demand and supply and the state of the global economies. In the short term, month-to-month electricity sales to metal mines are relatively independent of commodity price fluctuations because these mines are fixed-cost operations, running on a continuous basis. Since the most of B.C. metal mining production is exported, mining sales are not overly dependent on domestic economic activity, but rather correlated to the global economy. The top destinations for B.C. mining exports include Japan, the United States, China and South Korea.

7.3.3.1.2 Metal mining segment forecast results

Over the five years ending fiscal 2018, sales to the metal mining segment increased by 730 GWh or 28%. The increase was caused by new metal mining loads in addition to expansions for existing customers. The increase was partially offset by the loss of several customers (Huckleberry, Endako) due to lower commodity prices and the temporary shutdown of Mt. Polley due to the dam event. Table 7-1 shows the history and forecast of metal mining sales before rate impacts.

Table 7-1 Metal Mining Sales History and Forecast Before Rate Impacts

Fiscal year	October 2018 Forecast (GWh)
Actual	
F2013	2,561
F2014	2,978
F2015	3,247

F2016	3,338
F2017	3,321
F2018	3,291
Forecast[2]	
F2019[1]	3,294
F2020	3,427
F2021	3,501
F2022	3,488
F2023	3,457
F2024	3,360
5 Yr. Actual (F13 to F18)	5.1%
5 Yr. Forecast (F18 to F23)	1.0%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.
2. Forecast includes fuel switching estimates.

As result of the market outlook and internal information related to service requests from potential new customers, we are expecting minimal growth in the metal mining load between fiscal 2018 and fiscal 2024. Some equipment upgrades to existing operations are expected to occur between fiscal 2018 and fiscal 2021, which will increase load by approximately 200 GWh. However, any potential (probability weighted) new mining loads between fiscal 2022 and fiscal 2024 are more than offset by expected end of life shutdowns to several existing customers. As a result, the metal mining load in fiscal 2024 remains close to the current level of 3,300 GWh in fiscal 2018.

The copper market outlook[30] which underpins our forecast is summarized as follows:

- although high volatility is inherent with copper prices, the average annual price is expected to continue around $3/lb as global demand grows at a moderate pace driven by construction activity in China and global electrification of various sectors (transportation, manufacturing),
- trade wars are expected to have an effect in short term, but not drive the global economy into a recession,

[30] Copper market outlook is informed by Wood Mackenzie subscription and other sources described in the methodology section.

- new copper supply is coming online but still weighed down by financing constraints. A potential supply gap could emerge around fiscal 2024, and
- absent a geo-political crisis and US dollar fluctuations, gold prices are expected to stay in the range of $1,300/lb in the next few years, which is in line with recent history.

At these price levels BC Hydro expects existing customers to operate normally and there is low incentive to bring new projects into production.

7.3.3.1.3 Metal Mining Uncertainties

The major risks and uncertainties around the metal mine segment over the forecast period include:

- price volatility, boom and bust cycles,
- financial situation for Imperial Metals,
- closures due to accidents,
- rising trend in trade protectionism which impacts global economic growth,
- demand erosion due to substitution effects from other sources (aluminium, steel, composite materials) and rise in scrap recovery,
- higher/lower than anticipated global economic growth mirrored in increased/decreased demand for metals,
- higher/lower than anticipated electrification of transportation and manufacturing,
- outcome of future Environmental Assessment applications from a number of proposed mines, and
- skilled labour shortages for mining companies due to aging workforce and competition with other sectors.

High and low metal mine load forecasts were included into our Monte Carlo uncertainty analysis. These forecasts were developed from high and low commodity price forecasts which are described as follows:

The high forecast was developed base on the following market assumptions:

- higher than anticipated global economic growth and associated increase demand for copper,
- reduced trade tensions,
- increased electrification rates in the transportation and manufacturing sectors,
- increased demand for electronics and electrical products increases,
- increased industrial development increases demand for machinery and equipment. The expansion of the power sector in China and India increases demand for wires and cables,
- as demand continues to grow at higher than expected rate, higher cost copper supply is brought into production, increasing the long-term marginal cost to approximately $4/lb, and
- life expansion and equipment upgrades for certain projects beyond expected assumptions.

The low forecast was developed based on the following market assumptions:

- above average mine supply growth with projects in Panama, Chile, Central Africa and even China hitting the markets in the next few years,
- no mine disruptions weighing on supply,
- demand erosion due to substitution effects from other sources (aluminium, steel, composite materials) and rise in scrap metal recovery, and

- prices drop to $2/lb in the next two years. As mines don't recoup total costs (including cost for sustaining production), higher cost mines exit the market resulting in a small recovery in price over the longer term.

The high, mid and low metal mining forecasts before rate impacts are shown in Table 7-2.

Table 7-2 Metal Mining Mid, High and Low Forecasts Before Rate Impacts

Fiscal year	High Forecast (GWh)	Mid Forecast (GWh)	Low Forecast (GWh)
Actual			
F2018	3,291	3,291	3,291
Forecast			
F2019[1]	3,294	3,294	3,271
F2020	3,427	3,427	3,080
F2021	3,905	3,501	2,344
F2022	4,123	3,488	2,081
F2023	4,553	3,457	2,081
F2024	5,146	3,360	1,839
5 Yr. Forecast (F18 to F23)	6.7%	1.0%	-8.8%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

7.3.3.2 Metallurgical coal segment

7.3.3.2.1 Metallurgical coal segment description

Coal mines account for about 15 per cent of BC Hydro's total mining sector sales. Teck's Elk Valley Coal Partnership in southeast B.C. supplies about one sixth of the world's seaborne metallurgical coal market. Metallurgical coal is also produced in northeastern B.C.

In the long term, coal mining sales are tied to price expectations for metallurgical coal. Export markets for B.C. coal include China, Japan, South Korea, and to a lesser extent India, Europe, South America and the United States. As a result, the state of B.C.'s economy has little effect on coal sales; however, provincial regulatory and policy actions can have a significant impact.

7.3.3.2.2 Metallurgical coal forecast results

Over the past five years ending fiscal 2018, sales to the metallurgical coal segment increased by 48 GWh or 9 per cent. This increase was caused by equipment upgrades at existing customer sites. Table 7-3 shows the history and forecast of metallurgical coal sales before rate impacts.

Table 7-3 Metallurgical Coal Mining Sales History and Forecast Before Rate Impacts

Fiscal year	October 2018 Forecast (GWh)
Actual	
F2013	541
F2014	551
F2015	560
F2016	545
F2017	562
F2018	589
Forecast	
F2019[1]	533
F2020	558
F2021	567
F2022	563
F2023	563
F2024	579
5 Yr. Actual (F13 to F18)	1.7%
5 Yr. Forecast (F18 to F23)	-0.9%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

The metallurgical coal market outlook which underpins our forecast is summarized as follows:

- the price for metallurgical coal has recovered sharply over the last two years after the significant downturn that occurred from 2013 to 2016,
- however, global supply restarts are expected to reduce prices in the next few years to approximately $USD140/tonne, and
- at this level, we expect existing coal operations to continue to operate normally, but there are no new mine additions in the forecast range.

The forecast expects the load impacts from equipment and production upgrades to be offset by the recent shutdown of Teck's Coal Mountain operations.

7.3.3.2.3 Metallurgical coal uncertainties

The major risks and uncertainties around the metallurgical coal segment over the forecast period include:

- global economic outlook: higher/lower than anticipated demand for steel in Asia,
- supply disruptions (or expansions) in Australia. Australia accounts for roughly two-thirds of the global metallurgical coal production; Floods during the rainy season in Australia have caused major supply disruptions in recent years,
- environmental lawsuits with regards to Teck operations,
- rail and terminal capacity constraints in B.C, and
- future regulations and policies that could impact future coal exploration or development.

High and low metallurgical coal mine forecasts were included as inputs into the Monte Carlo uncertainty analysis. These forecasts were developed from high and low commodity price forecasts which are described as follows:

The high forecast was developed based on the following market assumptions:

- higher than expected demand for steel in Asia,
- potential disruptions to Australian coal supply, and
- prices increase to a long-term level $USD175/tonne, which is sufficient to incent new supply additions.

The low forecast was developed based on the following market assumptions:

- lower than expected demand for steel in Asia,
- expansion to Australian coal supply, and
- prices drop to $USD100/tonne below the estimated long term operating cost of 75 per cent of the world's seaborne metallurgical coal production.

The high, mid, and low metallurgical coal forecasts are shown in Table 7-4.

Table 7-4 Metallurgical Coal Mid, High and Low forecasts Before Rate Impacts

7.4 FORESTRY

7.4.1 Forestry sub-sector description

The forestry sub-sector's once dominant share of the large industrial sector has steadily declined over time. While still significant, the sub-sector now only accounts for about 50 per cent of sales to the large industrial sector. Forestry is categorized into the following three segments:

- pulp and paper,
- wood products, and
- chemical.

Proportionally, the pulp and paper segment comprises 61 per cent of forestry sales, chemical sales 21 per cent and wood products 18 per cent. Pulp and paper production is evenly split between those two products. Paper production consists primarily of newsprint and newspaper inserts. Our chemical customers produce bleaching agents to whiten the products produced by the pulp and paper industry. They also produce cleaning and water purification agents for oil and gas producers and municipalities. In addition, our wood products customers produce lumber, panel sheets (like plywood and oriented strand board) and pellets for fuel. Products produced by the forestry sub-sector are primarily destined for the U.S., Chinese and B.C. economies. Detailed descriptions are provided within each forestry segment's description.

7.4.2 Forestry segment methodologies, forecast results and uncertainties

The methodologies used by each of the segments within this sub-sector are consistent with the methodology used for the large industrial sector. The forecasts are developed on an account by account basis.

7.4.2.1 Pulp and paper

7.4.2.1.1 Pulp and paper segment description

Sales to the pulp and paper segment represent 61 per cent of all forestry sales and 31 per cent of the total Large Industrial sector sales.

Pulp and paper consists of 19 mills located primarily in the south-western and north-eastern parts of B.C. These mills produce and export a wide variety of products including newsprint, coated and uncoated ground wood paper, bleached and unbleached Kraft, dissolving pulp, thermo-mechanical pulp (TMP), and bleached chemical-thermo-mechanical pulp (BCTMP). Historically, sales to this segment have been declining and we expect this to continue.

7.4.2.1.2 Pulp and paper methodology

While consistent with the large industrial sector forecast methodology, the pulp and paper segment forecast incorporates additional market evaluations and mill assessments. These are developed by third party industry experts. They forecast commodity supply, demand and prices in the markets where B.C.'s pulp, paper and wood products are sold. They also project B.C. regional market conditions for fibre supply (sawmill residuals, whole log chipping, etc.) and fibre demand (for bioenergy, pulp and paper and wood product mills). They consolidate these to produce mill line production forecasts and operational probability assessments to reflect a mill line's closure and start-up risk.

The production forecast and probability assessments are internally reviewed with input from a number of BC Hydro departments, including Key Account Management. Mill line load forecasts are developed by multiplying production forecasts, probability assessments, and mill line electricity intensities. Mill line forecasts are then aggregated to the plant level, which forms the customer load forecast. Customer account forecasts are then aggregated to form the pulp and paper forecast.

A number of pulp and paper mills also sell power to us under Electricity Purchase Agreements (EPAs). For those mills, the conditions of these agreements are taken into account for developing the customer's forecast.

The main drivers for this segment include:

- pulp and paper prices,
- economic growth and associate pulp and paper demand internationally,
- U.S. import duties on B.C. publication paper,
- regulations in China banning paper recycling which lift kraft and BCTMP prices and incent B.C. publication paper producers to convert paper lines to recycling,
- consumer preference for various pulp and paper products,
- B.C. fibre availability,
- global preferences for substitutes over B.C.'s pulp and paper products - particularly new eucalyptus pulp supply from the southern hemisphere,
- folding box demand in China (a major driver for TMP), and
- new market development in China, India and emerging markets for publication papers.

7.4.2.1.3 Pulp and paper forecast results

B.C.'s pulp and paper mills can be further categorized into the customer products they primarily produce:

- TMP and BCTMP,
- Kraft,
- publication paper, and
- tissue & other.

Over the past five years ending fiscal 2018, sales have declined by 1,377 GWh or 25 per cent. Reduced sales occurred across all four product types (arising from mill and mill line closures across the province). The decline is sales within each product type can be seen in Table 7-6 shows historical and forecast pulp and paper sales before rate impacts for each product category.

Table 7-6 Pulp and Paper Segment Sales History and Forecast Before Rate Impacts

Fiscal year	BCTMP (GWh)	Kraft (GWh)	Publication Papers (GWh)	Tissue & Other (GWh)
Actual				

F2013	1,318	1,508	2,642	143
F2014	1,137	1,580	2,685	104
F2015	1,120	1,607	2,434	101
F2016	1,216	1,123	2,290	97
F2017	1,072	906	2,098	97
F2018	1,060	923	2,151	100
Forecast				
F2019[1]	1,029	873	2,082	100
F2020	1,017	873	2,184	99
F2021	1,017	894	1,468	98
F2022	1,017	903	1,080	99
F2023	966	894	1,066	99
F2024	1,145	877	1,009	99
5 Yr. Actual (F13 to F18)	-4.2%	-9.3%	-4.1%	-7.0%
5 Yr. Forecast (F18 to F23)	-1.8%	-0.6%	-13.1%	-0.2%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

Factors contributing to mill closures were aging equipment, declining fibre availability (due to pine beetle infestation), strong competition from Kraft mills in South America, displacement of newspaper by digital media, adoption of power saving projects, and increased use of electronic media by advertisers.

For the period fiscal 2019 to fiscal 2021, sales are forecasted to decline by 606 GWh or 15 per cent. Expected reductions in publication paper and BCTMP production are the main reasons behind this decline.

Over the period of fiscal 2018 to fiscal 2024, sales are projected to decline by 1,105 GWh or 26 per cent. Most of the decline is attributed to higher closure risk assigned to publication paper mills. Electricity sales to Kraft mills are expected to remain stable over the forecast period as Kraft prices and fibre availability are anticipated to remain favourable.

7.4.2.1.4 Pulp and paper uncertainties

The major risks and uncertainties for pulp and paper over the forecast period include:

Upside risks:

- market opportunities for publication paper mills (e.g., converting newsprint lines to waste paper recycling lines),
- BCTMP mill restart due to continued high growth trend in the folding box market in China,
- biofuel production at B.C. Kraft mills due to growing demand for renewable fuels, and
- Kraft mill sustainability due to higher than expected fibre supply in B.C.

Downside risks:

- publication paper mill closures (from publication paper demand shrinkage in the North American market as the public continues to switch from print to electronic media),
- BCTMP mill failure to restart (caused by reduced Chinese market demand for B.C. BCTMP imports and increased reliance on lower cost, lower quality domestic producers),
- Kraft mill closures due to pulp fibre supply shortages caused by wildfires, beetle infestation and sawmill closures, and
- foreign market import duties imposed by the US and/or Chinese governments on B.C. pulp and paper.

High and low pulp and paper load forecasts were developed and included in the high and low forecasts for the forestry sub-sector as inputs into the Monte Carlo uncertainty analysis. Table 7-7 shows the high, mid, and low forecasts before rate impacts.

Table 7-7 Pulp and Paper Segment Mid, High and Low Forecasts Before Rate Impacts

Fiscal year	High Forecast (GWh)	Mid Forecast (GWh)	Low Forecast (GWh)
Actual			
F2018	4,234	4,234	4,234
Forecast			
F2019[1]	4,196	4,083	3,907
F2020	4,611	4,174	3,695
F2021	4,652	3,477	3,078
F2022	4,407	3,099	2,429
F2023	4,344	3,025	2,330
F2024	4,384	3,129	2,352
5 Yr. Forecast (F18 to F23)	0.5%	-6.5%	-11.3%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

The high and low forecasts are not symmetric around the mid forecast. Table 7-7 shows the high forecast is proportionally higher relative to the mid forecast than is the low forecast. The high forecast assumes market conditions evolve such that publication paper customers profitably retool and expand production. For instance, our pulp and paper market consultant has identified new growing markets like waste paper recycling, tissue and paper packaging to displace plastic. These new market opportunities represent potential mill line conversion opportunities for B.C. publication paper mills. Moreover, with waste paper recycling, the Chinese government has banned waste paper imports into the country to reduce water pollution. Consequently, Chinese paper recyclers are no longer able to buy waste paper from North America. As a result, North American paper mills are being converted into waste paper recyclers to meet growing paper demand in China with abundant supplies of low cost waste paper, including in B.C.

7.4.2.2 Wood products

7.4.2.2.1 Wood products segment description

Wood products sales make up 18 per cent of all the forestry sub-sector sales and 9 per cent of Large Industrial sector sales. Wood products consists of large industrial customers who use electricity to produce dimensional and structural lumber, oriented strand board, medium density fiberboard, plywood, fuel pellets, and other specialty wood products. There are 35 such mills, which are primarily located in the North and South Interior regions. B.C. mills are among the lowest cost lumber producers in the world.[31]

Electricity sales to the wood products segment depends on regional B.C. lumber supply, global demand for wood products and the viability of some pulp and paper mills. Recent growth in lumber demand was driven by the growth in U.S. housing starts. However, B.C. lumber supply will be constrained by saw-log scarcity due to the mountain pipe beetle devastation and recent record wildfires in the province. Although the Ministry of Forests, Lands, Natural Resource Operations and Rural Development is undertaking measures to address these, we anticipate reductions in annual allowable cuts will be imposed such that sales to this sector will start declining around fiscal 2023.

7.4.2.2.2 Wood products methodology

Similar to the pulp and paper segment, the process for developing the wood products load forecast is based on mill line production forecasts that are determined from macro and regional market assessments developed by a number of third party industry experts retained by BC Hydro.

Like the pulp and paper forecast, the wood products forecast is produced as a product of mill line production forecast, electricity intensity and probability for each customer operation. The loads for individual mill lines are aggregated to the entire load for the customer and all the customers forecasts are aggregated together to develop the forecast for the wood product segment.

The primary market drivers for wood products are:

- the U.S. market (for housing starts and repair and remodeling),
- the Chinese market (lumber and logs), and
- Japan (hemlock and SPF lumber).

B.C. is the largest Canadian exporter of softwood lumber to the U.S., making up about half of Canada's total lumber exports. Exports to China have been growing and B.C. could soon displace Russia as the dominant lumber supplier to the Chinese market.

[31] There are hundreds of other smaller wood products mills served on distribution service which are included in the forestry sub-sector in the light industrial sector.

7.4.2.2.3 Wood products forecast results

Table 7-8 shows the history and forecast of the wood products segment before rate impacts. For the most part, sales to this segment have declined over the historical period up to fiscal 2017. Between fiscal 2017 and fiscal 2018 there was a significant increase of electricity sales to the wood product segment driven by record high U.S. lumber prices in response to increases in U.S. housing starts.

Table 7-8 Wood Products Segment Sales History and Forecast Before Rate Impacts

Fiscal year	October 2018 Forecast (GWh)
Actual	
F2013	1,164
F2014	1,148
F2015	1,155
F2016	1,208
F2017	1,141
F2018	1,243
Forecast	
F2019[1]	1,223
F2020	1,228
F2021	1,231
F2022	1,231
F2023	1,224
F2024	1,193
5 Yr. Actual (F13 to F18)	1.3%
5 Yr. Forecast (F18 to F23)	-0.3%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

Page 77 of 170

For the period fiscal 2019 to fiscal 2021, sales are expected to increase by only 8 GWh or 1 per cent. The reasons for this are two offsetting impacts: continued demand from the U.S. housing market, albeit influenced by the U.S.-Canada softwood lumber dispute, and B.C. fibre shortages from mountain pine beetle damage and recent record wildfires.

From fiscal 2018 to fiscal 2024, sales are projected to decline by 50 GWh or 4 per cent. Expectations for this period can best be described as mixed and somewhat uncertain. Electricity sales are projected to slightly increase in the short run with a decline thereafter. U.S. housing starts are expected to continue to rise through the forecast period but the U.S.-Canada softwood lumber dispute and B.C. fibre shortage (from mountain pine beetle and recent record wildfires) will raise mill production costs and put downward pressure on sales to various mills and the sector.

7.4.2.2.4 Wood products uncertainties

The major risks and uncertainties for wood products over the forecast period include:

Upside risks:

- removal of softwood lumber tariffs. The U.S. government has imposed an average 20 per cent tariff on B.C. lumber imports. Removal of the tariff would raise revenues to B.C. producers and stimulate sawmill production,
- higher than expected in U.S. housing start levels. The U.S. is B.C.'s largest export market. Although US housing starts hit 10 year highs in 2018 and have been trending upward, they are still at historically stagnant levels (in the context of US housing starts over the past 50 years), and
- a stronger U.S. dollar.

Downside risks:

- useable timber reductions in B.C. Large wildfires and/or accelerated beetle kill deterioration of affected timber, will reduce harvestable areas, increase harvesting costs and contribute to wood product mill closures,
- lower than expected U.S. housing start levels. The U.S. is B.C.'s largest export market; depressed levels of U.S. housing starts that cause lumber prices to decline and increase wood product mill closure risk,
- U.S. recession. This would cause a prolonged economic downturn would cause housing starts to decline and remain at low levels. This would reduce cause lumber and panel prices to decline; this in turn would increase wood product mill closure risk, and
- reduced demand from China. This could arise from a prolonged economic slowdown in China and/or the Chinese government imposing import duties on Canadian lumber.

High and low forecasts for the wood products segment were developed and rolled up into the high and low bands for the forestry sub-sectors and used in the Monte Carlo uncertainty analysis.

Table 7-9 shows the historical and high, mid, and low forecasts for wood products segment before rate impacts. The high and low forecasts are symmetrical projections around the mid forecast.

Table 7-9 Wood Products Segment Mid, High and Low Forecasts Before Rate Impacts

Fiscal year	High Forecast (GWh)	Mid Forecast (GWh)	Low Forecast (GWh)
Actual			
F2018	1,243	1,243	1,243

Forecast			
F2019[1]	1,247	1,223	1,192
F2020	1,320	1,228	1,045
F2021	1,366	1,231	1,041
F2022	1,366	1,231	1,045
F2023	1,358	1,224	1,035
F2024	1,326	1,193	995
5 Yr. Forecast (F18 to F23)	1.8%	-0.3%	-3.6%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

The high forecast assumes higher than expected demand from U.S. housing starts and lumber exports to China. While this forecast assumes high lumber prices, increased production is assumed to be constrained by increased logging and stumpage costs resulting from deteriorating fibre supply.

The low forecast assumes some mills operate at reduced capacity or are closed. This is assumed to occur as a result of weaker demand from the U.S. and Chinese markets and deteriorating fibre supply. For the U.S. market, housing starts are assumed to only moderately rise and the softwood lumber dispute to remains unresolved.

The low forecast also assumes slower economic growth in China with increased market competition for B.C. wood products from other jurisdictions (Russia, New Zealand, and Europe). Both U.S. and Chinese market assumptions result in lower lumber prices for B.C. producers. In addition, wood harvesting costs are assumed to increase as a result wildfire and mountain pine beetle effects on fibre supply. The net effect of the market and fibre supply conditions is assumed to trigger mill closures or mills to operate at lower production levels.

7.4.2.3 Chemical

7.4.2.3.1 Chemical segment description

The chemical segment represents 21 per cent of Forestry sub-sector sales and 11 per cent of the large industrial sector. Chemical plants produce bleaching agents for the pulp and paper industry, cleaning agents or the oil and gas industry, and water purification products for municipalities. Since chemical companies use electrolysis to produce their products, electricity represents a significant component of their operating costs.

7.4.2.3.2 Chemical methodology

Consistent with the large industrial sector methodology, the chemical segment is forecast on an individual account basis. For this segment, the forecast relies on customer information provided by our Key Account Management group. The chemical forecast methodology is mainly informed via discussions with customers. Key drivers for the chemicals segment are electricity prices, demand for bleaching agents from the pulp and paper industry, and cleaning agents from the oil and gas industry. The industry also has the ability to export its products should B.C.-based demand decline.

7.4.2.3.3 Chemical segment forecast results

From fiscal 2013 to fiscal 2018, chemical sales declined by about 98 GWh or 6 per cent. This decline was primarily due to savings achieved through our DSM programs as well as a plant closure in fiscal 2018. Table 7-10 shows the history and forecast of sales to the segment before rate impacts.

Table 7-10 Chemical Segment Sales History and Forecast Before Rate Impacts

Fiscal year	October 2018 Forecast (GWh)
Actual	
F2013	1,575
F2014	1,580
F2015	1,541
F2016	1,456
F2017	1,409
F2018	1,477
Forecast	
F2019[1]	1,350
F2020	1,349
F2021	1,349
F2022	1,347
F2023	1,347
F2024	1,347
5 Yr. Actual (F13 to F18)	-1.3%
5 Yr. Forecast (F18 to F23)	-1.8%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

From period fiscal 2019 to fiscal 2021, sales are forecast to decline by 1 GWh. Sales beyond fiscal 2021 are expected to remain stable.

Page 80 of 170

7.4.2.3.4 Chemical Uncertainties

The major risks and uncertainties for the chemical segment include the following:

Upside risks:

- higher than expected bleaching agent demand from global pulp and paper producers experiencing a sustained increase in pulp and paper prices, and
- higher than expected cleaning agent demand from oil and gas producers.

Downside risks:

- global slowdown in demand from global pulp and paper producers,
- domestic pulp and paper closures, and
- rationalization of a chemical company operating in B.C. to close and resupply from a plant outside the province.

High and low forecasts for the chemical segment were developed and included in the forestry sub-sector's high and low bands, which then became inputs into the Monte Carlo uncertainty analysis. Table 7-11 shows the high, mid, and low forecasts before rate impacts.

Table 7-11 Chemical Segment Mid, High and Low Forecasts Before Rate Impacts

Fiscal year	High Forecast (GWh)	Mid Forecast (GWh)	Low Forecast (GWh)
Actual			
F2018	1,477	1,477	1,477
Forecast			
F2019[1]	1,374	1,350	1,325
F2020	1,472	1,349	1,288
F2021	1,471	1,349	1,288
F2022	1,469	1,347	1,286
F2023	1,469	1,347	1,286
F2024	1,470	1,347	1,286
5 Yr. Forecast (F18 to F23)	-0.1%	-1.8%	-2.6%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

There is relatively low uncertainty in the loads that make up the chemical segment. This is demonstrated in the historical sales between fiscal 2013 and fiscal 2018. Besides the aforementioned plant closure, there is little historical load variation. Going forward, we do not expect any material operational changes by customers within the chemical segment. We assume chemical plants have the ability to sustain operations by exporting product in the event there are pulp and paper mill curtailments in B.C. The high forecast is higher in magnitude relative to the mid forecast than is the low forecast. This is based on the assumption that prices and market conditions in the pulp and paper and oil and gas segments will be remain favourable.

7.4.3 Forestry forecast results

Sales to forestry customers have declined by 1,396 GWh or 17 per cent from fiscal 2013 to fiscal 2018[32]. This decrease occurred most in pulp and paper segment where a number of mill line closures occurred during this period. Table 7-12 shows the high, mid, and forecasts for the forestry sub-sector before rate impacts.

Table 7-12 Forestry Sub-Sector Mid, High and Low Forecasts Before Rate Impacts

Fiscal year	High Forecast (GWh)	Mid Forecast (GWh)	Low Forecast (GWh)
Actual			
F2018	6,954	6,954	6,954
Forecast			
F2019[1]	6,817	6,656	6,424
F2020	7,403	6,751	6,028
F2021	7,489	6,058	5,407
F2022	7,242	5,677	4,760
F2023	7,172	5,596	4,650
F2024	7,179	5,669	4,634
5 Yr. Forecast (F18 to F23)	0.6%	-4.3%	-6.6%

Table notes:

1. Forecast for fiscal 2019 does include any actuals.

For the period fiscal 2019 to fiscal 2021, the mid forecast of sales shows a decline of 598 GWh or 9 per cent. All segments contribute to this decline. From fiscal 2018 to fiscal 2024, mid sales are projected to decline by 1,285 GWh or 18 per cent. This decline is primarily due to reduced sales to the pulp and paper segment, which is driven by continued softening in demand for publication papers. The primary driver of variation in sales between the high and low forecasts is from publication paper mills. The asymmetrically wider high forecast is due to upside potential that could occur from publication paper mill lines successfully retooling production for new markets. The low forecast arises from mill and / or mill line closures in the pulp and paper and wood products segments.

[32] Forestry is the sum of pulp and paper segment, wood products and chemical segments as shown in Tables 7-22 to 7-24. The historical data indicates that sales to the forestry sub-sector were 8,351 GWh in Fiscal 2013 and 6,954 GWh in fiscal 2018, the difference between these two values over this time period is 1,396 GWh or 17 per cent.

7.5 OIL AND GAS

7.5.1 Oil and gas sub-sector description

Sales to the large industrial oil and gas sub-sector account for 11 per cent of the total large industrial sales. Electricity is used by oil and gas customers connected to the transmission system for various operations including refining and shipping petroleum, processing, natural gas production and liquid rich natural gas processing into various liquids. Most of the electricity is used to drive compressors for production and pipeline transportation.

The oil and gas sub-sector is categorized into two segments:

- shale gas (i.e. production/processing plants), and
- other large oil and gas operations.

The other large oil and gas operations consist of:

- conventional gas processing plants,
- oil (and condensate) pipelines,
- oil refineries and oil producers,
- natural gas pipelines,
- propane terminals, and
- LNG terminals.

Sales to LNG terminals are included in the other large oil and gas operations segment to maintain confidentiality on the specific nature of individual LNG projects included in the load forecast. This is consistent with our practice of not publishing specific customer history and forecast. The remainder of this section provides a summary of the forecast results for the entire sub-sector followed by a detailed discussion of the two major segments.

7.5.2 Oil and gas segment methodologies, forecasts results, and uncertainties

The methodology in the oil and gas sub-sector is consistent with the large industrial forecast process articulated in section 7.2. However, the depth of analysis carried out for each of the segments within the oil and gas sub-sector varies depending on segment size and complexity. For example, we apply a more robust and detailed analytical approach for the large and growing shale gas segment; conversely we adopt a less rigorous approach for the oil refineries and oil producer sub-segments, which are relatively small and static. Overall, each segment forecast is developed on an individual customer account basis, with probabilities applied, to develop an expected load forecast.

7.5.2.1 Shale gas

7.5.2.1.1 Shale gas segment description

In fiscal 2018 electricity sales to the shale gas segment represented 47 per cent of the total oil and gas sub-sector sales and 5 per cent of large industrial sales. Electricity is mainly used to drive plant compression and processing requirements.

The shale gas segment includes the production of raw natural gas from shale or tight sedimentary formations located in the B.C. Montney shale basin. The process starts with drilling wells into the formations using hydraulic fracturing techniques to access the gas. Since this technique differs from the older conventional process, gas produced in this manner is also called unconventional gas. Gas from these wells, is under high pressure, and is connected to gathering pipes which bring the gas to gas plants. These plants (increasingly being served by BC Hydro), perform light processing of the gas including refrigeration if needed to recover gas liquids (propane, butane and condensates).

7.5.2.1.2 Shale gas methodology

Consistent with the large industrial sector methodology, the shale gas segment is forecast on an individual customer account basis. However, the shale gas segment is the fastest growing within our large industrial sector, and given the complex nature of the industry requires more detailed analysis relative to other industrial sectors. A comprehensive analytical framework is used to directly link BC Hydro's internal assessment of customer accounts and new service requests (i.e., bottom up assessment) with supply and demand outlooks for natural gas, natural gas liquids and oil natural gas production forecasts developed by third party industry experts (i.e., top down assessment).

The main process steps are as follows:

- organize customer load requests into regional load forecasts,
- for the same regions, convert third-party gas production forecast to equivalent electrical loads estimates, and
- align the customer requested and expert produced forecasts by adjusting probability assessments and market assumptions, respectively, until they produce similar results.

This process produces a customer forecast that is supported by industry expert and market assumptions.

As noted in section 3.2.6, we retained the services of an oil and gas consulting company (GLJ Petroleum Consultants) to enhance our existing analysis.

The industry expert information provided by the consultant along with market intelligence information provided various subscription services and publicly available sources improves the performance of our assumptions.

7.5.2.1.3 Shale gas forecast results

Over the past five years ending fiscal 2018, sales to the shale gas segment have increased by 594 GWh or 511 per cent. Table 7-13 shows the history and forecast of sales before rate impacts.

Table 7-13 Shale Gas Segment Sales History and Forecast Before Rate Impacts

Fiscal year	October 2018 Forecast (GWh)
Actual	
F2013	116
F2014	261
F2015	280
F2016	440
F2017	549
F2018	710

Forecast	
F2019[1]	1,418
F2020	1,759
F2021	1,953
F2022	2,197
F2023	2,556
F2024	2,782
5 Yr. Actual (F13 to F18)	43.7%
5 Yr. Forecast (F18 to F23)	29.2%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

From fiscal 2018 to fiscal 2021 sales are forecast to increase by 1,243 GWh or 175 per cent. This increase is primarily driven from projects that recently started commercial operations or are currently under construction and are expected to come into service by fiscal 2021.

From fiscal 2018 to fiscal 2024, sales are projected to increase by 2,072 GWh or 292 per cent. As above, most of this growth (1,800 GWh) is driven by recently started and committed projects supplying the natural gas liquids market. While some of the other growth is related to plants that will be supplying downstream LNG operations.

Broadly speaking, our analysis leads us to believe that much of the increase in global natural gas supply will occur in North America. In this context, B.C.'s Montney shale basin is considered to be a competitive low cost gas supplier as the basin's size, productivity and mix of liquids enables it to compete with other sources of gas supply. The consultant reported that the basin's competitiveness is not considered to be dependent on access to LNG markets and forecasts continued natural gas production growth in B.C. with an increasing share of the Western Canadian gas supply market.

7.5.2.1.4 Shale Gas Uncertainties

While additional load growth potential is relatively low in the short term, there is significant, albeit uncertain long term potential. The potential downside is considered low for both the near and long term. Upside and downside risks include the following:

Upside risks include:

- future North American LNG development (B.C., U.S. west coast and U.S. gulf coast) increasing demand for B.C. natural gas,
- continued expansion of Alberta oil sands and associated demand for gas liquids,
- continued displacement of net U.S. gas liquids imports to Alberta with B.C. gas liquids, and
- higher than expected natural gas, liquids, and oil prices.

Downside risks include:

- condensate production in Alberta (large basin in Western central Alberta has a logistical advantage to oil sands producers than B.C. producers),
- Alberta importation of U.S. condensate for heavy oil productions (threatens B.C. producer growth),
- increased gas liquids production in Alberta (closer to petrochemical plants in Alberta),
- lower than expected natural gas prices caused by increased natural gas production in other North American production regions, and
- delay of LNG terminal operational dates.

Table 7-14 shows the high, mid, and low forecast of sales to the Shale Gas segment before rate impacts.

Table 7-14 Shale Gas Segment Mid, High and Low Forecasts Before Rate Impacts

Fiscal year	High Forecast (GWh)	Mid Forecast (GWh)	Low Forecast (GWh)
Actual			
F2018	710	710	710
Forecast			
F2019[1]	1,529	1,418	1,207
F2020	1,972	1,759	1,505
F2021	2,114	1,953	1,669
F2022	2,491	2,197	1,709
F2023	3,016	2,556	1,761
F2024	3,735	2,782	1,906
5 Yr. Forecast (F18 to F23)	33.6%	29.2%	19.9%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

High and low forecasts for the shale gas segment were developed and included in the high and low forecasts oil and gas sub-sectors as inputs in the Monte Carlo uncertainty analysis.

The high shale gas forecast assumes higher natural gas production growth to serve higher LNG terminal requirements, higher downstream gas and liquids exports to stronger North American markets and higher electrification percentages for new production facilities. The low shale gas forecast assumes slower production growth trending rise in natural gas production to supply lower LNG terminal requirements, weaker North American natural gas demand, and lower electrification percentage for new production facilities.

7.5.2.2 Other large oil and gas operations

7.5.2.2.1 Other large oil and gas operations segment description

Sales to the other large oil and gas operations segment represents 53 per cent of all the sales to the oil and gas sub-sector and 6 per cent of all Large Industrial sector sales. This segment consists of the following facility types:

- Conventional gas processing plants,
- Oil (and condensate) pipelines,
- Oil refineries and oil producers,
- Natural gas pipelines,
- Propane terminals, and
- LNG terminals.

Conventional gas processing plants comprises 16 per cent of BC Hydro's sales to the oil and gas sub-sector. These customers use conventional means to recover gas, perform gas liquids extraction (ethane, propane, butane and pentane) and extract acid gases. Historically, the processors have served conventional gas producers. However, conventional gas production in B.C. has been declining over the past 10 years and as conventionally gas production declines, processing plants are increasingly being supplied by shale gas producers.

Oil pipelines constitute 13 per cent of BC Hydro's sales to the oil and gas sub-sector. These customers operate pipelines which serve to transport crude oil and petroleum products. Electricity is primarily used in pumping stations with power sales being correlated to the volume of liquids shipped. Future growth opportunities for this industry are due to B.C.'s proximity to Asian oil markets where oil demand is increasing and U.S. west coast oil refineries.

Oil refineries and oil producers currently make up 23 per cent of BC Hydro's sales to the oil and gas sub-sector. These customers include tank farms, oil refineries (which also produce gasoline and jet fuel) and oil producers. Electricity sales are related to B.C.'s oil pipeline shipments and to a lesser degree oil prices.

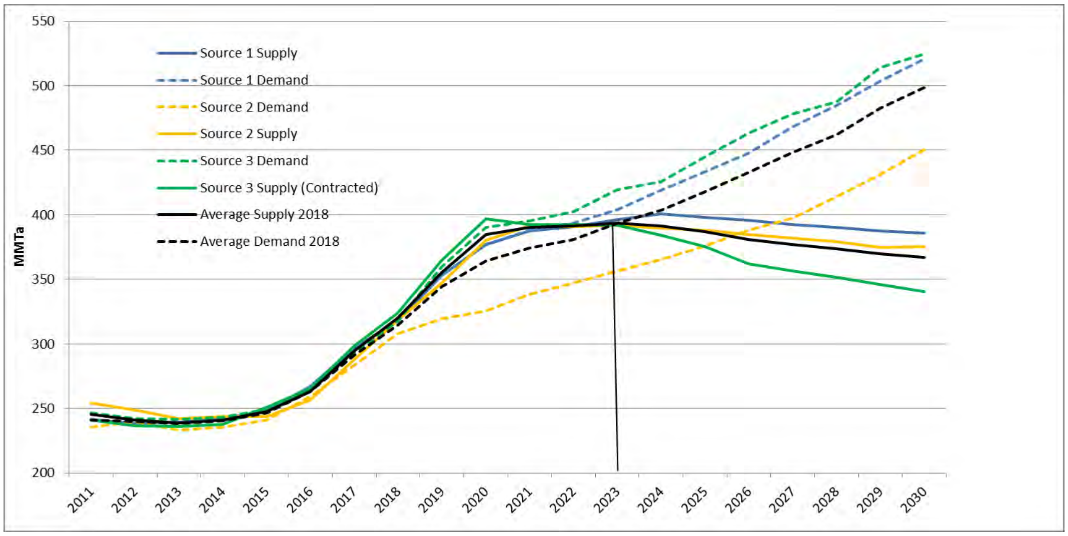
Natural gas pipelines encompass 1 per cent of BC Hydro's sales in the oil and gas sub-sector. These customers ship natural gas via pipeline. Natural gas pipelines use gas compressors instead of electrically-driven compressor to power booster stations.

Propane terminals are an emerging B.C. industry with two new terminals currently under construction. When construction is complete, these customers will receive the propane by rail, store it in tanks and then pump the propane from the terminals onto ships for export. Our industry consultant produced a B.C. propane terminal supply analysis, which was used to inform the propane terminal forecast. Electricity will be used for pumps and compressors with future sales related to world propane prices, Asian demand and B.C. terminal propane. Propane supply is expected to be sourced from the B.C. Montney and the Alberta Duverney shale gas basins.

LNG is natural gas that has been cooled to a liquid state, at about negative160 degrees celsius, for shipping and storage. The volume of natural gas in its liquid state is hundreds of times smaller than its volume in its gaseous state. This process, allows the transportation of natural gas to places pipelines do not reach. LNG is shipped in special tankers between export terminals, where natural gas is liquefied, and import terminals, where LNG is returned to its gaseous state (regasified).

British Columbia has the advantage of shorter shipping distances to Asia relative to other LNG supplier, and significant natural gas reserves including the Montney, Horn River and Liard formations. After an initial boom in global LNG project development, global LNG investment decreased following a drop in LNG prices in 2014. Investment appetite was further diminished by fears of an extended supply surplus. British Columbia's LNG sector followed similar pattern with the more than 20 LNG project proposals, followed by a number of project cancellations. More recently there has been a dramatic shift in the market outlook as higher than expected demand for LNG in growing economies such as China and India has reversed the supply/demand balance from one of extended supply surplus to supply deficit within five years. Based on an aggregation of market outlooks from different subscription sources, the current supply/demand balance is expected to occur around 2023. This is illustrated in Figure 7-3.

Figure 7-3 Global LNG Supply – Demand Balance



Over the past few years, BC Hydro and the provincial government have been closely working with LNG proponents on options for meeting energy needs of LNG plants with power from the BC Hydro system. LNG-related electricity demand falls into two general categories: compression and non-compression. The compression energy is about 85 per cent of the total plant's energy needs. The remaining (non-compression) energy requirement is from plant pumps, motors, other equipment, heating and lighting. Compression energy is typically supplied with direct-drive natural gas turbines, although this can also be accomplished with electric drives.

In October 2018, LNG Canada announced a positive final investment decision to proceed with its project located in Kitimat, B.C. LNG Canada is the single largest private sector investment project in Canadian history. The first phase of the project includes a $6.2-billion natural gas pipeline through northern British Columbia and an $18-billion liquefaction facility in Kitimat, B.C.

In addition to LNG Canada, a number of other B.C. based LNG projects are continuing to advance. These include Woodfibre LNG, Kitimat LNG and Kwispaa. FortisBC's Tilbury LNG plant is operating and taking electricity service from BC Hydro.

7.5.2.2.2 Other large oil and gas operations methodology

Consistent with the large industrial sector methodology, the other large oil and gas sector is forecast on an individual customer account basis. Within this customer based forecasting process, various calculation techniques are used to arrive at the customer's energy and peak forecasts.

The primary method is the product of expected peak demand, load factor and probability. The load factor is a measure of the utilization rate, or efficiency of electrical energy usage. Generally, the underlying drivers of the forecast are the customer's requested load, estimated operational hours, historical load patterns and operational probabilities. In case of existing customers, historical consumption information is used as starting reference point updated with newest information (such as facility expansion or contraction plans). The probability weightings are informed by considerations such as the project's economics, availability of financing, regulatory progress and BC Hydro interconnection status. A facility's economics is analyzed in the context of the market outlooks informed by external and internal information. For the current forecast, BC Hydro relies on the following subscription services:

- Bloomberg,
    - Terminal

  - New Energy Finance
- Wood Mackenzie North America Gas Service,
- IHS Connect, and
- RBN Energy's paid for information services on North American: oil, natural gas liquids, natural gas and the Permian basin.

Additional information was obtained through an oil and gas consultant. This information included:

- B.C. conventional gas basin forecasts,
- oil price forecasts and Alberta oil supply forecasts,
- reporting on natural gas pipeline development, and
- analysis on B.C. propane terminal propane supply.

LNG customers are included in the large oil and gas segment to protect the confidentiality of our assessment of LNG projects. In developing the LNG forecasts we continue to include in the forecast only those LNG projects that are already operational or have requested service. Probably assessments of individual LNG projects were developed based on:

- professional input from Key Account Management, Load Interconnections and Customer Service business units, and
- third party expert assessments of the global LNG market, relative competitiveness of B.C. LNG, and specific B.C. projects.

To do this we rely on the Wood Mackenzie LNG, Bloomberg LNG and IHS LNG subscriptions, as well as information from publically available sources such as McKinsey's Energy Insight, National Energy Board, International Energy Agency, Canadian Energy Research Institute.

In line with how we forecast other large industrial sectors, the probability assessment informs a binary "in/out" call in the first three years of the forecast period and then a probability weighted forecast for the remainder of the forecast period.

7.5.2.2.3 Other large oil and gas operations forecast results

Over the past five years ending fiscal 2018, sales to the other large oil and gas segment declined by 47 GWh or 6 per cent. The decline is primarily due to lower sales to conventional gas producers and processors. These customers have been impacted by the downward trend in natural gas prices that have occurred during this period. Table 7-15 below shows the actual and forecast before rate impact to the other oil and gas segment.

Table 7-15 Other Large Oil and Gas Operations Segment Sales History and Forecast Before Rate Impacts

Fiscal year	October 2018 Forecast (GWh)
Actual	
F2013	845
F2014	771
F2015	835
F2016	836

F2017	824
F2018	798
Forecast	
F2019[1]	914
F2020	1,011
F2021	1,045
F2022	1,105
F2023	1,198
F2024	2,063
5 Yr. Actual (F13 to F18)	-1.1%
5 Yr. Forecast (F18 to F23)	8.5%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

From fiscal 2019 to fiscal 2021, sales are forecast to increase by 130 GWh or 14 per cent. This is primarily due to sales related to LNG terminals and conventional gas processing plants. From fiscal 2018 to fiscal 2024, sales increase by 1,265 GWh or 159 per cent. This growth is attributed to sales to LNG terminals, pipelines and conventional processing plants.

Publically available information on LNG projects is included in our load forecast:

- LNG Canada recently made a positive final investment decision. Only construction-related load from this LNG facility is expected within the window of our load forecast.
- Woodfibre LNG decision to proceed with the project has not been yet announced. We included a probability weighted sales forecast from this facility in our load forecast.
- FortisBC Tilbury is in operation and we included forecast sales to this LNG facility.

7.5.2.2.4 Other large oil and gas operations uncertainties

The various industries making up this segment face somewhat different risks and uncertainties. This is because the products and markets within the sub-segments are different. The description for the major risks is provided below. LNG-related risks are described separately.

The risks associated with the large oil and gas operations, excluding LNG terminals, collectively tend to weigh more on the downside than the high side in terms of potential impacts to BC Hydro sales.

The upside risks include:

- Higher than expected Asian demand for propane would incent propane terminal expansions in B.C.,
- Higher than expected oil sands transport venues and expanded fossil fuel processing capacity in Alberta would stimulate the conventional gas processing plants to recover more natural gas liquids,
- Higher than expected oil prices would increase B.C. oil refinery oil production and oil pipeline activity, and
- Minimal fossil fuel related construction delays would lower perceived risk and incent further development.

The downside risks include:

- Oversupply of fossil fuels in global, Alberta and U.S. markets and lower than expected prices to B.C. producers. This will cause B.C. oil refineries, oil producers and conventional gas processing plants to reduce production, defer new projects, and shut plants,
- New gas liquids pipeline from the U.S. into Alberta. This will reduce profit margins for B.C. producers and reduce conventional gas processing plants activity, and
- Longer than expected infrastructure construction delays or project cancellations.

For LNG terminals, the major risks are identified below. Notwithstanding LNG Canada's positive investment decision, LNG development in B.C. remains an emerging industry with significant but uncertain growth potential. The risk profile for this industry is asymmetrical in that the potential for higher load growth relative to what is reflected in the load forecast is greater than the potential for lower load. Various risks that have can have either positive or negative impacts on B.C. LNG development include:

- Federal/provincial policies that support or restrict domestic LNG development,
- Large upturns/downturns in the energy markets leading to unexpected supply surpluses or deficits,
- Legislation that supports or restricts nuclear power in Japan and coal generation in China,
- Climate action policies that increase or decrease global demand for natural gas, and
- Competition with U.S. based LNG and other major LNG export countries.

High and low forecasts for the other oil and gas operations segment, were developed and aggregated within the high and low forecasts for the oil and gas sub-sector for inputs into the Monte Carlo uncertainty analysis.

Table 7-16 shows the mid, high and low forecast before rate impacts.

Table 7-16 Other Large Oil and Gas Operations Segment Mid, High and Low Forecasts Before Rate Impacts

Fiscal year	High Forecast (GWh)	Mid Forecast (GWh)	Low Forecast (GWh)
Actual			
F2018	798	798	798
Forecast			
F2019[1]	946	914	858
F2020	1,082	1,011	876

F2021	1,120	1,045	913
F2022	1,238	1,105	963
F2023	2,369	1,198	1,043
F2024	2,929	2,063	1,367
5 Yr. Forecast (F18 to F23)	24.3%	8.5%	5.5%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

The risk profile for this segment is asymmetrical in that the potential for higher load growth relative to what is reflected in the load forecast is greater than the potential for lower load. This asymmetry is primarily due to LNG terminals.

7.5.3 Oil and gas sub-sector forecast results

Over the past five years ending fiscal 2018, sales to the large industrial oil and gas sub-sector have increased by 546 GWh or 57 per cent. This based on the combined total of sales to shale and other large oil and gas customers as shown in Table 7-23 in section 7.8. This increase is primarily due to growth in the shale gas segment, which itself is driven by demand for gas liquids present in B.C.'s Montney shale basin. Table 7-17 shows the mid, high and low forecast before rate impacts for this sub-sector.

Table 7-17 Oil and Gas Sub-Sector Mid, High and Low Forecasts Before Rate Impacts

Fiscal year	High Forecast (GWh)	Mid Forecast (GWh)	Low Forecast (GWh)
Actual			
F2018	1,507	1,507	1,507
Forecast			
F2019[1]	2,475	2,332	2,065
F2020	3,055	2,770	2,382
F2021	3,233	2,998	2,583
F2022	3,729	3,301	2,673
F2023	5, 385	3,753	2,804
F2024	6,664	4,845	3,272

5 Yr. Forecast (F18 to F23)	29.0%	20.0%	13.2%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

From fiscal 2018 to fiscal 2021, the expected (mid) sales are forecast to grow significantly by 1,490 GWh or 99 per cent. This growth is primarily driven by new shale gas production plants that: have switched to BC Hydro service, have started operations and are ramping up production or are under construction. The forecast of mid sales from fiscal 2018 to fiscal 2024 are projected to increase by 3,338 GWh or 221 per cent.

Although the oil and gas sub-sector is comprised of customers all related to the fossil fuel industry, the major risks and uncertainties for each are generally different. This is because the products and markets within the segments and sub-segments are different. Nevertheless, the risk profile for this segment is asymmetrical in that the potential for higher load growth relative to what is reflected in the load forecast is greater than the potential for lower load. This asymmetry is due to LNG terminals and pipelines, as well as potential for increased electrification in natural gas production and processing associated with the recently announced CleanBC Plan.

7.6 OTHER LARGE INDUSTRIAL

7.6.1 Other large industrial sub-sector description

The other industrial sub-sector is comprised of a range of customers from universities, ports, terminals and wire manufacturers to cement companies and water pumping stations. The other industrial sub-sector also includes incremental cannabis and cryptocurrency loads that we expect to be connected at transmission voltages. More detail on cannabis and cryptocurrency loads is found in Section 8.

7.6.2 Other large industrial methodology

Customers in the other category are forecast on an individual customer account basis consistent with the large industrial sector methodology. However, this sub-sector forecast is not directly informed by specific commodity price or market outlooks due to sub-sector's diversity. The forecast is primarily based on customer information provided via our Key Accounts Management and Interconnection business units.

7.6.3 Other large industrial forecast results

Over the past five years ending fiscal 2018, sales to the Other Large Industrial segment increased by 54 GWh or 0.9 per cent. This was caused by increased load and equipment upgrade made by existing customers. Table 7-18 shows the total forecast of the other large industrial sub-sector, with the transmission voltage connected cannabis and cryptocurrency loads presented separately. All forecast are before rate impacts.

Table 7-18 Other Large Industrial Sub-Sector Sales History and Forecast Before Rate Impacts

Fiscal year	October 2018 Other Large Industrial Customers Excluding Cannabis and Cryptocurrency(GWh)	October 2018 Cannabis and Cryptocurrency Load Additions (GWh)[1]	October 2018 Total Large Industrial Sub-sector (GWh)
Actual			
F2013	1,117		1,117

F2014	1,177		1,177
F2015	1,173		1,173
F2016	1,149		1,149
F2017	1,126		1,126
F2018	1,171		1,171
Forecast			
F2019[2]	1,145	66	1,211
F2020	1,181	375	1,556
F2021	1,213	403	1,616
F2022	1,226	403	1,630
F2023	1,233	403	1,636
F2024	1,245	403	1,649
5 Yr. Historical (F13 to F18)	0.9%		0.9%
5 Yr. Forecast (F18 to F23)	1.0%		6.9%

Table notes:

1. As of fiscal 2018 there were no light industrial customers classified as cannabis and cryptocurrency loads. As such, historical and forecast compound growth rates are not shown on the table above.
2. Forecast for fiscal 2019 does not include any actuals.

The growth in the other sub-sector between fiscal 2018 and fiscal 2024 is primarily driven by new cannabis and cryptocurrency operations connected at the transmission service level. These operations account for approximately 400 GWh of the overall sub-sector growth over the period. However, given the unique characteristics of cannabis and cryptocurrency loads as emerging industries we describe them separately in Section 8.

In addition to transmission-connected cannabis and cryptocurrency, there is a small amount of growth over the entire forecast period which is primarily due to upgrades and expansions from other existing customers in this sub-sector.

7.6.4 Other large industrial uncertainties

The major uncertainties around the other large industrial loads include:

- uncertainty in cannabis and cryptocurrency (See Section 8),
- economic growth and construction activity, which in turn affects the demand for cement and other industrial products,
- sectorial shifts in B.C. economy (e.g., shift from manufacturing to services, emerging sectors such as data centres, cannabis or cryptocurrency), and
- slowdown or increase in shipping.

The high and low load forecasts for the other large industrial sub-sector were developed and included Monte Carlo uncertainty analysis.

The high forecast was developed based on the following assumptions:

- higher global economic growth results in higher demand for industrial products and shipping affecting cement plant production, ports, terminals and manufacturing, and
- higher than anticipated growth for universities and new customers.

The low forecast was developed based on the following assumptions:

- lower global economic growth results in lower demand for products and shipping affecting cement plant production, ports, terminals and manufacturing, and
- universities, airports and municipal customers remain flat.

Table 7-19 shows the high, mid, and low forecasts for the other large industrial customers (excluding cannabis and cryptocurrency) before rate impacts. The high and low other large industrial load forecasts were developed and included as inputs into the Monte Carlo uncertainty analysis. Table 7-19 shows the high, mid, and low forecasts before rate impacts.

Table 7-19 Other Large Industrial Sub-Sector Mid, High, Low Forecasts Before Rate Impacts

Fiscal year	High Forecast (GWh)[1]	Mid Forecast (GWh)	Low Forecast (GWh)[1]
Actual			
F2018	1,171	1,171	1,171
Forecast			
F2019[1]	1,167	1,145	1,135
F2020	1,231	1,179	1,129
F2021	1,290	1,210	1,122
F2022	1,306	1,226	1,122
F2023	1,312	1,233	1,122
F2024	1,324	1,245	1,122

5 Yr. Forecast (F18 to F23)	2.3%	1.0%	-0.9%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

7.7 LARGE INDUSTRIAL LOAD FORECAST BUILD-UP F2019 TO F2021

The following tables show the build-up of the Large Industrial Load Forecast for fiscal 2019 and the test years of our F20-F21 RRA.

Table 7-20 Fiscal 2019 Large Industrial Sector Load Forecast Buildup

Large Customer Forecast GWh[1]	Fuel Switching Load Additions (GWh)	Rate Impact[2] (GWh)	DSM (GWh)	Large Industrial Load Forecast (GWh)[3]
14,024	1	(5)	(164)	13,856

Table notes:

1. Large industrial customer forecast is the sum total of the individual customer forecasts for all sub-sectors.
2. Rate Impacts are load reductions based on formula that include our real rate increase projection, a price elasticity assumption of -0.1 and the large industrial customer forecast and the large industrial load additions.
3. Large Industrial Load Forecast is an aggregation of large industrial customer forecasts plus load additions less rate impacts less DSM savings.

The forecast value of 13,856 GWh for fiscal 2019 does not include any actuals over the current fiscal year, while the forecast of 13,810 GWh, as shown in the executive summary, reflects six months actual billed sales and six months forecast. To derive this value, the load forecast for the sub-sectors were allocated into 12 months and the first six months of forecast are replaced with actuals billed sales.

Table 7-21 Fiscal 2020 and Fiscal 2021 Large Industrial Sector Sales Forecast Buildup

Large Industrial Customer Forecasts GWh[1]	Fuel Switching Load Additions (GWh)	Rate Impacts[2] (GWh)	DSM (GWh)	Large Industrial Load Forecast[3] (GWh)
15,056	5	(12)	(347)	14,702
14,675	65	(20)	(477)	14,243

Table notes:

1. Large industrial customer forecast is the sum total of the individual customer forecasts for all sub-sectors.
2. Rate Impacts are load reductions based on formula that include our real rate increase projection, a price elasticity assumption of -0.1 and the large industrial customer forecast and the large industrial load additions.

3. Large Industrial Load Forecast is an aggregation of large industrial customer forecasts plus load additions less rate impacts less DSM savings.

7.8 LARGE INDUSTRIAL FORECASTS RESULTS

The next three tables in this section summarize the history and forecasts:

- before rate impacts,
- after rate impacts, and
- after rate impacts and DSM savings

for the large industrial sector, its sub-sectors and segments.

Table 7-22 Large Industrial Sales History and Forecast Before Rate Impacts

Table notes:

1. Other large industrial includes transmission connected cannabis and cryptocurrency loads.
2. Forecast for fiscal 2019 does not include any actuals.

8.0 Cannabis and Cryptocurrency Forecast

8.1 EMERGING INDUSTRIES DESCRIPTION

As emerging industries, loads from cannabis and cryptocurrency customers are included as separate load additions to the October 2018 Load Forecast. The forecast for these loads are incremental to base year fiscal 2018. While there are existing cannabis operations that pre-date the passing of legislation legalizing cannabis production and use, the intent of this chapter is to summarize the expected incremental load growth associated with legalization. Existing loads are recognized in the forecast as well as additional incremental loads that are not part of the fiscal 2018 base year. The approach has been applied to cryptocurrency as well; there are some existing loads in the base year that have transitioned into operations in addition to new, incremental loads.

The aggregated cannabis and cryptocurrency load forecast is made up of individual customer loads connected at both transmission and distribution levels of service. However, for the overall Load Forecast, these loads are incorporated as follows:

- customer loads connected at the transmission service level are incorporated within the other large industrial sub-sector category, and
- customer loads connected at distribution service level are incorporated within the other light industrial sub-sector category.

8.1.1 Cannabis

In October 2018, the Government of Canada enacted the *Cannabis Act*, which began the process of winding down the prohibition of non-medical cannabis in Canada. The *Cannabis Act* provides a framework for the production, distribution and sale of cannabis. The Government of B.C. outlined a series of regulations in the *Cannabis Distribution Act*, which creates a public wholesale distribution monopoly, and *Cannabis Control and Licensing Act*, which outlines the rules for consumption.

Two of Canada's largest cannabis product suppliers are Vancouver-based Aurora Cannabis Inc. and Nanaimo-based Tilray. For a brief period in September 2018, Tilray held the number one spot as the world's most valuable cannabis producer company, surpassing US-based Canopy with a $14 billion market capitalization.

According to Arcview Market Research and its research partner BDS Analytics, consumer spending on legal cannabis worldwide is expected to hit $57 billion by 2027.[33] Within this consumer demand, the recreational market is expected to make up two-thirds of the spending while medical marijuana is expected to make up the remaining third. North America will continue to represent the largest spending volume, with sales going from $9.2 billion in 2017 to $47.3 billion a decade later.

8.1.2 Cryptocurrencies

Cryptocurrencies are electronic peer-to-peer currencies that have value and trade on a virtual marketplace. Cryptocurrencies operate outside of traditional financial institutions by trading through blockchain technology. Blockchain is a digital infrastructure that acts as an electronic ledger for cryptocurrencies, and facilitates the transfer of cryptocurrency. Participants in the cryptocurrency market often call themselves miners, because they operate high-powered computers who compete with other participants to solve complex mathematical equations to store and conduct cryptocurrency transactions.

[33] https://bdsanalytics.com/press/new-report-worldwide-spending-on-legal-cannabis-will-reach-57-billion-by-2027/

Before 2018, China accounted for the majority of cryptocurrency mining globally. However, in an effort to alleviate demands on its electrical system, China has implemented regulations that have effectively caused crypto miners to explore moving their operations to other jurisdictions, including British Columbia.

8.2 CANNABIS AND CRYPTOCURRENCY METHODOLOGY

BC Hydro has received a large number of formal requests for service and general inquiries from both cannabis and cryptocurrency operations. By September 2018, the total number of general inquiries for both types of load approached a combined total of 20,000 GWh, illustrated in Table 8-1 below. The table includes two categories, one showing the total level of general inquiries by sector, the other one showing the total level of customer service requests received by the Load Interconnections group.

Notwithstanding the large number of service requests and inquiries, we adopted a conservative approach to developing the load forecast by only including loads that meet the following criteria:

- the loads are associated with customer service requests that are in advanced stages of our load interconnection process, and
- of those service requests, BC Hydro considers the customer's project to have a very high probability of proceeding.

A short list of projects meeting the first criteria was assembled and collaboratively reviewed to determine a high likelihood of proceeding by a number of business units, including Load Forecasting, Key Account Management, Distribution Planning and Economic Development.

Table 8-1 Cannabis & Cryptocurrency Inquiries and Service Requests

Status as of September 2018		
Cryptocurrency	**MW**	**GWh**
General Inquiry	1,892	14,088
Formal service requests/Interconnection Applications	87	648
Cannabis	**MW**	**GWh**
General Inquiry	873	4,971
Formal service requests/Interconnection Applications	177	1,008

8.3 CANNABIS AND CRYPTOCURRENCY FORECAST RESULTS

Table 8-2 below shows the incremental total of cannabis and cryptocurrency loads at the transmission and distribution voltage level included in the October 2018 Load Forecast before rate impacts and DSM savings. This combined load is expected to increase to 650 GWh by F2021.

Table 8-2 Cannabis and Cryptocurrency Forecast Before Rate Impacts

Fiscal year	October 2018 cannabis and cryptocurrency load transmission connected (GWh)[1]	October 2018 cannabis and cryptocurrency load distribution connected (GWh)[1]	October 2018 cannabis and cryptocurrency total load (GWh)[1]
	A	B	A+B
Actual			
F2018	N/A	N/A	N/A
Forecast			
F2019[2]	66	42	108
F2020	375	79	453
F2021	403	242	646
F2022	403	244	648
F2023	403	246	649
F2024	403	247	650
5 Yr. Forecast (F18 to F23)	N/A	N/A	N/A

Table notes:

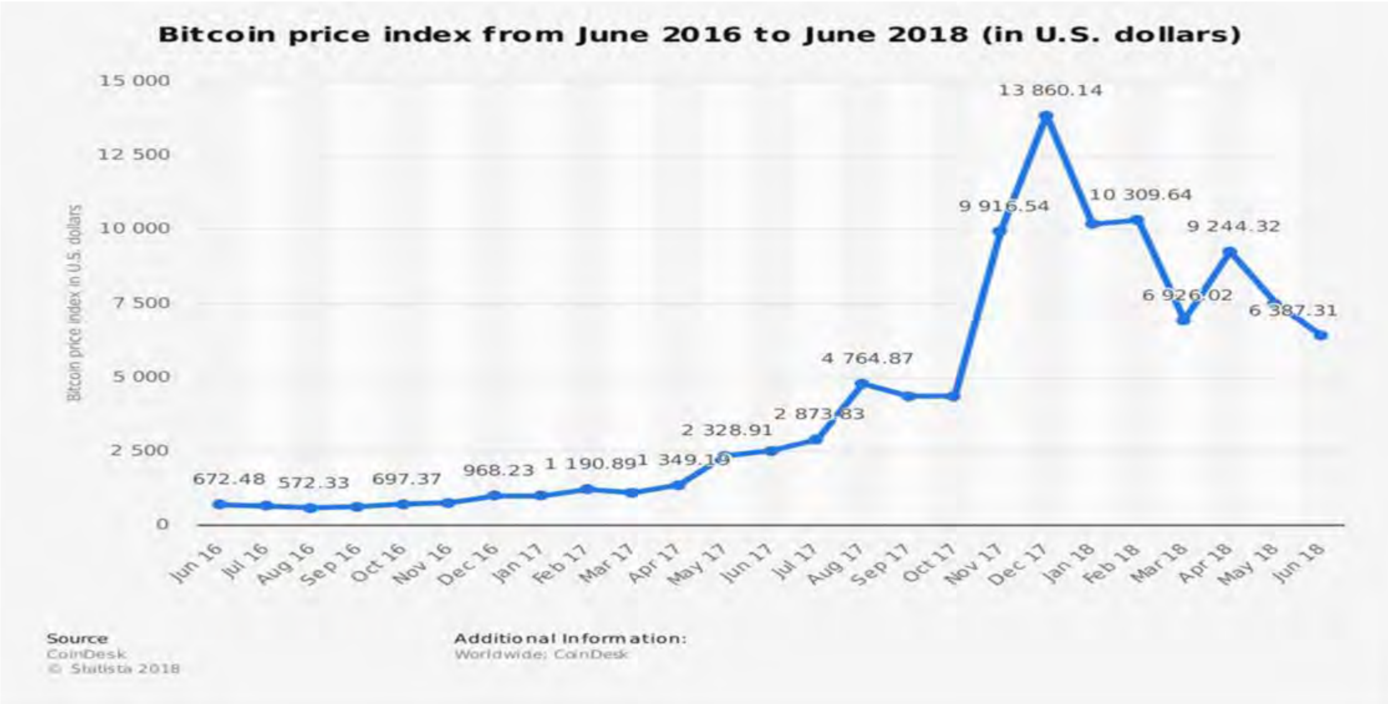
1. N/A means that there were no customers classified as cannabis or cryptocurrency as part of our historical sales in fiscal 2018 or earlier. As such, the historical data to compute growth rate is not applicable.
2. Forecast for fiscal 2019 does not include any actuals.

8.4 CANNABIS AND CRYPTOCURRENCY UNCERTAINTIES

Cannabis and cryptocurrency are both emerging industries where there is minimal existing load and significant, albeit, uncertain growth potential. The risk profile for these industries is asymmetrical in that the potential for higher load growth relative to what is reflected in the load forecast is greater than the potential for lower load. However, little consensus exists about the future of cannabis and cryptocurrency's pace of growth. This is acutely the case for cryptocurrency.

The risk that cryptocurrency loads included in the forecast will not materialize or existing operations will cease operations during the forecast period is the largest risk associated with this emerging industries load forecast. The business viability is ultimately dependent on cryptocurrency prices which are extremely volatile. Figure 8-2 shows the bitcoin price index from 2016-2018.

Figure 8-1 Bitcoin Price Index June 2016 to June 2018



This figure highlights the significant price volatility associated with cryptocurrencies, such as bitcoin; and is indicative of the uncertainty associated with cryptocurrency mining as a sustainable growth industry. Cryptocurrency exchanges also face regulatory risks as governments are taking various actions to mitigate customer exposure to fraud and unlawful business practices. Given this, the regulatory environment can affect the international development of cryptocurrency. In March 2018, bitcoin prices fell below $10,000 after the Securities and Exchange Commission announced the requirement that digital asset exchanges must register with the agency. The Canadian government has postponed the release of its final regulations for cryptocurrency and block-chain companies initially announced for August 2018. Depending on the nature of the regulations this could either help or hinder the development of the cryptocurrency industry as well impact the development of the load.

In contrast, cannabis loads reflected in the load forecast are exposed to significantly less uncertainty. Reasons for this include:

- most of the cannabis operations included in the forecast have long-term agreements for their product or own their site locations, and
- a large cannabis load included in the forecast is an established international greenhouse operator.

The high forecast was developed by including additional (lower probability) loads from projects requesting service via our interconnection process. The low forecast removes some projects from the mid load forecast and assumes service for cryptocurrency customers terminates before the end of the forecast period.

High and low cannabis and cryptocurrency load forecasts were developed and included in the high and low forecasts for the other large industrial sub-sector as inputs into the Monte Carlo uncertainty analysis. Table 8-3 shows the high, mid, and low forecasts before rate impacts.

Table 8-3 Cannabis and Cryptocurrency Mid, High and Low Forecast Before Rate Impacts

Fiscal year	High cannabis/cryptocurrency total incremental sales (GWh)[1]	Mid cannabis/cryptocurrency load additions total incremental sales (GWh)[1]	Low cannabis/cryptocurrency total incremental sales (GWh)[1]
F2018	N/A	N/A	N/A
F2019[2]	108	108	48
F2020	749	453	99
F2021	941	646	190

1. N/A means that there were no customers classified as cannabis or cryptocurrency as part of our historical sales in fiscal 2018 or earlier. As such, the historical data to compute growth rate is not applicable.
2. Forecast for fiscal 2019 does not include any actuals.

9.0 Electric Vehicle Forecast

9.1 DESCRIPTION

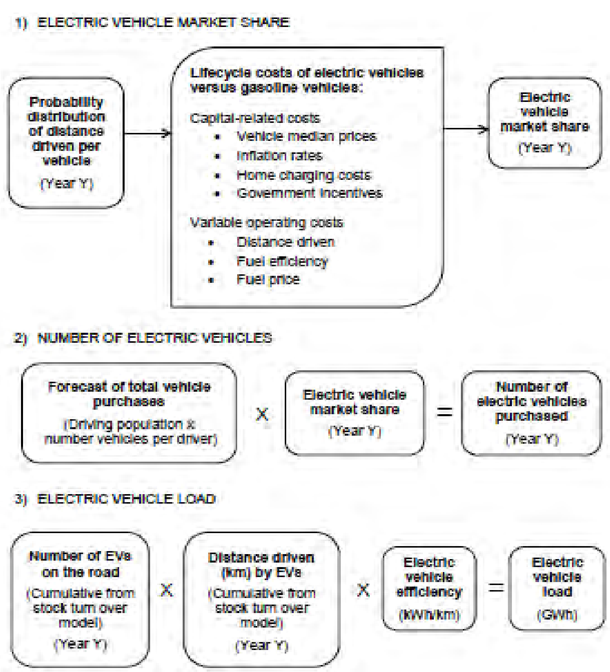
BC Hydro develops an electric vehicle (EV) load forecast to estimate electricity sales across our system due to growth in the total number of electric vehicles. The electric vehicle forecast is split amongst the residential sector and commercial sectors based on Insurance Corporation of British Columbia (ICBC) data on the number of light duty electric vehicles that are for personal and business use. As a result, 85 per cent of the total electric vehicle load forecast is allotted to the residential sector and 15 per cent is allotted to the commercial sector.

9.2 ELECTRIC VEHICLE METHODOLOGY

BC Hydro's electric vehicle load forecast is based on our in house electric vehicle stock turn over model (EV model). The EV model combines both types of EVs (battery plug-in vehicles and plug-in hybrid vehicles) rather than a separate model and a separate forecast for types of plug-in electric vehicles.

The EV model develops a forecast of the total stock of electric vehicles. Our EV model does distinguish between luxury EVs[34] and non-luxury EVs. A trend analysis is used to develop a forecast for the number of luxury EVs, where the trend analysis informs the load projection for these types of EVs. The load forecast for luxury EVs is added to the load forecast for the non-luxury EVs which is developed by the EV model discussed below. Figure 9-1 below illustrates the key inputs and calculations of our EV model (non-luxury vehicles).

Figure 9-1 Electric vehicle model



[34] Luxury EVs are not eligible for government incentives as such these are modelled and forecasted separately.

9.2.1 Computation of annual EV market share

The EV model starts with a forecast of the annual EV market share (ratio of the annual number of EVs to the annual number of vehicles). The key drivers for determining the market share include: (i) a distribution of the driving distance for all types of vehicles; and (ii) the costs of electric vehicles relative to gasoline vehicles which are broken down to fixed and variable costs. The fixed cost reflects the capital related costs of vehicles, which include median sales prices (for both EVs and gasoline vehicles), announced government incentives, and home charging costs for EVs. Variable costs reflect operating costs which are determined by the annual distance driven, fuel efficiencies, and electricity rates versus gasoline prices.

The EV model randomly selects an annual distance driven from an overall probability distribution of annual distance driven per vehicle (fitted to historical data). Next, the model computes the total cost as per the randomly selected annual distance driven and compares it to a break even cost as well the range constraint, which is the maximum annual distance driven or maximum range (in kilometers) for EVs. The break-even cost is the cost at which the model estimates an indifference to gasoline vehicles and EVs. The comparison analysis results in the initial annual EV market share.

The initial market share is adjusted over the near term of the forecast period to reflect an assumed gradual development of adoption of EVs. We assume electric vehicle adoption will grow gradually because of a number of factors such as gradual increases in consumer preference, vehicle range, infrastructure improvements, and EV model availability. However, the growth of EVs is likely to increase more rapidly than currently assumed as a result of government policies, such as those contained in the CleanBC plan, which are targeting greenhouse gas (GHG) emissions reductions. As mentioned in the introduction, the CleanBC Plan actions are not reflected in the October 2018 Load Forecast.

9.2.2 Computation of the total number of electric vehicles

The forecast of the annual total number of electric vehicles is determined by the product of the EV market share and the total vehicle purchase forecast. The total vehicle purchase forecast is determined by the product of the driving population forecast and an estimate of the number of vehicles per driver. The stock turn over portion of the EV model keeps track of the vehicle life expectancy and the annual distance driven of electric vehicles. As such, the year over year change in the total number of electric vehicles as shown in Table 9-1 below does not equal to the annual number of vehicles purchased.

9.2.3 Computation of electric vehicle load

Part three of Figure 9-1 illustrates the annual electric vehicle load in GWh resulting from a product of three variables which include the total number of electric vehicles, the annual distance driven per EV, and the average efficiency of electric vehicles.

9.2.4 October 2018 mid EV forecast model assumptions

The October 2018 mid EV forecast includes the following main assumptions:

- constant energy efficiency of 7.8 L per 100 km for gasoline vehicles and 0.20 KWh per km for EVs,
- existing government subsidies as of August 2018 are taken into account, but no new policies or initiatives are assumed,
- the same projection of electricity rates (i.e. future bill impacts) are used to develop the rate impacts for our October 2018 mid forecast with rate impacts before DSM,
- the average (mid) capital cost of EVs in real dollars is $37,657 and the average (mid) capital cost of gasoline vehicles in real dollars is $27,591. Each of which are assumed to increase at the rate of inflation,
- the average cost of installing an EV charging station which is assumed to be $2,000 as part of the fixed cost, and
- over the near term of the forecast period, the initial EV market share is adjusted to account for a gradual development of EVs in the market.

Page 107 of 170

9.3 ELECTRIC VEHICLE FORECAST RESULTS

Table 9-1 below shows the EV stock shares for the mid forecast and high forecast. The EV stock share is a ratio of the total number EVs to all vehicles.

The EV stock share for the high forecast is developed by assuming that EV incentives reflected in the mid case continue over the entire forecast period and a +/- 10 per cent variability around the mid capital cost of EVs, the mid capital cost of gasoline cars and mid forecast of gasoline prices.

Page 108 of 170

Table notes:

1. The allocation factors are 85 per cent for the residential and 15 per cent for commercial sector based EV data obtained from ICBC.
2. Forecast for fiscal 2019 does not include any actuals.

9.4 ELECTRIC VEHICLE UNCERTAINTIES

The EV load forecast results before rate impacts consist of a mid and high forecast. A mid forecast of the number of EVs and the annual electricity consumption of EVs is estimated using the EV model described above. The detailed assumptions used to develop the mid EV load forecast are outlined in Section 9.2.4 above.

The high EV load forecast comes from a separate Monte Carlo analysis built into our in house EV model. The EV Monte Carlo analysis includes assigning a distribution of outcomes for gasoline prices and capital costs of both types of vehicles. In addition, the analysis assumes that EV incentives known at the time of developing the October 2018 Load Forecast will continue over the forecast period. The Monte Carlo analysis produces a range of EV load forecasts. The p-90 EV load forecast outcome from this range is an input into the Monte Carlo uncertainty model as described in Section 11.2.2. Depending on the actual duration and dollar amount of government incentives, which may differ from our assumptions, this could alter the p-90 EV load forecast result. This uncertainty is not reflected in the overall Monte Carlo uncertainty model as the model is bound between the mid and high EV load forecast.

Given the significant growth potential in EVs, its associated growth drivers and historical sales growth pattern, we consider the mid load forecast to be a reasonable forecast of future EV load. Consequently, only the high forecasts generated from the EV model are reflected in the uncertainty bands.

10.0 Non-Integrated Areas and Other Utilities Forecast

This section is divided into two main parts: (i) Non–Integrated Areas and (ii) sales from BC Hydro to other utilities. We begin with describing the Non-Integrated Area sales followed by sales to other utilities. In both sections we describe the methodology and then the forecasts results.

10.1 NON-INTEGRATED AREAS (NIA)

10.1.1 NIA description

The non-integrated areas consist of a number of small communities located in parts of B.C. not connected to BC Hydro's integrated transmission grid. The communities of our Non Integrated Areas (NIA) include:

- Customers in the Purchase Areas in the South Interior. The Purchase Areas consists of the following six locations: Lardeau, Shutty Bench, Crowsnest, Newgate, Kingsgate-Yahk, and Kelly Lake. To serve customers in the Purchase Areas, BC Hydro purchases electricity from a number of neighbouring electric utilities,
- Customers in Zone II communities in the North Region and Vancouver Island. Zone II non-integrated area customers include 15 communities from the following locations[35]: Masset, Sandspit, Atlin, Dease Lake, Telegraph Creek, Anahim Lake, Bella Coola, Hartley Bay, Good Hope Lake, Toad River, Jade City, Fort Ware, Kwdacha, and Tsay Keh Dene,
- Customers in Zone 1B community of Bella Bella in the North Region, and
- Customers in the Northern Rockies Regional Municipality (Fort Nelson area) in the North Region.

As of fiscal 2018, total gross requirements for the entire NIA were 315 GWh, where more than half of this amount is in the Fort Nelson area.

10.1.2 NIA forecast methodology

Various methodologies are used to develop the forecast for communities that make up the NIA areas. The methodologies range from trend analysis, developing specific customer load forecasts, and regression models. All of the forecasts developed from these methods are supplemented with information from local community members about future loads. BC Hydro's Distribution Area Planners, which look after planning distribution station assets within the NIA areas, gather information from local connection offices and communities about load increase or decrease for all NIA areas.

For the Purchase Areas, the forecast is developed by a trend analysis of the historical total gross requirements of the communities that makes up the Purchase Areas.

For Zone II and Zone 1B communities, the forecasts are developed using a trend analysis of the historical loads that make up major sectors in these areas. A trend analysis is carried out for the residential sector, commercial and light industrial sector and other loads such as street light customers, irrigation customers and BC Hydro own use. The trend analysis establishes a base load forecast which is supplemented by other forecast information on individual projects or customers loads. This additional load information is obtained from customer service requests via local BC Hydro personal or identified by our Distribution Area Planners. These load additions tend to be the main drivers of load growth within all of these communities.

[35] In Table 10.1, loads for the community of Eddontenajon are not included because this community is connected to our integrated transmission grid.

For Fort Nelson area sales, the forecast is developed as the sum of the forecast for each of the major customer sectors including residential, commercial and light industrial and a large industrial sector, which consists of two major loads which are derived as follows:

- The forecast for the residential sector is the product of the accounts and the average use per account. The account projection and the average use per account projection are based on a trend analysis of historical billing data. A trend analysis is used because there is not enough resolution (i.e. detail in our residential end use survey) to develop a statistically sound SAE model for the residential and commercial load in communities that make up the NIA areas.
- The forecast for the commercial and light industrial sector is developed with a regression model involving historical sales and employment where the history and forecast of employment comes from Conference Board of Canada June 2018 Economic Forecast. The forecast for the wood product segment which consists of two mills, currently shutdown, is developed on an account by account basis.
- The forecast for the two large industrial customers in the Fort Nelson area are also developed on an account by account basis using the same methodology that applies to other oil and gas loads connected to the integrated grid.
- The forecasts for street lighting customers, irrigation customers and BC Hydro own use within the Fort Nelson area is developed based on a trend analysis.

The Non-Integrated Area Load Forecast is the result of an aggregation of our load forecasting analysis (i.e., trends, customer projections, and regression models, and load additions as requests for service) for all parts of the NIA listed above, less load reductions for rate impacts and load reductions for savings from our DSM plan.

Rate impacts are developed in the same manner as they are developed for the main customer sectors described in this Report. Savings from our DSM plan identified for the NIA area are allocated to each of the four main parts that make up the NIA on an historical sales percentage basis. An allocation of the DSM savings is used because it is not exactly known which individual part of the NIA will engage in demand side management activities.

10.1.3 NIA forecast results

The Non-Integrated Area Load Forecast results are shown in Table 10-1.

Table 10-1 NIA Total Gross Requirements Sales History and Forecast After Rate Impacts and After DSM

Fiscal year	Purchase area Load Forecast (GWh)	Zone II and Zone 1B Load Forecast (GWh)	Fort Nelson Load Forecast (GWh)	Total NIA Load Forecast (GWh)
Actual				
F2013	12	116	202	329
F2014	12	115	202	330
F2015	12	112	205	329
F2016	11	114	202	324
F2017	13	114	201	326
F2018	14	115	185	315
Forecast				
F2019[1]	14	115	192	322
F2020	15	119	194	328
F2021	15	120	195	329
F2022	15	120	230	365
F2023	15	120	231	366
F2024	15	120	231	366
Growth rates				
5 Yr. Actual (F13 to F18)	4.0%	-0.1%	-1.7%	-0.9%
5 Yr. Forecast (F18 to F23)	1.0%	0.9%	4.5%	3.1%

Table notes:

1. Forecast for fiscal 2019 does not include any actuals.

For the most part, the loads that make up the NIA are stable and the forecasts indicate a slow increase much like the historical trend. The largest growth is anticipated to occur in the Fort Nelson area over the period of fiscal 2021 to fiscal 2022. During this period it is expected that there will be an increase in the demand for electricity by the wood product segment.

10.1.4 NIA uncertainties

The main risks to the NIA forecast are discrete events such as the opening or closing of operations. In some instances, the exact timing of when these projects are expected to transpire are difficult to predict as major developments, such as large residential or commercial projects, within the smaller communities often require external funding. Our BC Hydro planners, NIA station managers and other personal with BC Hydro keep in contact with various communities to gather information on the types of future loads and when future loads are expected come on line.

Some of the loads in the Fort Nelson area are dependent upon the future development of the resource sector. These loads can vary from the forecast due to changes in external market conditions such as fluctuations in natural gas prices and wood segment prices.

10.2 OTHER UTILITIES

The other utilities served by BC Hydro are listed below:

- City of New Westminster, located within BC Hydro's Lower Mainland Region,
- FortisBC Electric, located in southeastern B.C.,
- Seattle City Light, located in the state of Washington, USA, and
- Hyder, Alaska, located in Alaska, USA.

Hyder is served at distribution voltage while the other three utilities are served at transmission voltage.

All of these utilities have formal arrangements with BC Hydro for electrical service. In fiscal 2018, annual energy sales to City of New Westminster, FortisBC Electric, Seattle City Light, and Hyder were 465 GWh, 551 GWh, 312 GWh, and 1 GWh, respectively. Firm exports include Seattle City Light and Hyder, while sales to inter-utilities include City of New Westminster and FortisBC Electric.

10.2.1 Other utilities forecast methodology

The forecast methodology varies by utility, as follows:

- The forecast for the City of New Westminster is based on trend analysis and information from BC Hydro's distribution planners on new larger projects that have requested electricity service.
- The forecast of sales to FortisBC Electric is based on a modelled comparison of the relative cost of purchasing electricity from BC Hydro (including future rate increases) applied to Rate Schedule 3808 versus the cost of market purchases. The model also considers information provided by FortisBC Electric on their expected purchase of electricity from BC Hydro. Since the forecasting model determines the forecast of sales to FortisBC Electric by the relative costs of purchases (i.e., market vs BC Hydro rates) it already accounts for the impact future changes in our electricity rates. As such, there is no need to apply a further rate impact to the results of the model.
- The forecast for Seattle City Light is prescribed within a treaty between British Columbia and Seattle dated March 30, 1984 and which expires on January 1, 2066.
- The sales forecast for Hyder, Alaska is based on a trend analysis.

10.2.2 Other utilities load forecast results and risks

Table 10-2 shows the other utilities' forecast with rate impacts.

Table 10-2 Other Utilities Sales History and Forecast After Rate Impacts

Fiscal year	City of New Westminster (GWh)	FortisBC Electric (GWh)	Seattle City Light (GWh)	Hyder, Alaska (GWh)	Total other utilities (GWh)
Actual					
F2013	455	340	310	1.1	1,106
F2014	457	492	308	1.0	1,258
F2015	444	522	305	0.9	1,272
F2016	455	516	308	0.9	1,280
F2017	463	588	318	0.9	1,370
F2018	465	551	312	0.8	1,330
Forecast					
F2019[1]	469	492	310	1.0	1,272
F2020	470	542	310	1.0	1,323
F2021	471	555	310	1.0	1,337
F2022	474	582	312	1.0	1,369
F2023	476	599	310	1.0	1,386
F2024	479	592	310	1.0	1,382
Growth Rates					
5 Yr. Actual (F13 to F18)	0.4%	10.1%	0.1%	-6.2%	3.8%
5 Yr. Forecast (F18 to F23)	0.5%	1.7%	-0.1%	4.5%	0.8%

Table notes:

1. Excluding the forecast for FortisBC Electric, the forecasts for fiscal 2019 for other utilities does not include any actuals.

Electricity sales to the City of New Westminster are forecast to grow about 0.5 per cent over the next five years, which is keeping in line with historical sales growth. Sales to FortisBC Electric are forecast at an annual compound growth rate of 1.7 per cent over the next five years. Both Seattle City Light and Hyder are forecast to have no significant growth.

10.2.3 Other utilities uncertainties

The main risk to the forecast of electricity sales to the City of New Westminster is a discrete event such as a further large new load addition. The risks to the forecast of sales to FortisBC Electric would be unforeseen changes in the market conditions which may impact how that utility plans to meet its supply arrangements.

Given that the forecast for Seattle City Light is based on a signed treaty, there is minimal sales risk over the entire forecast period. The sales risk for Hyder is also minimal given that its load is so small.

11.0 Monte Carlo Methods and the High and Low Uncertainty Bands

11.1 INTRODUCTION

Load forecasting involves a considerable amount of uncertainty. The demand for electricity depends on a large number of factors which can fluctuate relative to expected outcomes. Some of these factors include: the economy, weather, technology, electricity rates, and changes in the way electricity is consumed. Monte Carlo simulation is our approach to demonstrating uncertainty. This section describes how the Monte Carlo uncertainty model is used to develop the uncertainty bands around our mid total forecast after rate impacts. High and low uncertainty bands are the simulated outcomes of our Monte Carlo uncertainty model, which includes uncertainty variables, statistical distributions, mathematical models, impact factors and a method of random simulation.

11.2 MONTE CARLO METHODS AND SIMULATION PROCESS

Our Monte Carlo uncertainty model contains the following elements:

Uncertainty Variables

A main feature of the model is the inclusion of uncertainty variables. These are:

- economic growth (measured by real provincial GDP growth),
- electricity rates (expressed as real dollar bill impacts),
- temperature (measured by heating degree days),
- economic elasticities (elasticity of load with respect to real provincial GDP); and
- electricity price elasticities of demand.

In addition to these major uncertainty drivers, we also include high and low large industrial forecasts for each sub-sector. The high and low forecasts account for the diversity and uncertainty within this sector. Also included in the model is a range for electric vehicle load and a range for adjustments to codes and standards.

Probability Distributions

- The other feature of the model includes probability distributions which are assigned to the uncertainty variables. This assignment enables a statistical range to be established around the mid forecast of the uncertainty variables.

Impact Factors

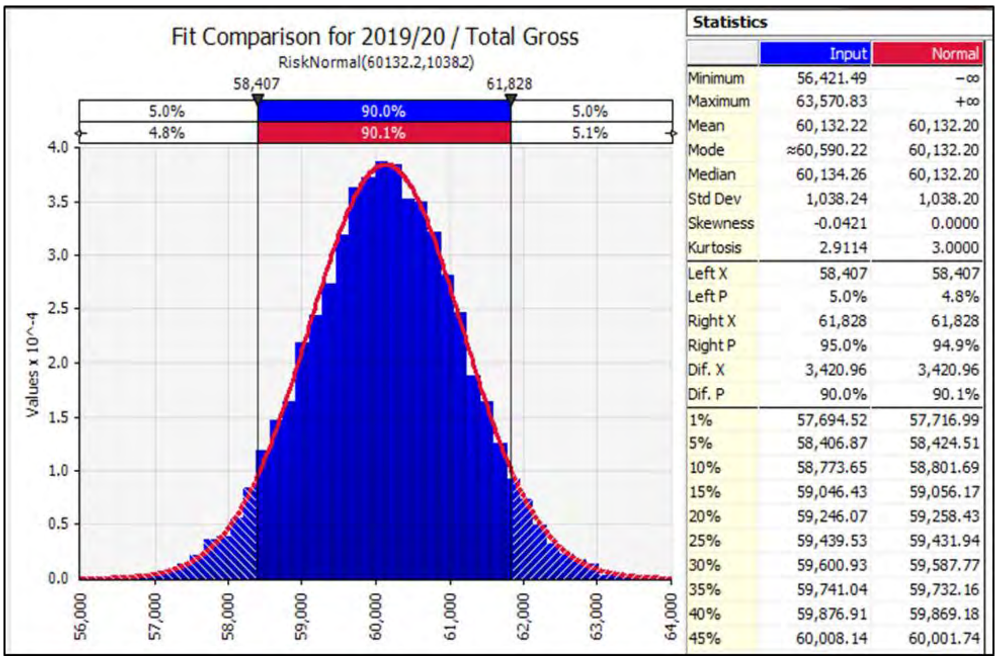
- In addition to probability distributions, there are impact factors which are random variables that perturb (i.e., alter through simulation) the mid load forecasts for residential sector, combined light industrial and commercial sectors, and the large industrial sub-sectors. The sectors which make up about two-thirds of the total area sales (i.e., residential, and commercial and light industrial) have their own impact factors.
- For the remaining one-third of our total area load, the large industrial sector, the range of load outcomes is determined by a different mathematical model. This model uses another set of random impact factors that apply to each of the four main industrial sub-sectors including, mining (metal and coal), forestry (pulp and paper, wood and chemical), oil and gas (shale gas and other large oil and gas operations) and the other large industrial customers. We also include transmission service-connected cannabis and cryptocurrency loads. These are included with all the customers that make the other large industrial sub-sector. The models

are connected through a correlation matrix that consists of correlations between GDP growth and the entire range of load for the large industrial sub-sectors.

Simulation Process and Output

- To calculate its outputs, the model undergoes a simulation (Monte Carlo) process by randomly sampling the probability distributions. The outcome of this process is a range of load outcomes in the form of a probability distribution for each customer sector, total firm sales, and the total system and total integrated system gross requirements. The Monte Carlo simulation process is run 5,000 times for each year of the forecast. Mathematically, with a large number of random simulations, this process results in a symmetric distribution. An example of the model's output for a given year is shown in Figure 11-1.

Figure 11-1 Symmetrical distribution output of our Monte Carlo Uncertainty Model



11.2.1 Large industrial impact factors

The impact factors and the equation that results in the ranges of load outcomes for the large industrial sector is expressed by the following equation:

Equation 11.1a

$$E_t = {}_0E_t I_t^P I_t^S$$

The parts of this equation are explained below.

The term I_t^p in equation above applies to each of the four main large industrial sub-sectors. Where p standards for the forecast of real electricity rates (i.e., real dollar bill impacts). The term I_t^S is the impact factor that applies to the large industrial sub-sectors and transmission service-connected and cannabis and cryptocurrency loads.

The equation for I_t^S is as follows:

Equation 11.1b

$$I_t^S = {}_0E_t^S + \left({}_0E_t^S - E_t^S \right)$$

Page 119 of 170

In equation 11.1b, the superscript S represents each of the large industrial sub-sectors, ${}_0E_t^S$ is the mid electricity sales forecast before rate impacts for those sub-sectors, and E_t^S represents a randomly selected forecast from a triangular distribution of the mid forecast before rates for each sub-sector. See section 11.3.8 below for the high and low forecasts for each sub-sector that bound the triangular distributions for each large industrial sub-sector.

11.2.2 Residential and light industrial and commercial impact factors

The impact factors that results in the range of load outcomes for the residential and combined commercial/light industrial sectors is expressed by the following equation:

Equation 11.1c

$$E_t = 0E_t I_t^P I_t^G I_t^W$$

In the above formula E_t is the electricity sales outcome, $0E_t$ is the mid electricity sales forecast with rate impacts for the sector (i.e. residential or commercial/light industrial). P stands for the mid real electricity price forecast (i.e. real dollar bill impacts), G stands for the mid real provincial GDP growth forecast, and W stands for temperature expressed as heating degree days. Rates, economy, and temperature are the main uncertainty drivers contained in the impact factors. However, the Monte Carlo uncertainty model also accounts for uncertainty for economic elasticity, EV load, and adjustments for codes and standards as described below.

11.2.3 Economic uncertainty

Impact of economic uncertainty (i.e., real GDP growth): This applies to the residential sector and combined commercial / light industrial sectors. In order to assess the impact of economic uncertainty on the loads, the forecast of real provincial GDP growth that is used in our mid load forecast is perturbed randomly through a series of equations as shown by equations 11.2b to 11.2c. The mid GDP growth is denoted by ${}_0g_t$ and the perturbed GDP is denoted byG_t. The perturbed GDP starts off being equal to the mid GDP growth in the first year. It then grows at a growth rate equal to the mid GDP growth rate (${}_0g_t$) plus a random perturbation growth rate (g_t). This random perturbation is a normally distributed random variable with zero mean and a standard deviation of 1.70 per cent, which is denoted as the equation below:

Equation 11.2a

$$g_t \sim N(0, 1.70\%)$$

The perturbed mid GDP is calculated by:

Equation 11.2b

$$G_t = G_{t-1}\left[1 + {}_0g_t + g_t\right]$$

The impact factor for GDP is then given by the following equation.

Equation 11.2c

$$I_t^G = exp\left(\propto ln\left({G_t}/{{}_0G_t}\right)\right) = \left({G_t}/{{}_0G_t}\right)^\alpha$$

Where α is the elasticity of load with respect to mid GDP growth.

11.2.4 Impact of economic uncertainty reflects updated economic elasticities

Table 11-1 shows the mid and a range of economic elasticities as well as the distributions around the economic elasticities used in the Monte Carlo uncertainty model for the residential and combined commercial / light industrial sectors. The residential sector economic elasticity is the elasticity of use per account to real disposable income. The economic elasticity for the commercial sector is the elasticity of commercial sales to real commercial GDP.

These mid economic elasticities for residential sector are developed based on a regional sales weighted average of the economic elasticities included in our SAE models. The mid commercial elasticity is developed in the same way. Information on the economic elasticities contained in our residential and commercial SAE models is found in Appendix C. The high and low ranges of elasticities are also based on the economic elasticities in our SAE models, where the low value is the minimum elasticity and the high is the maximum. The economic elasticities are not specific to GDP but are consistent to the new updated elasticities between load variables and other economic variables that are correlated with GDP.

Table 11-1 Economic Elasticity included in Monte Carlo Uncertainty Model

Sector	Probability Distribution (low, mid, high)
Residential	Triangular (0.19, 0.19, 0.27)
Light industrial/Commercial	Triangular (0.10, 0.21, 0.24)

11.2.5 Electricity rate uncertainty

Impact of Electricity Rate Uncertainty: This applies to all customer sectors. The calculation of the impact factor for electricity rates (I^P_t) is similar to the impact factor of GDP described above. As such, there are two variables that determine the uncertainty of load with respect to electricity rates. The first variable is the mid projection of real electricity rates which is represented as projections of real dollar bill impacts and the second variable is electricity price elasticity of demand. For the October 2018 Load Forecast, the result of the Monte Carlo model in the tables below do not reflect variability around the projection of future electricity rates. This is because the bill impact projections reflected in the October 2018 Load Forecast are based the last five years of the 2013 10-Year Rates Plan as described in our F2017 to F2019 Revenue Requirements Application.

11.2.6 Temperature uncertainty

Impact of Temperature Uncertainty: This source of uncertainty applies to the residential sector and to a lesser extent the commercial/light industrial sector. In British Columbia, the impact of colder weather and temperatures on the residential sector results in additional heating load during the winter months. As such, customer response to colder temperatures (i.e., heating sensitivity) is modelled with a range of heating degree days (HDD)[36] and elasticities of load to heating degree days.

The range of heating degree days is determined from the annual sales weighted total heating degree days over the last 10 years ending fiscal 2018. To develop the range we first constructed a monthly sales weighted (i.e., a sales weighting of the monthly heating degree days across our four services regions) heating degree day variable from actual monthly heating over the past 10 years. Next, from the monthly data series, we found the annual sales weighted total heating degree days over past 10 years and calculated the mean over the same period, which is 1,022 heating degree days.

[36] Heating degree days are calculated for every day. The number of heating degree days in one region such as the Lower Mainland is calculated by the formula: $HDD = max(0, Daily\ Temperature - 15)$. Then, the annual sum of HDD is calculated for each year.

To determine the uncertainty of temperature on the load, a normal probability distribution is used in combination with a temperature impact factor which perturbs the residential and light industrial / commercial mid forecast. The temperature impact factor is shown below in equation 12.3a.

Equation 12.3a

$$I_t^w = exp\left\{\varepsilon_w \, log\left({}^{HDD_t}/_{1,022}\right)\right\}$$

In the equation above ε_w is the elasticity of annual residential sales with respect to annual heating degree days. The value ε_w is estimated to be 0.20 for the residential sector and 0.05 for combined commercial/light industrial sectors. HDD_t in the equation above represents the historical annual sales weighted total HDD over the past 10 years. The probability distribution that is fitted to the historical annual sales weighted total HDDs over the past years is a truncated normal distribution with the parameters shown in Table 11.2 below.

Table 11-2 Temperature Distribution Parameters

Sector	Probability Distribution of HDD (min, mean, max)
Residential	Truncated Normal (831, 1,022, 1,219)
Light Industrial / Commercial	Truncated Normal (831, 1,022, 1,219)

The temperature impact factor does not cause the high and low band to increase over the forecast period because the impact of variability of temperature on the load in a year does not impact the loads in the future years. As such, the impact of temperature is independent amongst all the years over the forecast period. This property is different to the GDP and electricity rate impact factors which have year to year cumulative effects over the forecast period.

11.2.7 EV and overlap in codes and standards uncertainty

Impact of EVs and Overlap in Codes and Standards: The Monte Carlo uncertainty model also considers the uncertainty of EV load and uncertainty in adjustments for overlap in codes and standards. This is accomplished by establishing distributions for each of EV load and adjustment in codes and standards. For EVs uncertainty, a log normal distribution is fitted around the mid and high EV load forecast. There is a triangular distribution around the load additions for overlap in codes and standards included in our mid load forecast. The distribution is +/- 50 per cent of the load additions for overlap in codes and standards in our mid forecast.

11.2.8 High and low large industrial sub-sector forecast

Table 11-3 below contains the low, mid, and high large industrial sub-sector forecasts before rate impacts. These forecasts are inputs to the Monte Carlo uncertainty model and were developed as per the assumptions described in Section 7.

Table 11-3 Large Industrial Sub-Sector Mid High and Low Forecasts Before Rate Impacts Included in the Monte Carlo Uncertainty Model

Fiscal year	Sub-sector	Low Mid High Large Industrial Sales (GWh)

		Low	Mid	High
F2019[1]	Mining	3,804	3,827	3,853
	Forestry	6,424	6,656	6,817
	Oil and Gas	2,065	2,332	2,475

F2024	Mining	2,340	3,939	5,937
	Forestry	4,634	5,669	7,179

Table notes:

	Oil and Gas	3,272	4,845	6,664
	Other Large Industrial	1,274	1,896	2,270

1. Forecast for fiscal 2019 does not include any actuals.

11.2.9 Correlations included in the Monte Carlo uncertainty model

The uncertainty model contains a correlation matrix between the large industrial sub-sectors and GDP growth that gets applied to the residential and combined commercial/light industrial sectors. The correlation matrix ensures that if a series of high draws for the large industrial sub-sector occurs in any single simulation then a high draw of a random GDP disturbance term occurs with a certain probability. This brings together the element of correlation between high and low large industrial load with a high and low residential and combined commercial/light industrial loads. In addition to this correlation matrix, the Monte Carlo uncertainty model contains a correlation matrix between oil and gas and LNG loads. This is included because development of the LNG industry can impact the oil and gas industry and subsequent load growth in this sub-sector.

11.3 MONTE CARLO RESULTS FOR OCTOBER 2018 LOAD FORECAST

The output of the Monte Carlo uncertainty model provides a range of forecasts around the mid forecast after rate impacts. We demonstrate this range by showing high and low bands which are the p-10 and p-90 outcomes from model. The high and low bands are summarized in the following tables[37]

- Table 11-4 contains the low, mid and high band for the total gross system requirements forecast after rate impacts before DSM savings.
- Table 11-5 contains the low, mid and high forecast of total Firm sales after rates before DSM savings, and
- Table 11-6 contains the low, mid and high Total Domestic Load Forecast after rates and DSM savings. The high and low forecasts in Table 11-6 are determined by a post-processing of the high and low bands of total firm sales contained in Table 11-5. This post-processing involves reducing the high and low bands of total firm sales by the mid forecast of BC Hydro own use and the mid forecast of DSM savings.

Table 11-4 Low, Mid and High Total System Gross Requirements After Rate Impacts Before DSM savings

Fiscal year	October 2018 Low Total Gross Requirements GWh	October 2018 Mid Total Gross Requirements GWh	October 2018 High Total Gross Requirements GWh
Actual			
F2013	56,584	56,584	56,584
F2014	57,712	57,712	57,712
F2015	55,807	55,807	55,807

[37] The tables in this section show the history and forecast on a billed basis.

F2016	56,525	56,525	56,525
F2017	56,893	56,893	56,893
F2018	57,842	57,842	57,842
Forecast			
F2019[1]	57,494	58,472	59,465
F2020	58,844	60,299	61,772

11.3.1 Monte Carlo model simulation produces separate load results

The high and low uncertainty bands for above loads segments (i.e. total gross requirements and total frim sales) should be viewed as a separate set of outcomes from the random simulation process. The random simulation process produces an outcome distribution around the mid forecasts with rate impacts each of the main customer sectors (i.e. residential, combined commercial / light industrial and large industrial), total firm sales, and total integrated and gross requirements. Since the Monte Carlo simulation process is random and involves multiple simulations, the combination of uncertainty variables that makes up the low and high bands for any particular customer sector is not the same combination of the uncertainty variables that makes up the low and high band for total firm sales or total system gross requirements.

12.0 Overlap in Codes and Standards

12.1 DESCRIPTION

Codes and standards are minimum end-use efficiency requirements that come into effect in a jurisdiction, and that are enabled by legislation or by regulation of manufacturers. U.S. based codes and standards are reflected in the average stock efficiency forecast of residential and commercial end uses of electricity. The average stock efficiency forecasts are produced by the U.S.EIA. The EIA efficiency forecast is one of the main inputs of the residential and commercial SAE models and the forecasts from these models are the starting point for the load forecasts for these sectors.

BC Hydro's DSM plan also includes savings that can be achieved from B.C. and Canadian Federal codes and standards that target similar end uses as those represented in the EIA efficiency forecast data. As such, there is a potential for overlap in efficiency requirements for end uses of electricity that are enabled from codes and standards as modelled by EIA assumptions and our DSM plan.

12.2 AREAS OF OVERLAP IN CODES AND STANDARDS BETWEEN EIA AND OUR DSM

The EIA assumes that no new legislation or regulations fostering efficiency improvements beyond those currently embodied in law or government programs will take place over the forecast horizon. These efficiency level assumptions are documented by the EIA in the annual energy outlook. BC Hydro has reviewed the EIA's documentation on minimum efficiency standards on end use of electricity and technologies and compared those to the efficiency standards of end use electricity and technologies, contained in our DSM plan, that are enabled by B.C and Canadian Federal codes and standards. Using this information, BC Hydro was able to determine where there were overlaps in codes and standards on various residential and commercial end uses of electricity and technologies. Table 12-1 below shows some of the end uses and technologies where there was an overlap in codes and standards.

Table 12-1 Examples of Overlap in Codes and Standards

Sector	Examples of Areas of Overlap between EIA Codes and Standards and BC Hydro DSM Plan
Residential Sector	Lighting, dishwashers, stand-by power, TVs, freezers, refrigerators and clothes washers
Commercial Sector	Lighting, large clothes washers, walk in coolers, large refrigerators, air conditioning, packaged terminal air conditioning, and dry transformers.

12.3 ESTIMATES OF OVERLAP BETWEEN EIA CODES AND STANDARDS AND CODES AND STANDARDS IN OUR DSM PLAN

After the areas where overlap or double counting in codes and standards are determined, an adjustment is made to our SAE model projections to account for the overlap in codes and standards. We adjust the SAE models' projections to mitigate potential double counting by using an estimate of the overlap between EIA assumptions reflected in our models and codes and standards that result in electricity savings which are contained in our DSM plan.

Previous forecasts (those prior to October 2018) also reflected load adjustments for overlap in codes and standards. Load adjustments for overlap in codes and standards, including lighting, has been in place since our 2010 Load Forecast. In that forecast, we responded to BCUC directive number 6 as per its Decision on BC Hydro's 2008 Long Term Action Plan (LTAP).That directive required BC Hydro to review the potential for double counting DSM and address it in its next LTAP. The review we completed resulted in applying load adjustments to SAE model projections, where these load adjustments accounted for areas where there was overlap in codes and standards.

For the non-lighting code items that were considered to be an overlap, BC Hydro applied 50 per cent of the forecast of DSM savings of these various codes and standards which overlapped with the EIA. These estimates were then used as the adjustments to the SAE model projections.

The 50 per cent assumption is a high level estimate because there are a number of uncertainties we were not able to address as part of our evaluation. These uncertainties include the following:

- There are differences in timing between our service area relative to the geographic areas incorporated in the EIA model (Pacific region) on when the various code and standards come into place,
- There are differences in end uses and technology modelled in the DSM plan and those modelled in the EIA. For example, in the area of refrigeration, not all of the same types of refrigerators are modelled from the same starting point on efficiency and types of various refrigerators. There may also be differences in compliance rates between our service area relative to what is assumed in the EIA model,
- The EIA model only includes the impacts of past U.S, legislation and regulations and does not include future codes and standards. Our DSM plan includes savings from future regulations that are planned and announced, and
- Using the savings from the DSM plan as the basis to determine the impact of the overlap of codes and standards on our load forecast is at best a proxy estimate.

For lighting codes and standards, where there is also double counting for various lighting technologies (i.e. different types of a light bulbs), we have left the base year (i.e. 2018) efficiency level of indoor and outdoor lighting as provided by the EIA unchanged over the forecast period. This method for lighting was chosen to provide consistency with previous forecasts that had already identified a double counting issue with lighting codes and standards.

We continue to assess the extent of the overlap over the various diverse set of electrical appliances and uses of electricity as part of our continuous improvement efforts. Further work in this area may lead to revised overlap projections.

13.0 Glossary

Accrued Sales are an estimate of electricity delivered within a specific month. Most customer meters are not read at every month-end, so the amount of electricity delivered in a month is not known precisely. In accordance with GAAP, monthly accrued sales are used for monthly financial reporting.

Back-casting Estimating econometric or other models over a historical time period and comparing the predictions of the models to actual results over the same time period.

Billed Sales The amount of electricity billed. Because bills are produced after the electricity has been delivered, monthly billed sales lag monthly delivery of electricity.

Binary Variable is a variable whose value is either zero or one. Binary variables are often used as independent variables in regression models in order to account for events that either occur or do not occur. In this latter context, binary variables are often referred to as "dummy variables" in regression.

Calibration Estimating econometric or other models over a historical time period.

Coincidence Factor A ratio reflecting the relative magnitude of a region's (or customer's or group of customers') demand at the time of the system's maximum peak demand to the region's (or customer's or group of customers') maximum peak demand.

Commercial Output Commercial output focuses on the provisions of services in the economy and so includes such things as public administration, insurance agents, bankers, wholesale and retail trade, food services, accommodation provisions etc.

Consumer Price Index (CPI) An inflation index calculated by comparing the price of a typical bundle of goods in the year in question to the price of the same goods in a set reference year.

Cooling Degree Day (CDD) is a measure of warmness, defined by the number of degrees above a certain daily average temperature measured in Degrees Celsius CDDs are drivers of utility air-conditioning electricity loads.

Demand-Side Management (DSM) Activities that occur on the demand side of the revenue meter and are influenced by the utility. DSM activities result in a change in electricity sales. Past DSM savings include incremental load displacement and energy efficiency savings. Note that BC Hydro's historical sales include the impact of DSM savings realized up to that year.

Design Temperature Rolling average of the coldest daily average temperature over the most recent 30 years

Distribution Voltage Customer A BC Hydro customer who receives electricity via distribution lines that operates at lower voltages (60 kV and less).

Domestic System Peak includes the peak requirements for BC Hydro's distribution and transmission customers in its service territory; sales to the City of New Westminster and system transmission and distribution losses.

Econometric Modelling The use of statistical techniques, typically regression analysis of time-series and/or cross-sectional data, to detect statistically verifiable relationships, coherent with economic theory, between an explained variable (e.g. electricity consumption) and explanatory variables (e.g. industry output, prices of alternative energy inputs and GDP).

Elasticity The proportionate change in a dependent variable (e.g. electricity consumption) divided by the proportionate change in a specified independent variable (e.g. electricity price). A dependent variable is highly elastic with respect to a given independent variable if the calculated elasticity is much greater than one. The dependent variable is inelastic if the elasticity is less than one.

End-use Model A model used to analyze and forecast energy demand, which focuses on the end uses or services provided by energy. Typical end uses are lighting, process heat and motor drive. For a given industry, the model estimates the influence of prices and technological change on the evolution of the secondary energy inputs required to satisfy the industry's end uses over time.

Page 130 of 170

Energy The amount of electricity delivered or consumed over a certain time period, measured in multiples of watt-hours. A 100-watt bulb consumes 200 watt-hours in two hours.

Energy Efficiency Is the ratio of the energy service delivered from a process or piece of equipment to the energy input. Energy efficiency is a dimensionless number, with a value between 0 and 1 or, when multiplied by 100, is given as a percentage.

EV Electric Vehicle

Fuel Switching is specific to the October 2018 forecast as presented in this report. Fuel switching means switching from one kind of energy source or use to another that decreases GHG emissions in B.C., and the estimated fuel switching load included in the October 2018 forecast is based on specific government or BC Hydro programs that incent customers to switch from fossil fuel-based energy to clean electricity.

GAAP Generally Accepted Accounting Principles

Gigawatt-hour (GWh) A measure of electrical energy, equivalent to one million kilowatt-hours. (See Units of Measure)

Gross Domestic Product (GDP) A measure of the total flow of goods and services produced by the economy over a specified time period, normally a year or quarter. It is obtained by valuing outputs of goods and services at market prices (alternatively at factor cost), and then aggregating the total of all goods and services.

Heating Degree Day (HDD) Is a measure of coldness, defined by the number of degrees below a certain daily average temperature measured in Degrees Celsius. HDDs are drivers of utility space heating electricity loads.

Integrated System That portion of the BC Hydro's electricity system which is connected as one whole by a high voltage transmission grid.

Integrated System Peak includes the peak requirements for BC Hydro's distribution and transmission customers in its service territory; sales to Other Utilities, which includes Seattle City Light, New Westminster, FortisBC and Hyder Alaska (Tongass Power and Light Co. Inc.); and system transmission and distribution losses.

Intensity A unitized measure of energy consumption, typically in kilowatt-hours per unit of stock. For example, intensity is kWh per account in the residential sector or kWh per unit of production in the industrial sector.

Kilowatt (kW) A kW is 1000 watts and a watt is measure of power that can be transferred instantaneously

Kilowatt-hour (kWh) A measure of electrical energy over a period of time, equivalent to the energy consumed by a 100-watt bulb in 10 hours. (See Units of Measure)

Liquefied Natural Gas (LNG) is natural gas that has been converted temporarily to liquid form for ease of storage or transport. This process involves refrigeration, and requires no chemical transformations.

Load The total amount of electrical power demanded by the utility's customers at any given time, typically measured in megawatts.

Load Displacement Projects that involve the installation of self-generation facilities at customer sites, with the electricity generated being used on-site by the customer, with a resultant decrease in the purchase of electricity from BC Hydro.

Megawatt (MW) A unit used to measure the capacity or potential to generate or consume electricity. One MW equals one million watts. (See Units of Measure)

Megawatt-hour (MWh) A measure of electrical energy, equivalent to 1,000 kWh. (See Units of Measure)

Monte Carlo Method A technique for estimating probabilities involving the construction of a model and the simulation of the outcome of an activity a large number of times. Random sampling techniques are used to generate a range of outcomes. Probabilities are estimated from an analysis of this range of outcomes.

Megavolt-Amps (MVA) – a unit of apparent power, which is real power in MW, divided by power factor.

Natural conservation The increase in energy efficiency that would occur in the absence of any utility-induced demand-side management program, all other things being equal.

Non-coincident In general is the magnitude of a region's (or customer's or group of customers') demand at the time of its peak.

Non-Integrated Area (NIA) Non-integrated facilities refer to generating facilities that are not connected to the system, located in remote areas of the province

Normalization The correction of actual customer sales and peak demand for factors such as unusually warm or cold weather.

Ordinary Least Squares (OLS) is a method of estimating parameters to minimize the sum of squares errors in a regression model.

Price Elasticity of Demand The percentage change in quantity demanded, divided by the percentage change in price that caused the change in quantity demanded.

Real Price Increases that have been adjusted for changes in prices of all goods. The nominal price of an item may rise by 10 per cent over a year, but inflation (and assumed wages) may have risen by 7% over the same time period. Therefore the effective price increase faced by the consumer is close to 3 per cent. It is necessary to deflate current prices by an appropriate inflation index (the CPI in Canada) to convert money values to constant prices or real terms.

Region A geographical sub-division of the BC Hydro service area used for Load Forecast purposes. Four regions exist: Lower Mainland, Vancouver Island, South Interior and the Northern Region.

Stock A quantity representing a number of energy consuming units. For example, in the residential sector, stock is the number of accounts or housing units; in the commercial sector, stock is represented by the floor area of commercial building space.

System Coincident Peak Demand The greatest combined demand of all BC Hydro customers faced by the generation system during a given fiscal year.

Transmission Voltage Customer A BC Hydro customer that is supplied its electricity via high-voltage transmission lines (60 kV or above).

Trinary variable is another type of binary variable that accounts for instances where sales or use per account in one moth is observed to be shifted from one month to the other.

Units of Measure The large amounts of electricity generated and consumed on a system-wide basis are discussed in multiples of the basic units of watt and watt-hours. Kilowatts and megawatts are used to measure power, and kilowatt-hours, megawatt-hours, and gigawatt-hours are used to measure energy. The equivalence is:

1 kilowatt (kW)	= 1,000 watts
1 megawatt (MW)	= 1,000 kilowatts or 1 million watts
1 kilowatt-hour (kWh)	= 1,000 watt-hours
1 megawatt-hour (MWh)	= 1,000 kilowatt-hours or 1 million watt-hours
1 gigawatt-hour (GWh)	= 1,000 megawatt-hours or 1 billion watt-hours

14.0 Overview of Appendices

The Appendices cover five elements of the October 2018 Load Forecast:

A. **October 2018 vs. May 2016 Load Forecast:** this Appendix contains a table showing a comparison between the October 2018 Load Forecast and the May 2016 Load Forecast after DSM and Loss Reductions savings.

B. **SAE Equations and Forecasting Models:** this Appendix provides an explanation of the general framework and equations of the SAE model.

C. **SAE Model Improvements:** this Appendix includes an explanation on the revised economic elasticities and the revised heating and cooling variables incorporated into the 2018 SAE models.

D. **October 2018 SAE Models:** this Appendix contains the regression results and statistical data from the October 2018 residential and commercial SAE models.

E. **Temperature Normalization and Residential Accounts Forecasts Improvements:** this Appendix includes: (i) a description of our temperature normalization process for the residential and commercial sectors; and (ii) a comparison between the results of previously issued residential accounts forecasts and revised forecasts with our new methodology.

F. **Economic Forecast and Other Drivers:** we provide a list of the economic forecast and sources that were used to develop the October 2018 residential (unadjusted), commercial (unadjusted) and light industrial unadjusted) forecasts. We also include the EIA 2018 average efficiency forecast used to develop the residential and commercial forecasts.

G. **October 2018 Load Forecast Tables:** contains a series of tables showing the October 2018 forecast before rate impacts, after rate impacts and after DSM savings and loss reductions.

15.0 Appendix A: October 2018 vs May 2016 Load Forecasts

15.1 COMPARISON OF TOTAL LOAD AFTER DSM SAVINGS

Table 15-1 below compares the mid October 2018 Load Forecast and mid May 2016 Load Forecast of the total (Domestic) Load after DSM savings and loss reductions.

Over the same time period (i.e., fiscal 2018 to fiscal 2023) the October 2018 Load Forecast is expected to grow more slowly compared to the May 2016 Load Forecast. This is because of changes (updates) in various factors that impact load growth in the residential and commercial sectors which make up two thirds of the total load as well changes in the LNG load forecast.

The lower October 2018 Load Forecast for the residential and commercial sectors reflects several factors. These factors include the updated (last 10 years ending fiscal 2018) calibration period, an updated (slower growing) forecast of economic drivers, the recalibration of relationships between economic variables and sales (lower economic elasticities) and the updated (mainly higher) projection of average efficiency various end uses of electricity. These changes which have resulted in lower residential and commercial sector forecasts do not offset the increases in revised forecasts for the oil and gas sub-sector and the light industrial sector. The October 2018 Load Forecast for the light industrial sector is higher over the entire forecast period relative to forecast contained in the May 2016 Load Forecast due to incremental load from the emerging cannabis and cryptocurrency industries. The October 2018 Load Forecast for the oil and gas sub-sector is higher compared to the May 2016 forecast due to expected growth in the shale gas sector.

As for the change in the LNG load forecast, which accounts for most of the difference between the two forecasts by the end of the forecast period, the updated (October 2018) LNG load forecast for LNG terminals is lower relative to the May 2016 forecast due to:

- a revised methodology for developing the forecast for LNG terminals, and
- a change in the timing and the expected load for LNG terminals.

Table 15-1 Comparison of Total Domestic Load After DSM Savings

Fiscal year	October 2018 Load Forecast (GWh)[1]	May 2016 Load Forecast (GWh)[1]	October 2018 Forecast minus May 2016 Load Forecast (GWh)	Difference to the May 2016 Load Forecast (per cent)
Actual (temperature normalized)				
F2013	51,107	51,108		
F2014	51,957	51,958		
F2015	52,283	52,284		
F2016	51,724	52,071[2]	(347)	-0.7%
F2017	51,597	51,858[2]	(261)	-0.5%
F2018	52,024	51,823[2]	201	0.4%
Forecast				
F2019	52,594[3]	52,652	(58)	-0.1%
F2020	53,562	53,025	537	1.0%
F2021	53,252	54,337	(1,085)	-2.0%
F2022	53,088	56,100	(3,012)	-5.4%
F2023	53,433	57,164	(3,731)	-6.5%
F2024	54,553	58,052	(3,499)	-6.0%
5 Yr. Avg. Historical (F13 to F18)	0.4%	0.3%		
5 Yr. Avg. Forecast (F18 to F23)	0.5%	2.0%		

Table notes:

1. Domestic sales include loads for our main customer sectors, irrigation customers, street light customers, sales to inter-utilities and frim exports supplied by BC Hydro. Both load forecasts in the table above include load reductions for DSM savings and loss reductions savings.
2. Indicates that the value is based on the May 2016 Load Forecast.
3. Indicates the load forecast does not include any actuals for the current fiscal year (i.e., fiscal 2019).

16.0 Appendix B: SAE Equations and Forecasting Models

16.1 INTRODUCTION

Our unadjusted sales forecasts[38] for residential and commercial sectors are based on:

- the estimated coefficients of the SAE, and
- the forecasts of economic data, temperature data, average efficiency data and saturation data. All of these are included in the SAE models.

Section A1.2 below covers the general framework of the SAE model, the development of its main variables (i.e., Heating, Cooling and Other) and the equations for these variables.

16.2 STATISTICALLY ADJUSTED END USE FRAMEWORK

The description of the SAE framework described below for the residential sector generally applies to the commercial sector. The main difference between the residential and commercial framework is that the dependent variable in the residential framework is the average use per account and the dependent variable in commercial framework is commercial sales.

The statistically adjusted end-use modeling framework begins by defining the dependent variable: the average electricity use per account (Use_m) in a month (m) as the sum of the average electricity use by per account from heating equipment ($Heat_m$), cooling equipment ($Cool_m$), and other equipment ($Other_m$). Formally, this is written as:

Equation B.1

$$USE_m = Heat_m + Cool_m + Other_m$$

Equation B.1 can be written in the format of a linear regression model as:

Equation B.2

$$USE_m = a + b_1 \times XHeat_m + b_2 \times XCool_m + b_3 \times XOther_m + \varepsilon_m$$

Where: USE_m is the dependent variable of the above regression model or average use per account (monthly). The independent variables in the regression model are $XHeat_m$, $XCool_m$, and $XOther_m$. These are the main explanatory variables, which are constructed monthly (m) from end-use information, economic drivers, and temperature data. The parameter ε_m represents the random error term in the above regression model. The parameters b_1, b_2, and b_3 are the coefficients of the regression model which represent the relative contribution of the main explanatory variables (i.e., major end uses) to the average residential use per account.

The equations below show the construction of the main independent variables. For each variable there is data in the historical period (i.e., estimation period) and data in the forecast period. The estimated coefficients of the model and the forecast data for each main variable determine the results (i.e., forecast of average use per account) that come from the SAE model.

XHeat: represents average heating use per account. The amount of electricity used per account for heating depends on the following types of variables:

[38] In this Appendix as well all of the other sections and appendices contained in this report, the term “unadjusted forecast” and the “term model projections” are used interchangeably.

- heating degree days (temperature),
- heating equipment saturation levels (percentage of accounts that have a certain type of heating equipment),
- average efficiency of heating equipment,
- average number of days in the billing cycle for each month, and
- economic variables. For the residential sector this includes people per account and real personal disposable income. For the commercial sector this includes employment, real retail sales, and real commercial GDP.

The heating variable $XHeat_m$ is a product of a monthly equipment index and a monthly usage multiplier. In equation form this is expressed as:

Equation B.3

$$XHeat_m = HeatIndex_m \times HeatUse_m$$

Where: $\mathrm{XHeat_m}$ is the average heating use per account in a month (m). This variable is a product of two monthly index variables: (i) $\mathrm{HeatIndex_m}$ is the aggregate amount of heating use per account in a month for the various types of heating equipment; and (ii) $\mathrm{HeatUse_m}$ is monthly index of heating usage.

The sub-equation for $HeatIndex_m$ in equation B.3 is:

Equation B.3.1

$$HeatIndex_m = \sum_{SpaceHeating} EndUseEnergy_{e,BaseYear} \times \frac{\left({}^{Share_m}/_{Eff_m} \right)}{\left({}^{Share_{BaseYear}}/_{Eff_{BaseYear}} \right)}$$

Where: End Use Energy is the average use per account for each type of heating equipment, e refers to the different categories of space heating, BaseYear represents the base year for the SAE model, Share mean saturation levels[39] of the different types of heating equipment which comes from our Residential End Use Survey data (REUS), Eff is the average efficiency of the different types of space heating equipment.

The heating equipment index (i.e., HeatIndex) depends on heating equipment saturation levels normalized (i.e., divided) by average efficiency level. As a result, the heating index will increase over time if there are changes in heating equipment saturation levels, and will decrease over time if there are improvements in the average equipment efficiencies or the thermal efficiency of residences.

Space heating usage level (i.e., $XHeatUse_m$) is a function of temperature (Heating Degree Days) and economic factors. The sub-equation for $XHeatUse_m$ in equation B.3 is:

Equation B.3.2

$$HeatUse_m = \left[\frac{BDays_m}{30.5}\right] \times \left[\frac{WgtHDD_m}{HDD_{BaseYear}}\right] \times \left[\frac{PeoplePerAccount_m}{PeoplePerAccount_{BaseYear}}\right]^{EI1} \times \left[\frac{Income_m}{Income_{BaseYear}}\right]^{EI2}$$

Where: m refers to monthly values, Base Year is the base year of the SAE model, BDays refers to billing days and *EI1 and EI2* are the economic elasticities of average use per account for people per account and real disposable income respectively. Each annual economic variable is converted into a monthly indices which is developed as a 12 month rolling average of the annual economic variable weighted (i.e., divided) by its average monthly value in the base year of the model. The variable $WgtHDD_m$ is the actual weighted heating degree days in a month divided by the average monthly heating degree days in the base year of the model. The weights applied to the monthly heating degree days are used to align the actual monthly heating degree days to the billing cycle data on

[39] Saturation levels are defined as the percentage of accounts that have a certain type of electrical equipment or appliance.

the residential sales over the year. For the forecast period, the variable $WgtHDD_m$ is the 10 year rolling average (i.e., temperature normalized) of heating degree days in each month.

XCool: represents the average cooling use per account. This variable is constructed in a similar manner to heating. The amount of electricity use per account for cooling depends on the following types of variables:

- cooling degree days (temperature variable),
- cooling equipment saturation levels (percentages of residential accounts that have a cooling appliance),
- average efficiency of cooling equipment,
- average number of days in the billing cycle for each month, and
- economic variables including people per account and disposable income.

The cooling variable, $XCool_m$, is represented as the product of an equipment-based index and monthly usage multiplier. In equation form this represented as:

Equation B.4

$$XCool_m = CoolIndex_m \times CoolUse_m$$

Where: $XCool_m$ is the average electricity use per account for cooling in a month (m), $CoolIndex_m$ is an index of average cooling equipment use per account in a month (m); and $CoolUse_m$ is the monthly usage multiplier for cooling.

The sub-equations for $CoolIndex_m$ and $CoolUse_m$ are the same equations as those above for heating (i.e., equations B.3.1 and B.3.2) with the exception the last equation B.3.2 includes cooling degree days instead of heating degree days.

As with space heating, the cooling equipment index ($CoolIndex_m$) depends on the cooling equipment saturation levels normalized (i.e., divided) by average efficiency levels. As a result, the cooling index will increase over time if there are changes in cooling equipment saturation levels, and will decrease over time if there are improvements in equipment efficiencies or the thermal efficiency of buildings. Space cooling system usage levels ($CoolUse_m$) are driven on a monthly basis by several factors, including temperature (Cooling Degree Days) and similar economic factors used to develop heating usage.

XOther: represents the average use per account for residential end-uses of electricity that are not temperature sensitive. Some examples of non-temperature sensitive end-uses are lighting, refrigeration, cooking, clothes washing and drying, entertainment equipment (TVs) and other plug in equipment. The average use per account of electricity for other equipment is driven by:

- appliance and equipment saturation levels,
- appliance efficiency levels,
- average number of days in the billing cycle for each month, and
- economic variables.

The explanatory variable $XOther_m$ is defined as:

Equation B.5

$$XOther_m = OtherEqpIndex_m \times OtherUse_m$$

The first term on the right hand side (i.e., $OtherEqpIndex_m$) of the above equation embodies information about the average usage per month of various non-temperature dependent appliances as well as their saturation levels and their average efficiency ratings. The second term ($OtherUse_m$) captures the impact of economic variables of the overall average use of electricity through the use of other non-temperature dependent equipment. These economic variables are the same ones used for explaining heating and cooling use.

The first term has the following sub-equation:

Equation B.5.1

$$Other\ Eqp\ Index_m = Weight^{Type} \times \frac{Sat_m^{Type} / Eff_m}{Sat_m^{Type} / Eff_m} \times MoMult_m^{Type}$$

The weight term is the non-temperature dependent average use per account for specific residential end uses of electricity such as lighting, dishwasher, refrigerators etc. Sat_m^{Type} is the saturation level (i.e., percentage of accounts having at least one of these types of end uses). *Eff* is the average stock efficiency from the EIA of the various non–heating and non-cooling end uses. *MoMult* is a monthly multiplier that shapes the index to our billing data on the average use per account.

The equation for second term on the right hand side of equation B.5 above can be expressed as:

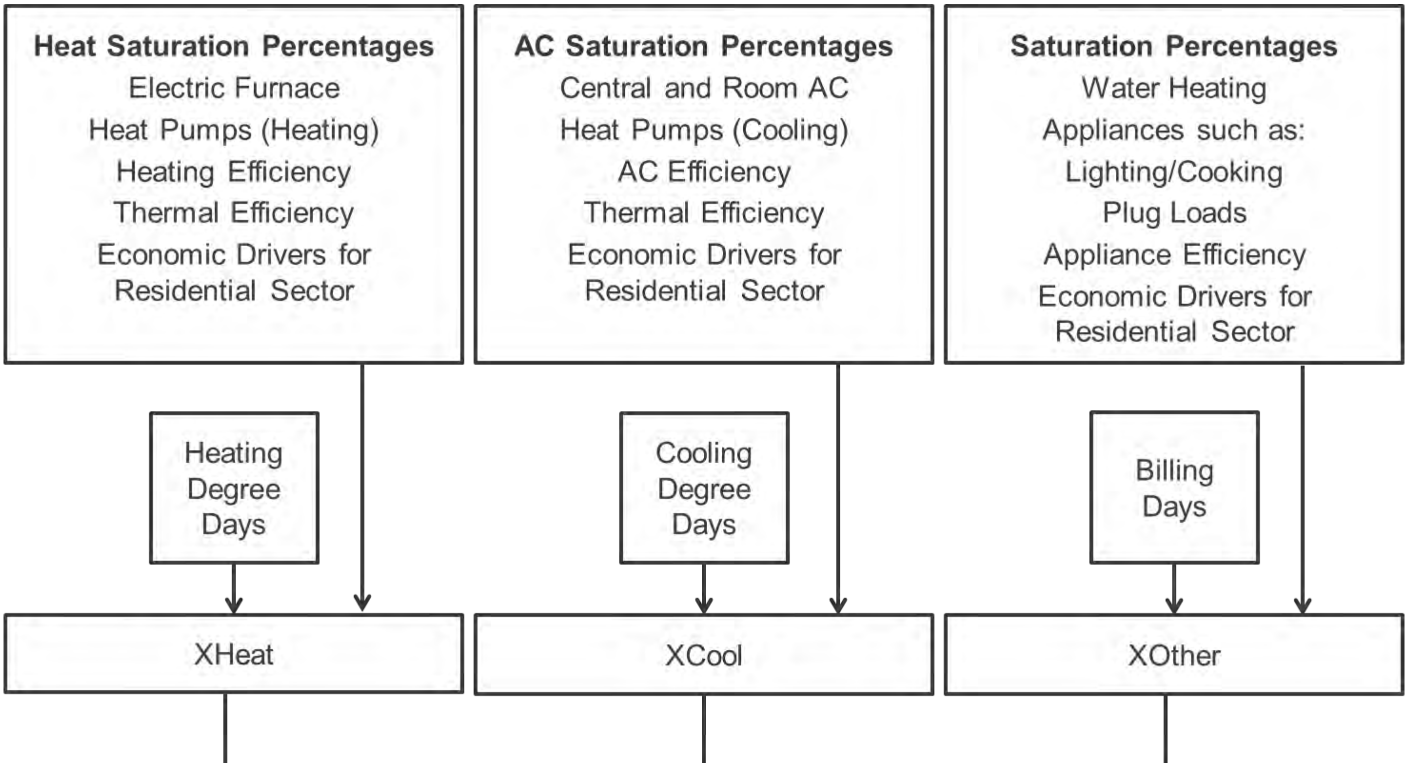
Equation B.5.2

$$Other\ Use_m = \left[\frac{BDays_m}{30.5}\right] \times \left[\frac{PeoplePerAccount}{PeoplePerAccount}\right]^{EI1} \times \left[\frac{Income_m}{Income}\right]^{EI2}$$

Where: $BDays_m$is billing days and *EI1* and EI2 are the economic elasticities of average use per account for people per account and real disposable income respectively.

In summary, Figure 16-1 below shows the inputs used in the construction of the regression variables (i.e. the independent variables) for the residential SAE models. As mentioned above the residential SAE model dependent variable is the average use per account and the commercial SAE model dependent variable is commercial electricity sales. The residential and commercial SAE models also differ in inputs in terms of economic variables, elasticities, and the regional temperatures that determine heating and cooling degree days. The latter of these two variables are discussed in Appendix C below.

Figure 16-1 Statistically Adjusted End Use (SAE) Model



$$USE_m = a + b_1 \times XHeat_m + b_2 \times XCool_m + b_3 \times XOther_m + \varepsilon_m$$

17.0 Appendix C: SAE Model Improvements

17.1 SAE ELASTICITY PARAMETERS

As mentioned in Section 3.2.5 of this report, we have updated the economic elasticity parameters used in our residential and commercial statistically adjusted end use models. The elasticities in the context of the SAE model framework are intended to represent the percentage change in use per account or sales due to a one percentage change in any specific economic driver.

To update these economic elasticities for our SAE models we developed a series of linear regression models and from these results we computed elasticities. For example, to determine the elasticity of sales to employment for the commercial SAE models we developed linear regression model such as:

Equation C.1a

$$USE_m = a + b_1 \times XHeat_m + b_2 \times XCool_m + b_3 \times XOther_m + b_4 \times Employment_m + b_5 \times Accounts_m + \varepsilon_m$$

Where: USE_m is monthly electricity sales for the Lower Mainland commercial general over 35 kw segment, employment is a 12 month moving average of employment created from annual employment data from the Conference Board of Canada, June 2018 Economic Forecast, accounts is the monthly number of commercial general over 35 kW accounts, b_1 to b_5 are the coefficients of the model and ε_m is the error term.

The *XHeat* variable in the above regression model contains the $\mathrm{HeatIndex}_m$ as described in equation B.3.1 above and the temperature portion of $\mathrm{HeatUse}_{\mathbf{m}}$ as described in equation B.3.2 above. This means that *XHeat* reflects the average weighted saturation and efficiency portion and the temperature portion of the two indices that make up the *XHeat* variable. All of the main variables (i.e., *XHeat*, *XCool*, *XOther*) in the regression model above are constructed in a similar manner (i.e., they excluded the economic variable in the index driver) so that separate elasticities could be computed from the regression results. In this example, the elasticity of commercial Lower Mainland over 35 kW sales to employment is determined from the estimated coefficients of the regression model above and the following equation:

Equation C.1b

$$Elasticity\ of\ Sales\ to\ Employment = b_4 \times \frac{Mean\ Value\ of\ Employment}{Mean\ Value\ of\ Sales}$$

Where: b_4 is the estimated coefficient from the model above (i.e., C.1a) which is multiplied against the ratio of the mean value of employment and the mean value of commercial sales where the means are computed from historical data used in the calibration (i.e., estimation) period.

17.2 SAE ELASTICITY RESULTS

For the residential and commercial sectors, linear regression models, such as the one shown in equation C.1a above, were estimated with data using the last 10 years ending fiscal 2018. For the residential sector we considered the economic variables of people per account and real disposable income and the average use per account as the dependent variable. The economic variables for the commercial sector included employment, real retail sales and real commercial GDP.

We developed regression models with different combinations of economic variables and other independent variables such as the number of commercial accounts. This exercise produced many regression models (i.e. over 100), which we then assessed to determine the elasticities for the economic drivers for each sector on a regional basis. All of economic data, on a regional basis, came from the Conference Board of Canada, June 2018 Economic Forecast.

Page 141 of 170

Tables 17-1 and 17-2 below contain the update economic elasticities for the residential and commercial sectors compared to the elasticities used in the May 2016 Load forecast. These elasticities are lower than those used in the May 2016 Load Forecast, for which we explain below for the commercial sector.

Over the estimation period, we experienced slower growth in commercial sales and use per account relative to growth in the economic drivers. For example, Figure 17-1 below show actual year over year growth in commercial sales for the BC Hydro service area and the year over year growth in employment and real commercial GDP over for the BC Hydro service area over the past 10 years. The figure clearly shows a weaker linkage between growth in sales and economic drivers. Given this, our updated economic elasticities are smaller relative to that those previously reflected in the other forecasts such as the May 2016 forecast.

17.3 SAE TEMPERATURE VARIABLES

As mentioned in Section 3.2.4 of this report, we have updated the temperature variables (i.e., heating and cooling degree days) used in in our October 2018 residential and commercial SAE models. The key work in this area was to determine the temperature where we see a customer response to decreasing temperatures (i.e., heating) and increasing temperatures (i.e., cooling). The daily average temperature at which we see increases in electricity sales or use per account to heating and cooling temperatures is known as the cut point temperature. The cut point temperature determines a heating or cooling degree day. A heating or cooling degree day which is calculated for each day in the year is determined as the difference between the daily average temperature on that day and the cut point temperature.[40] In the May 2016 Load Forecast the cut point temperature was 18 Degrees Celsius for all four regions within our service area. As such, the daily and monthly (i.e., total number of degree days in a month) heating and cooling degree variables were calculated as the difference between this cut point temperature and dry bulb daily average temperatures from data at four representative weather stations[41].

For the October 2018 Load Forecast, we updated the cut point temperatures for all four regions that make up our residential sector. We also updated the cut point temperature for our commercial sector on a regional basis. This results in eight different cut point temperatures (i.e., one for each commercial load segments that make up our commercial sector). The cut point temperature analysis was based on using load shapes for various load segments. The load shape data comes from our in-house load shape model that uses our smart metering infrastructure (SMI) data to develop historical load shapes by region and by customer segments for the residential and commercial sectors. We used load shape data from fiscal 2017 and fiscal 2014 as both of these years had several periods of cold and warm temperatures which we believe would be indicative of customer response to heating and cooling degree days.

Tables 17-3 and 17-4 below summarize the updated heating and cooling cut point temperatures for the residential and commercial sectors on a regional basis.

[40] As an example, heating degree day = maximum of (18°C – daily average temperature, zero). In this example 18°C is the cut point temperature.

[41] The four weather stations are located at YVR, or Vancouver International Airport for the Lower Mainland, Victoria International Airport for Vancouver Island, and Kelowna Airport represents the South Interior and Prince George Airport represents the North Region. Dry bulb means precipitation impact on daily average temperature is not included.

18.0 Appendix D: October 2018 SAE Models

Tables 18-1 to 18-12 below show the statistical estimation results of the October 2018 residential and commercial SAE models. Each SAE model produces the following statistical outputs which are used to assess the statistical robustness of model results:

- Estimated coefficient of the independent variable and standard error of the estimate,
- A t-test statistic on the statistical significance of the independent variable,
- P-value indicating the statistical significance of the independent variable. P-values greater than 5 per cent indicate that the variable is not statistically significant from zero,
- R-square statistic, R-squared adjusted statistic- which is adjusted for the number of variables. These statistics indicate the goodness of fit of the models over the calibration (estimation) period,
- Mean Absolute Percentage Error is a measure of the prediction accuracy of the model to predict over the calibration period, and
- The Durbin Watson statistics test for auto-correlation.[42] The Durbin Watson statistics are compared to values that come from the Durbin Watson significance tables to assess whether or not the estimated errors from the regression model have auto-correlation.[43]

All models are estimated with monthly billed sales or monthly average billed sales per account over the last 10 years ending fiscal 2018 (i.e., 120 data points), unless the model is corrected for auto-correlation then it is estimated with less data points. Each model is estimated with the method of Ordinary Least Squares estimation.[44]

Binary variables included in our SAE models take on the value of 1 or 0. For example, a Binary Variable for a specific month means 1 for that month otherwise 0. Trinary variable is another type of variable that accounts for instances where sales or use per account in one moth is observed to be shifted from one month to the other.

[42] A linear regression model that has auto-correlated errors means that the estimated error term in one period is correlated with an estimated error term in a previous period. The implication is that regression model is not statistically robust and R-square statistics and the t-test statistics are not reliable because the error terms are correlated.

[43] Durbin Watson significance tables can be found at https://www3.nd.edu/~wevans1/econ30331/Durbin_Watson_tables.pdf

[44] A description of ordinary least squares estimation can be found at: https://en.wikipedia.org/wiki/Ordinary_least_squares

19.0 Appendix E: Temperature Normalization & Residential Accounts Improvements

19.1 INTRODUCTION - TEMPERATURE NORMALIZATION

As mentioned in Section 5.1 of this report we develop a forecast of the average use per account and residential sales on a temperature normalized basis. We also develop a forecast of commercial sales on a temperature normalized basis. The forecasts for both of these sector forecasts are derived from our SAE models that include various drivers such as our heating and cooling degree day variables.

Since the forecasts are developed on a temperature normalized basis, we need to take the actual sales and temperature normalize them (i.e., adjust the historical sales for instances where actual temperature were different than assumed normal) to report variances and determine the accuracy of our forecasts. Temperature normalization is an estimation process because it involves using models and a series of steps to determine what the actual sales would have been if the actual temperatures variables (i.e., heating and cooling degree days) were at their normalized values (i.e., which is defined as the 10 year rolling average).

Each month, we temperature normalize the residential use per account and subsequently normalize the sales by multiplying the temperature normalized use per account by the accounts. We also temperature normalize the commercial sales. We currently temperature normalize the commercial sales at the end of the fiscal year using our SAE models. As part of the audit recommendations[45] we are working towards developing models and a process to temperature normalize commercial sales much like the way we normalize the actuals from residential sector, which is described below.

The following sections explain the temperature normalization process for the residential and commercial sectors.

19.2 TEMPERATURE NORMALIZATION PROCESSES STANDING APPROACH

Our current temperature normalization process for the residential and commercial sectors is described below. However, we are continuing to review the applicability of the residential approach described below to the commercial sector.

The central equation in determining a temperature normalized actual is:

Equation E.1

$$Temperature\ Normalized\ Actual = Actual + Model\ Projections\ Under\ Normal\ Temperatures - Model\ Projections\ Under\ Actual\ Temperatures$$

Where: Actual is the actual data from our billing system, Model Projections under Normal Temperature is an estimate[46]using our normal assumptions for heating and cooling degree days, and Model Projections under Actual Temperature is an under actual temperatures (i.e., actual heating and cooling degree days). The model projections are developed with an estimation period that does not include any of the forecast years. For example, our normalized residential and commercial results were done with data ending fiscal 2018.

[45] One of the Load Forecast Audit findings was to update our monthly variance report by including temperature normalized commercial monthly sales and comparing those estimates to the forecast on a monthly basis.

[46] Estimate in the context of temperature normalization means predication of average use per account for the residential sector and prediction of sales for the commercial sector.

19.3 RESIDENTIAL TEMPERATURE NORMALIZATION

To temperature normalize the use per account we use equation E.1 above use the in conjunction with model projections from the following regression model (equation E.2) below:

Equation E.2

$$USE_m = \alpha + \beta_1 \times WgtHCDD_m + \beta_2 \times WgtHCDD_m^2 + \beta_3 \times WgtHCDD_m^3 + \varepsilon_m$$

Where: USE_m is monthly average use per account per account for eight segments of residential load we normalize[47], β_1 to β_3 are the coefficients of the above cubic regression model, $WgtHCDD_m$ is a combination of weighted cooling and heating degree days in a month, $WgtHCDD_m^2$ and $WgtHCDD_m^3$ are squared and cubic weighted heating/cooling degree days[48]; and ε_m is the error term. The weights are used to align the combo of heating and cooling degree days to the monthly billing data.

The most recent 36 months of data is used to estimate the regression model as described in the equation E.2 above for each of the eight residential load segments that get normalized. Every month we determine the temperature normalized average use per account and the residential billed sales using the following steps:

1. we estimate the coefficients of the regression model using data from the past 36 months,
2. from estimated coefficients in equation E.2 we determine the model's prediction of the average use per account under actual temperatures for the past 36 months, including the prediction for the last month,
3. from the estimated coefficients in equation E.2 we determine the model's prediction under normal temperature by replacing the actual combined weighted heating and cooling degree days variables with these variables on a normalized basis; and
4. finally, we determine the temperature normalized average use per account for the month we are normalizing using equation E.1 above.

Normalized residential sales are then calculated for each load segment as the normalized average use per account multiplied by the average number of accounts for the segment. The total BC Hydro service area normalized residential sales in any month is equal to the sum of normalized sales for each segment; and the total normalized sales for a year would be sum over the past 12 months.

19.4 COMMERCIAL TEMPERATURE NORMALIZATION

The process for commercial normalization is similar to the four step process outlined above for the residential sector. The main differences to the residential process are: (i) the eight commercial SAE models and the last 10 years of monthly commercial sales data are used in the normalization process rather than monthly regression models using the past 36 months; (ii) the commercial sales are normalized at the end of year fiscal year using the commercial SAE model; and (iii) the heating and cooling degree variables in the commercial SAE models and the weights of these variables are different compared to the weights in the above residential models because the billing cycle is different for the commercial segments of load compared to the residential sector.

[47] The residential load segments we normalize are the heating and non-heating accounts in each of the four service regions, as such there are eight load segments (2 heating types and 4 regions).

[48] Because billing data of use per account is used in the temperature normalization process, the combined cooling and heating degree-days are weighted as percentages of the current and previous month to match the meter reading cycle for our residential customers. The weighting process is also an element of our SAE model.

19.5 RESIDENTIAL ACCOUNTS IMPROVEMENTS

As mentioned in Section 3.2.4 of this report, we indicated that we have modified our methodology on how we forecast residential accounts. The new methodology recognizes that based on a historical analysis of account growth and housing growth that there is not a one to one ratio in these variables which was assumed in previous forecasts. The details of the revised method of forecasting the residential accounts are contained in Section 4.2.1 above.

We have not re-estimated the accounts forecast for the past 10 successive forecasts with the revised methodology because of the considerable effort that would be required. However, to demonstrate our belief that the new approach will lead to a more accurate forecast, we re-estimated the 2012 and 2011 accounts forecast using the main aspect of the new methodology. The 2011 and 2012 accounts forecasts were re-developed by applying historical ratio of accounts growth to housing starts growth.[49]

Table 19-1 below summarizes the variance (i.e., actual less forecast of accounts) for the total BC Hydro service area of the original 2011 and 2012 accounts forecast and our re-estimated accounts forecast that was developed by applying a historical ratio of account growth and housing starts to the housing starts forecast. This ratio was determined at the BC Hydro service area level by computing a five year average of historical account growth to housing growth prior to the forecast period. The re-estimated accounts is a simplified version of our new method in that the ratios used for the re-estimated forecasts were developed at the BC Hydro level rather than ratios from a detailed analysis of the15 areas for which we develop an accounts projection. As well, the re-estimation of the accounts for the 2011 and 2012 forecast periods do not include a separate analysis for the first year of the forecasts using the billing data trends at the time when these forecasts were prepared.

The results summarized in Table 19-1 show lower variances of re-estimated forecast vintages using the new method compared to the original accounts forecasts. This illustrates the new method is an improvement (i.e., greater accuracy) in the approach to developing our accounts forecasts.

[49] At the time, the 2012 and 2011 accounts forecast used net housing starts rather than growth in net housing stock.

Table 19-1 Variance Analysis of 2011 and 2012 Residential Account Forecasts

Fiscal year	2011 Variance of Original Forecast	2011 Variance Re-Estimated Forecast Reflecting Ratio Methodology Approach	2012 Variance of Original Forecast	2012 Variance Re-Estimated Forecast Reflecting Ratio Methodology Approach

20.0 Appendix F: Economic Forecasts and Other Drivers

Table F-1 and Table F-2 contains a summary of the forecasts of the economic drivers, at the BC Hydro service area, used in developing the October 2018 Load Forecast for the residential, commercial and light industrial sectors.

The forecasts of these economic drivers comes from the Conference Board of Canada June 2018 Economic Forecast. The Conference Board of Canada was selected by BC Hydro to provide a history and forecast of economic variables for 15 sub areas, 4 service regions, and the total province. The regional break-down of the economic drivers in Table F-1 and Table F-2 are included in the Statistically Adjusted End Use (SAE) models for the residential and commercial sector.

Table F-2 also contains the five year forecast (2018 to 2022) of real provincial GDP growth from the BC Ministry of Finance as per their First Quarterly Report issued September 7, 2018. The provincial GDP forecast for the first five years is used to develop an unadjusted electricity sales forecast for the other light industrial sub-sector.

Notes

2 . History and Forecast for all data in the table above comes from the Conference Board of Canada June, 2018 Economic Forecast.

3. History comes from BC Stats while forecast of real BC GDP growth from 2018 to 2022 comes of BC Ministry of Finance, First Quarter Report, issued September 7, 2018.

Forecast of Real BC GDP for calendar 2023 comes from the Conference Board of Canada June 2018 Economic Forecast.

Table F-3 below is the 2018 EIA projections of average efficiency residential end uses for the Pacific Region which are include in the October 2018 residential SAE models. Table F-4 contains the 2018 EIA projections of average efficiency projection commercial end use of electricity for Pacific region which are contained the commercial SAE models. The lighting efficiency is unchanged from the EIA's 2017 level which is how we account for overlap in codes and standards for lighting. For additional details on overlap in codes and standards see Section 12.

Equipment Definitions and Units		
EFurn	Electric furnace and resistant room space heaters	Constant
HPHeat	Heat pump space heating	HSPF
GHPHeat	Ground-source heat pump space heating	COP
SecHt	Secondary heating	Constant
CAC	Central air conditioning	SEER
HPCool	Heat pump space cooling	SEER
GHPCool	Ground-source heat pump space cooling	EER
RAC	Room air conditioners	EER
EWHeat	Electric water heating	EF
ECook	Electric cooking	kWh/year
Ref1	Refrigerator	kWh/year
Ref2	Second refrigerator	kWh/year
Frz	Freezer	kWh/year
Dish	Dishwasher	EF
CWash	Electric clothes washer	kWh/load
EDry	Electric clothes dryer	EF
TV	TV sets	kWh/year
FurnFan	Furnace fans	kWh/year
Light	Lighting	kWh/year
Misc	Miscellaneous electric appliances	kWh/year
HSPF :	Heating Seasonal Performance Factor. The total heating output of a heat pump in BTU during its normal annual usage	
	period for heating divided by total electric input in watt-hours during the same period.	
COP :	Coefficient of Performance: Energy efficiency rating measure determined, under specific testing conditions, by dividing the energy output by the energy input.	
SEER :	Seasonal Energy Efficiency Ratio: The total cooling of a central unitary air conditioner or a unitary heat pump in	
	Btu during its normal annual usage period for cooling divided by the total electric energy input in watt-hours during the same period.	
EER :	Energy Efficiency Ratio. A ratio calculated by dividing the cooling capacity in Btu per hour by the power input in	
	watts at any given set of rating conditions, expressed in Btu per hour per watt.	
EF :	Efficiency Factor. Efficiency (measured in Btu out / Btu in) of water heaters under certain test conditions specified	
	by the US Department of Energy.

Notes:

1 Light Industrial/Commercial is the sum of the loads in the light industrial sector and commercial sector.
2 Domestic sales equals total firm sales less sales to BC Hydro own use.
3 Forecast for fiscal 2019 does not include actuals sales over the first six months of fiscal 2019
4 Growth rates are computed over a five year period on an annual compound growth basis.

Notes:

1 Forecasts in table above includes all load reductions from rate impacts, DSM savings and loss reductions.
2 Light Industrial/Commercial is the sum of the loads in the light industrial sector and commercial sector.
3 Domestic sales equals total firm sales less sales to BC Hydro own use.
4 Forecast for fiscal 2019 does not include actuals sales over the first six months of fiscal 2019
5 Growth rates are computed over a five year period on an annual compound growth basis.

Load Forecasting Audit F2018

AUDIT TYPE	AUDIT RATING
RISK BASED AUDIT	G

Legend:

Minor issues and impacts identified

Critical issues and impacts identified

Audit Objective

- Review the load forecasting process to ensure timely and reliable energy and peak demand forecasts which supports operational, financial and strategic planning at BC Hydro.
- This audit was conducted in conformance with the International Standards for the Professional Practice of Internal Auditing.

Background

- Load forecasting is essential for long-term planning, medium-term investment, and short-term operational activities. The load forecast is the starting point for many BC Hydro planning and operational activities and is an integral part of applications to the British Columbia Utilities Commission (BCUC).
  - Key internal users of the load forecast include Finance (financial modelling, planning), Generation (system optimization, winter peak planning), Transmission and Distribution (planning, investment), and Regulatory (rate designs, regulatory filings).
  - BC Hydro's total energy requirements, including losses and sales to other utilities and non-integrated areas, were 56,240 gigawatt hours in F2016.
- The Load Forecast group within the Corporate Affairs business group prepares the annual load forecast, and monitors and reports variances between forecast and actual load.
  - Key process activities include data collection and analysis, reviewing key assumptions and input parameters, reviewing outputs from various models, and performing scenario analysis.
- The load forecast covers a 20-year period and has two parts; an energy sales forecast measured in gigawatt hours, and a peak demand forecast measured in megawatts.
  - The energy sales forecast is a projection of annual total electricity demand. Key factors that influence the forecast include housing starts, appliance efficiency standards, residential electricity use-rates, gross domestic product, employment and weather.
  - The peak demand forecast is an estimate of maximum expected one-hour demand during the year based on normalized weather conditions.
- Load forecasting is a complex process and has been subject to a number of reviews by various parties including BC Hydro Audit Services (2007), BC Government (2011), and an external Consultant (2014). The BCUC has also commented on the process in past years in various regulatory applications.
- This audit was selected for inclusion in the F2018-2019 Audit Plan as load forecast risk has been identified as one of the top strategic enterprise risks. Load forecast risk is defined as a significant inaccuracy in estimating future loads.
- The Audit Services team was supplemented by a subject matter expert from GDS Associates Inc., a US based firm with extensive experience with load forecasting in the electrical utility industry.
  - The subject matter expert is a principal at GDS Associates Inc. with over 30 years of load forecasting experience including preparing load forecasts for various utility clients (ranging from day ahead to annual long-term horizons), and filing testimony on issues relating to load forecasting and other statistical analyses.

Load Forecasting Audit F2018

Key Findings

Overall Summary

- Overall, the load forecasting function at BC Hydro compares favorably to industry standards and to other large electric utilities in North America. No critical weaknesses were found.
- Load forecasting methodologies are consistent with best practices and load forecast outputs are provided to users and stakeholders on a timely basis.
- The greatest risk of load forecasting inaccuracy falls on the industrial class and is due to the uncertainty of future economic activity at the global, domestic, and service area levels, and the volatility of many individual customer loads.
- Areas identified for improvement primarily relate to making adjustments to forecast models and inputs to enhance overall forecast accuracy.

Governance

- Oversight structure of the load forecasting function is well-defined with various levels of management review and approval. The Load Forecast group is comprised of qualified staff with relevant educational background and work experience. Processes are in place for the development of a timely and reliable load forecast.
  - Based on the current scope of activities and outputs, the subject matter expert indicated that additional staff members should be considered to assist with the preparation of forecasts for the industrial class sector, data analysis, and to minimize employee succession risk.
- Appropriate objectives for the Load Forecast group have been established and include providing timely and reliable energy and peak demand forecasts, cross-training of staff, and performing continual process review.
- Management recognizes the importance of risk management and continues to mitigate load forecasting risks to the extent possible. Improved information flow between the Load Forecast team and other groups (Key Account Management, forecast users, the Executive Team) could be useful in mitigation efforts.
  - Key risks associated with load forecasting include process, methodology, key assumptions, employee succession, and regulatory.
  - Key risk mitigation activities include periodic external review of load forecasting models to reduce methodology risks; use of industry benchmark surveys, external sector experts and subscriptions for market research to reduce key assumptions risks.

Forecast Methodology

Specific Methodologies

- Statistically adjusted end-use models, which are considered industry best practice, are used to forecast energy sales for the residential and commercial customer classifications. Models are periodically reviewed by an external modelling consultant for continuous improvements.
  - Recent April 2017 industry benchmark survey of 75 electric and gas utilities in North America highlights that 57% and 54% of participants use these models to forecast sales for residential and commercial classes respectively.
- Primary forecasting methodology for the industrial class is to develop individual customer forecasts within each sector derived as the product of three inputs: facility production, electricity intensity and the percent load supplied by BC Hydro (probability weighting). Inputs for these components are

Load Forecasting Audit F2018

based on information from Key Account Managers, external consultants and industry subscription services.

- This methodology is preferred to other methods as it provides greater flexibility to quantify relevant factors for the sector and individual customer energy sales. It also provides greater detail for tracking and explaining forecast variances.

- The Load Forecast group prepares high and low forecast scenarios using a Monte Carlo simulation model at a total system level to address load forecast uncertainty. Simulation analysis is the best approach for developing the high and low forecast scenarios since it is statistically based and can include multiple input variables.
- While no critical weaknesses were identified, a number of technical recommendations related to model inputs were provided to Management to enhance forecast accuracy. Key recommendations relate to appliance stock and efficiency inputs, and elasticity assumptions.
  - Appliance stock and efficiencies are two critical inputs for the residential and commercial forecast models. Projections for these inputs are based on U.S. data and not specific to BC Hydro service regions. An internal prototype model to address this is under development.
  - Changes in energy sales due to changes in electricity price, household size and income, employment, gross domestic product, and retail sales are quantified in development of the residential and commercial forecasts (through elasticity coefficients). The coefficients should be reviewed and updated as the relationship between these variables and energy consumption has most likely changed over time.

Demand Side Management Integration

- Demand Side Management impacts on the Load Forecast are accounted for as a post-modelling adjustment developed by the Conservation and Energy Management group. According to the subject matter expert, this is the best approach and consistent with industry benchmark surveys.

Developing Industries

- The load forecasting process adequately accounts for growth and impacts associated with electric vehicles as a post-modeling adjustment. Given the relatively immature market and the uncertainty surrounding electric vehicle adoption in future years, analyzing and projecting vehicle electricity consumption as a stand-alone component is appropriate.

- The Load Forecast group's approach of including energy and peak demand only for known liquefied natural gas customers and known electrification projects in the base case forecast is appropriate. The base case load forecast includes energy and peak demand only for liquefied natural gas customers that have requested electric service from BC Hydro.

Forecast Variance

- Review of prior load forecasts reveal that forecast variances for the residential and commercial classifications are within a range of expectancy based on industry benchmarks developed by Itron Inc. and the US Energy Information Administration.
- Variances for the industrial class are higher than those for the residential and commercial classes. This is expected given the volatility of loads and the uncertainties of future economic activity in the forestry, oil and gas, and mining sectors, which comprise the significant portion of total energy sales for the industrial class.
  - Large industrial customers comprise less than 1% of total customers, but nearly 24% of total domestic sales.

Load Forecasting Audit F2018

Outputs and Reporting

- The Load Forecast group provides the needed forecast outputs and supporting documentation to users on a timely basis. Providing the long-term forecast once a year is sufficient for long-term planning.
  - Key outputs include: the annual Service Plan Forecast which is a preliminary forecast with a 10-year horizon prepared in October; the annual Long-Term Forecast prepared in December which covers a 20-year forecast horizon, and reflects any adjustments made to the forecast between October and December.
  - Variance reports are distributed to user groups monthly providing high-level reasons for forecast variances.

Management Comments and Action Plans

- Management agrees with the recommendations in the audit report and will address the majority of recommendations by August 2018. The remaining recommendations, which require some planning and research time, will be implemented by December 2018.

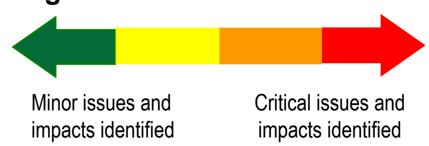
Load Forecasting Audit F2018

CONTENTS

AUDIT	TYPE	RATING
1. LOAD FORECASTING AUDIT 	RISK BASED AUDIT	G

Legend:



Load Forecasting Audit F2018

1a. Executive Summary

- For each audit, Audit Services provides two separate Audit Reports. The first report is a Summary Audit Report prepared for Senior Management and the Audit & Finance Committee (AFC) of the Board. This Management Audit Report provides additional information and related audit recommendations for management purposes and will not be presented to the AFC.
- Management should also refer to the Summary Audit Report for high level conclusions and findings.

1b. Background

- Load forecasting is essential for long-term planning, medium-term investment, and short-term operational activities. The load forecast is the starting point for many BC Hydro planning and operational activities and is an integral part of applications to the British Columbia Utilities Commission (BCUC).
  - Key internal users of the load forecast include Finance (financial modelling, planning), Generation (system optimization, winter peak planning), Transmission and Distribution (planning, investment), and Regulatory (rate designs, regulatory filings).
  - BC Hydro's total energy requirements, including losses and sales to other utilities and non-integrated areas, were 56,240 gigawatt hours in F2016.
- The Load Forecast group within the Corporate Affairs business group prepares the annual load forecast and monitors and report variances between forecast and actual load.
  - Key process activities include data collection and analysis, reviewing key assumptions and input parameters, reviewing outputs from various models, and performing scenario analysis.
- The load forecast covers a 20-year period and has two parts, an energy sales forecast, measured in gigawatt hours and a peak demand forecast, measured in megawatts.
  - The energy sales forecast is a projection of annual total electricity demand. Key factors that influence the forecast include housing starts, appliance efficiency standards, residential electricity use-rates, gross domestic product, employment and weather.
  - The peak demand forecast is a projection of maximum expected one-hour demand during the year based on normalized weather conditions.
- Load forecasting is a complex process and has been subject to a number of reviews by various parties including BC Hydro Audit Services (2007), BC Government (2011), and an external Consultant (2014). The BCUC has also commented on the process in past years in various regulatory applications.
- This audit was selected for inclusion in the F2018-2019 Audit Plan as load forecast risk has been identified as one of the top strategic enterprise risks. Load forecast risk is defined as a significant inaccuracy in estimating future loads.
- The Audit Services team was supplemented by a subject matter expert from GDS Associates Inc., a US based firm with extensive experience with load forecasting in the electrical utility industry.
  - The subject matter expert is a principal at GDS Associates Inc. with over 30 years of load forecasting experience including preparing load forecasts for various utility clients (ranging from day ahead to annual long-term horizons), and filing testimony on issues relating to load forecasting and other statistical analyses.

Load Forecasting Audit F2018

1c. Audit Objective and Scope

Objective

- Review the load forecasting process to ensure timely and reliable energy and peak demand forecasts which supports operational, financial and strategic planning at BC Hydro.

Scope

- With the assistance of a load forecasting subject matter expert, the audit focused on the following areas:
  - **Governance** - structure, oversight, resources, process, risk management
  - **Forecast Methodology** - models, inputs, assumptions, methodologies, variance analysis
  - **Outputs & Reporting** – energy load and peak forecasts, forecast updates
- Integration of Demand Side Management Plans and Load Forecasts was also reviewed.
- This audit was conducted in conformance with the International Standards for the Professional Practice of Internal Auditing.

Load Forecasting Audit F2018

1d. Findings, Recommendations and Management Action Plans

Summary

Overall, the load forecasting function at BC Hydro compares favorably to industry standards and to other large electric utilities in North America. No critical weaknesses were found.

Load forecasting methodologies are consistent with best practices and load forecast outputs are provided to users and stakeholders on a timely basis.

The greatest risk of load forecasting inaccuracy falls on the industrial class and is due to the uncertainty of future economic activity and the volatility of many individual customer loads.

Areas for improvement identified primarily relate to making adjustments to forecast models and inputs to enhance overall forecast accuracy.

Governance

Overall Conclusion

A well-defined oversight and management structure has been established with appropriate departmental objectives in place. Adequacy of current resourcing levels should be reviewed and detailed procedural documentation is required to enhance transparency and staff cross-training.

Key Conclusions and Findings

This section focuses primarily on oversight, resources, objectives, and risk management.

Oversight and Resources

- Oversight structure over the load forecasting function is well-defined with various levels of management review and approval. Manager of Load Forecast reports to the Director of Energy Planning, who reports to the Senior Vice President Corporate Affairs.
  - Director of Energy Planning holds regular bi-weekly meetings with his departments to share ideas, questions and concerns. This provides a high level of interaction and communication among all energy planners, which in turn increases overall planning efficiency.
  - The Annual Load Forecast is reviewed by the Director of Energy Planning, the Senior Vice President Corporate Affairs, and members of the Executive Team before presentation to the Board of Directors.
- The Load Forecast group is comprised of qualified staff with relevant educational background and work experience. The current team is comprised of a manager, a senior forecaster, and 3.5 full-time equivalent forecasters. Work experience for the team ranges from 4 to 25 years, with educational backgrounds in economics, finance, engineering and mathematics.
  - Based on the current scope of activities and outputs, the subject matter expert indicated that additional staff members should be considered to assist with the preparation of forecasts for the industrial class sectors, analysis of high volume of data, preparation of documents for regulatory hearings, and to minimize employee succession risk.

Load Forecasting Audit F2018

Objectives

- Appropriate objectives for the Load Forecast group have been established and are being achieved. These include providing timely and reliable energy and peak demand forecasts, cross-training of staff, and performing continual process review.
  - Continual process review involves Management and peer review of load forecast methodologies and related processes for the residential, commercial and industrial customer classifications. Several noteworthy research initiatives (discussed in the Methodology section) were in progress that will enhance overall accuracy.

Processes

- Processes are in place for the development of a timely and reliable load forecast. A schedule for completing all aspects of the Annual Load Forecast has also been developed and communicated by the Manager of Load Forecast to all core forecast users.
  - Load forecasting processes include: data collection, database updates, data review and analysis, development of key assumptions impacting future electricity consumption, forecast model development or updates, forecast development, and managerial and executive review.
- Process flow charts have been created to present a high-level description of steps taken to complete various load forecasting tasks; however, more detailed descriptions for each step would provide more complete information for forecast users and new staff.

Risk Management

- Key risks associated with load forecasting include process, methodology, key assumptions, employee succession, and regulatory.
  - Process risk occurs when a key process is neglected that could negatively impact the reliability of the forecast. Methodology risk occurs when improper or outdated methods are used to develop the forecast. Key assumptions risk occurs when information used to develop industrial or economic activity assumptions over a forecast horizon is not reliable or outdated. Such problems increase the likelihood of forecast inaccuracies.
  - Employee succession risk occurs when a key load forecaster leaves the Company without any succession plans or staff training documentation in place. Regulatory risk occurs when BC Hydro does not meet minimum filing requirements or when filed applications are denied.
- Management recognizes the importance of risk management and continues to mitigate load forecasting risks to the extent possible. Improved information flow between Load Forecast and other groups (Key Account Management, forecast users, the Executive Team) could be useful in mitigation efforts.
  - Key risk mitigation activities include periodic external review of load forecasting models to reduce methodology risks; use of industry benchmark surveys, external sector experts and subscriptions for market research to reduce key assumptions risks.
  - An internal dashboard that presents key metrics and risk indicators would provide stakeholders and core users with current information. Increased awareness and communication between Load Forecast Management, staff, and Key Account Managers could improve overall forecast accuracy.

Load Forecasting Audit F2018

	Recommendations	Management Action Plans
	Governance	
1	❑ Review adequacy of existing resources and consider increases to current staffing level.	❑ Director of Energy Planning will provide resourcing recommendations on staffing, as well as consulting and subscription services to Senior VP Corporate Affairs by December 31, 2017. ◆ Ability to address the majority of the recommendations is contingent upon staffing levels.
2	❑ Prepare load forecasting detailed procedural documentation to supplement the high-level process documentation.	❑ Documentation will be completed by March 30, 2018 as part of the F2019 load forecast cycle.
3	❑ Consider developing a dashboard to highlight key information and current assumptions/outlook that impact the load forecast.	❑ Work has already starting in this area and Load Forecast will work with other groups such as Key Account Management and Finance groups to finalize format and content by December 31, 2017.

Forecast Methodology

Overall Conclusion

Methodologies consistent with industry best practices are used to develop the energy sales forecast. Historical forecast variances for the residential and commercial classifications are lower than industry benchmarks, while variances for the industrial class have been more volatile.

Key improvement areas to further improve forecast accuracy include completion of the stock and flow model development and the update of elasticity coefficients.

Key Conclusions and Findings

General Forecast Approach

- The energy sales forecast is developed using a bottom-up approach and in line with best practices. Forecasts are developed separately for the residential, commercial, and industrial classes. Most electric utilities in North America follow a bottom-up approach as it provides for greater explanatory power in developing and explaining the forecast and its driving influences.
  - The industrial class is further broken down by sector (Forestry, Oil and Gas, Mining, and Other), which provides the means for capturing sector specific factors. Similar to other electric utilities, BC Hydro also forecasts their largest industrial customers on an individual basis.

Load Forecasting Audit F2018

Specific Methodologies

Residential

- Residential energy sales are projected for each of BC Hydro's four customer service areas (Lower Mainland, Vancouver Island, South Interior and Northern Region). The forecast is computed as the product of the projected number of residential customers and average kilowatt hour use per customer.

- Forecast number of customers is based on projected housing starts and dwellings by housing types which are provided by an external economic consultant.

- Statistically adjusted end-use (SAE) models, which are considered industry best practice, are used to forecast average residential use per customer account for each of the four customer service regions.
  - A recent benchmark survey from Itron Inc. (Itron) highlights that 57% of electric and natural gas utilities in North America use SAE models to analyze and forecast long-term residential sales, 33% use econometric models, and 10% use other methods.
    - Itron provides consulting services in multiple areas, including load forecasting, to utilities across the world. They periodically survey utilities across North America to develop load forecasting benchmarks.
- SAE models provide the means for quantifying the impacts of multiple driver variables, including economic drivers, housing and building characteristics, appliance saturations and efficiencies, and weather. This method provides load forecasters detailed information to better explain historical electricity sales trends and variances from projected sales.
  - The SAE models produce monthly projections which provide the outputs needed for the development of monthly and annual forecasts for up to 21 years.

Commercial

- For the four planning regions, SAE models are developed to project sales by two commercial groups (less than or equal to 35 kw, and greater than 35 kw). Similar to the residential model, the commercial SAE models produce monthly projections, which provide the outputs needed for the development of monthly and annual forecasts for up to 21 years.
- The subject matter expert and industry surveys support the use of the SAE methodology as the best approach for modeling commercial sales. A recent Itron industry benchmark shows that 54% of reporting utilities use SAE models to forecast long-term commercial sales, 38% use econometric models, and 8% use other methods.

Light Industrial (Distribution)

- Light Industrial sales are the sum of sales for coal, wood, oil and gas and other industrial loads connected at the distribution level. Loads for the coal, wood, and oil and gas sectors are developed using the same methodology as the Large Industrial class (discussed in the next section).
- An econometric model is used to forecast the other customer categories within the light industrial energy sales. The primary economic driver variable is regional gross domestic product (GDP).
- The methods used to forecast energy sales for the Light Industrial class are appropriate. Enhancements can be made to the econometric model used to forecast the other customer category as it does not quantify the impacts of heating, ventilation, and air conditioning equipment (HVAC) or motor efficiencies.

Load Forecasting Audit F2018

- The relationship between energy sales and GDP has most likely changed in recent years to reflect lower energy intensity (energy sales per GDP) due to continued increases in average end-use efficiencies and energy management systems.

Large Industrial (Transmission)

- BC Hydro currently has a large number of customers that make up the subsectors of Mining (coal and metal), Forestry (pulp and paper, wood, and chemical), and Oil and Gas (gas producers and processors, gas pipelines, oil pipelines, oil refineries, and liquefied natural gas).

- The general forecasting methodology is to develop individual customer forecasts within each sector derived as the product of three inputs: facility production, electricity intensity, and the percent load (probability weighting) supplied by BC Hydro. Inputs for the three forecast components are based on information obtained from BC Hydro's Key Account Managers, external consultants and subscription services.

- The methodology to forecast large industrial sales for transmission customers is preferred to other methods. It provides greater flexibility to quantify relevant factors for the sector and individual customer energy sales and peak demand. It also provides greater detail for tracking and explaining forecast variances.
  - A bottom-up methodology is used to forecast energy sales for the forestry and mining sectors. Forecasts are developed individually for each customer and aggregated to the sector levels.
  - A top/down, bottom/up methodology is used to forecast energy sales for the oil & gas sector. Top/down forecasts are prepared at the sector level and based on key input from external service providers and sector-specific consultants that provide commodity price forecasts and sector-specific outlooks.
    - The top/down and bottom/up analyses are iterated until results from the two approaches converge.
- The forecast approach is dependent upon detailed and reliable information from external sources and internal key account managers. BC Hydro has established procedures and schedules for obtaining that information.

- The sector-specific industrial models for forestry, oil and gas, and mining are prepared in Excel spreadsheets. Clarity and interpretation of spreadsheet formulas can be difficult for persons other than the model developer. More detailed process documentation would provide for greater transparency and clarification.
  - Further efforts should be taken to identify areas where the process could be streamlined as Load Forecast staff indicated that maintaining the individual customer models is time consuming.

Model Reviews

- SAE models are periodically reviewed by BC Hydro's modelling consultant (Itron) for continuous improvements. External model reviews help to improve the overall reliability of BC Hydro's forecasting models and results. This process also allows Load Forecast staff to leverage the modeling expertise of Itron, as well as discuss industry trends and how best to capture them in the modeling process.

Load Forecasting Audit F2018

Forecast Scenarios

- To address load forecast uncertainty, Load Forecast group prepares high and low forecast scenarios at the system level using a Monte Carlo simulation model, which produces a probability distribution of forecast outcomes used to develop the forecast ranges. The process is well documented in the 2012 Electric Load Forecast.

- Simulation analysis is the best approach for developing the high and low forecast scenarios since it is statistically based, can include multiple input variables, and produces a probabilistic forecast based on input probability distributions. However, GDP is not the best model input to represent the residential and commercial classes.
  - Load Forecast group includes GDP as a driver variable of residential and commercial energy sales; however, the relationship between GDP and energy sales has changed considerably in recent years according to Itron's 2016 Forecasting Benchmark Study. The predominant influence on sales for these two classes may now be the number of customers.

Forecast Variance

- Review of prior load forecasts reveal that forecast variances for the residential and commercial classifications are within a range of expectancy based on industry benchmarks developed by Itron and the US Energy Information Administration (EIA). The following table compares BC Hydro forecast variances to industry benchmarks.
  - EIA collects, analyzes, and disseminates independent and impartial energy information, including electric load forecasts at the international, national, and regional levels.

Comparison of BC Hydro Forecast Variances to Industry Benchmarks[1]

Forecast Period	Class	BC Hydro	EIA	Itron
1 yr. out	Residential	1.0%	1.9%	1.7%
3 yr. out	Residential	1.3%	3.9%	na
6 yr. out	Residential	4.6%	8.2%	na
1 yr. out	Commercial	0.9%	1.2%	1.7%
3 yr. out	Commercial	1.8%	2.3%	na
6 yr. out	Commercial	2.3%	8.2%	na
1 yr. out	Industrial	1.3%	1.9%	3.5%
3 yr. out	Industrial	9.5%	6.2%	na
6 yr. out	Industrial	19.6%	11.4%	na

- Variances are low for the residential and commercial classifications and fall below industry benchmarks. As a result, no changes to the methodology used to forecast energy sales for these two classes are required based on subject matter expert's assessment.

[1] Reported variances represent the average of mean absolute percent errors (MAPE). MAPE measures the size of the forecast error in percentage terms and is calculated as the average of the unsigned percentage error.

Load Forecasting Audit F2018

- Residential class: For the eight forecasts developed in F2008 through F2015, the average variance between actual and weather adjusted energy sales is 1.0% for the first forecast year, 1.3% for three years out and 4.6% for six years out.

- Commercial class: The average variance between actual and weather adjusted energy sales is 0.9% for the first forecast year, 1.8% for three years out, and 2.3% for six years out.

- Variances for the industrial class are higher than those for the residential and commercial classes. This is expected given the volatility of loads and the uncertainties of future economic activity in the forestry, oil and gas, and mining sectors, which comprise the significant portion of total energy sales for the industrial class. Large industrial customers comprise less than 1% of total customers, but nearly 24% of total domestic sales.

  - The greatest risk identified during the audit is potential forecast inaccuracies pertaining to the industrial class and corresponding to the uncertainty of future load economic activity at the global, domestic, and service area levels. Many industrial customer loads are quite volatile given the relative uncertainty of economic activity (e.g., one or two years out), and therefore cannot be modeled or forecasted with a high degree of accuracy.

  - While the forecast variance for the Industrial class is higher than industry benchmarks beyond the first-year period, BC Hydro should continue with the same forecast methodologies.

Economic / Industry Outlooks and Market Research

Economic Outlook

- Economic outlooks obtained from external economic consultant exceed industry standards in providing reliable inputs for the residential, commercial, and light industrial forecasting models. While no benchmarks are available for comparative purposes, the outputs provided by the consultant exceed what the subject matter expert is accustomed to seeing for electric utilities in North America.
  - The economic outlook is obtained annually and contains forecasts and discussions broken down by the four customer service areas.
    - Area forecasts are constructed using regional macroeconomic models, assumptions concerning the economic performance of BC's major trading partners, commodity prices, interest rates, exchange rates, fiscal policy, information on future major projects, and input from BC Hydro staff.
  - To further improve forecast accuracy, Management could request a review and reconciliation of prior economic projections and actual data. This could be useful to Load Forecast staff in analyzing and explaining load forecast variances.

Industrial Sector Outlook

- Load Forecast group collects high quality, sector-specific industrial data for development of their industrial energy forecast. These include subscriptions to multiple sources of commodity price forecasts and consulting services of sector-specific experts.

Load Forecasting Audit F2018

- Data from each source is not always updated annually due to budget constraints. The commodity price and sector-specific outlooks are critical inputs for the development of the large industrial energy sales forecasts.

- To further improve forecast accuracy, consultants could provide explanations and/or reasons for the variances between industry outlooks once actual or estimated data becomes available.

Market Research

- Load Forecast group follows industry best practices in obtaining service area specific data that is otherwise not available. Similar to other large electric utilities in North America, BC Hydro conducts residential surveys every two years, while commercial surveys are conducted on a less frequent basis.

  - Surveys are performed to collect data on building characteristics and appliance stock, which is used to develop inputs for the residential and commercial forecasting models. Residential surveys may be conducted every three years instead if the key housing and appliance market share trends are not changing significantly over time to achieve potential cost savings.

Specific Input Assumptions

Appliance stock and efficiencies

- Appliance stock and efficiencies are two critical inputs for the residential and commercial forecast models. However, projections for these inputs are based on the U.S. Pacific Region (developed by Itron) and not specific to BC Hydro service regions. An internal prototype model ("stock and flow") is under development to address this issue.

  - The prototype model would establish a single (historic) baseline and forecast assumptions on natural growth, natural conservation, impact of codes and standards on minimum efficiency requirements, average stock efficiency and saturations of various residential end uses.

  - The prototype model is at its early stage and work needs to be accelerated. The availability of data corresponding to BC Hydro's service area may increase overall forecasting accuracy.

Elasticity Coefficients

- Elasticity coefficients for energy consumption with respect to electricity price, household income, household size, employment, commercial GDP, and retail sales are all quantified in development of the residential and commercial class energy sales forecasts. However, the coefficients should be reviewed as the relationship between these variables and energy consumption has mostly likely changed over time.

  - Current price elasticity coefficients are based on a 2007 external study. Other elasticities are based on default values provided by Itron in the residential and commercial SAE models. An internal price elasticity study is currently in progress to update the coefficients however progress needs to be accelerated.

  - In response to directives made by the BCUC, BC Hydro applies the price elasticity coefficient as a post-modeling adjustment to report the energy sales.

Load Forecasting Audit F2018

Peak Demand

- Peak demand, known as the highest hourly load measured over a defined period, is a comprehensive, iterative process between the Load Forecast group and Distribution Area Planning group.

- The current process of forecasting peak demand is comprehensive and incorporates best practice methodologies. The process involves Area Planners' expertise on expected near-term changes in load for 220 substations, and Load Forecasters modeling expertise and oversight in maintaining consistency between the energy and peak demand forecasts.

Weather Normalization

- Load Forecast group uses regression analysis to weather normalize energy sales. The technique is common among electric utilities and has been accepted as the best practice by many regulatory entities across North America.

- Weather normalization refers to the practice of estimating actual energy sales under normal, or average, weather conditions. Load Forecast group computes normal degree days on a rolling 10-year average. There is no clear consensus among utilities in North America regarding the number of years upon which to calculate normal degree days.

  - Itron benchmark information shows that 22% of participants base normal degree days on a 10-year or less average, 32% base on a 30-year average, 26% base on a 20-year average, and the remaining 20% base on other periods.

- The weather normalization process for residential sales is based on a statistically sound regression model; however, a more transparent and simpler model would separate the impacts of heating and cooling degree days. If air conditioning load continues to increase, establishing two separate parameters will provide more detailed information on their respective impacts.

  - Most utilities in North America separate heating and cooling impacts when weather normalizing energy sales.

  - An additional area for improvement is to ensure actual sales for the commercial sector are weather normalized when performing monthly variance analysis, similar to the residential sector.

Demand Side Management (DSM) Integration

Integration Approach

- The method used by Load Forecast group to account for DSM impacts is the best approach, as it uses post-modeling adjustments developed by Conservation and Energy Management (C&EM) group. Use of an alternative method would more than likely produce results that are inconsistent with, and not as fully developed as those provided internally.

  - The load forecast includes the impacts of existing and future DSM programs. The impacts associated with participants in existing programs are reflected in the historical electricity sales data in the residential and commercial forecasting models.

Load Forecasting Audit F2018

- The impacts associated with future participants in existing programs and all participants in future programs are reflected in the forecast as a post-modeling adjustment.

- The 2013 Itron survey shows that 38% of 72 reporting utilities account for DSM impacts through post-modeling adjustments. 22% through estimating the forecasting model with historical DSM net of past and future DSM savings, 11% through the SAE model specification, and 29% through other methods.

Overlap of Codes and Standards

- Impacts associated with the overlap of codes and standards between the Load Forecast and DSM plan are reasonably accounted for in the Load Forecast.

  - An analysis performed by the Load Forecast and C&EM groups identified areas of codes and standards overlap. Beginning with the 2010 Electric Load Forecast, energy sales and peak demand projections reflect adjustments to address the overlap and potential double counting of DSM impacts.

Developing Industries

Electric Vehicles (EVs)

- Load forecasting process adequately accounts for growth and impacts associated with EVs as a post-modeling adjustment since the 2010 Electric Load Forecast. Given the relatively immature market and the uncertainty surrounding EV adoption in future years, analyzing and projecting EV electricity consumption as a stand-alone component is appropriate.

  - Electricity consumption for EVs currently comprises less than 1% of total retail sales and is projected to comprise just over 2% by F2036. Itron's 2016 Forecasting Benchmark Survey highlights that 55% of all reporting utilities include EVs in their load forecasts.

Liquefied Natural Gas (LNG)

- Load Forecast group's approach of including energy and peak demand only for known LNG customers in the base case forecast is appropriate. The LNG sector has not yet been developed, and the uncertainty surrounding future growth in sales is high due to global competition.

  - BC Hydro's 2016 base case forecast includes electric sales to LNG customers beginning in F2017. The base case load forecast includes energy and peak demand only for LNG customers that have requested electric service from BC Hydro.

Electrification

- BC Hydro's current process of including energy demand from known electrification projects in the base case forecast is appropriate. The 2016 Load Forecast does not include potential increases in energy and peak demand associated with BC Hydro electrification efforts.

  - Future demand associated with electrification will largely depend on greenhouse gas related legislation, City of Vancouver electrification initiatives, and future industrial related activity.

Load Forecasting Audit F2018

	Recommendations	Management Action Plans
	Methodology	
4	**Light Industrial** ❑ Review and update the light industrial econometric model to quantify the impacts of HVAC and motor efficiencies. ❑ Consider a model parameter reflecting the implementation of energy management systems.	❑ Load Forecast group will review possible methodology change in collaboration with Conservation and Energy Management group. Any changes will be implemented by August 31, 2018 in time for inclusion in the F2019 load forecast cycle.
5	**Large Industrial** ❑ Review existing processes and consider streamlining opportunities such as automation of spreadsheets and develop process documentation.	❑ Documentation to be completed by February 28, 2018 prior to the start of the F2019 load forecast cycle. ❑ Load Forecast group will have discussions with the Information Technology group to identify processes that can be automated. Identification will be completed by April 30, 2018 with implementation by August 31, 2018.
6	**Forecast Scenarios** ❑ Review and replace the GDP parameter in the Monte Carlo model used to simulate energy sales with number of customers.	❑ Management needs to verify underlying assumption. ◆ This could entail significant work for both system and regional (distribution planning) high low bands. ❑ If required, a methodology change will be recommended by October 31, 2018 to run parallel with existing Monte Carlo model as part of the F2019 load forecast cycle.
7	**Economic / Industrial Outlooks** ❑ Request industrial and economic consultants to provide explanations and/or reasons for the variances between outlooks provided and actual output once actual or estimated data becomes available.	❑ Variance explanations will be included in future consultant reports, beginning with those developed to support the F2019 load forecast cycle.
8	**Market Research** ❑ Consider conducting residential customer surveys once every three years if the key trends being measured are not changing significantly over time.	❑ Load Forecast group will discuss the recommendation with Conservation and Energy Management and advise Senior VP Corporate Affairs by December 30, 2018. ◆ With evolving electrification loads and advancing energy efficiency participation, biannual may still be required.

Load Forecasting Audit F2018

	Recommendations	Management Action Plans
		◆ There may be other survey users which require maintaining the current survey frequency. Discussions to include commercial end-use survey as well as residential end-use survey.
9	**Specific Input Assumptions** ❑ Accelerate internal studies / development on: ◆ The stock and flow model. ◆ Elasticity coefficients updates used in the development of the load forecast.	❑ Stock and Flow: Tentative schedule to have fully functional model to run in parallel with the SAE model by November 30, 2018 as part of F2019 load forecast cycle. ◆ Load Forecast group will confirm timeline, scope and resource requirements with project manager. This will likely require additional resources to support input verification and possible software development. ❑ Price Elasticity Coefficients: Load Forecast group in collaboration with other groups will develop a study scope on price elasticity by August 30 2018. Study to be completed in Fiscal 2019 subject to funding approval. ❑ SAE Model Elasticity Coefficients: SAE model coefficients to be reviewed with model vendor (Itron) by March 30, 2018. Itron recommendations and testing by the Load Forecast group to be completed by August 30, 2018 in time for inclusion in the F2019 load forecast cycle.
10	**Weather Normalization** ❑ Consider updating the specification for the model used to weather normalizes residential sales to separate the impacts of heating and cooling. ❑ Update the monthly forecast variance process to include weather normalized energy sales for the commercial classification.	❑ Weather normalization: Load Forecast group will review possible methodology change in collaboration with model vendor (Itron). Any change will be implemented by August 30, 2018 in time to be included in F2019 load forecast cycle. ❑ Monthly Variance: Load Forecast group will collaborate with Customer and Energy Analytics group to confirm data availability. Tentative schedule, subject to data availability, is to include weather normalized sales for the commercial sector by March 30, 2018.

Load Forecasting Audit F2018

Outputs & Reporting

Overall Conclusion

Load Forecast group provides the needed forecast outputs and supporting documentation to users on a timely basis. Providing the long-term forecast once a year is sufficient for long-term planning.

Key Conclusions and Findings

- Key outputs include the following: The annual Service Plan Forecast which is a preliminary forecast with a 10-year horizon prepared in October; the annual Long-Term Forecast prepared in December which covers a 30-year forecast horizon, and reflects any adjustments made to the forecast between October and December. Variance reports are distributed to user groups monthly providing high-level reasons for forecast variances.

- Based on interviews with various user groups and review of relevant documentation, the subject matter expert believes that providing the long-term forecast once a year is sufficient for long-term planning. The needed outputs are provided to users in sufficient detail and are generally delivered on time. Memos were provided with the forecast to summarize highlights, changes from prior forecasts, and other information as requested.

- Management indicated that an on-line repository is being created for central retention of annual load forecasts and official planning studies. The Energy Planning Information Central site, when completed, will enable forecast users to easily identify the specific load forecast used to better support various studies and filings made with the BCUC.

DNV·GL

Memo to:
BC Hydro

From: DNV GL
Date: 9/6/18

Subject: Memo - Price Elasticity Findings and Recommendations

1 PROJECT OVERVIEW

BC Hydro hired DNV GL to provide an external review of how BC Hydro applies price elasticity estimates in various business applications, including load forecasting and rate design. This memo provides DNV GL's findings and recommendations on this topic.

In this section, we provide a background discussion on price elasticity, details on project goals, and a description of DNV GL's approach. We discuss our research, findings, and recommendations in section 2. We outline a few next steps in section 3 and provide the sources used in the research in the final section.

1.1 Background

Price Elasticity

Price elasticity of demand measures the responsiveness of quantity demand to a change in price, and is expressed as the percent change in quantity to a one percent change in price. When looking at the demand for electricity, price elasticity can be broken down into two components: a short-run elasticity reflecting changes in utilization of a given stock of equipment, and a long-run elasticity reflecting both changes in utilization and changes in the composition and efficiency of the energy using equipment.

While the concept of price elasticity is simple, the estimation (and interpretation) of price elasticities in any industry can be complicated. Estimates can depend on the type of study (such as time-series[1] or cross-sectional[2]), the type of elasticity being measured (such as long-run versus short-run), and the customer group being studied (residential/commercial, in mild/severe climate and high/mid/low incomes, etc.). In areas where there are significant policies or programs directed at influencing consumption (such as codes and standards and energy efficiency rebate programs), the ability to separate out the effects of these policies/programs from pure price effects can be challenging.

Utilities apply various price elasticity of demand estimates in two separate load forecasting processes: long-run integrated resource planning (IRP) and short-run revenue requirements that are used to set rates utilities charge customers. Examples of challenges in estimating price elasticity include those that may arise due to variations in time-of-use of end-use equipment and differences in their distribution among customer groups. Time-of-use variations can occur because different end-uses operate at different times and elasticities can vary by end-use (e.g. space heating where the thermostat can change versus refrigeration where usage is mainly determined at the point of purchase). Different customer groups will have different distributions of end-uses and will also have different consumption patterns that can both affect overall price elasticities.

---

[1] Time-series is a sequence of observations collected for a variable (such as energy consumption) at fixed intervals of time. For instance, monthly energy use over a period of several years is an example of time-series data.

[2] Cross-sectional data are observations collected for a variable across many subjects (such as individuals and firms) at a point in time. For istnance, energy use data collected for many different households at a given point in time is an example of cross-sectional data.

To complicate matters, price elasticities will inevitably change over time as consumption habits change and response options evolve. For example, increased automation may facilitate a larger response to short-run price signals, and the presence of more space heating efficiency options may facilitate a large long-run price response.

Given the above discussion, we see the price elasticity tool as more of a butcher knife than a scalpel. One should not expect high-accuracy price elasticity estimates to provide high-accuracy analytic results. Rather, one should look for reasonable price elasticity estimates that provide reasonable results.

1.2 Goals and Approach

The primary objective of this project was to determine if the price elasticity currently in use by BC Hydro in its business applications (including load forecasting and rate impact evaluation) is appropriate. To meet this objective, DNV GL undertook a literature review that focused on price elasticity in the utility context. DNV GL collaborated with BC Hydro to select 18 utilities in Canada and the United States to include in the literature review.[3] For the selected utilities, DNV GL concentrated its research on recent load forecast reports and documents such as Integrated Resource Plans (IRPs) and rate cases which often require the use of price elasticity to estimate the load impact of the rate change. In addition to the utility review, DNV GL researched academic documents focused on price elasticity, some of which were used as sources in various utility load forecast reports or rate cases. The goals of the literature review were to:

- Review and document elasticity estimates from jurisdictions and utilities like BC Hydro as well as recent academic studies on price elasticity
- Review BC Hydro's application of price elasticities in various business processes
- Identify the price elasticity estimates that best apply to BC Hydro
- If/where gaps are present, the review will also provide recommendations on how to bridge the gaps, including the development of targeted studies and/or the use of judgement based approaches

In addition to the primary elasticity review, BC Hydro was also interested in answers to several questions related to different aspects of price elasticities and their application, including:

DSM

- How does the presence of DSM affect price elasticity estimates over time (such as 20-year planning)?
- How does one identify pre-DSM plan and rate design elasticities when most utilities have both already included in their history?

Rate Structures and Customer Sectors/Segments

- Should elasticities be different depending on the rate structure to which they are assumed to apply (flat rate, time of use rate, tiered)?

[3] Same list of utilities as jurisdictional review included in 2015 BC Hydro rate design application.

- Does it make sense to apply elasticities to industrial sectors with few, large participants and where an assessment of future customer viability is already made based upon expert advice?
- What kind of behavioral and non-behavioral changes should be included in short-run and long-run elasticities of substitution (TOU rate)?
- What is the range of uncertainties on short-run and long-run elasticity of substitution (TOU rate) estimates?
- Under a TOU rate, how should consumption change during peak and off-peak hours be attributed to substitution (change consumption from peak to off-peak period) and change in demand (reduction in use during peak)?
- At what price, consumption, or other driver, do customers become inelastic?
- What is a reasonable substitution price elasticity, for customers and end uses for which natural gas is substitute for electricity?

Timing (long-run vs. short-run)

- How much difference is there between short-run and long-run elasticities and, given the rapidly changing world, how long should long-run elasticities be?
- What kind of behavioral and non-behavioral changes should be included in short-run and long-run elasticities of demand?
- What is the range of uncertainties on short-run and long-run elasticity of demand estimates?
- What are the differences in short-run and long-run elasticities of demand for residential customers by consumption level, region, heating fuel and dwelling type?

The overall objective of this project is to provide BC Hydro with recommendations on the appropriate price elasticities to use for various business purposes.

2 ELASTICITY

This section presents the elasticity findings and conclusions drawn from DNV GL's literature and jurisdictional review. In section 2.1 we briefly describe BC Hydro's current elasticity estimates and applications before presenting our findings from the literature and jurisdictional review in section 2.2. DNV GL presents its price elasticity analysis, conclusions and recommendations for BC Hydro in section 2.3.

2.1 BC Hydro - elasticity estimates and applications

For background information, DNV GL reviewed several documents provided by BC Hydro at the beginning of the project as well as additional documents that became available during the project, including:

- Direct testimony of Ren Orans in support of the 2008 Long-run Acquisition Plan
- Electric Load Forecast Fiscal 2013 to 2033
- Evaluation of the Large and Medium General Service Conservation Rates: F2014
- The jurisdictional review included in the 2015 Rate Design Application
- The load forecast section of the Fiscal 2017 to Fiscal 2019 Revenue Requirements Application

- The statistically adjusted end-use (SAE) model description referenced in the load forecast section
- Evaluation of the Residential Inclining Block Rate, Fiscal 2013 to 2017

Elasticity Estimates

As part of its 2008 Long-run Acquisition Plan, BC Hydro retained Dr. Orans to provide expert testimony regarding appropriate price elasticity estimates and their use in assessing rate-induced conservation. Dr. Orans recommended that BC Hydro adopt a single price elasticity to simplify its process, arguing that the distinction between short- and long-run elasticities is unnecessary because the effect of the latter are accounted for in DSM program/codes and standards savings. Long-term price elasticity reflects the effect of capital stock adjustment induced variations in consumption caused by both rate changes and DSM programs/codes and standards. He argued that in low electric rate jurisdictions, such as British Columbia, it is reasonable to assume that such long-term capital stock adjustment induced energy conservation are mostly due to DSM and related policy changes.

Dr. Orans expressed concern about the potential for double counting energy savings by applying a long-term price elasticity estimate on top of the effects of energy efficiency programs and codes and standards. Dr. Orans recommended that BC Hydro adopt a price elasticity of -0.1 to estimate the aggregate impact of a rate increase and rate design change (flat rate to inclining block rate). Lastly, Dr. Orans indicated that it was reasonable for BC Hydro to use a price elasticity of -0.05 to estimate the rate level change induced conservation to split total conservation effects under an inclining block rate structure into rate level and rate design change components. BC Hydro adopted these recommendations and has been using a price elasticity of -0.05 to estimate the impact of rate changes on load forecasts ever since.

In April 2018, BC Hydro published an evaluation of its residential inclining block rate (RIB) for fiscal years 2013-2017 which was a follow-up to the 2013 RIB evaluation.[4] The RIB has two tiers (with a bi-monthly consumption threshold of 1,350 kWh) and was designed to encourage additional conservation. Price elasticity estimates featured prominently in this evaluation including their appropriate values, differences by customer characteristics, and their use to estimate the conservation impacts of the RIB rate. The 2018 evaluation found tier-one price elasticity to be -0.14 and tier two-elasticity to be -0.08. The lower elasticity estimate for tier-two was somewhat surprising as it goes against prevailing assumptions and findings elsewhere of increasing price elasticity for inclining block rate designs. In the 2013 RIB evaluation, BC Hydro was not able to estimate a statistically significant price elasticity for tier 1 customers, but found tier-two price elasticities to range from -0.08 to -0.13.[5]

In addition to evaluating the price elasticities of the RIB, BC Hydro attempted to evaluate the energy savings associated with the inclining block rate design separate from the impact of rate increases. The evaluation assumed that the range of elasticities found between tier-one and tier-two (-0.08 to -0.14) represented the "natural conservation" or the conservation that would have happened under a flat-rate structure. Additional conservation above the natural conservation represented energy savings associated with the rate design. The RIB evaluation concluded that the 2016-17 RIB energy savings were small or zero.

Load Forecasting

BC Hydro uses a combination of historical trends, regional economic inputs, end-use average stock efficiency estimates, and site-specific estimates for the largest customers to produce sector-level load forecasts. Residential use per customer forecasts are based on an SAE model which incorporates regional economic variables, temperature, and the average stock efficiency of various end-uses while residential account number forecasts are based on housing starts. These values are combined to forecast residential load. The commercial and industrial sector forecasts are further segmented (e.g. large industrial customers (transmission), commercial, distribution, industrial distribution, streetlighting, irrigation, etc.) and include sub sector-level industrial forecasts, and in some cases customer-specific forecasts (and risk assessments) for the largest accounts. The commercial distribution forecasts also rely on SAE models that are driven by regional GDP, employment, retail sales, weather, and average stock efficiency of modeled end-uses. After the sector-level load forecasts are produced, BC Hydro incorporates the effect of rate impact. Currently, BC Hydro applies a price elasticity estimate of -0.05 to all sectors for this purpose. Lastly, BC Hydro includes incremental DSM savings to develop the total forecast.

2.2 Jurisdictional & literature review - elasticity estimates and applications

This section summarizes our findings from DNV GL's jurisdictional and elasticity literature review. DNV GL focused its review on selected utilities' long-run load forecast reports and rate filings, as well academic studies and other elasticity focused literature.

2.2.1 Summary of elasticity estimates

Table 1 provides a summary of price elasticity estimates used in load forecasting and rate impact assessments that DNV GL reviewed. In the first column, we indicate the source of the estimates (including of the data), which is either a utility that filed a jurisdictional case or a non-utility study. The details of the elasticity estimates, including their values, what sectors they apply to, and whether they are short- or long-run, are included in the" elasticity details" column. The third column presents the source of the elasticity estimates (internal or external study), the method, and time-period used to derive them (if available). The fourth column indicates the application in which the elasticities were used (e.g. in a load forecast or rate impact assessment used in regulatory filings or a non-utility elasticity estimate study). The final column provides the name and date of the source document.

Table 1: Summary of elasticity estimates[6]

Utility/Entity/Study	Elasticity Details	Elasticity Source & Methodology	Elasticity Application	Document/Date
Fortis BC (Fortis BC data)	Short-run residential = -0.09 Long-run residential = -0.16 to -0.20	Internal - Regression models of average use as a function of marginal price and	Rate impact estimate (RIB rates)	Residential Conservation Rate Information Report for the Period July 1, 2012

[6] We also searched for elasticity details from Hydro Quebec, Idaho Power, and Puget Sound Energy(PSE) but did find not useful information from their regulatory filings. We were, however, able to find a summary of the load forecasting methodology and price elasticity estimates used by PSE in its 2005 IRP filing in the Carvallo et al. (2016) study.

The research results indicate that there is a wide range of price elasticity estimates used in various applications. Some utilities use sector specific elasticity while others apply a singular estimate to all sectors (like BC Hydro). Similarly, there is no consistency between the use of short and long-run elasticity estimates by the utilities reviewed by DNV GL. We provide a more detailed discussion of short- and long-run price elasticity estimate definitions and uses in section 2.2.5 and the conclusions and recommendations in section 2.3. Here we note that our survey indicated short-run elasticities range from -0.06 to -0.26 for the residential sector[8], from -0.03 to -0.70 for the commercial, and -0.03 to -1.20 for the industrial sector. The long-run counterpart values range from -0.10 to -1.40 for the residential sector, from -0.50 to -1.30 for the commercial, and -0.50 to -1.40 for the industrial sector.

In our survey, the most commonly reported price elasticity for the residential sector is -0.10. While values as low as -0.06 and as high as -0.26 are in use among the utilities we reviewed, the most commonly reported value is a useful indicator of typical consumer response to rate changes. The -0.10 value is also most commonly reported for the two other sectors. Further, this value (-0.10) was recently recommended in an expert testimony to the Manitoba Public Utilities Commission presented in the table above. The expert in that testimony, Dr. Yatchew, cited numerous studies including a recent meta-analysis of price elasticity estimates which collected over 900 short and long-term elasticity estimates from over 400 papers published between 1990 and 2016. The meta-analysis found an average short-term elasticity of demand for electricity of -0.13 and an average long-term elasticity of -0.37.[9] Informed by findings from this and other studies, including a 2017 U.S. state level study[10], Dr. Yatchew recommended that Manitoba Hydro adopt a short-run price elasticity of -0.1 across all sectors.[11]

2.2.2 Price elasticity applications

In addition to looking at the specific elasticity estimates used by utilities included in the jurisdictional review and cited by academic studies, DNV GL also researched how the elasticity estimates were applied. We focused

---

[8] The range excludes an outlier value of 0.6 reported in the 2008 EPRI synthesis for the residential sector,

[9] Labandeira, 2017.

[10] Burke and Abayasekara (2017).

[11] He also recommended a long-run price elasticity of -0.4 when considering the proposed rate increase of 65% over time. This long-run price elasticity estimate is applicable when considering the long-term impact of rate increase inclusive of DSM that results in capital stock adjustments.

our jurisdictional research on utility load forecasting for long term resource planning and short term rate impact cases.

Load Forecasting

In IRPs and other long-term load forecasting exercises, price elasticity estimates are used to account for rate changes over the forecast period. Load forecast approaches vary by utility/jurisdiction and the models and inputs each utility uses are unique to their jurisdiction, but overall, the approach to load forecasting and application of elasticity is very similar amongst the utilities we reviewed. Utilities typically use one of two basic modeling approaches: statistically adjusted end-use (SAE) modeling or econometric modeling. SAE models forecast load (as a function of heating, cooling and base use) based on the saturation and efficiency of end-use appliances and the amount of energy they use. Econometric models forecast load based on the relationship between energy demand, weather, and economic variables (e.g. GDP, income, etc.) and price. In both cases, forecasts of energy use are made for residential, commercial and industrial rate classes separately. Like BC Hydro's approach, industrial load forecast is often not model based, but is developed based on customer specific information and other drivers such as commodity prices and global outlooks. In general, regardless of the modeling approach, price elasticity estimates are applied to rate escalation assumptions over the course of forecast to determine the rate impact on the forecast.

Rate Impacts

There is no real difference in the application of price elasticity in "load forecasting" and "rate impacts." In both cases, utilities use price elasticity to estimate the impact of rate changes on electricity demand. However, there appears to be increased regulatory scrutiny on the estimates and application of price elasticity in rate impact cases which tend to focus on the short-term (1-3 years) impact of the rate change. We observed examples of external stakeholders voicing concerns about the methodology used to assess the rate change (i.e. the application of elasticity) and the elasticity estimate used in rate filings. The methodology used to estimate the rate impact varied depending on the details of the rate case and was inconsistent across jurisdictions. In some cases, utilities developed models to estimate the price elasticity of their customers while other jurisdictions relied on academic studies or precedent set by other utilities.

The review of how price elasticity estimates can be used to determine rate impacts provided in a multi-utility rate case in California is particularly informative. Conducted by Dr. Faruqui, the case presents how the consumption effect of moving from a four- to two-tier pricing regime can be determined. Three methodologies, that are in use in the industry, are:

- The **tier-specific methodology**, where the price change in each tier is assumed to affect consumption in that tier, is from triangular probability distributions the Brattle Group computed for short-run and long run elasticities based on data from price elasticity studies.[12] Dr. Faruqui determined average short-run price elasticities to be -0.13 for tier 1 and -0.26 for tier 2 rates and long-run price elasticities to be -0.39 and -0.78 for tier 1 and 2 rates using this methodology.

[12] Faruqui, 2008.

- The **average price methodology**, where customers are assumed to respond to average price changes, is a consumption weighted average of the tier specific elasticities of -0.18 for PG&E and a price elasticity of -0.17 for SCE obtained from an internal study the utility conducted based on 15-year residential customers billing data.
- The **marginal price methodology**, where only the highest tier (marginal) price applicable to the last (highest) unit of consumption is assumed to affect change in consumption, is based on consumption weighted average of the tier specific prices for the outer tier (-0.18 for PG&E and -0.19 for SCE) and tier 1 value for the lower tier (of -0.13 for both).[13]

Dr. Faruqui did not identify a big range of results from the three methods. Two of the methods (the average price and tier-specific methodology) indicated a maximum consumption decrease of 2% while the third (the marginal price) indicated a maximum consumption increase of 1.7%. The base case scenarios from each methodology resulted in consumption changes much less than these for each utility studied. Overall, the results were used to justify why moving to a flat rate does not harm conservation. The results from these methods showed the full range of possible outcomes and the uncertainty inherent in customer response to rate/rate design changes.

2.2.3 DSM

How does one identify pre-DSM price elasticities?

We found an example of a load forecasting methodology that permits the identification of pre-DSM price elasticity. PNM's residential use per customer load forecasting model featured in Table 1 includes an energy efficiency proxy so that the estimated coefficient of price is an estimate of price elasticity of demand holding the effect of all factors, including energy efficiency program savings, constant.[14] The price elasticity estimate, in a sense then, is a pre-DSM value.

Other than PNM's study, no other utility provides how pre-DSM price elasticities can be identified. However, we found that it's common practice to adjust forecast model results for the incremental impact of DSM programs. For example, Nova Scotia Power accounts for past DSM savings in its load forecast by subtracting portions of DSM savings already accounted for in current load; it determines the level of DSM savings already in current load by including historical cumulative DSM values in the average use SAE regression models. Similarly, Portland General Electric adjusts its forecast to account for the impact of incremental energy efficiency programs; it reduces the forecast by the amount of incremental energy efficiency levels in the forecast year. California's IOUs, PSCo and PacifiCorp also follow a similar practice.

How does DSM affect price elasticity estimates over time?

---

[13] For customers whose consumption falls in tier-two, an income ("expenditure") effect for the tier-one energy they consume is also considered when estimating the impact of the rate design using the marginal price approach.

[14] The study used 1990/year(t) as a proxy for overall energy efficiency; 1990 was the start of the study period and the value of the proxy decreased over the study period that ended in 2008. The decreasing trend reflects improvements in energy efficiency of the capital stock increase but at a decreasing rate. The proxy reflects that idea that while the efficiency of energy using appliances and equipment improve every year, they will always use some amount of energy no matter how efficient they become. The coefficient estimate of this variable measured the average reduction in kWh/customer per day each month. Since PNM began DSM programs in 2007, the study did not use the energy efficiency coefficient estimate, which is inherently uncertain, to project DSM savings. But, it indicated how it is possible to account for DSM savings using a residential use per customer regression model.

The authors of the 2008 EPRI paper cite a study that indicates that the presence of DSM lowers price elasticity estimates over time.[15] Per the cited study, the level of price elasticity among California's customers was lower at the time of the study than 25 years earlier due to the state's aggressive promotion of energy efficiency measures and programs. The authors indicate that DSM programs have lowered customers' ability and willingness to respond to price changes. They do not provide the price elasticity estimates used in the earlier study they refer to nor the one they used in their study. Further, no other utility studies we found indicated how the presence of DSM affects elasticity estimates over time and, thus, we can only draw tentative conclusions that the presence of DSM may lower price elasticity estimates over time.

2.2.4 Rate Structures and customer sectors/segments

Should elasticities be different depending on the rate structure to which they are assumed to apply (flat rate, time of use rate, tiered)?

We identified only one study that uses different elasticities for different rate structures. That is PNM, which uses different price elasticity estimates for those on flat and tiered rates to generate load forecasts. It applies lower elasticity estimates to PNM South customers (of -0.06 to residential and -0.10 to commercial customers) that face a flat rate and higher price elasticity estimates to PNM North customers (of -0.19 for residential and -0.20 for commercial customers) that face increasing block rates. The values applied are based on elasticity estimates PNM developed for the two geographic areas, which happen to face different rate structures, separately and by sector.

We recommend that BC Hydro also applies price elasticity estimates that are relevant to its customers, who face tiered rates. Since it has estimates of the price sensitivity of its (residential) customers that face this type of rate, it can apply these values in its business applications. Where a single price elasticity estimate is needed, the estimates obtained from its empirical studies should inform that value. We discuss the value we recommend for this purpose and the rationale in section 2.3.

Does it make sense to apply elasticities to industrial sectors with few, large participants and where an assessment of future customer viability is already made based upon expert advice?

Yes, it does, unless a comprehensive and detailed assessment of price effects is already completed using an alternative method such as a survey that queries each customer about their response to rate increases. Large industrial customers are generally more price sensitive than residential and commercial customers. Several elasticity studies that we reviewed (including the Manitoba Hydro testimony of Dr. Yatchew and Ross (2017)) indicate price elasticity to be higher for the industrial sector than for the other sectors. In addition, we found several load forecasting studies (the California state-wide energy forecast, and forecasts for Public Service Colorado, Seattle City Light, Portland General Electric, and Puget Sound Energy) that apply price elasticity estimates to assess rate impact on their industrial load forecasts. The elasticity estimates applied to gauge the impact of rate changes on industrial load forecasts are either the same or higher than those used for the residential and commercial sectors except in one (Portland General Electric) case.

[15] Faruqui and George, 2005.

The remaining question then is the applicability of the practice the utilities we identified as using price elasticity estimates to alter industrial load forecast to BC Hydro's context. Three of the utilities above (Puget Sound Energy, Manitoba Hydro and Seattle City Light) are winter peaking and have substantial hydro generation. Public Service Colorado and Manitoba have industrial customers engaged in mining and extraction industries that are generally like those BC Hydro serves. All the utilities that adjust industrial load for price effect also have various types of large industrial customers.

Therefore, given that industrial load customers are generally more price sensitive than other sector customers; that it is common practice to apply price elasticities even for forecasts made based on site-specific information; that utilities like BC Hydro either in the large customer mix they serve or in being winter peaking follow this practice, we find that it is reasonable to adjust industrial load for rate impact using price elasticity estimates. This is the case even when BC Hydro’s large industrial customer-specific forecast already has some price response effects already built into it.

If BC Hydro were to survey all industrial customers about how they would respond to future rate changes, and BC Hydro were able to incorporate the results of that survey into load forecast, then it may not also be appropriate to apply a price elasticity. In order for the survey approach to be a valid alternative to the use of price elasticity, the survey would need to be comprehensive and would need to ask about response to rate changes alone in the absence of other drivers of changes to consumption.

What kind of behavioral and non-behavioral changes should be included in short-run and long-run elasticities of substitution (TOU rate)?

Time-varying rates (TOU, CPP and RTP) can induce both shifts in consumption from peak to off-peak periods and possible changes in overall consumption. In the former case, shifts in energy demand from periods where its price is higher (peak period) to periods where it is lower (off-peak) can be measured using substitution elasticities. Short-run substitution elasticities reflect behavioral changes such as pre-cooling homes before peak periods, and shifting laundry and dishwashing activities from peak to off-peak periods. In the long-run, both residential and non-residential consumers can adjust the stock of energy-using equipment in response to peak period price increases.

The relevant distinction between short- and long-run, is whether responses reflect behavioral changes only or both behavioral and capital stock/electricity using equipment changes (non-behavioral changes). As long there is data of sufficient length (which is at least two years or more post rate changes based on industry practice that we reviewed), it is possible to estimate the net effect on consumption of rate/rate design changes inclusive of both behavior and capital stock changes. Examples of behavioral changes and non-behavioral changes are useful, but an exhaustive list of these is not necessary.

What is the range of uncertainties on short-run and long-run elasticity of substitution (TOU rate) estimates?

Two sources from the literature helped us identify values and ranges for elasticities of substitution for TOU rates. These studies indicate that residential substitution elasticities can range from 0.04 to 0.21 while non-residential values can take on values from 0.03 to 0.17 (and 0.32 for agricultural customers). PacifiCorp used substitution elasticities that ranged from 0.08 to 0.09 for residential customers, 0.03 to 0.17 for non-residential customers, and 0.09 to 0.32 for agricultural customers to determine the demand impact of its proposed TOU rates. It used various studies to determine these values.[16] In addition, the EPRI (2008) study provides a synthesis estimate of substitution elasticities that range from 0.04 to 0.21 for residential customers and from 0.04 to 0.11 for commercial customers on TOU rates. These are short-run elasticities and there no indications of what long-run substitution elasticities values are likely to be.

Under a TOU rate, how should consumption change during peak and off-peak hours be attributed to substitution (change consumption from peak to off-peak period) and change in demand (reduction in use during peak)?

It is possible that time-varying rates not only affect patterns of consumption (shifts from peak to off-peak period), but also the level of consumption and peak demand. To estimate such changes, it is necessary to determine the price elasticity of demand for peak and off-period prices and apply those to energy use. Fortis BC applied a lower price elasticity (of -0.07) to off-peak and a higher price elasticity (of -0.14) to on-peak rates to assess the energy use effect of its propose TOU rate. These elasticity estimates were obtained from its RIB rates and it is not clear why they were deemed applicable to peak and off-peak rates.

While we have not conducted an exhaustive study on the topic, and leave this as one potential gap in our research, estimated substitution elasticities can be applied to determine peak to off-peak demand reductions. Energy use and peak demand reductions can be made using estimated price elasticity of demand. Past studies have indicated not only load shifting (peak to off-peak period), but also energy use reductions due to time-varying rates. The 2008 EPRI study indicates several pilots that run time-varying rates found a reduction in both peak-period and overall energy use.

What is a reasonable substitution price elasticity, for customers and end uses for which natural gas is substitute for electricity?

Estimates of cross-price elasticity for customers and end uses for which natural gas is a substitute for electricity is only reported in two cases. Carvallo et al. (2016) indicate Avista used a cross price elasticity of 0.10 for natural gas for all classes to forecast load in its 2005 IRP filing. Ros (2017) finds the cross-price elasticity of demand for natural gas to be 0.09 and 0.10 for residential and commercial customers, and 1.24 for industrial customers. The former two values are in line for those reported and used by Avista in its 2005 IRP.

2.2.5 Short vs. Long Run Price Elasticity

How much difference is there between short-run and long-run elasticities and, given the rapidly changing world, how long should long-run elasticities be?

In theory, the distinction between short-run and long-run price elasticities of electricity demand is clear. Short-run price elasticities are lower and reflect behavioral responses (such as turning off lights and lowering thermostat settings). Long-run price elasticities, on the other hand, are larger and reflect changes (including capital/durable goods adjustments, more efficient energy use processes and possible substitution to other fuels) that take sufficient time to materialize.

[16] Bernstein and Griffin, 2006, Edison Electric Institute, 2008, and Freeman, Sullivan & Co., 2012.

Short-run effects are estimated using limited time-series data, such as two years where enough time has not passed to permit adjustments in electricity using capital/equipment. Long-run effects can be estimated whenever there is data that incorporates adjustments in appliances and other electricity using equipment and processes. Cross-sectional data from different utilities or data from a single utility with multiple years of observations, and with sufficient variation in rates, enable the identification of long-run price effects. However, even in this setting if there are policies related to energy efficiency, technological or economic changes that also alter the capital stock in use by consumers, then models can only reflect the net effect of price changes over time.

Capital stock adjustment induced changes in consumption may be affected by rate changes, DSM/energy efficiency policies, technological developments and other factors. In jurisdictions with low electricity rates, it is reasonable to assume that capital stock changes are largely in response to factors other than electricity rates. However, measured price elasticities using data that already reflects lower energy use due to DSM and other factors that affect stock turnover can be taken to reflect net price effects. Thus, the real distinction is not whether short- or long-run price effects are estimated and applied, but whether the elasticity estimate controls for factors that influence capital stock turnover. Estimates based on data where DSM savings and other factors that affect stock turnover have been accounted for elsewhere, including in the lower historical trajectory of the energy use data, reflect price effects net of stock turnover effects.

To the extent that a demand forecast already accounts for the effect of capital stock turnover, it may be inappropriate to also apply a long run price elasticity that also attempts to capture this same effect. BC Hydro's Load Forecast accounts for the future impacts of a DSM plan that includes energy efficiency codes and standards and other measures that impact capital stock turnover. It also accounts for stock turnover though the SAE model for residential and commercial sectors Given this, our recommendation for BC Hydro is to eschew short- versus long- run price elasticity distinctions and instead to apply price elasticities estimated using energy data that already accounts for factors that impact stock turnover, such as past DSM initiatives. Further, price elasticity effects can change over time in response to rate and rate structure changes; potential changes in DSM policies and initiatives; and other changes in local conditions that affect demand. Determining the price elasticity is an empirical question that can only be answered with recurring (possibly every three to four years of) demand modelling of energy use.

What kind of behavioral and non-behavioral changes should be included in short-run and long-run elasticities of demand?

The residential conservation rate (RCR) impact study provided by Fortis BC indicates that short-run price elasticities should include behavioral responses such as turning off lights and lowering thermostat settings. In his testimony for PG&E's and SCE's residential rate design reform, Dr. Faruqui also considers behavioral changes (such as turning off lights and lowering thermostat settings) to drive short-responses. Long-run price elasticities, on the other hand, include appliance and structural changes including energy-efficient building shells. Yatchew's Manitoba Hydro testimony similarly indicates long-run price elasticities include the use of more efficient capital stock and migration to alternative fuels.

Given the distinction we made earlier of net and total price effects, estimated price elasticities do not reflect the effect of DSM. Therefore, DSM savings should be estimated separately and should be used to adjust load forecasts. In other words, the current practice that BC Hydro follows of adjusting load forecast for rate impacts and then for DSM activities is a sound one.

Our conclusion on this topic is that short-run price elasticities reflect all types of behavioral responses while long-run price elasticities reflect, additionally, changes in capital stock (including those induced by DSM activities). Thus, the distinction is not between short- and long-run price elasticities, but between price elasticity estimates that attempt to capture capital stock turnover and fuel switching as a price effect, and those that do not.

What is the range of uncertainties on short-run and long-run elasticity of demand estimates?

As indicated in section 2.2.1, short-run elasticities range from -0.06 to -0.26 for the residential sector, from -0.03 to -0.70 for the commercial, and -0.03 to -1.20 for the industrial sector. The long-run counterpart values range from -0.10 to -1.40 for the residential sector, from -0.50 to -1.30 for the commercial, and -0.50 to -1.40 for the industrial sector.

Given the literature we reviewed indicates -0.1 to be the most common elasticity; that BC Hydro's data indicates values (-0.08 to -0.14) that surround this value; that BC Hydro's consumption weighted tier-one and tier-two price elasticity is roughly -0.09; and that the previous assessment of elasticity by BC Hydro Expert Dr. Orans found -0.10 to be suitable for BC Hydro, we find a value of -0.10 for BC Hydro to be a reasonable value.

What are the differences in short-run and long-run elasticities of demand for residential customers by consumption level, region, heating fuel and dwelling type?

Our research yielded limited information on these topics and, thus, we can't draw conclusions on the matter. What we did find is estimates of short-run price elasticities for residential customers that vary by income and region in the 2011 rate application testimony filed by PNM. PNM's testimony indicates that low income customers' demand is more price elastic than higher income customers' demand. The short-run price elasticity of demand for low income customers, with less than $20,000 annual income, is estimated to range from -1.6 to -2.0 while that of customers with more than $20,000 annual income was estimated to range from -0.20 to -0.36. When the low-income threshold is $30,000, low-income elasticity is -1.3 and higher-income elasticity ranges from -0.10 to -0.14. We also found one study that indicated higher price elasticity for customers that use electric heat (Fortis BC 2014 RIB evaluation).

Based on the dearth of information we uncovered on the remaining issues (difference in elasticity by consumption level and dwelling type), apart from those in BC Hydro's RIB evaluation, we recommend a future study investigate this issue in more depth to fill this gap.

2.3 Elasticity analysis, conclusions and recommendations

This section contains DNV GL's analysis, conclusions drawn from our research and recommendations on price elasticity estimates and their application. DNV GL also provides a recommendation for how to approach the impact analysis when investigating a move from an inclining block rate to a flat rate structure. While not necessarily part of the original scope of work, DNV GL's price elasticity literature review uncovered a relevant example from California on the topic.

Elasticity estimate

The current investigation was prompted by the need to examine the price elasticity estimate of -0.05 that is used by BC Hydro to forecast load and assess the impacts of general rate increases. The price elasticities in use by utilities and reviewed in this study are wide-ranging. The variation in elasticity estimates across studies reflects the fact that consumer response to electricity price changes are not uniform, instead reflecting local conditions (such as weather, economic activity and energy efficiency policies) under which consumption takes place. From a practical point of view, however, they offer a range of price elasticities, and points of comparison for the business applications of interest to BC Hydro.

Based on our review, short-run elasticities range from -0.06 to -0.26 for the residential sector[17], from -0.03 to -0.70 for the commercial, and -0.03 to -1.20 for the industrial sector. The long-run counterpart values are two- to three-times larger than the short-run values. In our survey, the most commonly reported price elasticity for the residential sector is -0.10.

BC Hydro's current price elasticity estimate is derived from expert testimony provided by Dr. Orans as part of the 2008 Long Term Acquisition Plan. Dr. Orans recommended that BC Hydro "should adopt a conservative price elasticity of -0.1 to estimate the aggregate impact of an average rate increase and a rate design change from a flat rate to an inclining block tariff for residential and commercial customers." Dr. Orans suggested that it would be reasonable for BC Hydro to split the -0.1 elasticity estimate between rate level-induced and rate design-induced conservation, which resulted in BC Hydro's current price elasticity of -0.05 for all sectors. We did not see evidence of other utilities splitting elasticity between rate design and rate level effects (except Fortis BC, which follows an approach similar to BC Hydro). Further, BC Hydro's most recent RIB evaluation pointed to limited, and in some cases no savings, associated with the inclining block rate design. That being said, we note that Dr. Orans original price elasticity estimate of -0.1 is consistent with the wider literature on price elasticity.

Lastly, BC Hydro's work in this area provides useful data points that can inform reasonable price elasticity estimates for its residential sector. BC Hydro's two studies on the impact of the RIB rate on consumption indicate that price elasticities for its residential customers range from -0.08 to -0.14. BC Hydro's 2013 RIB evaluation identified price elasticities of -0.08, -0.1 and -0.13 for step 2 (tier-two) customers. Its 2016/17 RIB evaluation indicated price elasticities of -0.14 for step 1 (tier-one) and -0.08 for step 2 (tier-two) customers. Based on fiscal years' 2016 and 2017 average aggregate marginal consumption of 3,859 GWh/year for tier 1 and 11,943 GWh/year for tier 2, we note that about 24% of marginal consumption is in rate tier 1 and 76% in rate tier 2. Using these estimates, we derive a weighted average price elasticity for the residential sector of -0.09.[18]

Although not statistically significant, BC Hydro also finds a price elasticity of -0.10 for residential customers in New Westminster located in Lower Mainland BC served by another municipal electric utility; these customers are on a flat rate and considered comparable to BC Hydro's customers.

---

17 The range excludes an outlier value of -0.6 reported in the 2008 EPRI synthesis for the residential sector.

18 Several studies, including Ito (2014) and Borenstein (2009) indicate customers respond to average bill changes or perceived average rates. Thus, a consumption weighted average price elasticity is another good data on the price elasticity that is applicable for BC Hydro's residential sector.

Values from external sources, as well as those determined by BC Hydro from its own and neighbouring utility data, indicate a residential price elasticity value that centres around -0.10 is a reasonable value for BC Hydro's residential customers. Therefore, we recommend that BC Hydro increase the price elasticity in use to assess rate impact and determine load forecast growth for the residential customers. Based on the convergence of values, we find an increase to -0.10 to be reasonable.

Recommendation: DNV GL recommends that BC Hydro increase its current price elasticity estimate of -0.05 to -0.10. The -0.05 estimate is at the low end of the range of the all the price elasticity estimates reviewed by DNV GL. It is also lower than recent price elasticity findings of -0.08 to -.14 from BC Hydro's RIB evaluations. We believe there are two different but equally reasonable approaches for BC Hydro to take to increase its elasticity estimate. In an ideal world, BC Hydro would use its own empirical data to estimate price elasticity. This would yield the most accurate estimate for BC Hydro. However, it would also be reasonable for BC Hydro to adopt the price elasticity estimate produced by this research.

BC Hydro estimate. BC Hydro can produce price elasticity estimates using its own data. This is largely already complete for the residential sector and based on our rough estimate, would result in an average price elasticity of around -0.09 for the residential sector. This approach would likely require additional elasticity studies of the commercial and industrial sectors to at the very least test whether those sectors are different enough from the residential sector to warrant sector specific estimates. In the meantime, absent better information, the residential sector elasticity estimate would have to be applied to all sectors.

Academic research/expert. Elasticity studies are challenging, time consuming, and may not be worth the investment given the efforts involved. Many utilities take this route and rely on academic studies or expert recommendations for their elasticity estimates. If BC Hydro decides to bypass additional elasticity studies and adopt a "reasonable value" from academic research and expert recommendations, then DNV GL recommends adopting an elasticity estimate of -0.1 for all sectors. This is consistent with the original recommendation made by Dr. Orans and the expert recommendation made in a recent Manitoba Hydro rate case by Dr. Yatchew. It is also the most commonly used price elasticity estimate by the utilities we reviewed and is consistent with the weighted average elasticity from BC Hydro's most recent RIB evaluation.

Sector-level elasticity

The literature indicates that, when price elasticity estimates are available for industrial sector customers, these customers are more price sensitive than are other customers such as residential. While some utilities have sector specific elasticity estimates that indicate higher elasticities for industrial customers, there is also evidence that many jurisdictions use the same elasticity estimate across all sectors, including PSE, PacifiCorp, and California (for multiple utilities).[19] for long-term load forecasting. BC Hydro's past studies on price elasticity for industrial customers are dated and in need of updating.

[19] California Energy Demand 2018-2030 Revised Forecast, California Energy Commission, Commission Staff Report, Document No. 17-IEPR-03, 4/19/2018.

Recommendation: In general, we find BC Hydro's application of price elasticity to be consistent with that of many of the Canadian and U.S. utilities we reviewed. DNV GL supports the continuation of BC Hydro's approach to load forecasting which involves building up sector specific forecasts, including site-specific large commercial and industrial forecasts, and applying a single price elasticity to account for price changes in the forecast. Given that BC Hydro employs a site by site assessment for industrial facilities which captures price effect for a selection of energy intensive facilities, such as pulp mills; and precedent elsewhere, of applying the same price elasticity across all three sectors, we recommend that BC Hydro continue to use the same price elasticity estimate for all sectors. The actual elasticity value will depend on whether BC Hydro adopts the weighted average elasticity from its 2016/17 RIB evaluation (-0.09) or the recommended -0.10 price elasticity estimate from our research and expert recommendations.

Short vs. long run elasticity

In theory, the distinction between short-run and long-run price elasticities of electricity demand is clear. Short-run price elasticities are lower and reflect behavioral responses (such as turning off lights and lowering thermostat settings). Long-run price elasticities, on the other hand, are larger and reflect changes (including capital/durable goods adjustments, more efficient energy use processes and possible substitution to other fuels) that take sufficient time to materialize.

In practice, how price elasticities (demand response to price changes) are measured and classified varies widely. As Yatchew, in a 2017 expert testimony, indicates price elasticity of energy demand can be estimated using various models and data types. Cross-sectional data are effective in identifying long-term price elasticities because such data reflect highly diverse electricity rates and demand from many utilities. Time-series data from a single utility can accomplish the same if the time span used is long enough and rate changes are sufficiently large. Panel data that combine the two often serve as the best approach for this purpose, which is why studies such as those by Jos (2017) use them to study long-run demand response to price changes. Jos used data from 72 distribution utilities covering more than 30 years (1972-2009) to estimate long-run price elasticities of -0.38, -0.42 and -0.52 for U.S. residential, commercial, and industrial customers, respectively.

The utilities that estimate and use price elasticities that we reviewed mostly use their own data of varying time lengths to report elasticities as short-run, long-run or neither.[20] The number of years used in these studies vary from 3 to 30 years. Two cases where long-run price elasticities are reported and/or used are those of Fortis BC's second RIB impact study, which uses 4 years of data and reports the estimated elasticity as long-run, and a PacifiCorp study that uses long-run price elasticity estimates from the U.S. Pacific Coast to determine Class 3 DSM resource forecasts. Fortis BC considered two years of post-RIB period to be sufficiently long to allow for capital stock changes while the PacifiCorp study used long-run price elasticities to determine long-term (20 years) demand reductions from voluntary participation in time-varying rates (Class 3 DSM resources). All other elasticities deemed as either short-run or neither short- or long-run are applied to either

[20] We note that several utilities we reviewed (Newfoundland Power, New Brunswick Power, Nova Scotia Power, Yukon Energy, Public Service Company of Colorado (PSCo), Seattle City Light) use price elasticities of unknown origin and classified either as short-run or neither short- or long-run. These elasticities are used to forecast load.

assess rate impact or forecast load. The table below summarizes the number of years used in each study, the price elasticities estimated and where these estimates are applied.

Table 2: Data used in utility price elasticity estimates

UTILITY/STUDY	ELASTICITY	SECTOR	YEARS IN STUDY	CLASSIFICATION	APPLICATION
FORTIS BC	-0.086	Residential	3	short-run	rate impact
FORTIS BC	-0.160	Residential	4	long-run	rate impact
PUBLIC SERVICE NEW MEXICO	-0.06/-0.19	Residential	9	short-run	load forecast
PUBLIC SERVICE NEW MEXICO	-0.10/-0.20	Commercial	9	short-run	load forecast
SOUTHERN CALIFORNA EDISON	-0.170	Residential	15	short-run	rate impact
SAN DIEGO GAS & ELECTRIC	-0.100	Residential	not provided	short-run	rate impact
PORTLAND GENERAL ELECTRIC	-0.100	Residential	> 20	not classified	load forecast
PORTLAND GENERAL ELECTRIC	-0.030	Non-residential	> 20	not classified	load forecast
NV POWER/CARAVALLO ET AL. STUDY	-0.100	Residential	> 20	not classified	load forecast
PUGET SOUND/CARAVALLO ET AL. STUDY	-0.190	Residential	> 10	not classified	load forecast
PUGET SOUND/CARAVALLO ET AL. STUDY	0.160	Commercial	> 10	not classified	load forecast
PUGET SOUND/CARAVALLO ET AL. STUDY	-0.190	Industrial	> 10	not classified	load forecast
AVISTA/CARAVALLO ET AL. STUDY	-0.150	Residential	not provided	not classified	load forecast
AVISTA/CARAVALLO ET AL. STUDY	-0.100	Commercial	not provided	not classified	load forecast
PACIFICORP/CARAVALLO ET AL. STUDY	-0.100	All classes	not provided	not classified	load forecast
PACIFICORP - U.S. PACIFIC COAST ESTIMATE/NREL STUDY	-0.10 to -0.40	Residential	> 20	long-run	DSM resource forecast

The foregoing indicates that price elasticities estimated based on data of similar duration are classified as short- or long-run or neither. There does not seem to be a discernible pattern as to what duration of data results in short- versus long-run price elasticity estimates in these studies.

As noted earlier, price elasticities estimated using historical utility data, where factors that impact capital stock such as energy efficiency policies and technological changes, have been in place for some time, reflect net price effects. This is because past DSM and related policy induced savings are captured in historical energy use, which is on a lower trajectory because of these initiatives.[21] Estimated price elasticities with time series data in such a setting do not confound DSM and rate change effects.

[21] In its 2016 load forecast, Nova Scotia specifies use per customer or sales models that include cumulative historical DSM savings as an explanatory variable to determine what level of DSM is already captured in the load forecast. A model coefficient of -1 indicates no historical DSM is in the forecast while a value of 0 indicates that the forecast already includes 100% of historical DSM and does not need to be adjusted by incremental DSM savings forecast. It found the coefficient to be -0.6 for the residential sector and -0.5 for the commercial and industrial sectors. These coefficients reflect that 40% and 50% of DSM savings are already accounted for in the residential and C&I load forecasts, respectively.

Recommendation: DNV GL supports BC Hydro's current approach of using methods other than price elasticity (e.g. direct adjustment for expected savings from energy efficiency and codes and standards) to account for capital stock turnover in load forecasts. This approach is consistent with a recommendation to BC Hydro by Dr. Orans in 2007, and we agree with his assessment that this method will minimize double counting. Our jurisdictional review did not find any evidence of other utilities applying both a short-run and long-run elasticity estimate to their load forecast in addition to adjustments for stock turnover such as DSM savings.

Flat rate analysis

BC Hydro informed DNV GL that it is examining the potential impacts of transitioning its residential inclining block rate to a flat rate. DNV GL reviewed a similar rate case in California where the IOUs proposed to move from a 4-tier inclining block rate to two-tiers and many stakeholders were concerned that it would negatively impact conservation. The IOUs solicited expert advice from Dr. Faruqui, a principal at the Brattle Group, who performed empirical analysis that indicated negative or minimal consumption impact from a transition to such rates. Rather than adopt a single approach to estimating the impact, Dr. Faruqui used 3 different methodologies (average price, marginal price, and tier-specific) to estimate the impact of the rate change. This multi-method approach resulted in outcomes ranging from a 2 percent decrease in consumption to a 1.7 percent increase in consumption with two of the three indicating a decrease for each IOU. The results indicated that the effect of removing the tiers was unlikely to cause a negative conservation effect.

Recommendation: DNV GL recommends that BC Hydro uses a similar multi-method approach to model the potential change in its rate design from an inclining block rate to a flat rate.

3 RECOMMENDATIONS FOR FUTURE RESEARCH

This section includes a summary of topics that may warrant future research depending on BC Hydro needs and priorities. These topics were identified as secondary objectives for this project and there are still gaps in the research.

- BC Hydro elasticity studies for the commercial and industrial sectors
- Cross-price elasticity (electric vs. gas)
- TOU rates and substitution elasticity including methods to disentangle demand changes and peak to off-peak reduction
- Price elasticity segmentation (region, dwelling type, consumption, heating fuel type, etc.)

4 SOURCE LIST

This section includes a list of documents and reports reviewed and used in this memo. The bibliography does not contain documents that were reviewed by DNV GL but were not used due to lack of relevant information. The literature review subsection includes academic reports and articles while the jurisdictional review subsection is organized by utility and includes the rate cases and load forecasting documents cited in this memo.

Memo to:
BC Hydro

From: DNV GL
Date: 9/6/18

Subject: Memo - GDP Findings and Recommendations

1 PROJECT OVERVIEW

BC Hydro hired DNV GL to provide an external review of how BC Hydro uses gross domestic product (GDP) in load forecast uncertainty analysis. This memo provides DNV GL's findings and recommendations on this topic.

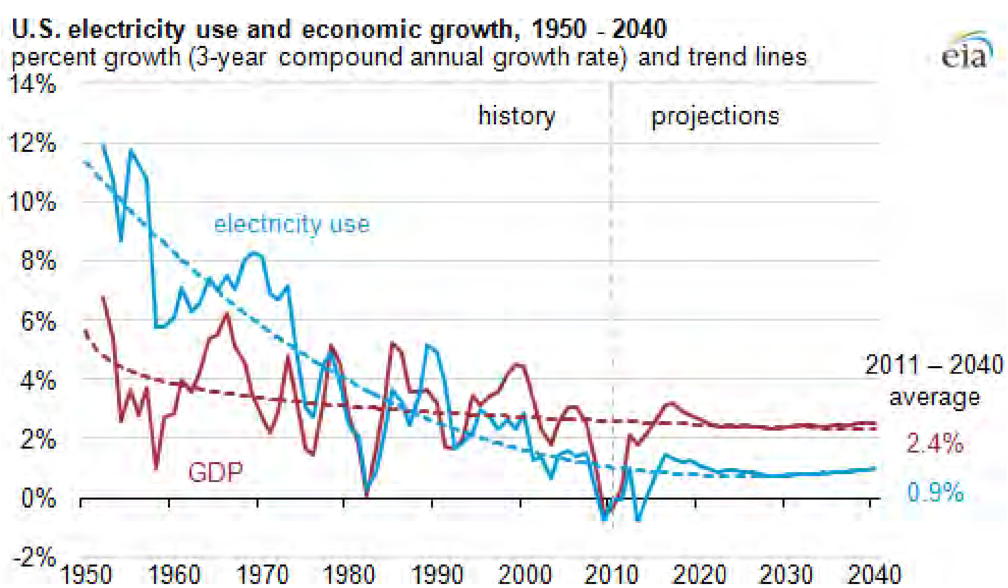
In this section, we provide a background discussion on the use of GDP in uncertainty analysis, details on project goals, and a description of DNV GL's approach. We discuss our research, findings, and recommendations in section 2. We outline a few next steps in section 3 and provide the sources used in the research in the final section.

1.1 Background

GDP/Uncertainty analysis

Regional GDP is a driver in parts of BC Hydro's distribution-connected load forecasting models. It is also a key driver of uncertainty bands for forecasted loads. Some research has shown the relationship between GDP and electricity usage is changing. The primary issue of concern to BC Hydro is whether and/or how GDP should continue to be used as a key driver in its uncertainty analysis, and what possible options there may be for adjusting or augmenting the GDP variable.

While the long-run relationship is changing, there is still a short-run correlation between GDP and electricity usage. The following chart, utilizing US data, demonstrates both long-run and short-run effects. Some key reasons for the long-run changes include responses to increasing electricity prices and technology change (which may also partly be tied to increasing electricity prices).



Source: U.S. Energy Information Administration, Annual Energy Outlook 2013 Early Release

Since the BC Hydro uncertainty analysis includes electricity prices as a variable, it is likely that it is at least partly capturing some of the reasons for the changing GDP/load relationship. In addition, since GDP also correlates well with electricity use in the short-run, GDP still may be a reasonable variable to include in an uncertainty analysis. There also may be variables that better capture the relationship between economic/demographic growth than GDP. For example, one could possibly break out GDP into 2 components – population and GDP per capita.

1.2 Goals and Approach

The objective of this project was to examine if the use of regional GDP in load forecast uncertainty is justified. DNV GL undertook a literature review to document the use of GDP and other economic variables in load forecast uncertainty. In collaboration with BC Hydro, DNV GL selected utilities in Canada and the United States to include in a literature review.[1]

The overall objective of this undertaking is to provide BC Hydro with recommendations on how to improve uncertainty analysis considering possible decoupling of GDP from electricity growth, keeping in mind that one possible recommendation could be to do nothing.

2 GDP/UNCERTAINTY ANALYSIS

This section presents the GDP and uncertainty analysis findings from DNV GL's literature and jurisdictional review. In section 2.1, we briefly describe BC Hydro's current use of GDP as a key input in its load forecasting process and uncertainty analysis. Section 2.2. provides an overview of how other utilities use GDP in load forecasting and uncertainty analysis. Finally, DNV GL presents recommendations for BC Hydro in section 2.3.

2.1 BC Hydro

One of the key drivers in BC Hydro's commercial and industrial load forecast is provincial GDP. Load forecasting is inherently uncertain as electricity demand is influenced by several difficult to measure and ever-changing factors like weather, technology, DSM programs, consumer behavior and market conditions for the largest customers. To quantify uncertainty in its load forecast, BC Hydro uses a Monte Carlo model and simulation technique. It uses variables of economic growth (measured by GDP), price of electricity (rates), heating degree days to represent the impact of temperature, elasticity of load (with respect to GDP and price), and it has 4 major distributions for the large industrial sector as major inputs in the simulation. In addition, BC Hydro includes uncertainty in electric vehicle adoptions, DSM, and codes and standards changes in the Monte Carlo model. Put simply, the model takes many random samples from the input scenarios to simulate output values that are used to construct the range and probability of sector level demand.

BC Hydro addresses the impact of GDP uncertainty in its load forecast in two ways. First, it addresses uncertainty in economic output by modeling a range of GDP scenarios. To do this, BC Hydro starts with the first-year base case GDP, which then grows at a rate equal to the base case growth rate plus a random perturbation amount. Second, BC Hydro addresses the uncertainty in consumer response to economic growth

[1] Same list of utilities as jurisdictional review included in 2015 BC Hydro rate design application.

by using triangular probability distribution around its GDP elasticity estimates. Currently, BC Hydro assumes a mean GDP elasticity of 0.67 for the residential sector and 0.78 for the commercial and industrial general service sectors.

2.2 Other jurisdictions

It appears that all the utility studies we reviewed (presented below) use GDP or some proxy for regional economic activity as a variable in their load forecast. Additionally, information on load forecast uncertainty analysis, where present, indicates the use of GDP to model the effect of different economic scenarios on load forecast. DNV GL did not find an example of a utility using alternatives to GDP to forecast or examine load forecast uncertainties. These findings suggest it's reasonable to use GDP in load forecasting and uncertainty analysis. Lastly, DNV GL would like to highlight the Manitoba Hydro and California state-wide approaches that use GDP in load forecasting and uncertainty analysis discussed below, as they are particularly informative and applicable for BC Hydro.

Nova Scotia Power

- Provincial GDP and employment used in SAE models to forecast small and general service commercial sector load
- No GDP elasticity term used in these end use models, which presumes a 1-to-1 correspondence between economic activity and commercial end-use
- Provincial GDP, exports, and manufacturing employment used in econometric models to forecast small and medium industrial sector load
- Large general service and industrial class loads forecast based on a combination of customer survey and historical sales information

New Brunswick Power

- General service (commercial) forecast based on an econometric model that relates changes in the level of sales to changes in provincial GDP, HDD, real price of electricity and previous year's sales level
- Industrial forecast also based on an econometric model where change in industrial use is based on change in GDP
- No details on GDP elasticity

Yukon Energy

- Commercial forecast based on SAE models include the effect of non-mining provincial GDP
- Industrial forecast is generated by a generalized economic model using forecasts for specific proxy mines
- No details on GDP elasticity

PSCo

- Gross State Product used in commercial and industrial end use models.

- Elasticity value of 0.7 used in these models.

Portland General Electric

- Real GDP and Oregon non-farm payroll employment used in PGE's regression forecast models
- No details on GDP elasticity

PSE

- Econometric models of residential, commercial, and industrial use per customer based on demographic and economic variables including GDP to forecast load
- No details on GDP elasticity, but expected high and low GDP growth scenarios used in uncertainty analysis

Manitoba Hydro

- Expert testimony indicates the relationship between GDP and electricity use has been weakening in advanced economies due to changes in the composition of their economies, where the share of manufacturing in GDP has been declining, and energy efficiency efforts
  - Energy intensity, quantity of energy used to produce a single dollar of GDP, declining by 1% per year in these economies since 1990
  - In Canada, energy intensity declining by more than 1% per year while energy use per capita is flat
- Nevertheless, electricity use still closely related to GDP with GDP elasticity of 0.8 (1% increase in GDP associated with 0.8% increase in electricity use)

CA state-wide

- Industrial model of energy demand driven by GDP or gross state product, employment and capacity utilization rates
- No details on GDP elasticity, but high, mid and low forecast scenarios include assumptions about high, low and medium economic growth
- Uncertainty analysis also includes variability in energy savings from energy efficiency programs, PV adoptions/self-generation, and electric vehicle (EV) adoptions

2.3 GDP conclusion and recommendations

As we mentioned in section 1.1, there is some indication of a decoupling between GDP and electricity use over the long-run. Partly this reflects declines in energy intensity due to structural changes in advanced economies, which have been undergoing de-industrialization. In addition, other factors such as increased energy prices and utility/government intervention via energy efficiency programs are responsible for the notable decoupling of GDP and electricity use. However, there is still a strong correlation in short-run variation between electricity use and economic activity most commonly measured by GDP. For a given set of explanatory variables (such as price and weather), variations in GDP growth will still have significant impacts on electricity demand growth.

Given that some of these variables (i.e. price) are also included in the uncertainty analysis, it seems reasonable to use variations in GDP growth in uncertainty analysis as well. The use of elasticities that are below 1.0 also makes sense and accounts for the fact that there is likely a fixed component of electricity use that would be present at most reasonable levels of GDP and ensures that a doubling of GDP won't translate into a doubling of electricity use.

As the jurisdictional review findings indicate, all of the utilities we reviewed use GDP or some proxy for regional economic activity as a variable in their load forecast. We did not find any evidence of new or alternative approaches for BC Hydro to consider.

Recommendation: We've concluded that the approach BC Hydro utilizes for addressing uncertainty in load forecasts by using variations in GDP growth and elasticity is reasonable and DNV GL recommends that BC Hydro continue its current approach. At the outset of this exercise we acknowledged that a possible outcome would be a recommendation to "do nothing" and based on our focused but limited research on the topic that is our current recommendation.

3 RECOMMENDATIONS FOR FUTURE RESEARCH

DNV GL recommends further investigation of the impact of splitting GDP into separate variables (population and GDP per capita) on load forecast uncertainty analysis. This is a topic of some relevance, but not one addressed in this research undertaking.

4 SOURCE LIST

This section includes a list of documents and reports reviewed and used in this memo. The bibliography does not contain documents that were reviewed by DNV GL but were not used due to lack of relevant information.

Brattle Group Benchmarking Study

BEFORE THE

BRITISH COLUMBIA UTILITIES COMMISSION

BC Hydro Fiscal 2020—Fiscal 2021 Revenue Requirements Application to the British Columbia Utilities Commission

EXPERT REPORT

OF

WILLIAM P. ZARAKAS

ON BEHALF OF

BC Hydro

February 8, 2019

TABLE OF CONTENTS

Appendices A through D follow.

BEFORE THE

BRITISH COLUMBIA UTILITIES COMMISSION

BC Hydro Fiscal 2020—Fiscal 2021 Revenue Requirements Application to the British Columbia Utilities Commission

EXPERT REPORT OF WILLIAM P. ZARAKAS

I. INTRODUCTION AND SUMMARY OF OPINION

1. BC Hydro asked The Brattle Group (Brattle) to conduct a cost benchmarking study of its operations and maintenance costs, excluding the costs of fuel and water rentals that are used in the power production process. These costs are frequently referred to as non-fuel operations and maintenance expenses (NFOM) and do not include capital costs that may be involved in building out new utility plants. I examined BC Hydro's NFOM costs against a peer panel of U.S. investor-owned electric utilities, primarily because of the availability of consistent and publicly available accounting data available for these utilities. U.S. investor owned electric utilities are required to file an annual report each year with the Federal Energy Regulatory Commission (FERC) following the accounting guidelines included in the FERC's Uniform System of Accounts (USoA).

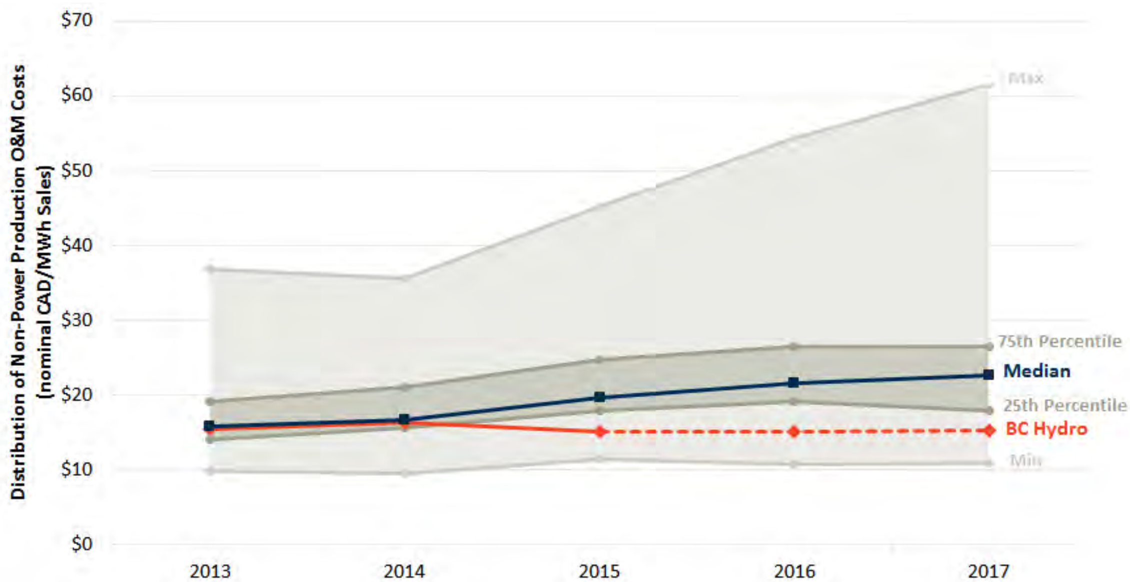
2. BC Hydro does not currently track its cost data following the USoA. In order to complete this cost benchmarking study, BC Hydro's accounting department reviewed accounting records and provided Brattle with the company's NFOM costs in USoA format. NFOM cost data in the USoA format were not available from other Canadian electric utilities. If so, some of these utilities would have also been included in the electric utility peer panel.

3. BC Hydro's total NFOM costs (on a per delivered MWh basis) are in the 1st quartile of the peer panel, the preferred position with respect to cost efficiency. However, in this particular case, I find that the measure of total NFOM is less informative than the disaggregated benchmarking results (for non-power production NFOM and power production NFOM), which are presented below. This is primarily due to BC Hydro's unique position with respect to comparable power production NFOM, which has a

strong influence on the total NFOM metrics. Nonetheless, in a "bottom line" sense, across the years included in the study, BC Hydro's overall NFOM unit cost is lower than nearly all of the U.S. utilities included in the peer panel.

4. The majority of BC Hydro's annual NFOM costs (more than 80%) are associated with its non-power production operations; i.e., transmission, distribution, customer service, and administrative and general functions. As demonstrated in Figure 1, the benchmarking analysis indicates that BC Hydro's costs (on a per delivered MWh basis) in this area are lower than most utilities included in the peer panel, and are frequently in the 1st quartile of the panel. As will be discussed in the main body of the report, my conclusions are similar if the benchmarking exercise is instead conducted on a $ per customer basis.

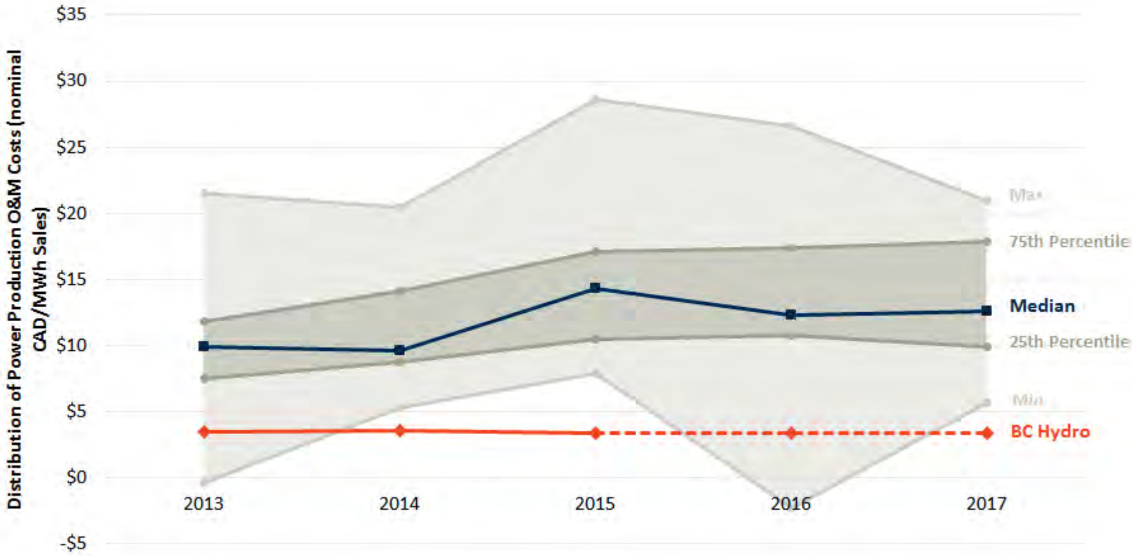
Figure 1: Non-Power Production NFOM ($ per Delivered MWh)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (pp. 321–323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

5. As shown in Figure 2 below, BC Hydro's power production NFOM costs (on a per generated MWh basis) are significantly lower than the U.S. utility peer panel. This is likely because the majority of BC Hydro's power plants are large scale hydroelectric plants, while peers in the panel generally own fewer and smaller scale hydro units. In addition, the peer utilities' power production portfolios are generally comprised of predominantly thermal units. Together, these factors likely contribute to peers having higher operations and maintenance costs than do BC Hydro's large scale hydro plants.

Figure 2: Power Production O&M Cost Benchmarking ($ per Generated MWh)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (pp. 320–321 and 401a), downloaded from Velocity Suite.

II. QUALIFICATIONS

6. I am William P. Zarakas. I am a Principal with The Brattle Group, an economics consulting firm. I was assisted by colleagues at The Brattle Group in conducting this benchmarking study, and have asked other Principals with expertise in cost analysis and total factor productivity analysis to review this report. While I benefited from the assistance and reviews provided by my colleagues, I alone am responsible for the contents and conclusions in this expert report.

7. I hold a leadership position in Brattle's Retail Energy Practice, and I lead much of Brattle's project work in the areas of performance based regulation, cost analysis and benchmarking, utility business models, benefit-cost analyses (e.g., grid modernization, reliability and resilience) and rate and pricing analyses. I also work on economic and regulatory matters in the telecommunications industry, including the economics and financial feasibility of building-out broadband infrastructure and regulatory matters concerning network access and pricing.

8. I have provided testimony and expert reports on matters concerning electric utility regulatory frameworks and approaches and cost analyses, as well as competition and

regulatory issues in the telecommunications industry. My testimony and expert reports have been presented before the Federal Energy Regulatory Commission (FERC), state regulatory commissions, the Federal Communications Commission (FCC), the Securities and Exchange Commission (SEC), the Copyright Royalty Judges (Library of Congress), the U.S. Congress, arbitration panels, and courts of law. I have also authored reports concerning special investigations on behalf of corporate boards of directors and audits of management practices and operational and financial performance on behalf of regulatory commissions.

9. I hold an M.A. in economics from New York University and a B.A., also in economics, from the State University of New York. I have authored articles in industry periodicals and journals on economic and regulatory matters. I have also taken and instructed courses on economic and regulatory matters. My curriculum vitae is provided in Appendix A.

III. DUTY OF INDEPENDENCE

10. I understand that while I have been hired by BC Hydro, I have a duty to assist the Commission and that I am not to be an advocate for BC Hydro or any other party ("Duty of Independence").

11. I certify that I am aware of my Duty of Independence, and that I have prepared my report in accordance with that Duty of Independence. Furthermore, I certify that if I am called to give oral or written testimony, I will give that testimony in conformity with the Duty of Independence.

IV. ISSUES

12. BC Hydro has asked me to provide my independent objective opinions on the following issues:[1]

    1. What would be the appropriate metrics for benchmarking BC Hydro's overall base operating costs and why?

[1] The questions that BC Hydro requested me to opine upon in my report were summarized in a letter of instruction, dated December 3, 2018, which has been provided as Appendix B to my report.

2. What would be an appropriate representative peer group for benchmarking BC Hydro's base operating costs and why?
3. What data is available from the selected peer group on the selected metrics over the last three or five years?
4. What methodology should be used to normalize the data and benchmark BC Hydro's base operating costs against its peer group?[2]
5. What are the results of this normalization and benchmarking analysis?

V. DISCUSSION

13. I have organized the remainder of my report in three sections. In this section, I provide: background on cost benchmarking and a description of the approach used for this study; a summary of BC Hydro's NFOM costs (the primary subject of this benchmarking analysis); the cost benchmarking metrics used; the peer panel selected; and, a description of the data set of comparable U.S. electric utilities. I then briefly discuss the methodology used and present the results of the cost benchmarking analysis in Section VI, and provide overall conclusions in Section VII.

A. BENCHMARKING CONTEXT

14. BC Hydro has asked me to perform a benchmarking analysis of its base operating utility costs against the comparable costs for a peer panel of U.S. electric utilities.[3] These costs include all operating and maintenance expenses excluding the cost associated with fuel, and are sometimes referred to as non-fuel O&M costs, or NFOM.[4] In its most basic sense, cost benchmarking involves comparing the cost performance of a subject utility with comparable peers. Accordingly, cost benchmarking requires

2 I discuss the components of base operating costs in Section V.

3 Annual cost data for U.S. investor owned electric utilities are publically available because each utility is required to file an annual report (Form 1) with the Federal Energy Regulatory Commission (FERC) with cost categorized into standardized accounts as defined in FERC's Uniform System of Accounts (USOA). To my knowledge, such reporting is not required for Canadian electric utilities. I understand that BC Hydro is compiling and examining the comparative costs of certain Canadian electric utilities. These cost data were not directly available to me at the time that I was conducting this benchmarking analysis and were therefore not included here.

4 For BC Hydro, fuel costs also include the cost of water rentals that are used in the generation of power.

standardization (to the extent possible) of cost categories and also involves selecting peers that are similar to the utility being examined.

15. Effective cost benchmarking requires that both elements—accounting standardization and the comparability of peers—are adhered to as closely as possible. However, it is widely recognized that inconsistencies in data and/or peers are inevitable. Furthermore, even when data and peers are well-matched, exogenous events and/or extenuating circumstances may impact comparative cost performance. Thus, benchmarking results do not necessarily indicate whether a utility's cost performance is due to managerial and/or operational efficiencies. Gaining an understanding of causation requires additional analysis and more thorough investigation, and is beyond the scope of this study.[5]

16. I undertook this benchmarking study in "layers," starting by comparing BC Hydro's total NFOM with peer utilities. I then de-composed the total cost into components: power production NFOM and non-power production NFOM, and then the components that made up non-power production NFOM. (The more detailed aspects of my analysis—the components of non-production NFOM are provided in Appendix D.)

B. BC HYDRO NFOM COSTS

17. BC Hydro provided me with a breakdown of O&M costs for 2013 through 2015 following the uniform systems of accounts (USoA) that are used by U.S. investor owned electric utilities.[6] I understand that BC Hydro began its derivation of these costs by examining its total cost of operations as provided in its Consolidated Statement of Operations (included in BC Hydro's annual reports).[7] For 2015, BC Hydro's total

---

5 Also, cost benchmarking, such as the NFOM discussed herein, reflect O&M costs only and assume that assets and facilities are already in place. NFOM cost benchmarking does not include capital costs, such as those involved in building new facilities. These latter costs are included in other types of cost and productivity analyses, such as calculations of total factor productivity (TFP).

6 BC Hydro annual data, as reported in its annual reports and as provided to me by company representatives, are based on its fiscal year (April 1 through March 31). For the remainder of the report, any reference to 2013, for example, refers to BC Hydro's fiscal year 2014, which covers April 1, 2013 through March 31, 2014. When referring to 2013 data for a U.S. utility, 2013 will correspond to calendar year 2013 (January 1, 2013 through December 31, 2013). I have adopted the same convention for all relevant years.

7 British Columbia Hydro and Power Authority 2015/16 Annual Service Plan Report, p. 27.

operating expenses were $5.002 billion. These expenses included: 1) roughly $1.9 billion reflecting its cost of energy, which includes purchases of electricity and gas, water rentals, and transmission charges; 2) roughly $1.2 billion in amortization; and 3) about $1.0 billion in finance expenses and grants, taxes and other costs. The remaining $905 million in 2015 were expenses associated with personnel, materials, and external services (PMAES) that reflect the utility's expenses associated with operating and running its utility system, which encompasses its generating stations and transmission and distribution assets, as well as its corporate, back office, and customer facing operations.

18. In order to benchmark these costs with peer U.S. utilities, BC Hydro adjusted these costs to be more in line with the NFOM costs included reported by U.S. utilities in the USoA, which involved two work steps completed by BC Hydro's accounting department. First, BC Hydro added and subtracted various cost categories to and from the expenses in its Consolidated Statement of Operations, primarily associated with reversing (for purposes of this exercise) certain deferral accounts and capitalized overheads and transfers to capital accounts, as well as removing that portion of expenses affiliated with Powerex and Powertech.[8] The adjusted NFOM that BC Hydro indicated was appropriate to use in this cost benchmarking study was $1.062 billion in 2015.[9] Second, BC Hydro broke this adjusted total NFOM into functional cost areas (e.g., annual O&M expenses for the power production, transmission, distribution, customer facing, and administrative and general).

19. BC Hydro has completed its accounting breakdown of functional costs for the years 2013–2015. However it currently only has accounting records for NFOM at the total level (i.e., not broken down by functional cost area) for 2016 and 2017; I have estimated the break down into functional cost areas based on historic percentages. BC Hydro confirmed this approach was reasonable. I show below (in Figure 3) that the percentage breakdown for functional cost for 2013, 2014, and 2015 are quite stable on a

---

8 Powerex Corp. and Powertech Labs Inc. are the wholly owned subsidiaries of BC Hydro.

9 The adjusted NFOM was $1.001 billion for 2013 and $1.022 billion for 2014.

year-to-year basis. A breakdown by functional costs for 2013 through 2017 is shown in Figure 3 below.

Figure 3: BC Hydro NFOM Costs By Major Functional Cost Area ($ Millions)

Functional Cost Area	2013	2014	2015	2016	2017
Power Production	$184	$185	$194	*$194*	*$193*
Transmission	$150	$161	$165	*$165*	*$164*
Regional Market	$0	$0	$0	*$0*	*$0*
Distribution	$176	$178	$186	*$187*	*$186*
Customer Accounts	$74	$75	$75	*$78*	*$77*
Customer Service and Informational	$4	$4	$6	*$5*	*$5*
Sales	$0	$0	$0	*$0*	*$0*
Administrative and General	$412	$420	$437	*$439*	*$436*
Total	**$1,001**	**$1,022**	**$1,062**	**$1,067**	**$1,061**

Sources and Notes: Calculations by The Brattle Group, based on Uniform System of Accounts data provided by BC Hydro. The 2016 and 2017 values highlighted in light grey are estimates based on each cost area's average share of total NFOM from 2013 through 2015.

C. Appropriate Metrics for the Benchmark Analysis

20. I was asked by BC Hydro to determine appropriate metrics for benchmarking BC Hydro's base operating costs. Cost benchmark metrics are the measures through which comparative cost performance are conveyed because, even for similarly situated utilities, absolute dollar costs tend to convey little information with regards to comparable cost performance. Benchmark comparisons are typically made on a unit basis, such as the cost per MWh or cost per customer. Additional unit measures may be used, depending on the purpose of the benchmarking exercise and the availability of data.

21. Benchmarking studies undertaken for purposes of process improvement may be based on more granular and detailed metrics, such as the cost of tree trimming per circuit mile. However, such benchmarking typically requires that utilities supplement their public filings with additional and usually proprietary data.[10] The subject study was undertaken in order to gain a more general understanding of BC Hydro's comparative

[10] Such detailed operating level cost benchmarking studies usually involve a group of utilities agreeing to share detailed data, usually in a masked fashion. The processing of data and presentation of results are usually conducted by an independent party.

costs of operations, and thus did not involve this level of data granularity. Furthermore, data for comparable utilities were limited to public data sources, also serving to limit the depth of possible metrics.

22. I use three primary benchmark metrics in this study, each of which is widely used and considered "standard" for use in cost benchmarking analyses: 1) cost per *delivered* MWh; 2) cost per *generated* MWh; and 3) cost per (end-use) customer. MWh (a measure of throughput) and number of customers are complementary indicators of system size; they are frequently, but not always, correlated. Delivered and generated MWh each measure different points on the utility value chain. Delivered MWhs are related to the throughput received by end-use customers (and are thus appropriate as a metric for delivery functions, such as distribution functional costs), while generated MWh reflect the energy at the production facility (and are appropriate as a metric for power production costs). BC Hydro's delivered and generated MWhs and customer count for 2013 through 2017 are shown in Figure 4 below:

Figure 4: BC Hydro Benchmark Metrics (Denominators)

Year	Delivered GWh	Generated GWh	Customer Count
2013	53,018	45,596	1,914,549
2014	51,213	41,443	1,935,068
2015	57,300	49,567	1,960,555
2016	57,652	48,810	1,987,963
2017	57,173	48,017	2,018,044

Sources: British Columbia Hydro and Power Authority Annual Service Plan Reports for 2013/14, 2014/15, 2015/16, 2016/17, and 2017/18.

D. PEER PANEL

23. The utilities that are cost benchmarked against BC Hydro are referred to as a "peer panel." Ideally, the utilities included in a benchmarking peer panel should be relatively similar to the utility under study, however, perfect matches are rarely achieved. Nonetheless, selecting a reasonable peer panel is a particularly important part of cost benchmarking—for somewhat obvious reasons. Selecting inefficient or otherwise high cost utilities for a peer panel—intentionally or otherwise—may make the utility under study appear more efficient than it actually is, and vice versa. Accordingly,

considerable attention is afforded the peer panel selection process. Generally, peers are selected based on similar situations, with factors including its density and geography, number of customers and sales, number of utility employees, and terrain, weather, and climate.[11] These factors tend to affect the size and complexity of a utility's distribution system as well as its back office, administrative, and customer facing operations. Selecting peers based on similar situations is particularly important when the benchmarking object is the absolute level of costs, as is the case in my analysis, as opposed to changes in costs over time, such as is the object in productivity analysis. In the former case, differences in customer density, geography, weather, *etc*. will likely lead to significant differences in the absolute level of costs per unit of output. In contrast, in the latter case, the relationship between customer density, geography, weather, *etc*. and productivity growth is ambiguous.

24. BC Hydro is a vertically integrated electric utility, which can have an impact on overall employee counts (compared to utilities that do not own and/or operate power production facilities). In addition, BC Hydro's power production is dominated by hydroelectric generation, which tends to have lower O&M costs than do thermal or nuclear units.

25. Review of U.S. utility data indicates that U.S. investor owned electric utilities have much smaller hydro power portfolios than does BC Hydro. There are roughly 100 GWs of conventional hydro capacity in the U. S., but most of it is owned and operated by governmental entities which do not directly serve customers (with the possible exception of some large industrial customers).[12] Only two U.S. entities—the U.S. Army Corp of Engineers and the U.S. Bureau of Reclamation—own and operate more

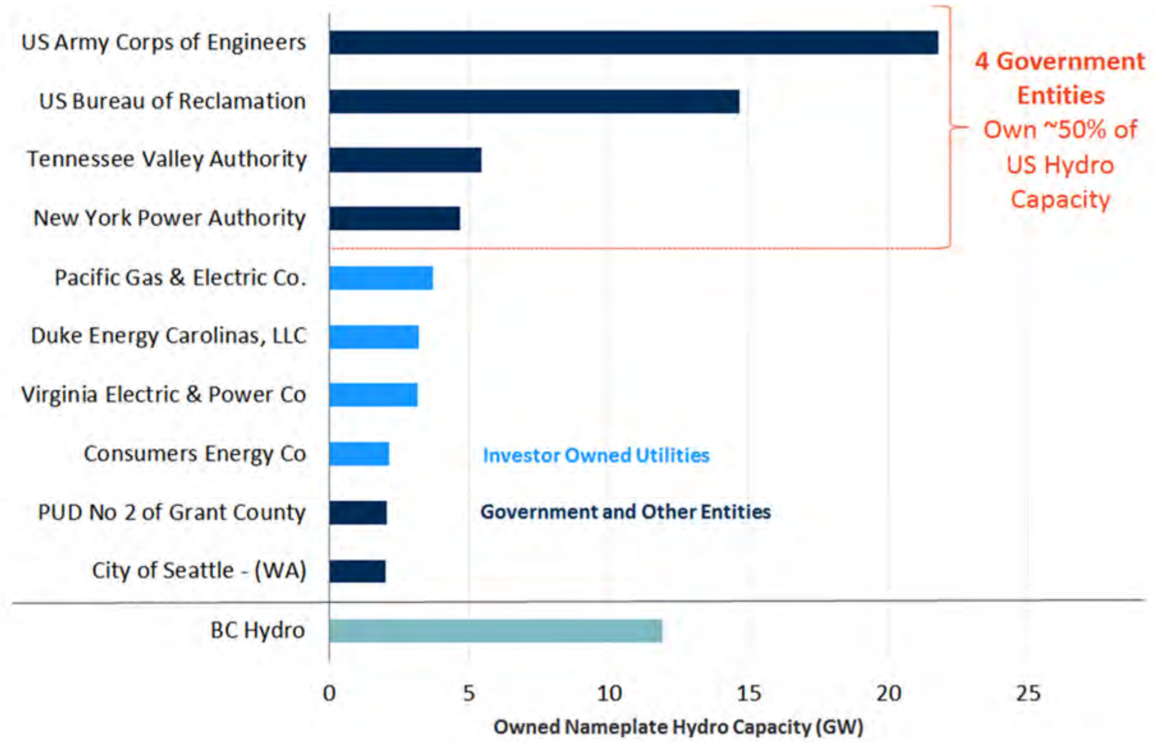
---

11 Specification of a peer panel may be driven by the intended use of the cost benchmarking exercise. For example, process improvement efforts sometimes deliberately select peer panels composed of very efficient firms, as these projects devote more effort in identifying ways for the subject company to improve performance than to assessing whether or not the company's spending levels are within prudent bounds.

12 For example, the 2017 Form EIA-860 Data – Schedule 3, "Generator Data" (Operable Units Only), available at: https://www.eia.gov/electricity/data/eia860/, indicated there were 101 GWs of conventional hydro capacity. Hereafter referred to as *2017 Form EIA-860 Data – Schedule 3.*

hydro capacity than does BC Hydro.[13] Figure 5 shows the top 10 entities (in terms of capacity) that own and/or operate hydro facilities in the U.S. Only three of these—Pacific Gas and Electric (PG&E), Duke Energy Carolina, Virginia Electric & Power Co. (Dominion), and Consumers Energy—are investor owned utilities.[14]

Figure 5: U.S. Entities Owning Large Amounts of Hydro Capacity



Sources: Data for BC Hydro are from the British Columbia Hydro and Power Authority 2017/18 Annual Service Plan Report. Data for U.S. Entities are from *2017 Form EIA-860 Data – Schedule 3.*

26. This makes it difficult to have a fully comparable peer panel on this dimension and, by extension, at a utility-wide level. However, it is possible (and meaningful) to benchmark costs at the functional level. To determine an appropriate peer panel, I

---

13 Major hydro facilities owned by the U.S. Army Corp of Engineers include Oahe (which has a nameplate capacity of 784 MW), Richard B Russell (628 MW), Garrison (614 MW), Carters (500 MW), Big Bend Dam (494 MW), and Hartwell Lake (420 MW). Major hydro facilities owned by the U.S. Bureau of Reclamation include Grand Coulee (6,809 MW), Glen Canyon Dam (1,312 MW), Hoover Dam (2,079 MW), Shasta (714 MW), and Hungry Horse (428 MW). See *2017 Form EIA-860 Data – Schedule 3*. However, I do not include these two entities as part of my benchmarking peer group because they are federal entities that do not own or operate transmission or distribution systems and do not report USoA data.

14 Neither PG&E nor Consumers are considered vertically integrated utilities. Pacific Gas & Electric Co underwent restructuring in the late 1990s, divesting its gas-fired generation, and Consumers divested its transmission assets.

initially started with a dataset of all 120 U.S. investor owned electric utilities. Then I narrowed this list down to 23 U.S. utilities to form the peer panel for this study. These include 20 U.S. utilities that are vertically integrated and meet a minimum size requirement of delivering at least 20,000 GWhs to customers per year (for reference, BC Hydro delivered 57,652 GWhs to its customers in fiscal year 2018).[15] I also included three utilities that did not strictly meet these criteria because their generation mix included a substantial amount of hydro. The list of utilities included in the peer panel is shown in Figure 6. In addition, a spreadsheet of the utilities considered and screening criteria is attached as Appendix C.[16]

15 An additional utility also cleared this screen, Entergy Louisiana, LLC, which recently was involved in a merger with Entergy Gulf States Louisiana. This made it difficult to determine the cost data for 2013–2017 for the combined utility.

16 Appendix C provides the data set of 120 U.S. investor owned utilities used as the population to draw upon in selecting a peer panel for this study.

Figure 6: Cost Benchmarking Peer Panel

Pacific Gas & Electric Co	CA	E/G	62	4,546	8	48%	69	17%	50%

Sources and Notes: Utility characteristics are reported for 2017. BC Hydro's sales, customer count and capacity data are from the BC Hydro's2017/18 Annual Service Plan Report. BC Hydro's Total Sources of Supply includes generation, net exchange, gas and transportation for thermal generation, and purchases; total and supply breakdown data were provided by BC Hydro. Sources and notes on the data for the U.S. peer panel are described below by [column]:

[B]: Some utilities have a service territory that spans more than one state. In such instances, the state with the highest 2017 sales has been listed, based on data from 2017 EIA 861 Schedule 4, downloaded from Velocity Suite.

[C]: "E" indicates the utility only provides electric service; "E/G" indicates the utility provides both electric and gas service.

[D] – [E]: Data from 2017 EIA 861 Schedule 4, downloaded from Velocity Suite.

[F] – [G]: Data from 2017 EIA 860, downloaded from Velocity Suite.

[H] – [J]: Total Sources of Supply includes net generation, power purchases, and net power exchange. Data are from 2017 FERC Form 1, p. 401a, downloaded from Velocity Suite.

27. As indicated in the above, seven of the utilities are larger than BC Hydro in terms of delivered MWhs (or sales), while 16 are smaller. Similarly, in terms of the number of customers (column [E]), five utilities are larger than BC Hydro, with the remaining 18 smaller. There are several utilities in the panel that are located in either the Pacific

Northwest or the American West. As indicated earlier, also included are three utilities with significant hydro resources in their power mix.

28. Selecting a peer panel is, unfortunately, not a fully prescribed and cut and dry exercise. Instead, it involves a degree of professional judgement; equally reasonable alternate panels may also be specified. I tested the reasonableness of the above panel by comparing benchmarking results across such an alternate panel, in order to ensure that panel selection did not inadvertently provide aberrant results. The results for the alternate panel were acceptably close to the results for the selected panel, removing concerns of selection bias. Thus, overall and for the purposes of this study, I find that the selected peer panel provides a reasonable point of reference for assessing BC Hydro's relative NFOM cost performance.[17]

E. DATA

29. As indicated earlier, conducting a cost benchmarking study requires consistency of cost data. The FERC's USoA provides reasonable assurance that cost data reported by U.S. electric utilities follows similar categorizations of costs, and thus is widely used in cost benchmarking analyses.[18] The USoA categorizes O&M costs by major functional category; detailed supporting accounts, which sum to the major functional category total, are also provided. I conducted this benchmark study at the functional cost area level.

30. BC Hydro informed me that Canadian electric utilities do not consistently employ USoA reporting, which can make comparisons of costs—NFOM or otherwise—challenging, and requires information to be provided by individual utilities (in contrast to the publicly available cost data in the U.S.). BC Hydro indicated that their preferred focus for this cost benchmarking study was the costs of personnel, materials, and

[17] The alternate panel tested was composed of all vertically integrated U.S. investor owned electric utilities. It is possible to specify many other alternate panels (of course), and these may produce different results than that realized from the selected and alternate panel tested.

[18] However, utilities apply their own accounting practices and judgements in completing the FERC Form 1. I have found that, in some cases, reported cost levels may vary among utilities due to reporting practices, more so than because of differences in incurred costs. For example, not all utilities record all sales related costs in USoA accounts 911–913 and 916 (Sales).

external services (PMAES) as reported in its annual Consolidated Statement of Operations. BC Hydro advised me that these costs are equivalent to BC Hydro's net operating costs provided in its Revenue Requirements Application, after adjusting for its subsidiaries, Powerex and Powertech. BC Hydro also advised me that these costs are roughly consistent with the NFOM costs reported by U.S. utilities in annual FERC Form 1 filings. Discussion with BC Hydro indicated that PMAES costs needed to be adjusted in order to more accurately equate to the USoA based NFOM costs. As discussed earlier, BC Hydro re-organized its accounting data to convey its cost data in a USoA compatible format.

31. BC Hydro recommended that the USoA data used for the U.S. peer utilities be adjusted slightly—in accordance with the adjustments made to the BC Hydro data, as discussed above—to ensure that peer panel costs are more closely comparable to BC Hydro's NFOM costs. A summary of the USoA accounts used for each functional cost area is provided in the Figure 7 below.

Figure 7: FERC USoA Accounts by Cost Area

Cost Area	All FERC USoA Accounts in Cost Area	Excluded FERC USoA Accounts in Cost Area
Power Production	500-514, 517-525, 528-532, 535-557	501, 503, 504, 509, 518-522, 536, 547, 555
Transmission	560, 560.1-560.8, 562-569, 569.1-569.4, 570-573	
Regional Market	575.1-575.8, 576.1-576.5	575.6-575.8, 576.1-576.5
Distribution	580-598	
Customer Accounts	901-905	
Customer Service and Informational	907-910	
Sales	911-913, 916	
Administrative and General	920-929, 930.1, 930.2, 931, 935	927

32. BC Hydro recommended excluding USoA accounts relating mainly to fuel, steam, and water rentals involved in power production, as these are considered part of its cost of energy, rather than its operating costs. BC Hydro advised us to exclude expenses associated with market monitoring and operations incurred by some of the U.S. peers who participate in regional wholesale markets (such as MISO) and franchise

requirements (included under A&G)—costs in these areas are incurred by BC Hydro's subsidiary, Powerex, rather than BC Hydro itself.

33. BC Hydro reported its cost data in its annual reports and provided cost data in USoA compatible format on a fiscal year basis, which runs from April 1 through March 31 of each year. This is different than the timing used by U.S. utilities when filing annual FERC Form 1 reports, which cover calendar years (January 1 through December 31 of each year). Thus, BC Hydro NFOM cost data is not completely compatible with the U.S. utility peers, even if the cost accounts can be appropriately adjusted to be in line with USoA cost accounts. However, both data sets—BC Hydro and the U.S. utilities—reflect 12 months of cost experience, even if slightly out of sync. I addressed this by comparing BC Hydro's NFOM for fiscal year spanning 2013–2014 (ending March 31, 2014) with USoA NFOM data for calendar year 2013, and so on.

34. Finally, as indicated earlier, while BC Hydro has completed its accounting breakdown of functional costs for the years 2013–2015, it currently only has accounting records for NFOM at the total level (i.e., not broken down by functional cost area) for 2016 and 2017. For use in this study, I have developed a proxy for the functional-level cost totals for 2016 and 2017 by calculating each functional area's average share of total NFOM costs over the 2013–2015 and using those proportions to allocate the 2016 and 2017 total NFOM costs to each functional area. As shown in Figure 8 below, review of these proportions for 2013, 2014, and 2015 indicates that they have been quite stable on a year-to-year basis. However, it is possible that the actual functional costs for 2016 and 2017 would have differed had BC Hydro conducted its accounting at this level of detail.

Figure 8: Breakdown of Functional Cost Categories as Percentage of Total NFOM

Functional Cost Area	2013	2014	2015
Power Production	18%	18%	18%
Transmission	15%	16%	16%
Regional Market	0%	0%	0%
Distribution	18%	17%	18%
Customer Accounts	7%	7%	7%
Customer Service and Informational	0%	0%	1%
Sales	0%	0%	0%
Administrative and General	41%	41%	41%
Total	**100%**	**100%**	**100%**

Sources and Notes: Calculations by The Brattle Group, based on Uniform System of Accounts data provided by BC Hydro. Breakdown percentages may not sum to 100% due to rounding.

VI. BENCHMARKING RESULTS

35. A key part of the cost benchmarking methodology involves specifying metrics (e.g., cost per MWh). With this in place as discussed above, the comparative analysis mainly involves observing the position of BC Hydro each year with respect to the peer panel.

36. I provide graphic representations of the results of the cost benchmarking below. I show results for non-power production O&M in total and, in Appendix D, by underlying functional cost areas: transmission, distribution, the customer facing functions (customer accounts, customer service and information, and sales), and administrative and general. I also provide results for power production related O&M and for total NFOM (i.e., the sum of non-power production and power production related O&M expenses).

37. I include benchmarking results for the O&M costs per MWh (delivered MWhs for the non-power production O&M and generated MWhs for power production related O&M) and per customer.

38. Benchmarking results are presented in four quartiles. For cost benchmarking, this means that 25% of the utilities in the peer panel with lowest unit cost (for the cost metric under study) are included in the 1st quartile, the next 25% of utilities (through the median) are included in the 2nd quartile, etc. The peer panel for this study includes

23 utilities: 6 are included in each of the 1st and 4th quartiles, 5 utilities are included in the 2nd and 3rd quartiles, with one utility occupying the median position (the dividing line between the 2nd and 3rd quartiles). All results are presented in nominal Canadian dollars.[19]

A. NON-POWER PRODUCTION O&M COSTS

39. Non-Power Production NFOM costs include USoA accounts for Transmission expenses (which includes Transmission and Regional Market expenses), Distribution expenses, Customer-Facing expenses (which includes Customer Service, Customer Accounts and Information, and Sales), and Administrative and General expenses. Non-power production costs account for over 80% of BC Hydro's total NFOM.[20]

40. Figure 9 and Figure 10 provide a comparison of BC Hydro's Total Non-Power Production costs to its peers on a $ per delivered MWh and $ per customer basis.

---

[19] The costs for the U.S. utilities were converted to Canadian dollars using yearly average currency exchange rates for the relevant period as retrieved from: https://www.irs.gov/individuals/international-taxpayers/yearly-average-currency-exchange-rates. As the 2018 exchange rate was not available at the time this analysis was completed, I use the 2017 exchange rate to convert 2018 U.S. dollars to Canadian dollars.

[20] In 2015, BC Hydro's Non-Power Production costs equaled

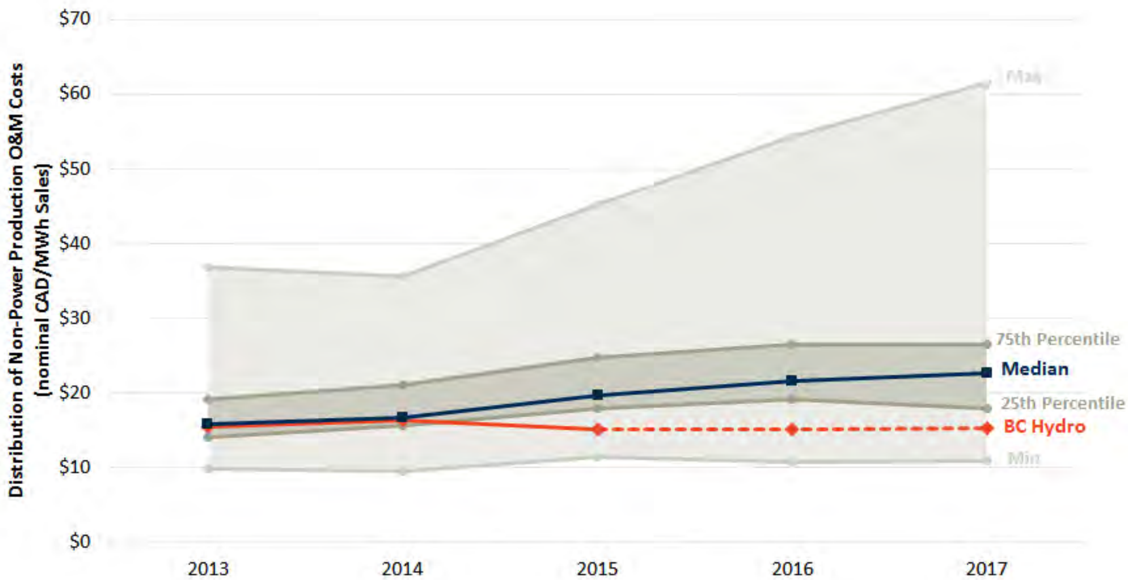
$868M = $165M (Transmission) + $186M (Distribution) + $81M (Customer-Facing) + $437M (Administrative and General).

BC Hydro's total NFOM in 2015 equals $1,062M. Therefore, the Non-Power Production cost share of total NFOM is equal to

82% = $868M / $1,062M.

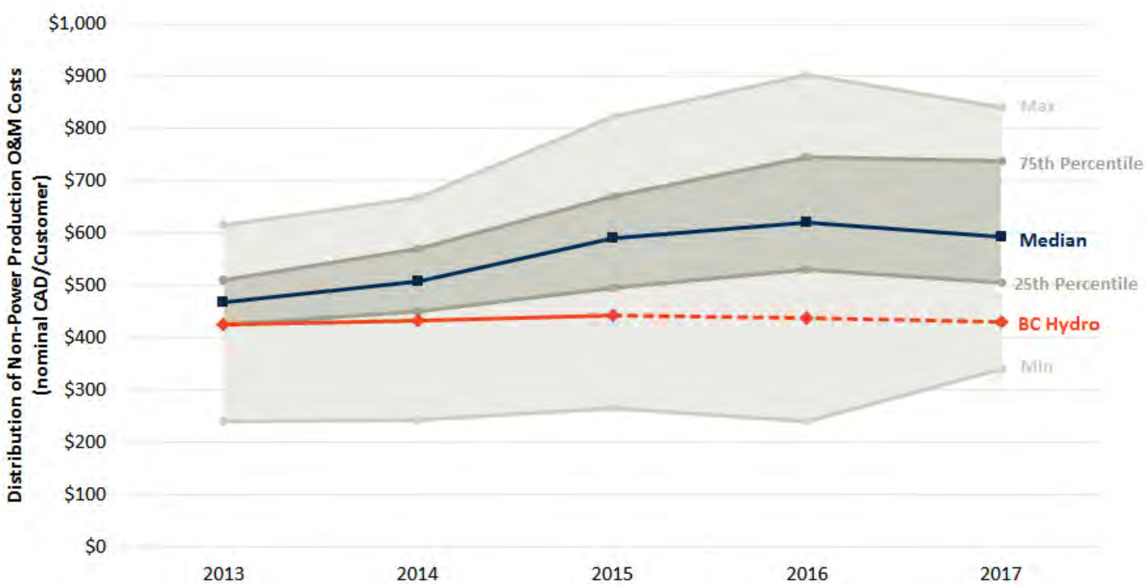
Non-Power Production expenses accounted for about 82% of total NFOM in 2013 and 2014 as well.

Figure 9: Non-Power Production NFOM ($ per Delivered MWh)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013-2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013-2017 FERC Form 1 data (pp. 321–323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

Figure 10: Non-Power Production NFOM ($ per Customer)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (pp. 321–323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

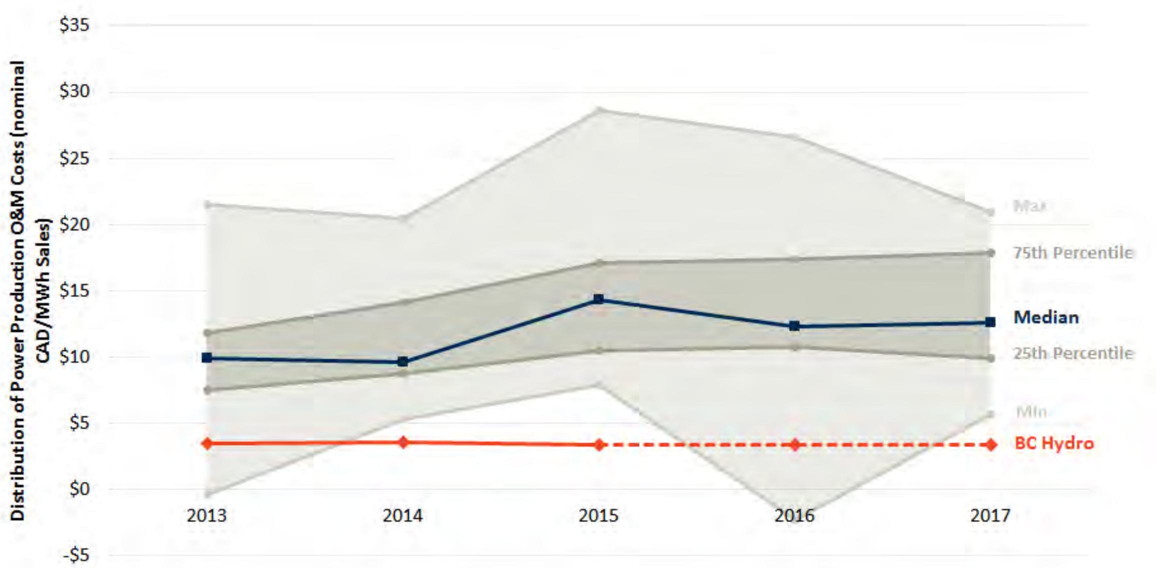
41. As shown in the figures above, BC Hydro's relative cost performance for the non-power production cost category is in the first or second quartile, depending on the year. Cost performance in this area appears to have improved in the latter years (2016 and 2017), but recall that these costs are estimated as a percentage of its recorded total

NFOM costs. A more detailed examination of the components of non-power production costs is provided in Appendix D to my report.

B. POWER PRODUCTION O&M COSTS

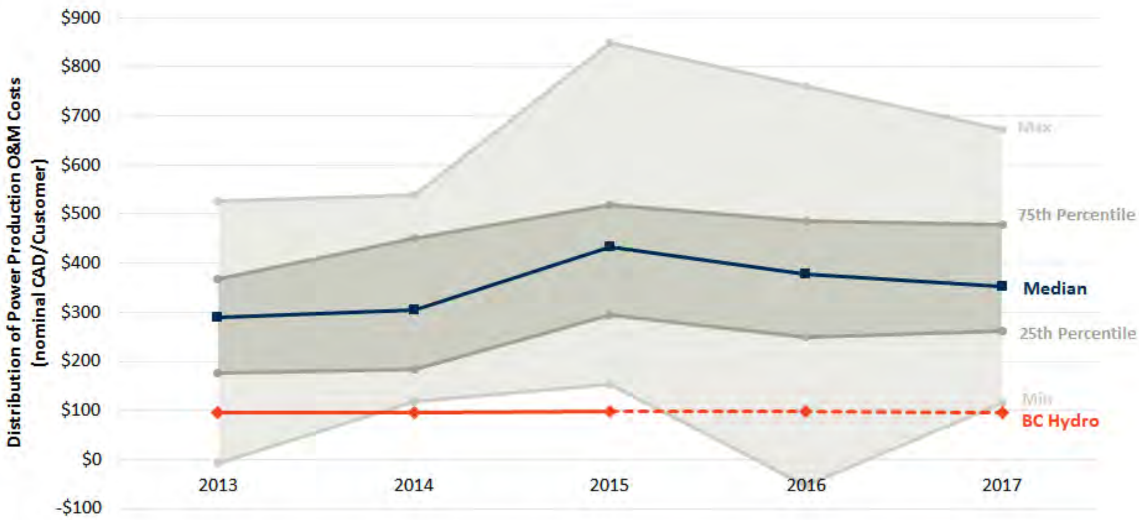
42. Power production O&M costs represent roughly 18% of BC Hydro's total NFOM costs. Cost benchmarking results for power production O&M excluding fuel costs (shown on a $ per generated MWh and $ per customer basis) are shown in Figure 11 and Figure 12, below.

Figure 11: Power Production O&M Cost Benchmarking ($ per Generated MWh)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (pp. 320–321 and 401a), downloaded from Velocity Suite.

Figure 12: Power Production O&M Cost Benchmarking ($ per Customer)



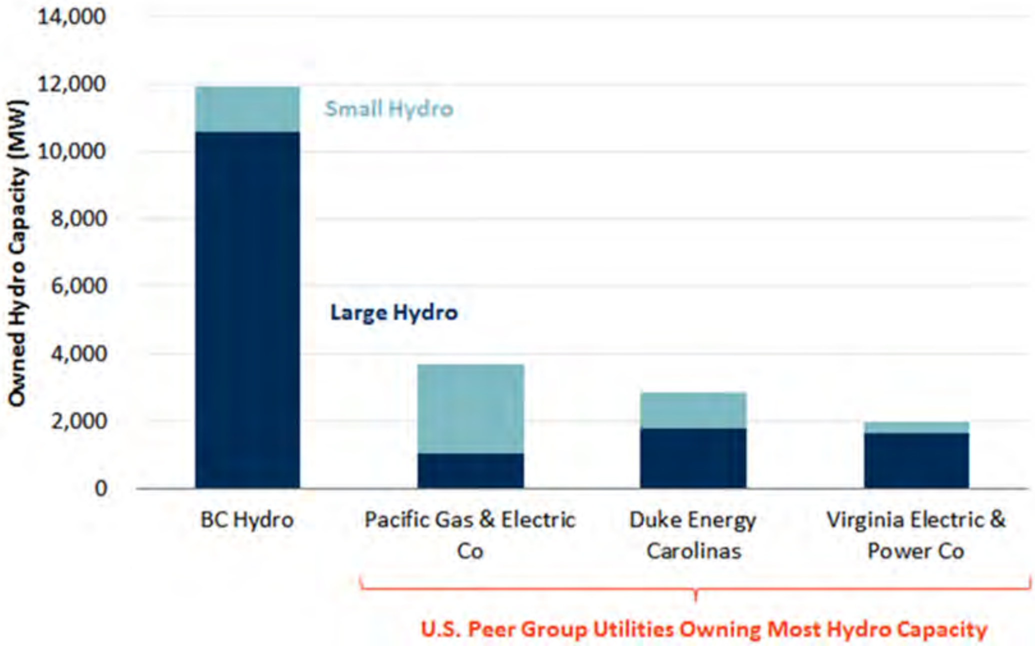
Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (pp. 320–321 and 401a), downloaded from Velocity Suite.

43. The figures show that BC Hydro's power production O&M are among the lowest of the peer group. However, the benchmarking results show that at least one utility (Nevada Power) shows zero and/or even negative O&M costs in some years. This is due to negative entries for USoA account 557 (Other expenses), most likely reflecting accounting adjustments and/or transfers.[21] Some other utilities in the panel have negative expenses under this account (although not large enough to offset the other positive costs), although BC Hydro does not. I elected not to exclude or make other adjustments to the panel or data, so as not to introduce selection bias.

44. BC Hydro's relative cost performance regarding power production O&M is likely explained by the high percentage of hydro facilities in its overall power production mix. Hydro facilities likely have lower O&M costs than do the non-hydro facilities that make up the majority of the power production facilities that are owned and/or operated by the other utilities included in the peer panel. Furthermore, as illustrated in Figure 13 below, BC Hydro has more large scale hydro than the other utilities in the panel. Smaller scale hydro facilities do not enjoy the same economies of scale as do larger scale units.

[21] Similarly, one peer group member incurs negative Transmission NFOM costs in some years; this is discussed in additional detail in Appendix D.

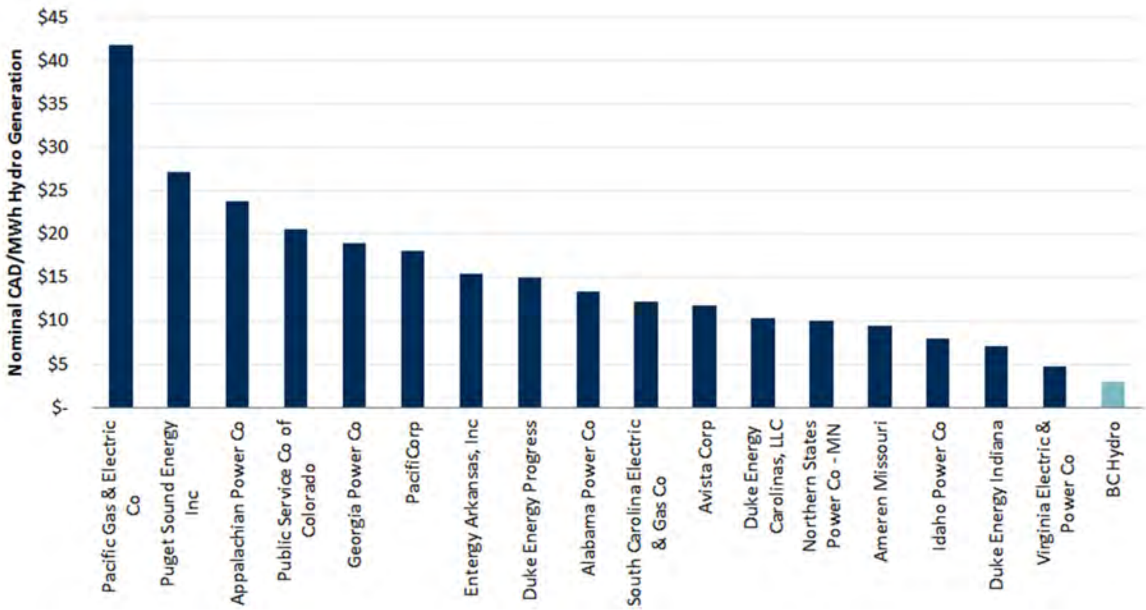
Figure 13: Hydro Generating Capacity by Facility Size, Selected Utilities



Sources and Notes: Data from EIA 860, downloaded from Velocity Suite. Hydro includes both conventional hydro generation and pumped storage. For the purposes of this chart, Large Hydro is defined as any hydro facility larger than 400 MW.

45. The volume and scale of BC Hydro's hydro-based generation appears to be a factor leading to its relatively low unit cost for power production O&M when compared to other utilities with hydro-based facilities. Figure 14 below shows the power production O&M costs (per MWh of hydro generation) for the hydroelectric plants owned and/or operated by 17 of the utilities included in the peer panel. BC Hydro's unit costs are the lowest, especially when compared with PG&E, whose mix of hydro resources includes a larger percentage of smaller scale resources than does that of BC Hydro.

Figure 14: 2015 Hydroelectric Power Production O&M
($ per MWh of Hydro Generation)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2015 USoA data and the 2015/16 Annual Report provided by BC Hydro. Values for the U.S. peer panel are based on 2016 FERC Form 1 data (pp. 320–321 and 401a), downloaded from Velocity Suite.

C. TOTAL O&M COSTS

46. I benchmarked BC Hydro's total NFOM on a $ per delivered MWh basis, with total NFOM defined as the sum of the individual functional cost areas that were benchmarked above. Figure 15 below shows BC Hydro's total NFOM costs for 2013 through 2017 as well as those costs on a per delivered MWh and per customer basis.

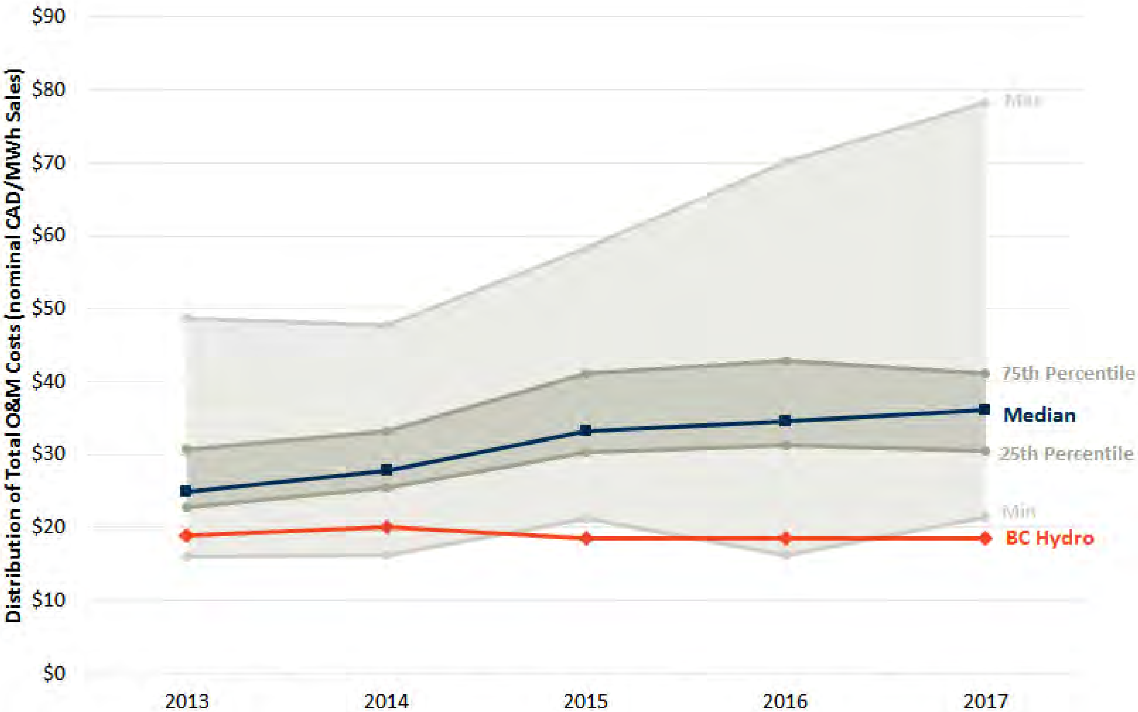
Figure 15: BC Hydro Total NFOM O&M Cost Metrics

Year	Total NFOM ($ millions)	Total Sales (GWh)	Total Customers	$ per Delivered MWh	$ per Customer
2013	$1,001	53,018	1,914,549	$18.88	$522.74
2014	$1,022	51,213	1,935,068	$19.96	$528.15
2015	$1,062	57,300	1,960,555	$18.54	$541.84
2016	$1,067	57,652	1,987,963	$18.51	$536.78
2017	$1,061	57,173	2,018,044	$18.55	$525.62

Sources: Calculations by The Brattle Group, based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro.

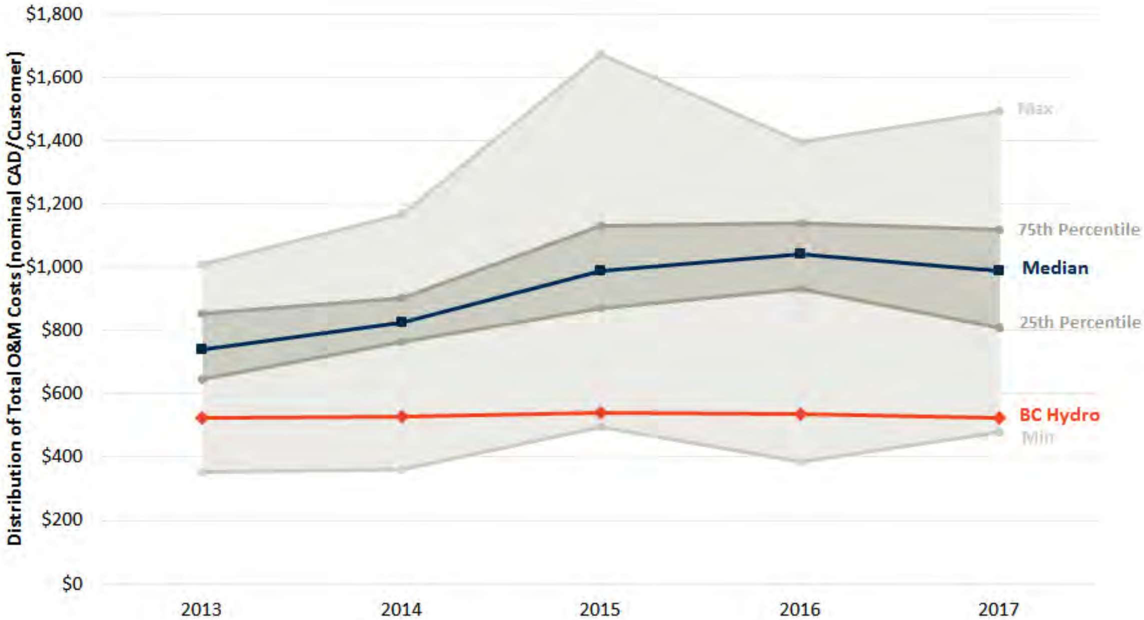
47. Figure 16 and Figure 17 show BC Hydro's total NFOM costs per delivered MWh and per customer in relation to comparable costs for the U.S. utilities included in the peer panel.

Figure 16: Total Non-Fuel O&M Costs ($ per Delivered MWh)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (pp. 320–323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

Figure 17: Total Non-Fuel O&M Costs ($ per Customer)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2017 total NFOM data and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (pp. 320–323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

48. As indicated in the figures, BC Hydro's total NFOM is among the lowest of the utilities in the peer panel for all of the years under study. However, this measure appears to be less informative than are the separated benchmarking results for non-power production NFOM and power production NFOM shown earlier in this report. This is primarily due to BC Hydro's unique position with respect to comparable power production NFOM, which has a strong influence on the total NFOM metrics.

VII. CONCLUSIONS

49. Conclusions with respect to cost benchmarking studies need to be accompanied by appropriate caveats concerning data and peers. That is, benchmarking results depend upon consistent data that accurately convey information about the cost areas under study. Cost benchmarking studies can almost always be improved upon with added levels of depth and investigation. "Peeling back the onion" is particularly important when benchmarking is undertaken for purposes of process improvement. I find that the level of depth included in the subject study is appropriate for assessing general NFOM unit cost comparisons.

50. I used standard metrics for this cost benchmarking analysis: costs per MWh and costs per customer. I have used these metrics in prior studies and have observed that they are routinely used in cost benchmarking studies. Other metrics may be applied in more focused or detailed analysis (e.g., the cost of tree trimming per distribution system mile); however this depth of benchmarking analysis typically requires additional and non-publicly available information, and was beyond the scope of my assignment.

51. The utilities used as points of comparison should represent a reasonable field of peers, with the important understanding that there will be few cases in which utilities are fully similarly situated. I used a relatively simple screening process in selecting a peer panel for this study in order to avoid "cherry picking," or deliberate selection bias. Peer panels can usually be improved upon with deeper analysis of candidate utilities and their related ecosystems and circumstances. For the purposes of this study, I find the peer panel appropriately representative of peer utilities in the U.S.[22]

52. I find that the USoA provides a reliable data set to represent the costs of U.S. utility O&M costs and, accordingly, used this format as the basis to conduct the subject cost benchmarking analysis. I noted earlier that these data are not perfect representations of costs (e.g., negative accounting entries, likely reflecting transfers and/or accounting adjustments). However, overall, I find that it is appropriate to base this cost benchmarking study on these data. I relied on BC Hydro to organize their accounting data in this USoA format.

53. Overall, in a "bottom line" sense, the cost benchmarking analysis indicates that BC Hydro's non-fuel operations and maintenance expenses, which cover utility, back office, and corporate operations (but excludes the costs of fuel and purchased power, depreciation, amortization, finance charges, and taxes), are comparatively lower than peer utilities, and in many cases fall in the first quartile, a sought-after position (from a cost perspective, assuming that the utility provides sufficient levels of service). Much of this strong showing is due to BC Hydro's strong unit cost performance in power production NFOM, in which BC Hydro is a 1st quartile performer. These results are

[22] Additional analysis can be brought to bear, including econometric analysis, to more fully explore peer panel options. Such analysis was outside of the scope of this study.

likely driven, at least in part, by differences in the generating fleet of BC Hydro, which is heavily focused on large-scale hydroelectric capacity, and those of the peer group utilities, which generally feature significant amounts of thermal capacity. Those peer utilities that do own hydroelectric capacity own fewer plants, and those plants are generally smaller-scale than the hydroelectric capacity owned by BC Hydro.

54. Excluding power production from NFOM provides a meaningful indicator for BC Hydro's comparative cost performance. This (total) non-power production NFOM metric includes transmission, distribution, customer-facing, and administrative and general expenses, which (as shown in Figure 1) accounts for over 80% of BC Hydro's total NFOM. BC Hydro was in the 2nd quartile of unit cost performance for this metric in the early years of this study (2013) and improved into the 1st quartile by 2015, mainly due to improvements in its cost performance in transmission and distribution.[23]

55. BC Hydro's performance with respect to NFOM costs in Transmission, Distribution, and Administrative and General accounts compares favorably with the rest of the peer group. In these measures, BC Hydro is in the first or second quartile or at the median, depending on the metric, and has generally improved its relative cost performance over the last five years.

56. BC Hydro's relative cost performance with respect to the Customer Facing functional area (made up of Customer Accounts, Customer Service and Informational Expenses, and Sales) is at or below the 1st quartile. BC Hydro has explained that its advances in these areas (e.g., its deployment of automated metering infrastructure (AMI) and paperless billing) might explain its relative cost efficiency.[24] However, review of the data set indicates that many utilities seem to treat Customer Facing costs in an aggregated fashion, or include these costs in other areas of operation. For example, some utilities (including BC Hydro) have not reported any costs in the Sales cost area, and have only minimal costs reported in the Customer Service and Informational

---

[23] A causal analysis concerning the specific reasons behind the changes in BC Hydro's non-power production NFOM costs was beyond the scope of this study.

[24] Recall that this cost benchmarking analysis includes O&M costs only, not the capital costs associated with infrastructure such as AMI.

expenses cost area. For this reason, I draw limited conclusions with respect to BC Hydro's benchmarking performance with respect to the Customer Facing area, and rely more heavily upon the cost benchmarking results for non-power production O&M on a total basis.

Appendix A:

Curriculum Vitae of William P. Zarakas

William Zarakas is a Principal with The Brattle Group, an economics consulting firm, and an expert on economic and regulatory matters in the electricity, telecommunications and media industries. He heads Brattle's retail energy practice, and leads much of Brattle's work concerning regulatory and business models, cost and rate analysis, infrastructure deployments and grid modernization, and smart grid and utility platform issues. Mr. Zarakas has authored reports and articles on performance based regulation (PBR), "utility of the future" visions and implementation, and inter-modal competition in the retail electricity sector.

Mr. Zarakas also has a leadership role in Brattle's practice in telecommunications and media. He has provided expert reports and testimonies in a range of regulatory proceedings concerning competition issues in the telecommunications industry, forbearance from price regulation, and price and foreclosure issues potentially associated with mergers among telecom carriers and media companies. He has also developed models concerning the economics and financial feasibility of building-out broadband infrastructure, conducted valuations of a wide range of wireless spectrum bands and holdings, and examined the distribution of royalties and retransmission fees in the cable and satellite television industries.

He has also led special investigations on behalf of corporate boards of directors and audits of management practices and operational and financial performance on behalf of regulatory commissions.

Mr. Zarakas has provided testimony and expert reports before the Federal Communications Commission, the Federal Energy Regulatory Commission, the Securities and Exchange Commission, the Copyright Royalty Judges (Library of Congress), the U.S. Congress, state regulatory agencies, arbitration panels, foreign governments and courts of law.

He holds an M.A. in economics from New York University and a B.A., also in economics, from the State University of New York.

Utility Regulatory and Business Models. Analyzed, advised and/or testified on matters concerning regulatory frameworks, performance-based regulation (PBR) and utility business models, notably with respect to emerging competitive alternatives and network integration. Recent work includes:

- Analyzed implementation of New York's Reforming the Energy Vision by modeling the economics of the utility platform model, access pricing and financial impacts of retail competition on utility.
- Analyzed, advised and/or testified on matters concerning performance incentive mechanism (PIMs); e.g., analyses of: New York's "earnings adjustment mechanisms" on behalf of New York's six investor owned utilities) and performance measures and incentive structures on behalf of the Hawaiian Electric Companies.
- Surveyed and analyzed PBR frameworks and applications, including multi-year rate plans (MRPs), PIMs and other alternative regulatory mechanisms, including the U.K.'s "RIIO" model.

- Surveyed and analyzed regulatory approaches to setting electric distribution reliability standards around the world on behalf of the Australian Energy Market Commission (AEMC).
- Modeled multi-variate "utility of future" scenarios using system dynamic approach on behalf of utilities and industry groups.
- Advised Board of Directors of a major generation and transmission (G&T) cooperative and its member electric distribution cooperatives on matters concerning: asset valuations, risk management strategy, merger and acquisition options, and outlook for retail electric markets.

Infrastructure and Investment Analysis. Analyzed and testified on matters concerning infrastructure economics and financial feasibility. Work includes:

- Led benefit-cost and economic "break-even" analysis of utility system reliability and resilience investment using a value of lost load (VOLL) methodology on behalf of Public Service Electric & Gas Company (PSE&G).
- Developed cost and revenue models to estimate costs, feasibility and customer rates associated with deploying wireless broadband to rural areas on behalf of GCI Communications.
- Conducted financial feasibility analysis concerning deployment of a broadband communications network for an Asian electric utility.
- Analyzed economics and financial feasibility of providing (wholesale) transport and (retail) broadband services for multiple U.S. electric utilities.
- Led comprehensive modeling concerning costs and rates for unbundled network elements (UNEs), undertaken in fulfillment of requirements associated with the Telecommunications Act of 1996, using the Total Element Long Run Incremental Cost (TELRIC) methodology.

Due Diligence, Valuation and Management Audits. Work includes:

- Due diligence of northwestern U.S. electric and gas utility on behalf of buyer; analysis included comprehensive sales, revenue, and operating and capital cost modeling and scenarios.
- Led numerous analyses of the values of wireless spectrum in the U.S., Canada, the Middle East and North Africa (MENA), and other geographic markets. Scope of analyses included: PCS, AWS, 2.3-2.5 GHz, SMR, PLMR, IVDS, MSS and Big Leo spectrum bands, among others, for purposes of planning, transactional analysis, regulatory proceedings, domestic and international arbitration, and commercial litigation.
- Led strategic organizational options analysis for the Board of Trustees of the Long Island Power Authority (LIPA).
- Led special investigations; e.g., economic analysis of "swap" transaction for the Special Committee of the Board of Directors of Global Crossing.
- Led management and/or regulatory audits of utilities and telecommunications carriers on behalf of state regulatory commissions Alabama, Kentucky, Maryland, New York and Pennsylvania.

Competition and Antitrust. Recent work includes:

- Analyzed prospective merger savings and divestiture losses for electric and gas utilities in merger applications before the U.S. Securities and Exchange Commission (SEC).
- Analyzed effectiveness of retail competition in U.S. electricity markets.

- Examined market structure and degree of competition in U.S. retail telecom markets, with regard to Petitions for FCC to forbear from price regulating resale services and UNEs.
- Conducted merger simulation and horizontal and vertical foreclosure analyses for telecom and media mergers; e.g., Comcast-Time Warner Cable; AT&T-Time Warner; Sinclair-Tribune; and, Disney-Fox.
- Led comprehensive analysis of competition in U.S. markets for business data services (BDS, previously referred to as special access).
- Analyzed acquisition price premium in merger of cross-state gas and electric utilities.

Other Regulatory Analyses. Recent work includes:

- Led benchmarking studies of utility costs and regulatory practices.
- Analyzed markets for and costs of providing utility pole attachments.
- Calculated total factor productivity (TFP) and X factors in price regulation proceedings involving utilities before state regulatory commissions and incumbent telecommunications carriers before the FCC.
- Analyzed costs and value of retransmitted television programming in cable and satellite video markets on behalf of Music Claimants in proceedings involving distribution of royalty funds.
- Examined impact of regulatory fees and constraints on economic output in 22 countries in the Middle East and Africa for international mobile carrier.

Expert Testimony

Direct Testimony of William P. Zarakas On Behalf of Public Service Company of Oklahoma Before the Corporation Commission of the State of Oklahoma In the Appication of the Public Service Company of Oklahoma For an Adjustment To Its Rates and Charges and the Electric Service Rules, Regulations and Conditions of Service For Electric Service in the State of Oklahoma, Cause No. PUD 201800085 (September 21, 2018).

Declaration of Joseph Harrington, Coleman Bazelon, Jeremy Verlinda, and William Zarakas Before the Federal Communications Commission In the Matter of Applications of T-Mobile US, Inc. and Sprint Corporation Consolidated Applications for Consent to Transfer Control of Licenses and Authorizations, WT Docket No. 18-197 Petition to Deny of Dish Network Corportation (August 27, 2018).

Declaration of William P. Zarakas Before the Federal Communications Commission In the Matter of Petition of USTelecom for Forbearance Pursuant to 47 U.S.C. § 160(c) to Accelerate Investment in Broadband and Next-Generation Networks WC Docket No. 18-141, Opposition of Granite to USTelecom's Forebearnace Petition (August 6, 2018).

Declaration of William P. Zarakas Before the Federal Communications Commission In the Matter of Petition of USTelecom for Forbearance Pursuant to 47 U.S.C. § 160(c) to Accelerate Investment in Broadband and Next-Generation Networks WC Docket No. 18-141, Opposition of Incompas, FISPA, Midwest Association of Competitive Communications, and the Northwest Telecommunciations Association (August 6, 2018)

Declaration (August 7, 2017) and Reply Declaration (August 29, 2017) of William P. Zarakas and Jeremy A. Verlinda Before the Federal Communications Commission In the Matter of Tribune Media Company (Transferor) and Sinclair Broadcast Group, Inc. (Transferee), Consolidated Applications for Consent to Transfer Control, MB Docket No. 17-179.

Before the State of New York Public Service Commission In the Matter of Earnings Adjustment Mechanism and Scorecard Reforms Supporting the Commission's Reforming the Energy Vision, Case 16-M-0429, On Behalf of the New York Joint Utilities (Central Hudson Gas and Electric Corporation, Consolidated Edison Company of New York, Inc., New York State Electric & Gas Corporation, Niagara Mohawk Power Corporation d/b/a National Grid, Orange and Rockland Utilities, Inc., and Rochester Gas and Electric Corporation), Report: "Assessment of Load Factor as a System Efficiency Earnings Adjustment Mechanism," William Zarakas, Sanem Sergicie, et. al. (February 10, 2017).

Declaration of William P. Zarakas Before the Federal Communications Commission In the Matter of Business Data Services in an Internet Protocol Environment, Investigation of Certain Price Cap Local Exchange Carrier Business Data Services Tariff Pricing Plans, Special Access for Price Cap Local Exchange Carriers, AT&T Corporation Petition for Rulemaking to Reform Regulation of Incumbent Local Exchange Carrier Rates for Interstate Special Access Services, WC Docket No. 16-143, WC Docket No. 15-247, WC Docket No. 05-25, RM-10593. Declaration of William P. Zarakas and Susan M. Gately (January 27, 2016); Supplemental Declaration of William P. Zarakas (March 24, 2016); Declaration of William P. Zarakas and Jeremy Verlinda (June 28, 2016, Attachment D to Comments of Sprint Corporation); Declaration of David E. M. Sappington and William P. Zarakas (June 28, 2016, Attachment E to Comments of Sprint Corporation); Further Supplemental Declaration of William P. Zarakas (August 9, 2016, Attachment A of Reply Comments of Sprint Corporation).

Declaration of William P. Zarakas Before the Federal Communications Commission In the Matter of Verizon Virginia. LLC and Verizon South, Inc., Complainants, v. Virginia Electric and Power Company d/b/a Dominion Virginia Power, Docket No. 15-90, File No. EB-15-MD-006 (November 18, 2015).

Declaration of William P. Zarakas and Matthew Aharonian in the United States Court for the District of Columbia Circuit United States Telecom Association, Petitioner, v. Federal Communications Commission and the United States of America, Respondents, Case No. 15-1063 (and consolidated cases) (May 22, 2015).

Declarations Before the Federal Communications Commission In the Matter of Application of Comcast Corporation, General Electric Company and NBC Universal, Inc. for Comcast to Assign or Transfer Control of Licenses, Federal Communications Commission, MB Docket No. 10-56. Analysis of the FCC's Vertical Foreclosure and Nash Bargaining Models Applied To The Proposed Comcast-Time Warner Cable Transaction (December 21, 2014) and Supplemental Declaration: Analysis of the FCC's Vertical Foreclosure and Nash Bargaining Models Applied To The Proposed Comcast-Time Warner Cable Transaction (March 5, 2015).

Before the Public Utilities Commission of the State of Hawaii, In The Matter of Public Utilities Commission Instituting an Investigation to Reexamine the Existing Decoupling Mechanisms for Hawaiian Electric Company, Inc., Hawaii Electric Light Company, Inc., and Maui Electric Company, Limited, Docket No. 2013-1041, On Behalf of the Hawaiian Electric Companies. Report: "Targeted Performance Incentives: Recommendations to the Hawaiian Electric Companies," Prepared For The Hawaiian Electric Companies, William P. Zarakas and Philip Q Hanser (September 15, 2014).

Before the New Mexico Public Regulatory Commission, In The Matter Of The Application of TECO Energy, Inc., New Mexico Gas Company, Inc. and Continental Energy Systems, LLC, For Approval of TECO Energy Inc.'s Acquisition of New Mexico Gas Intermediate, Inc. and For All Other Approvals and Authorizations Required To Consummate and Implement The Acquisition, Utility Case No. 13-00231-UT, On Behalf of TECO Energy, Inc., New Mexico Gas Company, Inc. and Continental Energy Systems, LLC, Joint Applicants (March 2014).

"Analysis of Benefits: PSE&G's Energy Strong Program," by Peter Fox-Penner and William P. Zarakas Before the New Jersey Board of Public Utilities In the Matter of the Petition of Public Service Electric and Gas Company for Approval of the Energy Strong Program, Docket No. EO13020155 and GO13020156 (October 7, 2013).

"Review and Analysis of Service Quality Plan Structure In The Massachusetts Department of Public Utilities Investigation Regarding Service Quality Guidelines For Electric Distribution Companies and Local Gas Distribution Companies." Philip Q Hanser, David E. M. Sappington and William P. Zarakas, Massachusetts D.P.U. 12-120 (March 2013).

"Alaska Mobile Broadband Cost Model, Before The Federal Communications Commission In The Matter Of Connect America Fund and Universal Service Reform – Mobility Fund. WC Docket No. 10-90 and WT Docket No. 10-208A." William P. Zarakas and Giulia McHenry (February 2013; updated May 2016, with David Kwok).

Expert Report of William P. Zarakas In The United States District Court For The Northern District of Florida MCI Communications Services, Inc., Plaintiff v. Murphree Bridge Corporation, Defendant, Case No. 5:09-cv-337 (February 19, 2010).

Testimony of William P. Zarakas Before The Copyright Royalty Judges, Library of Congress, Washington D.C. In The Matter of Distribution of the 2004 and 2005 Cable Royalty Funds, Docket No. 2007-3 CRB CD 2004-20 (June 1, 2009).

Declaration of William P. Zarakas In The Circuit Court of Fairfax County, Virginia In The Matter of Sharon Dougherty, Plaintiff Vs. Thomas J. Dougherty, Defendant Case No. CL 2007-008757 (October 2008).

Expert report Public Service Company of New Mexico vs. Smith Bagley, Inc. and Lite Wave Communications LLC In The United States District Court For The District of New Mexico (March 2007).

Attention: Bill Zarakas and Sanem Sergici

Dear Sirs/Mesdames

Re: British Columbia Hydro & Power Authority ("BC Hydro") Application to the British Columbia Utilities Commission ("Commission") for Approval of Revenue Requirements and Rates for Fiscal 2020 (the "Regulatory Proceeding")

As you are aware, we act on behalf of BC Hydro in the above referenced Regulatory Proceeding. This letter of instruction confirms your engagement for the provision of an independent expert report to be introduced into evidence in that Regulatory Proceeding. It outlines the issues to be addressed and provides some general guidance as to the format of your report.

Apart from our instructions below as to the issues to be addressed and the format of your report, the contents of your report are entirely for you in the exercise of your independent professional judgment. We are retaining you to provide independent expert evidence for the above captioned Regulatory Proceeding, not as an advocate for our client. The integrity of your conclusions is dependent upon your objectivity.

<u>Matters on Which Your Opinion is Requested</u>

We request that your report set out your independent objective opinion with respect to the following questions:

1. What would be the appropriate metrics for benchmarking BC Hydro's overall base operating costs and why?

2. What would be an appropriate representative peer group for benchmarking BC Hydro's base operating costs and why?

FASKEN

3. What data is available from the selected peer group on the selected metrics over the last three or five years?

4. What methodology should be used to normalize the data and benchmark BC Hydro's base operating costs against its peer group?

5. What are the results of this normalization and benchmarking analysis?

In order to facilitate your analysis and the preparation of your report, BC Hydro is making available information, e.g., on its costs and operations, that you request. You can assume, for the purposes of your analysis, that information provided by BC Hydro is accurate.

Overview of the Structure of Your Report

We request that your independent expert report be set out consistently with the following structure.

A. Introduction and Summary of Opinion

Your introduction should

- reference the nature of your engagement as an independent expert as per this letter,
- identify the questions posed to you, and
- set forth, in a summary fashion, your independent objective opinions on each question.

B. Qualifications

Please state your professional qualifications, technical education, training and experience. Explain how your expertise relates to the subject matter of your opinions. Your detailed *curricula vitae* should be attached as an appendix.

C. Duty of Independence

We confirm that you have a duty to assist the Commission and are not to be an advocate for any party ("Duty of Independence"). In this section of your report, we require that you certify the following:

- You are aware of your Duty of Independence,
- You have prepared your report in accordance with the Duty of Independence, and
- If called to give oral or written testimony, you will give that testimony in conformity with the Duty of Independence.

D. Issues

FASKEN

This section should set out the issues as posed in this letter.

E. Discussion

Under this heading, you should set out in full your independent objective opinions in the same order that the issues are presented. You should provide the reasons for your opinions including reference to pertinent facts or assumptions, any research you conducted that led you to form the opinion, and any applicable technical or other documents, standards, guidelines, etc.

F. Conclusion

You may provide a conclusion if you wish.

Appendices

Please include this letter, and the *curricula vitae* of those people responsible for the content of your report, as appendices to your report. If additional instructions are required, then supplementary letters of instruction from us should also be attached to your report. You may attach other documents or schedules that elaborate on, or are integral to your analysis.

In conclusion, if you have any questions with respect to the nature and scope of your engagement, please contact the writer at your soonest convenience.

Yours truly,

FASKEN MARTINEAU DuMOULIN LLP

Appendix C:

Determination of U.S. Peer Panel for BC Hydro

1. Tables C1 through C4 below show the full list of U.S. Investor Owned Utilities that were screened to determine BC Hydro's peer panel. Sources and notes for all four tables are included on the last page of this attachment.

2. Utilities in navy blue are the peer group that was determined from the initial benchmarking screen—these utilities are vertically integrated and had total sales greater than 20 TWh in 2017. I also include three utilities that do not fit one of the two criteria above but own a generation fleet that contains a significant percentage of hydro. These utilities are shown in light blue in the tables below. Avista Corp and Idaho Power Co have sales that are somewhat lower than 20 TWh (9 TWh and 15 TWh, respectively), but are vertically integrated, with hydro making up around 50% of total owned capacity. Pacific Gas & Electric Co is not vertically integrated, but has total sales of 62 TWh (comparable to BC Hydro's total sales of 57 TWh), with hydro again making up around 50% of total owned capacity.

Table C1: Peer Panel Screening – 1

		Initial Screening Characteristics		
Utility	State	Vertically Integrated	Total Sales *TWh*	Owned Hydro Capacity *% Total*

Sources and Notes:

Utilities in this list are Investor Owned Utilities have 2017 Sales, Customer, and Generation data available; “n/a” (in light gray) indicates missing capacity data. Utility characteristics are reported for 2017.

For utilities that have a service territory that spans more than one state, the state with the highest 2017 sales has been listed, based on data from 2017 EIA 861 Schedule 4, downloaded from Velocity Suite. A utility is generally assumed to be vertically integrated if it is located in a state that has a regulated electricity market (based on information from Energywatch, available here: https://energywatch-inc.com/regulated-vs-deregulated-electricity-markets/), although Appalachian Power Co and Virginia Electric & Power Co were determined to be vertically integrated based on information reported on the utility websites. Total Sales is from 2017 EIA 861 Schedule 4, downloaded from Velocity Suite. Owned Hydro Capacity is calculated by The Brattle Group, based on data from 2017 EIA 860, downloaded from Velocity Suite.

Appendix D:

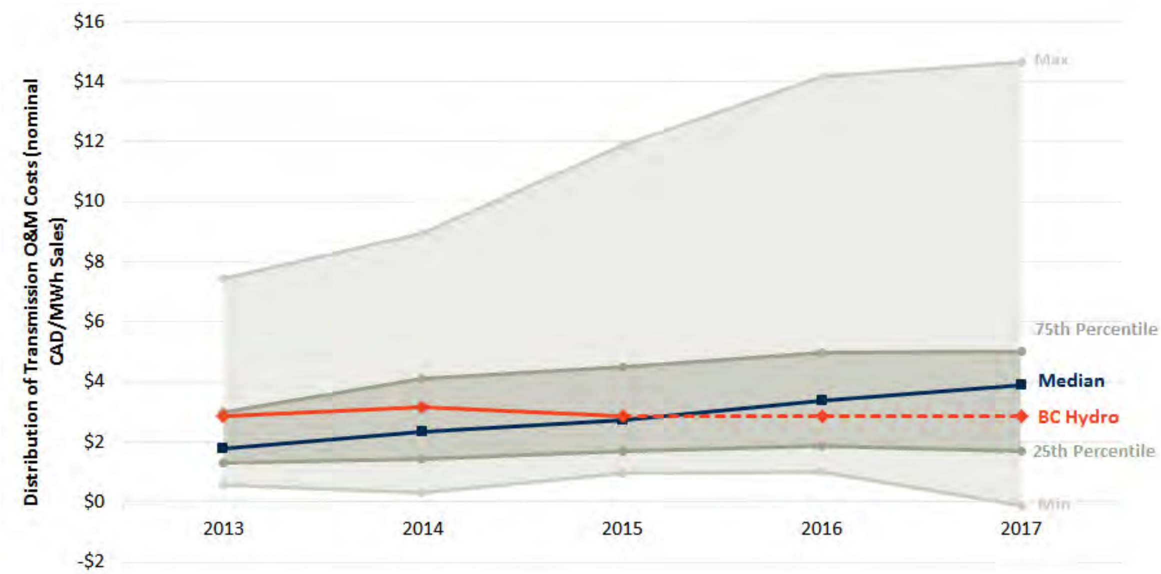
Detailed NFOM Cost Benchmarking for Non-Power Production Costs

1. This Appendix presents the benchmarking results for several more granular measures of NFOM, which together comprise the non-power production costs that are discussed in Section VI.A. of my report. The more granular measures presented here correspond to the functional categories used in USoA accounting.

A. Transmission O&M Costs

2. BC Hydro's cost performance with respect to Transmission O&M costs (which includes Transmission and Regional Market expenses) per delivered MWh and per customer are shown in Figures D1 and D2. Transmission O&M accounts for roughly 15% of BC Hydro's total NFOM costs. The O&M expenses that are included in the Transmission functional category include all of the O&M expenses in the USoA accounts for Transmission, as well as about half of the USoA accounts for Regional Market expenses.[1]

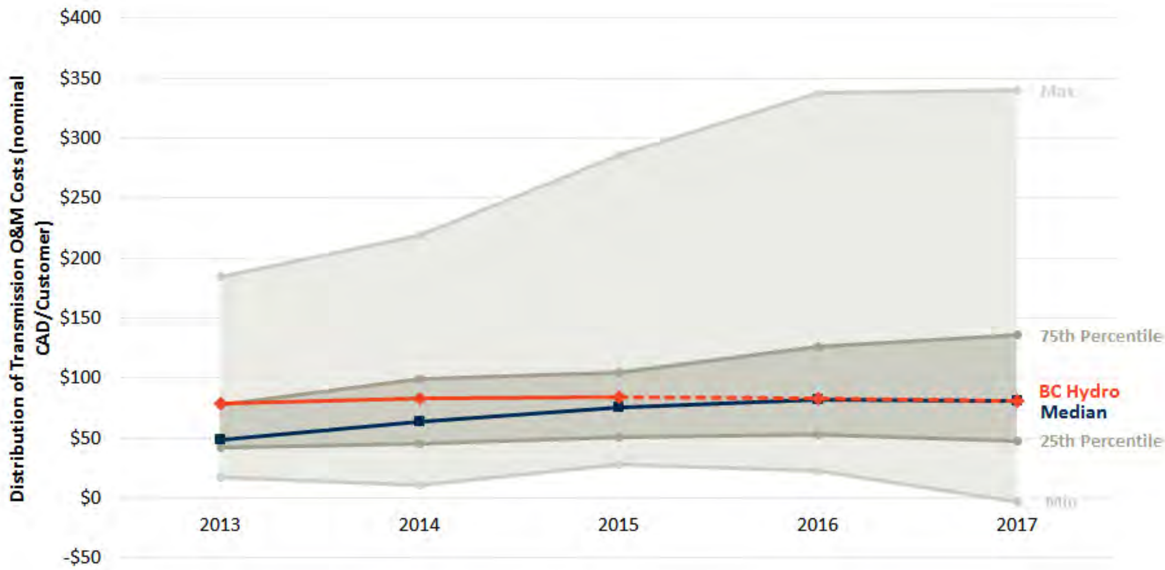
Figure D1: Transmission NFOM Benchmarking ($ per Delivered MWh)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (pp. 321–322) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

[1] The excluded accounts are Regional Market 575.6–575.8 and 576.1–576.5. These accounts include costs associated with market monitoring and compliance; less than half of the U.S. panel has incurred these costs. The remaining excluded accounts pertain to maintenance of regional market structures and equipment, but none of the peer group members has reported costs in these maintenance accounts.

Figure D2: Transmission NFOM Benchmarking ($ per Customer)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 321–322) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

3. BC Hydro's Transmission O&M costs per delivered MWh declined over the course of the study term, starting out in the third quartile and dropping after 2015, to the second quartile on a per delivered MWh basis, and to the median on a per customer basis.

4. Inspection of the figures indicates that the transmission NFOM cost for one of the utility in the panel peer group (Virginia Electric Power Company, or VEPCo) is negative in 2017.[2] This is the result of a negative accounting in USoA account 566 (Misc. Transmission Expenses), and likely reflects accounting adjustments and/or transfers. Other utilities in the panel have reported such negative values in the data set. Excluding VEPCo and/or other negative accounting from the peer data set would place BC Hydro in a more preferential position in the benchmarking study. I have elected to use the data set without such adjustments in order to avoid selection bias. In effect, using the data set on an unadjusted basis provides a conservative indicator of BC Hydro's comparable cost position.[3]

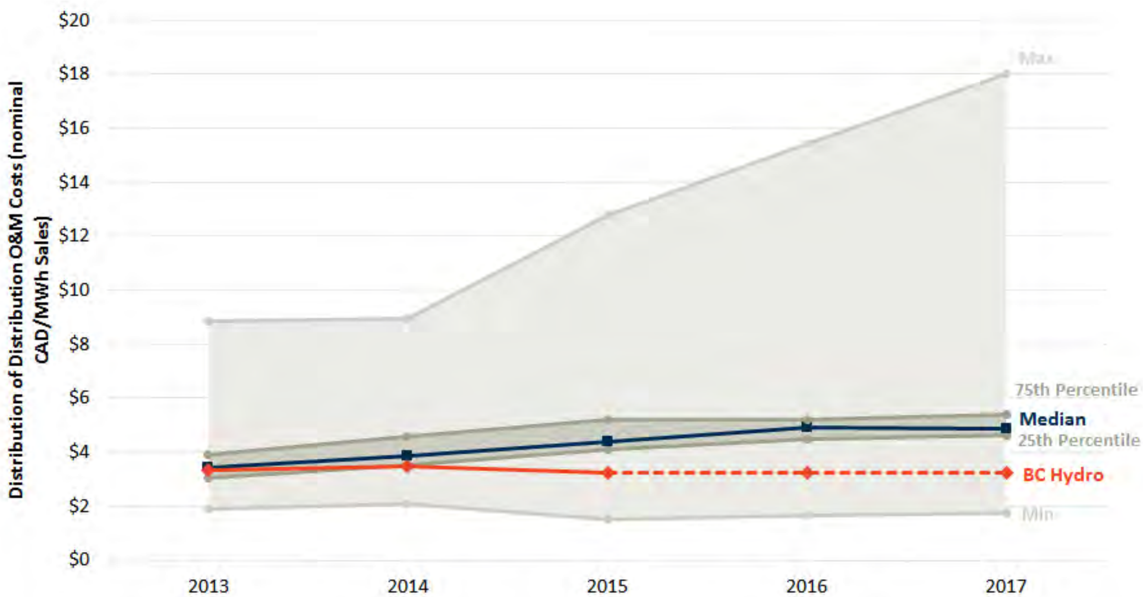
[2] Virginia Electric Power Company (VEPCo) is referred to as Dominion Energy or Dominion Virginia Power.

[3] Note that it is possible to exclude the affected utilities and/or data from benchmarking results without compromising the cost benchmarking study.

B. DISTRIBUTION O&M COSTS

5. Figures D3 and D4 show BC Hydro's Distribution NFOM costs on a per delivered MWh and per customer basis compared to the selected peer panel for 2013 to 2017. Distribution O&M accounts for roughly 17% of BC Hydro's total NFOM costs. The costs in this functional cost area include all of the O&M expense accounts included in the USoA for Distribution.[4]

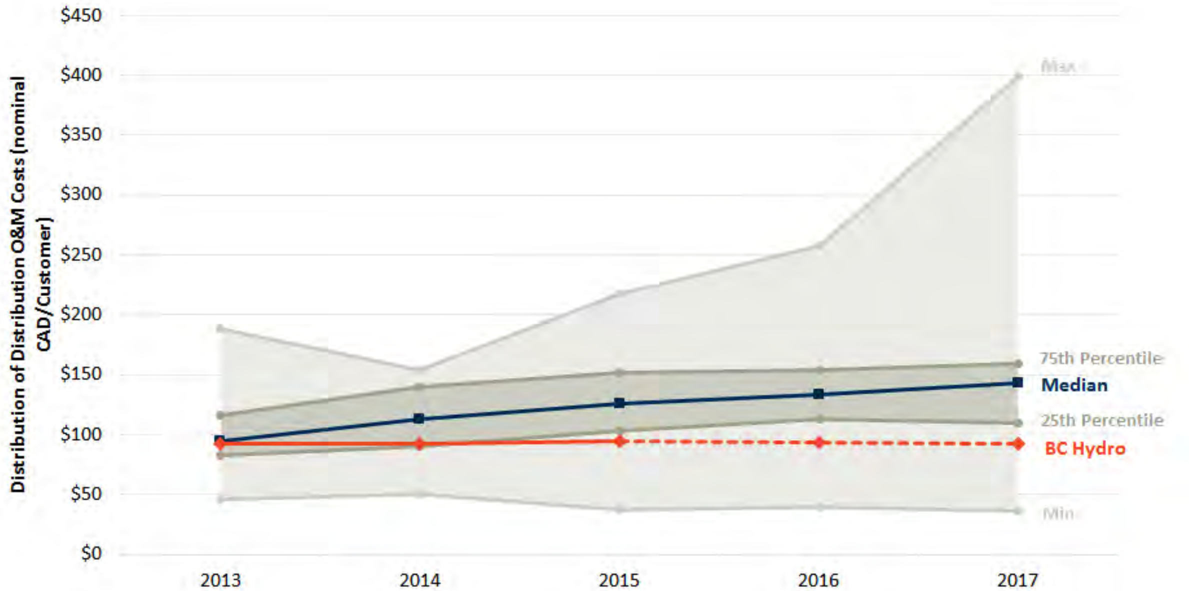
Figure D3: Distribution O&M Cost Benchmarking ($ per Delivered MWh)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 322) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

4 These are made up of USoA accounts 580–598.

Figure D4: Distribution O&M Cost Benchmarking ($ per Customer)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 322) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

6. As the figures indicates, BC Hydro's Distribution NFOM (on both a $ per delivered MWh $ per customer basis) are in the first and second quartile for the years under study, and were consistently in the first quartile after 2014.

C. CUSTOMER-FACING O&M COSTS

7. The O&M expenses that are included in the Customer-Facing functional category include all of the O&M expenses in the USoA accounts for Customer Accounts Expenses, Customer Service and Informational Expenses, and Sales Expenses.[5] These costs account for roughly 8% of BC Hydro's total NFOM costs.[6] Figures D5 and D6 show BC Hydro's Customer-Facing O&M costs compared to those of the selected U.S. peer panel for 2013 to 2017 on a $ per delivered MWh and $ per customer basis.

[5] These accounts are Customer Accounts 901-905; Customer Service and Informational 907–910; and Sales 911–913 and 916.

[6] In 2015, BC Hydro's Customer-Facing costs are equal to

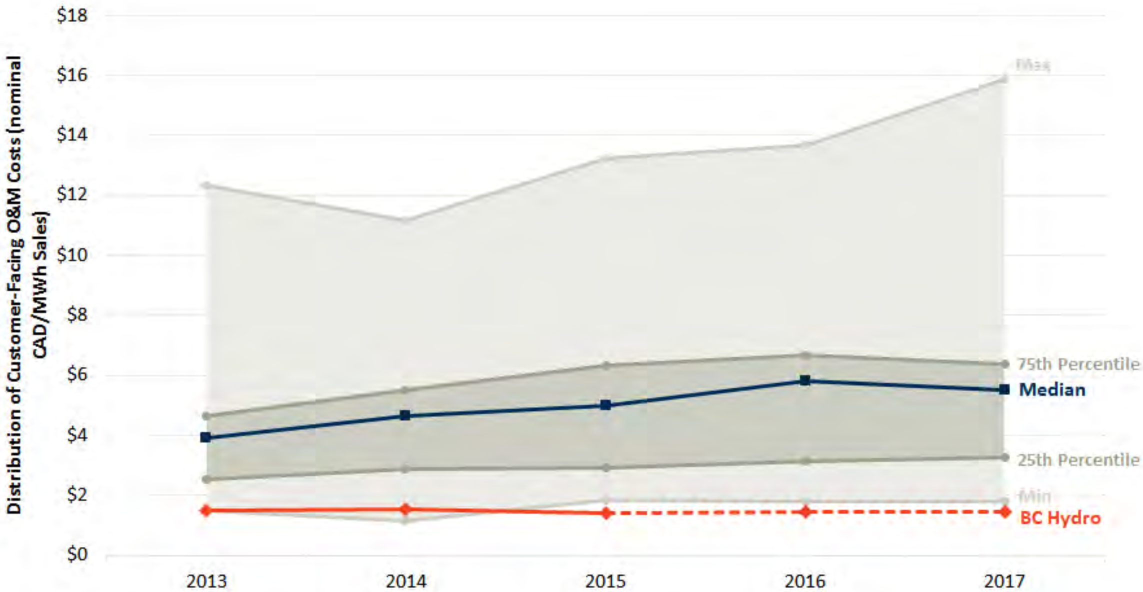
$81M = $75M (Customer Accounts) + $6M (Customer Service and Informational) + $0 (Sales).

BC Hydro's total NFOM in 2015 equals $1,062M. Therefore, the Customer-Facing cost share of total NFOM is equal to

8% = $81M / $1,062M.

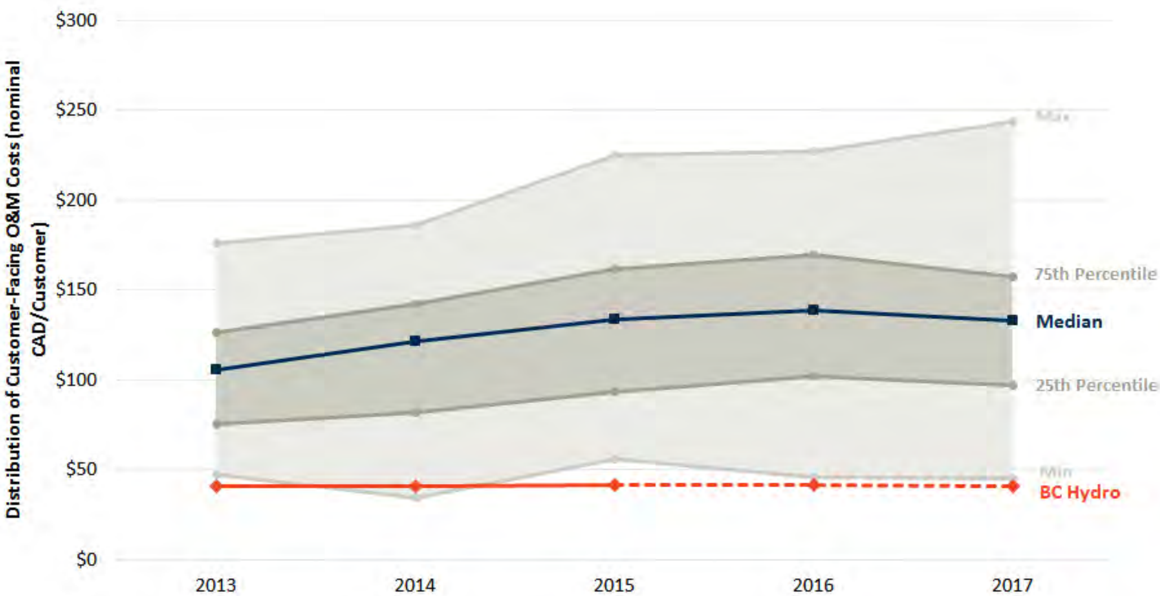
Customer-Facing expenses accounted for about 8% of total NFOM in 2013 and 2014 as well.

Figure D5: Customer-Facing O&M Cost Benchmarking ($ per Delivered MWh)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (pp. 322–323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

Figure D6: Customer-Facing O&M Cost Benchmarking ($ per Customer)

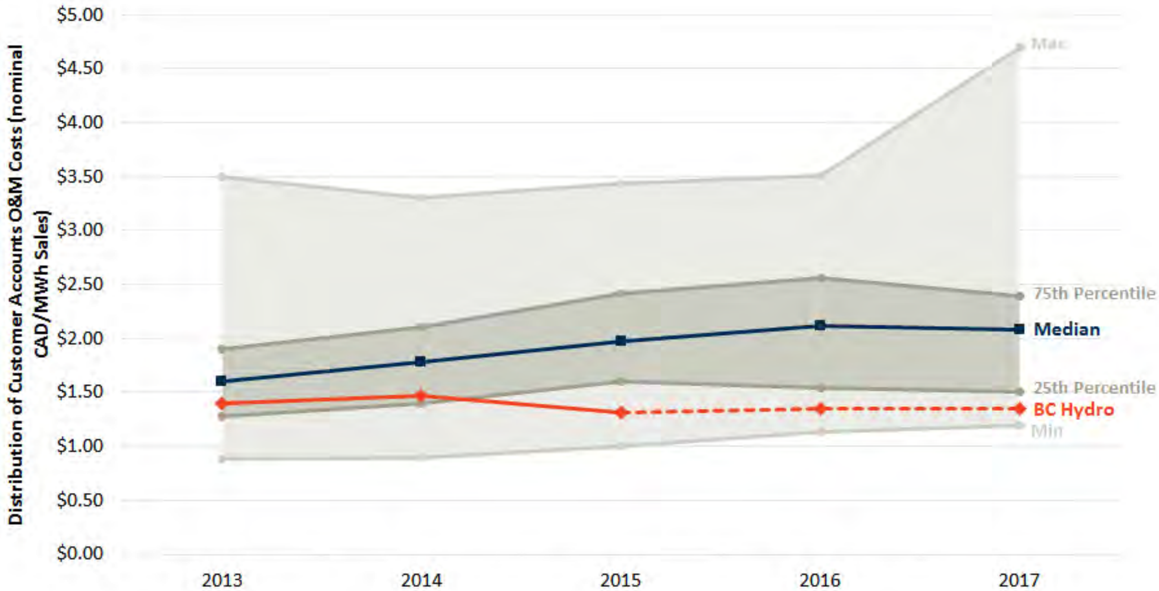


Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (pp. 322–323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

8. The figures indicates that BC Hydro's Customer-Facing costs have consistently been either at or below the minimum of the peer group. I have found that utilities do not necessarily report these costs in a consistent manner. For example, it is common for some utilities to not record any costs in the Sales functional cost area. In order to account for these inconsistencies in accounting for Customer-Facing costs, I examined

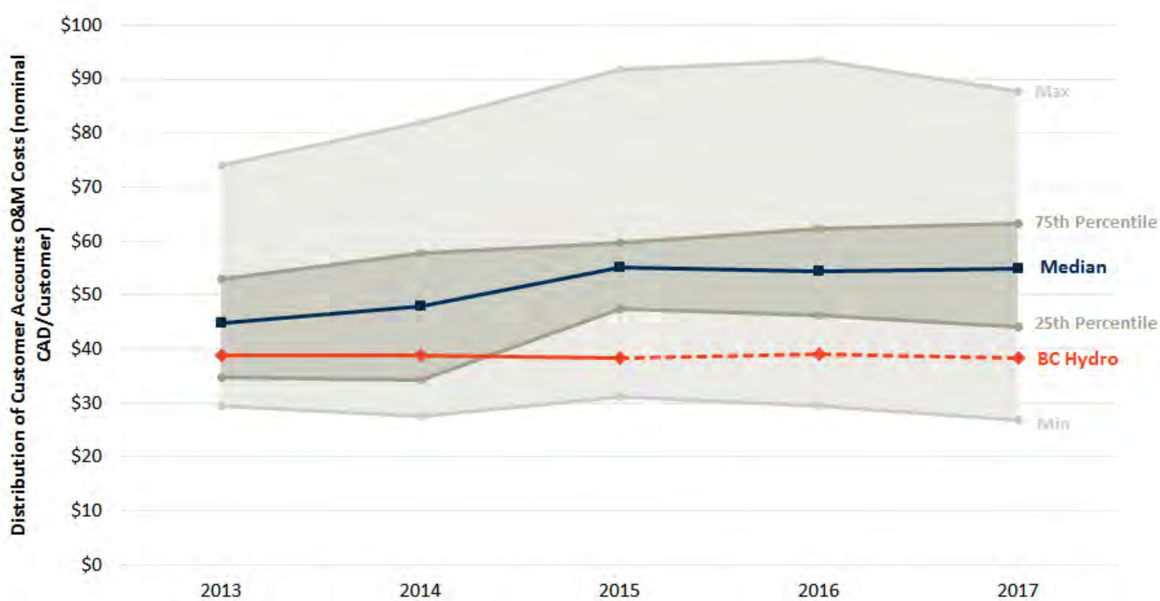
the functional cost areas that make up the broader Customer-Facing area below. Figures D7 and D8 shows cost benchmarking for the Customer Accounts; Figures D9 and D10 for Customer Service and Informational; and Figures D11 and D12 for Sales, all on a $ per delivered MWh and a $ per customer basis.

Figure D7: Customer Accounts O&M Cost Benchmarking ($ per Delivered MWh)



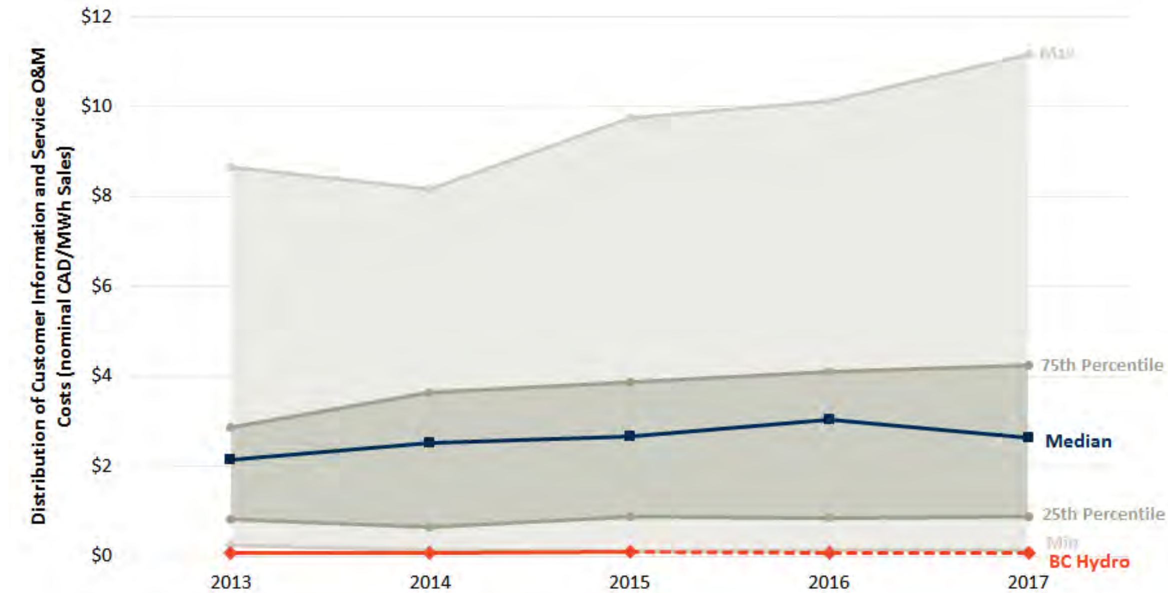
Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 322) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

Figure D8: Customer Accounts O&M Cost Benchmarking ($ per Customer)



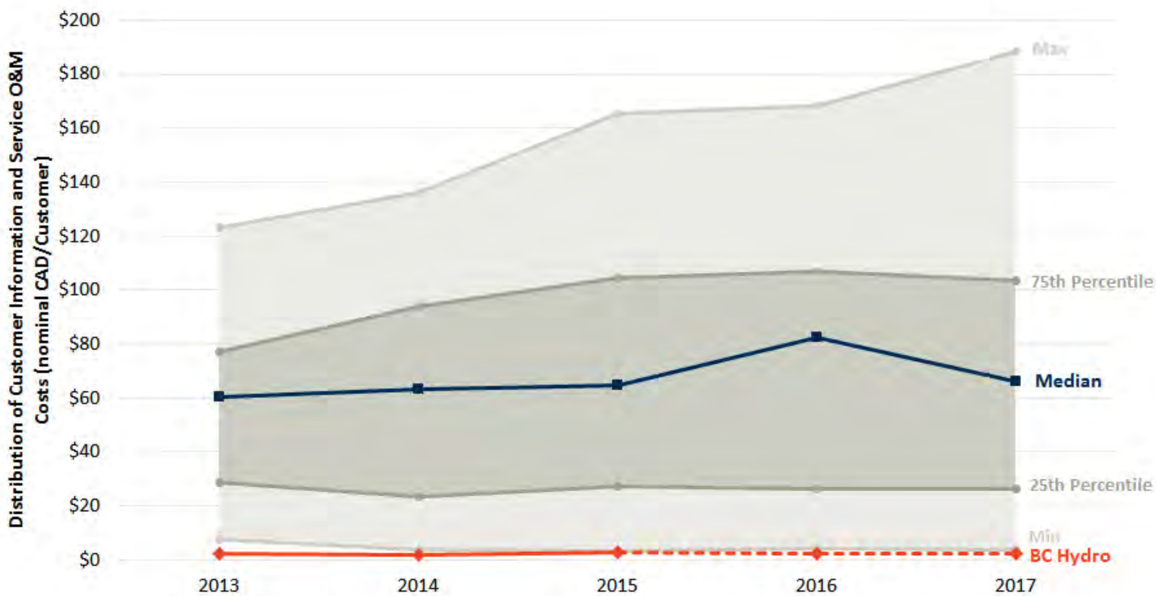
Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 322) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

Figure D9: Customer Service and Informational O&M Cost Benchmarking ($ per Delivered MWh)



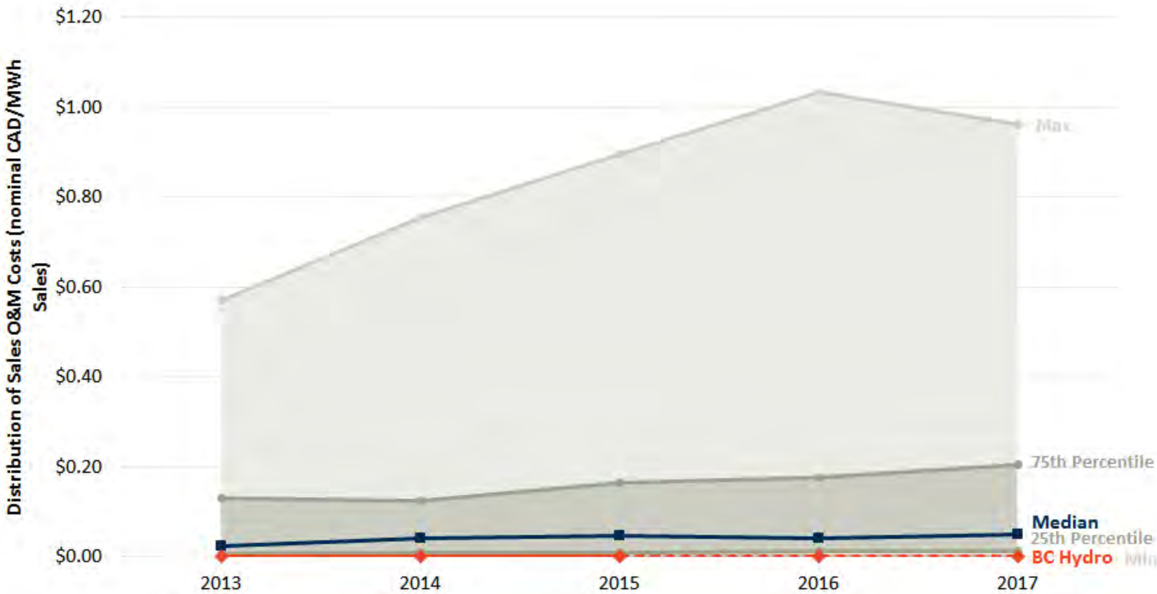
Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

Figure D10: Customer Service and Informational O&M Cost Benchmarking ($ per Customer)



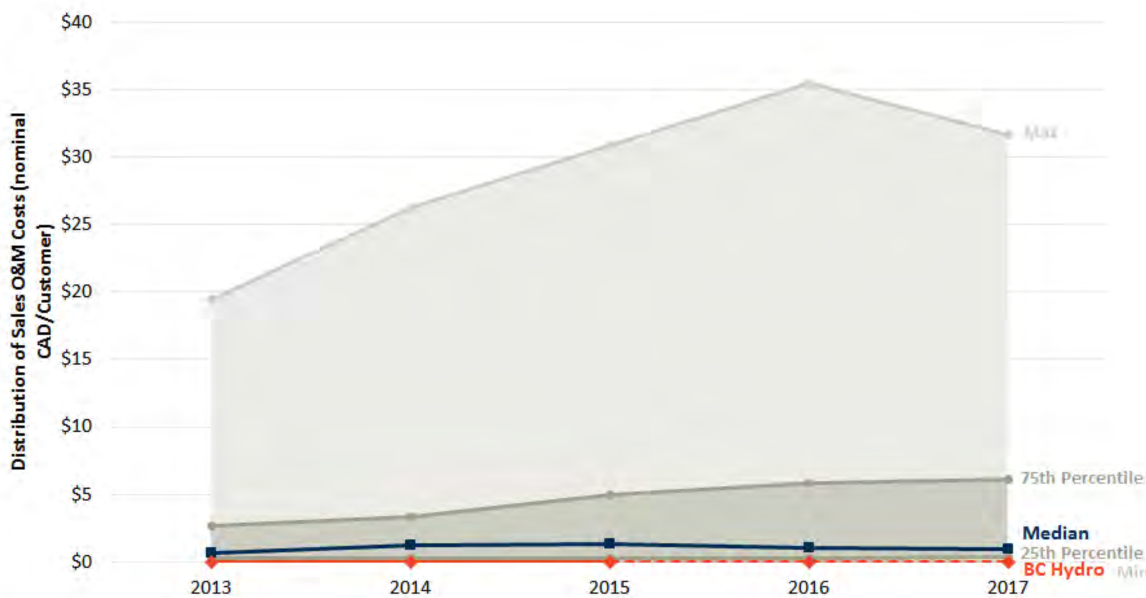
Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

Figure D11: Sales O&M Cost Benchmarking ($ per Delivered MWh)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

Figure D12: Sales O&M Cost Benchmarking ($ per Customer)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

9. A closer look at the Customer-Facing accounts indicates that several utilities in the panel (as well as BC Hydro) record very little or no expenses to the Customer Service and Informational and/or Sales functional cost areas. Expenses appear to be more consistently reported for Customer Accounts, which includes the costs of meter

reading, customer records and collection, and uncollectible accounts.[7] Figures D7 and D8 indicate that BC Hydro's Customer Accounts O&M costs, which in BC Hydro's case represent the largest portion of the Customer-Facing O&M costs, are within the range of the first quartile on both a $ per delivered MWh and $ per customer basis. For example, in 2015 BC Hydro's per delivered MWh cost in this functional area was $1.31/MWh, between the peer group minimum of $1.01/MWh and the 25th percentile of $1.60/MWh.[8]

10. Figures D9 and D10 show that BC Hydro is just below the minimum of the peer group with respect to Customer Service and Informational O&M costs on both a $ per delivered MWh and $ per customer basis. For example, in 2015 BC Hydro's per delivered MWh cost in this functional area was $0.10/MWh, whereas the peer group minimum was $0.11/MWh.[9] Finally, with respect to Sales O&M, BC Hydro does not classify any costs in these accounts, though it is not alone in doing so; six of the peer group utilities either failed to report costs in these accounts or reported costs so low that they amounted to less than $0.01 per delivered MWh.[10]

D. Administrative and General O&M Costs

11. Figures D13 and D14 show BC Hydro's Administrative and General O&M costs compared to those of the selected U.S. peer panel for 2013 to 2017 on a $ per delivered MWh and $ per customer basis. Administrative and General O&M accounts for roughly 41% of BC Hydro's total NFOM costs. The O&M expenses that are included in the Administrative and General functional category used in this benchmarking

7 These cover USoA accounts 901–905.

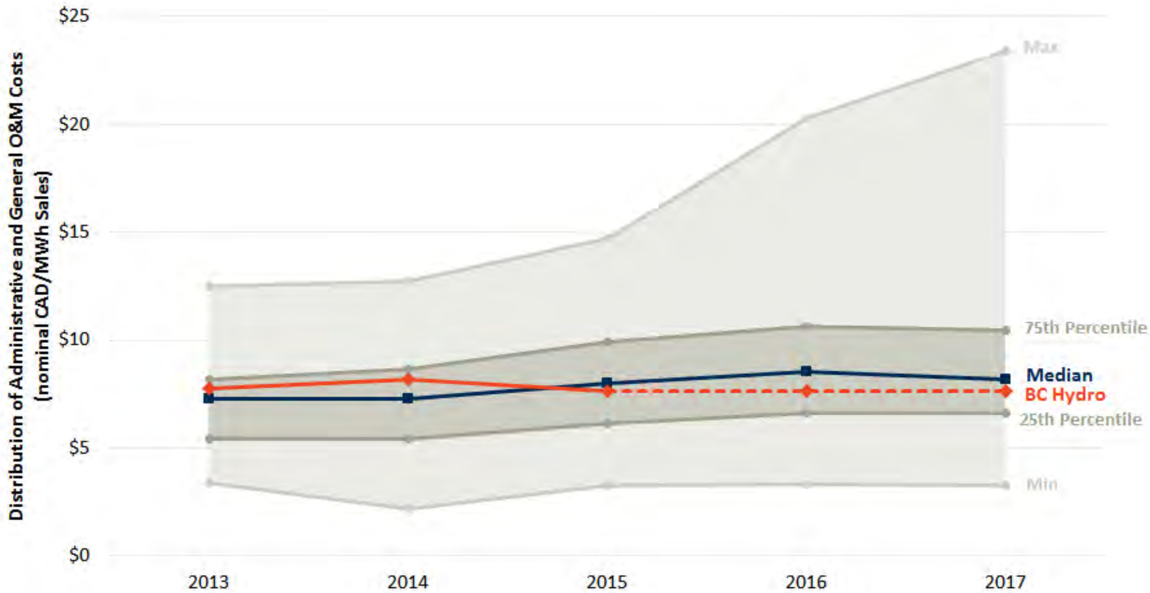
8 For both BC Hydro and the vast majority of the peer utilities, the largest of the Customer Accounts is Account 903 – Customer Records & Collection Expenses. In 2015, BC Hydro spent $27M in this account. However, the majority of U.S. peer utilities spent more; the peer group median was $35M. Similarly, many U.S utilities spent considerably more in Account 904 – Uncollectible Accounts. This is consistent with one of the possible explanations offered by BC Hydro for their stellar performance in this area; namely, that BC Hydro's unusually high smart meter penetration allows for remote service disconnection and reconnection, which facilitates better collections. Note that I have not independently compared BC Hydro's smart meter penetration with that of the U.S. peer group.

9 For the majority of peer group utilities, the account within Customer Service and Informational Expenses O&M that has the largest costs is Account 908 – Customer Assistance Expenses.

10 For the majority of peer group utilities, the account within Sales O&M that has the largest costs is Account 912 – Demonstrating and Selling Expenses.

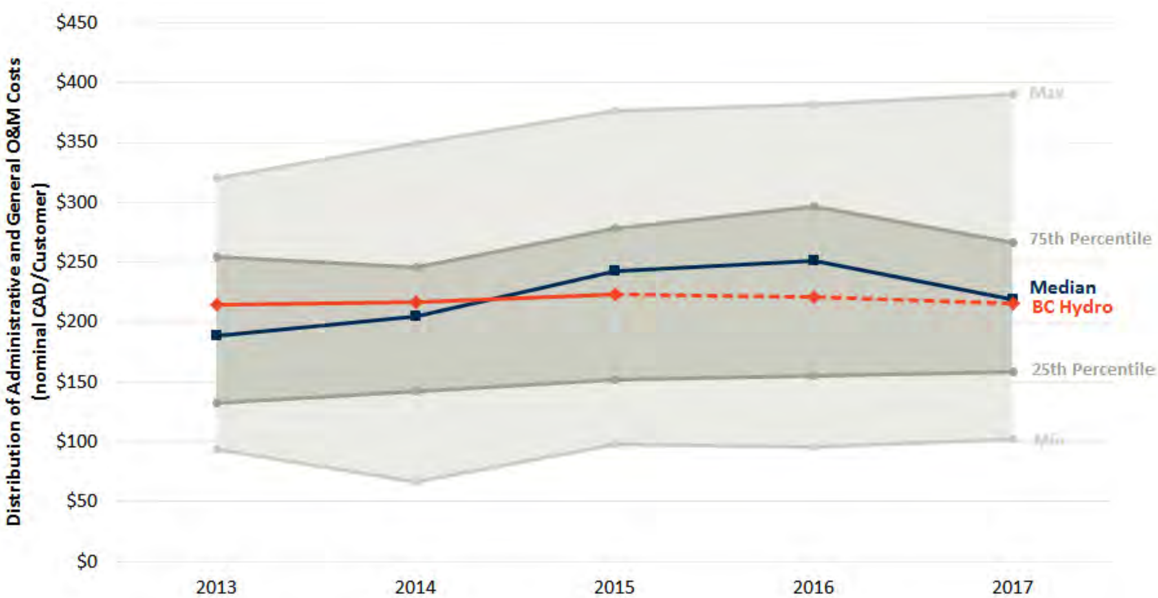
analysis include most of the O&M expenses in the USoA Administrative and General account.[11]

Figure D13: Administrative and General O&M Cost ($ per Delivered MWh)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

Figure D14: Administrative and General O&M Cost ($ per Customer)



Sources: Calculations by The Brattle Group. Values for BC Hydro are based on 2013–2015 USoA data, 2016–2017 total NFOM data, and 2013/14–2017/18 Annual Reports provided by BC Hydro. Values for the U.S. peer panel are based on 2013–2017 FERC Form 1 data (p. 323) and EIA 861 Schedule 4 data, downloaded from Velocity Suite.

[11] This includes USoA accounts 920–926, 928–929, 930.1–930.2, 931, and 935. The only excluded account is 927, which reports costs associated with franchise requirements.

12. BC Hydro’s Administrative and General costs are fairly comparable with those of the peer group, i.e., costs in this category have been similar to the median of the peer group. BC Hydro moved from the third quartile to the second quartile of the peer group in 2015.

	F2015	563	32,269	**17.45**	561,869	**1,002.01**
	F2014	491	32,875	**14.94**	555,760	**883.47**

1. Per Manitoba Hydro's Annual Report (above data reported for electric business area including subsidiaries). IFRS based financial statement except for fiscal 2014 (CGAAP).
2. Operating & Administrative Costs have been restated to net view for comparability, based on the information available. (Maintenance costs along with technology, consulting costs, DSM expenditures, restructuring and miscellaneous costs are included within the consolidated amount for "Other Expenses" on the I/S; these costs have either been included/excluded, based on best effort, in order to provide comparability to BC Hydro operating costs).
3. Extraprovincial sales includes Canadian and US export sales (export contracts and sales based on excess energy).
4. Results based on fiscal year reporting.

Hydro Quebec [1,2]	Calendar Year	Operating Costs ($ million) [1,3]	(Domestic + Export) [1,4]	$/unit of sale (MWh)	Customers (Domestic)[1]	$/customer
	2018			-		-
	2017	2,342	205,638	**11.39**	4,279,496	**547.26**
	2016	2,438	201,989	**12.07**	4,244,541	**574.38**
	2015	2,527	201,127	**12.56**	4,214,721	**599.57**
	2014	2,366	200,847	**11.78**	4,179,850	**566.05**

1. Per Hydro Quebec's Annual Report. Includes subsidiary costs.
2. Financial Statements are prepared using US GAAP in Canadian dollars.
3. Operating Costs reported on a net basis. Includes operations expenditures net of 'other components of employee future benefit costs'. However, detail breakdown of these costs is not available in the annual report, hence may include costs other than operating, maintenance and administrative costs. Adjustments, based on best effort, have been made to provide costs that are comparable to BC Hydro's operating costs.
4. Export sales includes sales to New England 57%, New York 23%, Ontario 15%, New Brunswick 6% and Other 4%.
5. Results based on calendar year reporting.

FortisBC Inc. (electricity) [1,2]	Calendar Year	Operating Costs ($ million) [3]	Sales (GWh) [1,5]	$/unit of sale (MWh)	Customers[1,4]	$/customer
	2018			-		-

December 11, 2018

Hon. Michelle Mungall
Minister of Energy and Mines and
Petroleum Resources
PO Box 9060 Stn Prov Govt
Victoria BC V8W 9E3

Dear Minister Mungall:

**RE: British Columbia Hydro and Power Authority (BC Hydro)
Electricity Rate Comparison Annual Report No. 11**

BC Hydro writes to file its Electricity Rate Comparison Annual Report (**Report**) which provides a comparison of BC Hydro's monthly bills and average prices for residential, commercial and industrial customers with other North American utilities as of April 1, 2018 (**Attachment A**). The comparison includes BC Hydro's 3.0 per cent rate increase that was effective on that date. The report is prepared in response to *Clean Energy Act* section 8(4), which states that:

> "The authority must provide to the minister, in accordance with the regulations, an annual report comparing the electricity rates charged by the authority with electricity rates charged by public utilities in other jurisdictions in North America, including an assessment of the extent to which the authority's electricity rates continue to be competitive with those other rates."

This Report adheres to the Province of British Columbia's Rate Comparison Regulation (Ministerial Order No. M167) (**Attachment B**). The Rate Comparison Regulation requires that the Report provide a comparison of BC Hydro's monthly electricity bills with at least one public utility in each of at least 15 other North American jurisdictions, including all of the following: the provinces of Alberta, Quebec, Ontario and Manitoba; and the states of Washington, Oregon and California. The comparison uses the previous year's applicable rates for residential, commercial and industrial customers in Canadian funds. In addition, it provides the previous five years of applicable rates for BC Hydro.

The Report consists of information taken from the Hydro-Quebec rate survey report titled "*Comparison of Electricity Prices in Major North American Cities*". The Hydro-Quebec report is prepared each year. Monthly bills and average prices are calculated and submitted to Hydro-Quebec by the participating utilities, including

BC Hydro, using the rates that are in place as of April 1 of that current year. Accordingly, some of the rates used may be interim rates that are approved and in effect at that time.

The 2018 Report indicates that BC Hydro's monthly bills and average prices for all power categories are in the first (i.e., lowest rate) quartile of the public utilities surveyed. On average, BC Hydro's residential rates are third lowest. BC Hydro's small power rates (defined as less than 100 kilowatts (**kW**)) are fifth lowest, medium power rates (defined as 100 kW to 5,000 kW) are fourth lowest, and large power rates (defined as greater than 5,000 kW) are fifth lowest. Applicable BC Hydro rates for each category are listed in Table 11 of Attachment A.

For further information, please contact Fred James at 604-623-4317 or by email at bchydroregulatorygroup@bchydro.com.

Yours sincerely,

Ken Peterson
Executive Chair

BC Hydro Electricity Rate Comparison
Annual Report

Report No. 11

Attachment A

Rates as at April 1, 2018

Table of Contents

List of Tables

Monthly Bills and Average Prices as at April 1, 2018

This is the eleventh Electricity Rate Comparison Annual Report (**Report**) prepared by BC Hydro in response to the Rate Comparison Regulation, issued by Ministerial Order No. M167 under the *Clean Energy Act* on June 28, 2011.[1] The Report provides a comparison of BC Hydro's monthly bills and average prices for residential, commercial and industrial customers with other North American utilities, including those in Alberta, Quebec, Ontario, Manitoba, Washington, Oregon and California in Canadian funds.[2]

Each year BC Hydro participates in the Hydro-Quebec rate comparison survey, submitting bill calculations based on electricity prices that are in place as of April 1 of the current year, and which may reflect approved interim rate increases. Hydro-Quebec compiles the information and provides the monthly bills and average prices for 12 Canadian utilities and 10 American utilities in an annual report. The Report provides survey information taken from the Hydro-Quebec report entitled *Comparison of Electricity Prices in Major North American Cities*.[3]

The Hydro-Quebec report provides the monthly bills, excluding taxes and non-utility levies, calculated for specific consumption points for four different customer segments: residential, small power, medium power and large power. The average price is also calculated, for each customer segment and specific consumption point, by dividing the monthly bill by the amount of monthly energy consumption. For example, if an electric bill for 1,000 kWh was calculated to be a monthly amount of $50, the average price would be $50 divided by 1,000 kWh, or 5 cents/kWh.

1 The first Electricity Rate Comparison Annual Report was issued on June 10, 2009 in response to Ministerial Order No. M114, which was subsequently replaced by Ministerial Order No. M167.

2 Monthly bills and average prices for American utilities have been converted to Canadian dollars using the exchange rate as at 12 p.m. Eastern on April 1, 2018 of $0.7747 (C$1 = US$0.7747). The Canadian dollar had depreciated by 3.74 per cent relative to the U.S. dollar since April 1, 2017.

3 [Hydro Quebec Comparison of Electricity Prices in Major North American Cities Report.]

The monthly bills for customers are presented in Table 1, Table 2, Table 3 and Table 4. The average prices for customers are presented in Table 5, Table 6, Table 7 and Table 8. BC Hydro's monthly bills and average prices over the past five years are summarized in Table 9 and Table 10.

The Hydro-Quebec residential segment includes calculations for BC Hydro's residential customers. The Hydro-Quebec small power segment includes calculations for BC Hydro's general service under 100 kW customers, while the medium power segment includes calculations for BC Hydro's general service 100 kW to 5,000 kW customers. Lastly, the Hydro-Quebec large power segment includes calculations for BC Hydro's general service and transmission service customers who are 5,000 kW and over. Table 11 shows the specific BC Hydro rate schedules that have been included in each Hydro Quebec segment. Table 12 summarizes BC Hydro's relative rankings in each rate class during the last five years of participation in the survey.

Based on the data from the Hydro-Quebec survey, BC Hydro's monthly bills and average prices for the residential, small, medium and large power categories are in the first (i.e., lowest rate) quartile of the public utilities surveyed. These low rates provide a competitive advantage to these customer segments in BC Hydro's service area. The rankings of the top five participating utilities, including BC Hydro, with the lowest monthly bills and average prices are noted in Tables 1 to 8. Of the 22 utilities providing data, BC Hydro's monthly bills and average price rankings against the other utilities are as follows:

Rate Class & Usage	Ranking at April 1, 2018
Residential	
Residential - 625 kWh	3
Residential - 750 kWh	3
Residential - 1,000 kWh	3
Residential - 2,000 kWh	7
Residential - 3,000 kWh	8
Small Power	
Small Power - 750 kWh/6 kW	8
Small Power - 2,000 kWh/14 kW	6
Small Power - 10,000 kWh/40 kW	5
Small Power - 14,000 kWh/100 kW	5
Small Power - 25,000 kWh/100 kW	6
Medium Power	
Medium Power - 100,000 kWh/500 kW	4
Medium Power - 200,000 kWh/500 kW	3
Medium Power - 200,000 kWh/1,000 kW	4
Medium Power - 400,000 kWh/1,000 kW	4
Medium Power - 1,170,000 kWh/2,500 kW	4
Large Power	
Large Power - 2,340 MWh/5,000 kW/25 kV	4
Large Power - 3,060 MWh/5,000 kW/25 kV	3
Large Power - 5,760 MWh/10,000 kW/120 kV	4
Large Power - 17,520 MWh//30,000 kW/120 kV	5
Large Power - 23,400 MWh/50,000 kW/120 kV	5
Large Power - 30,600 MWh/50,000 kW /120 kV	5

1) Customer-owned transformer.
2) These bills have been estimated by Hydro-Québec and may differ from actual bills.
3) Bills corresponding to consumption levels of 500 kW or more have been estimated by Hydro-Québec based on the applicable general rate.
4) Newfoundland Power and Labrador Hydro rates for customers with a power demand of 30,000 kW or more; Newfoundland Power rates for all other customer categories.

Note: The top five participating utilities including BC Hydro with the lowest average prices are ranked in the table above, from lowest to highest. The sort order indicates the utility's overall ranking in the category.

BC Hydro Electricity Rate Comparison
Annual Report

Report No. 11

Attachment B

Ministerial Order No. M 167

PROVINCE OF BRITISH COLUMBIA

REGULATION OF THE MINISTER OF ENERGY AND MINES
AND MINISTER RESPONSIBLE FOR HOUSING

Clean Energy Act

Ministerial Order No. M 167

I, Rich Coleman, Minister of Energy and Mines and Minister Responsible for Housing, order that the Rate Comparison Regulation, B.C. Reg. 140/2009, is repealed, and the following Rate Comparison Regulation is made.

RATE COMPARISON REGULATION

Definition

1 In this regulation:

"Act" means the *Clean Energy Act*;

"applicable rates" means, with respect to a public utility's electricity rates, the average monthly bill for electricity, but not any other terms and conditions of those rates.

Report requirements

2 In a report to be provided to the minister under section 8 (4) of the Act, the authority must do all of the following:

(a) include a comparison with at least one public utility in each of at least fifteen other jurisdictions in North America, including all of the following:

(i) the provinces of Alberta, Quebec, Ontario and Manitoba;

(ii) the states of Washington, Oregon and California;

(b) compare the previous year's applicable rates for residential, commerical and industrial customers with similar rates of the public utilities referred to in paragraph (a);

(c) express the monetary comparisons in Canadian currency;

(d) provide the authority's previous 5 years of applicable rates.

DEPOSITED
JUN 2 8 2011
B.C. REG. 119/2011

JUN 2 8 2011
Date

Minister of Energy and Mines and Minister Responsible for Housing

(This part is for administrative purposes only and is not part of the Order.)

Authority under which Order is made:

Act and section: *Clean Energy Act*, S.B.C. 2010, c. 22, s. 37 (f)

Other: *Utilities Commission Act*, R.S.B.C. 1996, c. 473, s. 125.1 (4) (c); M114/2009

Mr. Patrick Wruck
Commission Secretary and Manager
Regulatory Support
British Columbia Utilities Commission
Suite 410, 900 Howe Street
Vancouver, BC V6Z 2N3

Dear Mr. Wruck:

RE: British Columbia Utilities Commission (BCUC or Commission)
British Columbia Hydro and Power Authority (BC Hydro)
Annual Reporting of Reliability Indices
Annual Response to Directive 26 of Commission Decision on F2005/F2006 Revenue Requirements Application (F05/F06 RRA)

BC Hydro writes as required by Directive 26 of the Commission's decision on our F05/F06 RRA to provide an annual reporting of reliability indices.[1]

Directive 26 states that BC Hydro is expected to present reliability indices (SAIFI, SAIDI, CAIDI, ASAI, SARI, MAIFI, generation forced outages, availability, and generation outage rates) both combined and disaggregated (where applicable) on an annual basis with comparisons to Canadian Electricity Association (**CEA**) averages.

In this filing, BC Hydro is providing reliability indices for distribution, transmission and generation performance through F2018. As in previous years, BC Hydro reliability statistics are provided on a fiscal year basis and compared with the CEA calendar year data.

Distribution and Transmission Update

The most recent annual CEA reports for distribution and transmission are the 2016 Annual Service Continuity data on Distribution System Performance in Electrical Utilities and the Bulk Electricity System. CEA data on distribution and transmission

[1] BC Hydro submitted its initial distribution and generation reliability indices compliance filing in September 2005, and subsequently reported the available reliability indices in May 2006 as part of the F2007/F2008 RRA. Starting in May 2007, BC Hydro began filing annual reports with the Commission on these reliability indices. Transmission system reliability indices for the years prior to F2012 were provided separately by the British Columbia Transmission Corporation (**BCTC**) in its Transmission System Capital Plan filings. BC Hydro provided the transmission system reliability indices starting in F2012, subsequent to the integration of BC Hydro and BCTC in F2011.

performance for the 2017 calendar year are not yet available. The comparative reliability indices, both combined and disaggregated for BC Hydro's distribution and transmission systems, are presented in Attachment 1, in tabular and graphical form through to F2018.

Generation Performance Update

The most recent annual CEA report on generation performance is the 2016 Generation Equipment Status Annual Report. CEA data on generation performance for the 2017 calendar year are not yet available. The comparative reliability indices, both combined and disaggregated for BC Hydro's generation system are presented in Attachment 2, in tabular and graphical form for the ten-year period ending F2018.

For further information, please contact Chris Sandve at 604-974-4641 or by email at bchydroregulatorygroup@bchydro.com.

Yours sincerely,

(for) Fred James
Chief Regulatory Officer

Enclosures (2)

F05/F06 Revenue Requirements Application

Annual Response to Directive 26 of BCUC Decision

F2018 Annual Reporting of Reliability Indices

Attachment 1

Distribution and Transmission Reliability Indices

This section includes the following distribution and transmission indices:

SAIFI	a measure of the number of sustained interruptions (longer than one minute) an average distribution customer will experience in a year
T-SAIFI-MI	a measure of transmission interruptions of less than one minute in duration that a delivery point experiences in a year
T-SAIFI-SI	a measure of transmission interruptions of one minute or more that a delivery point experiences in a year
T-SAIDI	a measure of the average total interruption duration, in hours that a delivery point experiences in a year
SAIDI	a measure of the amount of time, in hours, an average distribution customer is without power in a year
CAIDI	a measure of the average interruption, in hours, per interrupted distribution customer in a year
%ASAI	a measure of the percentage of time service is available in the year
CEMI-4	percentage of customers experiencing four or more outages in a year
MAIFI	a measure of the frequency of momentary (less than one minute) interruptions per distribution customer served in a year
DPUI	a measure of overall bulk electricity system performance in terms of a composite index of unreliability expressed in system minutes in a year. It takes into account all forced and planned outages except interruptions attributed to generators
SARI	a measure of the average restoration time, in hours, for each transmission delivery point in a year

As noted in Provision 9x of the F2011 Revenue Requirements Application Negotiated Settlement Agreement, BC Hydro is also reporting its CEMI-4 reliability metric, and SAIFI, SAIDI, CAIDI, ASAI, and CEMI-4 metrics normalized using the IEEE 2.5 Beta method. CEMI-4 is not benchmarked externally as utilities are at varying stages in their development of this metric.

Definitions

Availability Factor = Operating Time + Available-But-Not-Operating Time / In Commercial Service Time Note 4

Forced Outage Count = Average Number of Forced Outages / Unit / Year (including Starting Failures)(Internal)

Forced Outage Factor = Forced Outage Time (including Starting Failures)(Internal) / In Commercial Service Time Note 4

Failure Rate = Forced Outage Count (excluding Starting Failures)(Internal) / Operating Time X In Commercial Service Time Note 4

Notes

1. Outages with causes that were external to Generation, such as Transmission System forced outages, are excluded from this measure.
2. Data excludes ALU Unit 1 and SHU Unit 1, which have been forced out of service for an extended period.
3. Data excludes ALU Unit 1, SHU Unit 1 and ELK Units 1 and 2 which have been forced out of service for an extended period.
4. In Commercial Service Time represents the number of hours in the measurement period that the unit(s) were considered part of the active fleet.

Fiscal 2020 to Fiscal 2022 Demand-Side Management Business Plan

Conservation and Energy Management

Table of Contents

List of Tables

Appendices

1 Demand-Side Management Plan Overview

This section provides an overview of the Demand-Side Management Plan covering the fiscal 2020 to fiscal 2022 period, and provides details of the requested expenditures.

The Plan includes energy-savings tools – programs (energy and capacity), codes and standards and rate structures as well as supporting initiatives to support the Plan's success. Most of the initiatives in the Plan are a continuation of existing activities and build upon knowledge gained in previous years.

The business plan is presented in the following sections:

- Section 1 provides an overview of the Plan and the evolution that has taken place over the past year;
- Section 2 describes the framework used in developing the Plan, and the changes made to respond to customer needs and expectations;
- Section 3 provides more details on the expenditures, energy and capacity savings, other benefits, and cost-effectiveness of the Plan;
- Section 4 demonstrates that the Plan is managed in a comprehensive manner, including assessing ongoing risk factors and management oversight and reporting;
- Section 5 provides the overall sector strategy, descriptions of the individual programs, and cost-effectiveness results for the residential sector
- Section 6 provides the overall sector strategy, descriptions of the individual programs, and cost-effectiveness results for the commercial sector
- Section 7 provides the overall sector strategy, descriptions of the individual programs, and cost-effectiveness results for the industrial sector;
- Section 8 provides a description of the planned capacity-focused trials and pilots
- Section 9 provides a description of codes and standards initiatives which drive and support energy efficiency code and standard development by governments;
- Section 10 provides a description of conservation rates, and

- Section 11 describes the public awareness and administrative activities which support the overall Plan effort.

1.1 Energy-Focused Programs

The Plan includes a suite of programs that deliver a mix of information, access to technology and services, technical assessment and support, and financial assistance to all customer classes to address barriers to cost-effective demand-side management. The programs are designed to capture additional demand-side management potential that remains beyond that obtained from codes and standards and rate structures. In addition, programs are designed to complement rates structures and are critical in setting the stage for changes to codes and standards. The programs are flexible and have been designed to allow for the addition of new technologies or offers including those that might emerge around capacity or low-carbon electrification.

Per the Demand-Side Measures Regulation, a new stand-alone energy management program category called Energy Management Activities has been created in each sector. This was a relabelling of current activities within existing programs that assist customers to optimize energy use and does not represent new activities. This is further discussed in section 2.1.

This plan focuses on demand-side management activities, yet provides the flexibility to efficiently leverage the existing program and operations structure to other initiatives such as low-carbon electrification. This expansion would achieve efficiencies and make it easier for customers to do business with us.[1]

Even as our customers undertake low-carbon electrification activities, it will continue to be important for BC Hydro to help our customers reduce their electricity use through conservation and efficiency, thereby optimizing the electrical system capacity and allowing for further electrification to address climate change. We also need to create opportunities to help our customers shift the timing of when they use electricity to optimize our grid and reduce costs and constraints across BC Hydro's system. Combining the low-carbon

[1] Any expansion into low-carbon electrification activities will come with incremental funding, outside of the expenditures identified in this Business Plan. Such expenditure requests will come forward separately.

electrification initiatives with our traditional demand-side management initiatives will facilitate this focus.

1.2 Capacity-Focused Offers

The Plan continues to include capacity focused pilot and trial offers that were identified in the Fiscal 2017 to Fiscal 2019 Revenue Requirements Application. The budget has subsequently been extended over a longer period of time, but the total amount of the required budget over fiscal 2017 to fiscal 2021 has been reduced by 12 per cent. Over the fiscal 2020 to fiscal 2022 period, this initiative will identify opportunities to use customer-based, demand-side measures as a resource to manage capacity constraints on the grid. These activities include trials looking at localized demand-side management, behavioural shifting during peak periods, direct control of various technologies, and exploration into the emerging area of Connected Homes and Buildings.

1.3 Codes and Standards

Codes and standards refer to a range of government policy instruments that influence the use of energy, including product/equipment regulations, building codes, tax measures. BC Hydro supports the development of these codes and standards and also works with communities on municipal zoning/building permitting processes, as well as enhanced approaches for Indigenous and remote communities. The Demand-Side Measures Regulation requires codes and standards support initiatives to be undertaken by BC Hydro. The Plan supports and relies upon government implementation of a suite of changes to codes and standards. As a result, BC Hydro does not claim to be exclusively responsible for these savings; however BC Hydro support plays an important role in the achievement of savings. BC Hydro's codes and standards initiatives are coordinated with programs to help drive efficient technologies and practices.

1.4 Rate Structures

Rate structures are changes to the design of electricity rates to provide more economically efficient price signals to customers which encourage conservation. BC Hydro currently has conservation rate structures in place for residential[2] and large industrial (transmission voltage) customers.

1.5 Supporting Initiatives

Supporting initiatives include public engagement and awareness activities and general management and infrastructure. Public engagement and awareness activities are designed to address two specific barriers to demand-side management participation: awareness of ways to increase energy conservation and energy efficiency including through BC Hydro's demand-side management programs, and acceptance of those programs in order to increase participation and seek out energy savings opportunities. General management and infrastructure supports the design, development and implementation of the Plan.

1.6 Plan Overview

In its decision on BC Hydro's Fiscal 2017 to Fiscal 2019 Revenue Requirements Application, the Commission Panel accepted BC Hydro's DSM expenditure schedule.[3] In that proceeding, the Commission examined three different levels of demand-side management, and concluded that BC Hydro had found an appropriate balance. The selected level of demand-side management represents a moderation compared to the level of demand-side management recommended in the 2013 Integrated Resource Plan. This moderation strategy arose in response to the identification of an extended period of surplus electricity and the need to address rate increase pressures. In addition to accepting the overall funding level, the Commission provided findings and directives on a few elements of the Demand-Side Management Plan which have been reflected in this Business Plan.

In developing the F2020-F2022 Demand-Side Management Plan, Conservation and Energy Management has continued with the moderation strategy and its funding envelope, given the continued period of surplus electricity and need to address rate increase pressure. The F2020-F2022 Demand-Side Management Plan also reflects changes in the external and internal considerations outlined in sections 2.1 and 2.2. This has resulted in reductions in

[2] The most recent Residential Inclining Block evaluation report (Evaluation of the Residential Inclining Block Rate F2013-F2017, April 2018) finds that no new incremental savings are anticipated in future years. However, the current pricing signal continues to encourage customers to maintain savings.

[3] BC Hydro Fiscal 2017 to Fiscal 2019 Revenue Requirements Application, Decision and Order no. G-47-18, March 1, 2018, page 75 of 118.

commercial and industrial expenditures to better align with expected future program spending, and increased expenditures in the residential sector and non-integrated communities to address affordability. The other major change to the Plan was the re-packaging of Energy Management Activities into a new energy management program category.

BC Hydro expects to be working with the Government of B.C. to support a roadmap for the future of B.C. energy. This roadmap along with the completed Conservation Potential Review study will subsequently inform the development of the next Integrated Resource Plan.

Until the energy roadmap and the next Integrated Resource Plan are available, it is reasonable to maintain the current funding envelope for demand-side management, and be prepared to respond when new directions are signaled. The current Demand-Side Management Plan maintains broad access to demand-side management programs and bill savings opportunities, continues to meet the at least 66 per cent target of the *Clean Energy Act*, supports government policy initiatives, and maintains the ability to ramp up in the future.

As a result, the Demand-Side Management Plan presented in this Business Plan provides an appropriate level of investment and savings over the next three years.

The following table summarizes the Plan's contents.

Table 1 Demand-Side Management Tools and Initiatives

Tools	Initiatives	
Programs	Residential	
	• Low Income (with an Indigenous customer offer launching fiscal 2020 or Q4 fiscal 2019) • Non-Integrated Areas (Launching fiscal 2020 or Q4 fiscal 2019)	• Retail • Home Renovation Rebate • Residential Energy Management Activities[4]
	Commercial	
	• Leaders in Energy Management, Commercial • New Construction	• Non-Integrated Areas (combined with residential offer) • Commercial Energy Management Activities[2]
	Industrial	
	• Leaders in Energy Management, Industrial	• Industrial Energy Management Activities[2] • Thermo-Mechanical Pulp
Capacity Focused DSM	• Localized demand-side management – geographically targeted, all sectors • Demand Response – Large Commercial & Small Industrial • Demand Response - Residential appliances, electric vehicle chargers, & devices • Peak Saver - Residential • Connected buildings – Residential, Commercial & Industrial	
Codes and Standards	Product and Equipment Standards	
	• Lighting • Residential appliances	• Residential electronics • Commercial/Industrial Equipment
	Building Codes	
	• B.C. Building Code (Residential and Commercial)	• City of Vancouver Building By-law (Residential and Commercial)
	Codes and Standards Strategy	
	• Sustainable Communities • Codes and Standards Investigation • Residential New Construction support	• Indigenous Communities Policy Support (completing Trial work in fiscal 2019, policy assistance ongoing)
Rate Structures	• Residential Inclining Block	• Transmission Service
Supporting Initiatives	• Public Awareness	• Indirect Support

[4] Per the Demand-Side Measures Regulation, a new program category of "Energy Management" has been established, and existing initiatives which fit into that new categorization have simply been repackaged. This is further discussed in section 2.1.

The following table summarizes planned Demand-Side Management expenditures over the three-year period.

Table 2 Planned Demand-Side Management Expenditure Summary ($ million)

	F2020 Plan	F2021 Plan	F2022 Plan	Total
Codes and Standards	5.2	5.3	5.4	16.0
Rate Structures	0.5	0.5	0.5	1.4
Programs (excluding TMP)	63.7	64.1	64.6	192.4
Capacity-focused	6.9	4.3	0	11.1
Supporting Initiatives	14.6	14.9	15.0	44.4
Total	90.8	89.1	85.5	265.4
Thermo-Mechanical Pulp	0	27.2	0	27.2
Total with Thermo-Mechanical Pulp	90.8	116.2	85.5	292.6

The following table summarizes the cost-effectiveness of the fiscal 2020 to fiscal 2022 demand-side management expenditures (detailed results are presented in section 3.4).

The cost-effectiveness results for the three years of activities (fiscal 2020 to fiscal 2022) are positive as shown in the table below.

Table 3 Benefit Cost Ratios and Net Levelized Costs for Fiscal 2020 to Fiscal 2022 Activities ($/MWh)[5]

	Benefit-Cost Ratios		Net Levelized Costs ($/MWh)[6]	
	Utility Cost Test (Market Price at $30 per MWh)	Modified Total Resource Cost Test (LRMC at $105 per MWh)	Utility Cost Test ($)	Total Resource Cost Test ($)
Codes and Standards	n/a	n/a	n/a	n/a
Rate Structures	11.1	1.4	(4)	73
Programs (including TMP)	1.7	3.6	12	(11)
Rate Structure and Programs (Including TMP)[7]	1.1	2.5	27	14

5 Cost-effectiveness results do not include capacity-focused demand-side management trials and pilots or Codes and Standards benefits.

6 A negative Net Levelized Cost indicates that other non-energy specific benefits such as capacity benefits and customer non-energy benefits (which are characterized as negative costs in the levelized cost formula) exceed the total costs.

7 Also includes Energy Management Activities, Supporting Initiatives and Codes and Standards costs.

1.7 Plan Updates

The Demand-Side Management Plan aligns with relevant requirements in the *Clean Energy Act* and the Demand-Side Measures Regulation. In general, the fiscal 2020 to fiscal 2022 expenditures are consistent with the demand-side management plan previously reviewed by the Commission (F2017-F2019 RRA DSM Plan[8]), with some subsequent expenditure re-allocations made to align with the April 18, 2018 Government Mandate letter and the BCUC Decision recommending more demand-side management programs directed at residential customers. These re-allocations included reductions in commercial and industrial expenditures to better align with expected program spending going forward, and expansions of the Low Income program, Home Renovation Rebate program, and the Non-Integrated Areas program to address affordability.

Overall Plan expenditures, including TMP, are $22.2 million (8.2 per cent) higher over fiscal 2020 to fiscal 2022 compared to the F2017-F2019 RRA Demand-Side Management Plan ($292.6 million vs. $270.4 million), while the sum of the new incremental savings over fiscal 2020 to fiscal 2022 are 9 GWh (0.4 per cent) lower (2,121 GWh vs. 2,130 GWh).

The table below shows the annual expenditures variance between the fiscal 2020-fiscal 2022 Demand-Side Management Plan and the Demand-Side Management Plan in BC Hydro's Fiscal 2017 to Fiscal 2019 Revenue Requirement Application over fiscal 2020 to fiscal 2022. The net increases are primarily due to the spread of expenditures for capacity-focused demand-side management activities over a longer period of time (to fiscal 2021), and an update in the timing of the TMP projects.

Table 4 Utility Costs in F2017-F2019 RRA DSM Plan and F2020-F2022 DSM Plan ($ million)

	F2020	F2021	F2022	Total
F2017-F2019 RRA DSM Plan	85.7	98.4	86.3	270.4
F2020-F2022 DSM Plan	90.8	116.2	85.5	292.6
Variance	5.1	17.9	(0.8)	22.2

[8] Including the updates as per BC Hydro's response to BCUC IR 2.314.3 from the Fiscal 2017 to Fiscal 2019 Revenue Requirement Application.

In addition to these net increases, funding reductions made in the commercial and industrial sectors allowed for the increase in residential affordability initiatives and the introduction of the Non-Integrated Areas program.

The table below compares the expected new incremental energy savings between the F2020-F2022 Demand-Side Management Plan and the Demand-Side Management Plan in BC Hydro's Fiscal 2017 to Fiscal 2019 Revenue Requirement Application over fiscal 2020 to fiscal 2022. Savings were eliminated for the Residential Inclining Block Rate, reduced for commercial programs, increased for residential programs, and updated for existing codes and standards regulations as well including new regulations; and a shift in the savings for general service lamp regulation as new information indicates that it is taking longer than expected for this regulation to drive a turnover in the stock of lamps in BC.

Table 5 New Incremental Energy Savings in F2017-F2019 RRA DSM Plan and F2020-F2022 DSM Plan (GWh/yr)

	F2020	F2021	F2022
F2017-F2019 RRA DSM Plan	632	888	610
F2020-F2022 DSM Plan	700	853	568
Variance	69	(36)	(42)

2 Demand-Side Management Plan Development

This section describes how the Demand-Side Management Plan was developed.

2.1 External Considerations

Development of the Demand-Side Management Plan takes into account a variety of external considerations.

2.1.1 Legislation and Regulation

First and foremost is the provincial legislation and regulation that governs demand-side management in B.C. The Demand-Side Management Plan meets the following legislated or regulated requirements:

- The *Clean Energy Act's* requirement that demand-side measures reduce BC Hydro's expected increase in demand for electricity by at least 66 per cent by the year 2020;
- The adequacy requirements in the Demand-Side Measures Regulation under the *Utilities Commission Act*:
  - ▶ A low income program targeted to low income households;
  - ▶ Measure to improve the energy efficiency of rental accommodations;
  - ▶ An education program for students enrolled in schools;
  - ▶ Education initiatives in post-secondary institutions;
  - ▶ Resources for standards-making bodies to support the development of or compliance with standards; and
  - ▶ Initiatives to encourage the adoption by local government and Indigenous Communities of a building step code and more stringent requirements within a building step code; and
- The Demand-Side Measures Regulation also specifies the various metrics to use in determining that the Plan programs are cost-effective.

The latest update to the Demand-Side Measures Regulation[9] established a new specified demand-side measure, an "energy management program". As defined, an energy management program is "a program to assist customers to optimize energy use". For Conservation and Energy Management, this categorization does not represent new demand-side management activities, but rather encompasses a number of our current initiatives that assist customers to optimize their energy use. For this plan, we have re-packaged those existing energy management related activities into the new specified demand-side measures category for greater transparency with respect to the Demand-Side Measures Regulation. An energy management program has been identified for each of the residential, commercial and industrial sectors, which provides assistance to customers to implement energy savings projects through programs and other initiatives.

2.1.2 Government of B.C. Mandate Letter

The Government of B.C.'s mandate letter to BC Hydro provides another set of considerations in the development of the Demand-Side Management Plan. Each of the government's key priorities articulated in the mandate letter are reflected in our demand-side management initiatives, as identified in the 2018/19 to 2020/21 BC Hydro Service Plan.

Government Priorities	Demand-Side Management Aligns with These Priorities by:
Making life more affordable	This has been accomplished by expanding the Low Income and Home Renovation Rebate programs, and launching the Non-Integrated Areas program. In addition, EE activities generally help to reduce bills for participating customers.
Delivering the services people count on	Supporting customers with initiatives to help them to make smart demand-side management choices through conservation and energy efficiency, capacity reduction and low carbon electrification.
A strong, sustainable economy	We expect to be working with the Government of B.C. in supporting the creation of a roadmap for the future of B.C. energy. Performance measures have been established to achieve new incremental demand-side management savings of 800, 700, and 700 GWh/year, over fiscal years 2019, 2020, and 2021, respectively.

9 B.C. Reg. 117/2017, March 24, 2017

2.1.3 BCUC Decisions

The focus on making life more affordable (with a resulting emphasis on the residential sector) also aligns with Direction 21 from the Commission's decision on BC Hydro's Fiscal 2017 to Fiscal 2019 Revenue Requirements Application,

> "The Panel recommends BC Hydro consider more targeted DSM programs directed at residential customers in the next DSM application"

2.2 Internal Considerations

Development of the Demand-Side Management Plan also takes into account several internal considerations. These include alignment with government and corporate priorities and strategies as described below.

2.2.1 BC Hydro Service Plan

BC Hydro's 2018/19 – 2020/21 Service Plan outlines four strategic goals that guide our actions, each supported by corresponding strategies, performance measures, and targets. Our demand-side management initiatives contribute to each of the strategic goals.

Goal 1 – Set the Standard for Reliable and Responsive Service	This goal is addressed through the strategy of supporting customers with initiatives that help them to make smart demand-side management choices through conservation and energy efficiency, capacity reduction and low-carbon electrification.
Goal 2 - Help Make Electricity More Affordable for our Customers	To address this goal, program expenditures have been increased in the residential sector and a new non-integrated areas program launched, all of which provide additional opportunities for customers to reduce their electricity consumption, and make their bills more affordable.
Goal 3 - Continue British Columbia's Leading Commitment to Renewable Clean Power	This goal is addressed through the strategy of implementing our energy conservation and energy management plan, which will exceed the *Clean Energy Act* requirements to meet at least 66 per cent of future demand growth by 2020. Performance measures have been established for the achievement of new incremental demand-side management savings in each year.
Goal 4 - Safety Above All	This goal is a core value at BC Hydro, and demand-side management activities (in particular, field visits to customer sites) are implemented consistent with this core value.

2.2.2 Conservation and Energy Management Objectives

Conservation and Energy Management's objectives are to provide a broad platform of cost-effective energy management products and services to our customers, and to deliver them efficiently. The Demand-Side Management Plan covers activities focused on energy savings in the residential, commercial and industrial sectors, as well as some initial activities to pursue capacity-focused demand-side management. With incremental funding, Conservation and Energy Management is also able to leverage its capabilities to broaden into low-carbon electrification offers.

An important principle in the design of the Demand-Side Management Plan is the emphasis on building trusted partnerships and transforming marketplaces. Almost every solution works with one or many of the following entities: all levels of government (municipal, regional districts, provincial, and federal), retailers, manufacturers, third-party customer energy analytic providers, and a wide variety of demand-side management service providers that through our guidance and support provide expertise to our customers. This principle helps Conservation and Energy Management drive forward with innovative ideas and keeps pace with a rapidly changing environment.

2.2.3 Development Framework

The Demand-Side Management Plan was also assessed against customer and strategic objectives, along the lines of the framework used in the Fiscal 2017 to Fiscal 2019 Revenue Requirements Application:

- Cost effectiveness (Total Resource Cost and Utility Cost perspectives, see section 3.4);
- Flexibility to ramp activities and expenditures up or down, as required
- Support for other BC Hydro or Government initiatives (e.g., Rates Plan);
- Customers broad access to demand-side management programs, and
- Missed demand-side management project opportunities.

2.2.4 Marketplace Information and Conservation Potential Review

Finally, the development of the Demand-Side Management Plan considered the results of the conservation potential review study that was completed in partnership with FortisBC. This review study prepared a conservation potential estimate for electricity and natural gas across all of British Columbia over a 20-year forecast horizon from 2016 to 2035. The review objective was to assess the energy efficiency potential in the residential, commercial, and industrial sectors by analyzing energy efficiency and peak-load-reduction measures, defining operational and maintenance activities to keep existing devices or equipment in good working order, and improving end-user behaviors to reduce energy consumption.

This review has provided both a long-term conservation potential assessment and confirmed the potential for technologies already included in the Plan. Given our current moderation strategy, the conservation potential review study will primarily be used to inform future planning exercises such as the Integrated Resource Plan and the government roadmap for the future of B.C. energy.

2.3 Demand-Side Management Plan Evolution

Conservation and Energy Management has made a numbers of changes to the Demand-Side Management Plan to address the external and internal considerations outlined above, including:

- Launching a new Non-Integrated Areas program to increase support for these remote and predominantly Indigenous communities;
- Increasing participation in the Low-Income program by including Crisis Fund participants in program outreach, and providing Energy Savings Kits at pre-qualified events (e.g., foodbanks, and Indigenous community events) which will not require a BC Hydro account number to receive a kit, introduction of an Indigenous offer within the Low Income Program for customers connected to the integrated BC Hydro electrical system;
- Reducing the budget for commercial and industrial programs to better align with expected future program spending, thus allowing for the expansion of residential initiatives while staying within the overall portfolio funding envelope;

- Aligning the energy management initiatives and sector enabling activities within each sector into an energy management program configuration consistent with the Demand-Side Measures Regulation;
- The Home Renovation Rebate budget was augmented to increase incentives for some measures (e.g., insulation) as well as expand the number of measures (e.g., heat pumps) for electrically heated customers; and
- The Leaders in Energy Management – Commercial program has also launched a new Social Housing Retrofit Support Offer for Multi-Unit Residential, providing an opportunity for qualifying social housing providers to minimize their operating costs and improve whole building performance.

These changes will allow Conservation and Energy Management to continue to respond to customer needs and expectations.

3 Demand-Side Management Plan Expenditures, Savings, Benefits and Cost-Effectiveness

This section provides a more detailed view of the expenditures, energy and capacity savings, other benefits and cost-effectiveness of the fiscal 2020 to fiscal 2022 demand-side management activities.

3.1 Expenditures

The following table summarizes fiscal 2020 to fiscal 2022 demand-side management expenditures.

Table 6 Demand Side Management Expenditure Summary ($ million)

	F2020 Plan	F2021 Plan	F2022 Plan	Total
Codes and Standards	5.2	5.3	5.4	16.0
Rate Structures	0.5	0.5	0.5	1.4
Programs				
Residential	18.4	19.7	21.0	59.1
Commercial	18.9	17.5	17.2	53.7
Industrial	26.5	26.9	26.3	79.7
Total Programs (excluding TMP)	63.7	64.1	64.6	192.4
Capacity-focused	6.9	4.3	0	11.1
Supporting Initiatives	14.6	14.9	15.0	44.4
Total	90.8	89.1	85.5	265.4
Thermo-Mechanical Pulp	0	27.2	0	27.2
Total with Thermo-Mechanical Pulp	90.8	116.2	85.5	292.6

Appendix A provides expenditures at the initiative level by incentive and non-incentive cost. Appendix A also provides a savings forecast to fiscal 2022 at the initiative level.

3.2 Energy and Capacity Savings

A breakdown of forecast energy and associated capacity savings from fiscal 2020 - fiscal 2022 demand-side management activities are provided in the following table. [10]

[10] Capacity savings from capacity-focused demand-side management activities have not been quantified or included.

Table 7 New Incremental Energy Savings and Associated Capacity Savings

	F2020 Plan	F2021 Plan	F2022 Plan
New Incremental Energy Savings (GWh/yr)			
Codes and Standards	356	411	282
Rate Structures	117	118	114
Programs			
Residential	36	36	36
Commercial	59	52	44
Industrial	132	136	92
Thermo-Mechanical Pulp	0	100	0
Total Programs	227	324	172
Total New Incremental Energy Savings	700	853	568
New Incremental Associated Capacity Savings (MW)			
Codes and Standards	79	88	54
Rate Structures	14	14	13
Programs			
Residential	10	10	10
Commercial	9	8	7
Industrial	16	16	11
Thermo-Mechanical Pulp	0	12	0
Total Programs	35	46	28
Total New Incremental Capacity Savings	128	147	95

3.3 Other Benefits

3.3.1 Reduction in Revenue Requirements

The fiscal 2020 to fiscal 2022 total portfolio of the Demand-Side Management Plan is forecast to have a net levelized Utility Cost of $27 per MWh (fiscal 2019 value), which is less than the B.C. border sell price forecast (approximately $30 per MWh).

Using these price forecasts, the demand-side management expenditures (at a net levelized Utility Cost of $27 per MWh) will reduce BC Hydro's revenue requirements, all else being equal. This also results in lower customer bills, on an aggregate basis.

3.3.2 Economic Development Benefits

The implementation of the Demand-Side Management Plan will continue to generate significant economic activity and jobs within the province. These jobs include direct employment through the purchase of labour and materials, spin-off jobs from business activity in the supply chain and the spending of wages, and jobs created by customers spending of energy bill savings from demand-side management. Demand-Side management actions undertaken by customers also make them more competitive through the better use of electricity, creating expanded economic development.

Conservation and Energy Management has updated a study completed by the Deetken Group (Economic Impact Study of BC Hydro's DSM Plan: fiscal 2017-fiscal 2026) which assessed the economic development benefits of the F2017 - F2026 Demand-Side Management Plan that was included in the Fiscal 2017 to Fiscal 2019 Revenue Requirements Application. For the fiscal 2020 to fiscal 2029 10-year period, economic impacts expressed in terms of GDP, employment and provincial tax revenues are as follows:[11]

- GDP impacts of $1.1 billion;
- Employment of 11,600 full-time equivalent positions; and
- Provincial tax revenue of $115 million.

3.3.3 Environmental Benefits

BC Hydro's electricity is clean, but demand-side management avoids the environmental impacts associated with the construction and operation of new electricity infrastructure. Continued energy efficiency efforts will enable the increased use of BC Hydro's clean electricity and its associated environmental benefits, stretching availability for new electrification opportunities.

3.3.4 Additional Customer Benefits

The implementation of demand-side management initiatives provide customers with additional benefits such as reduced waste generation or product losses, reduced

[11] These values exclude the economic development benefits from codes and standards.

maintenance costs in commercial and industrial facilities, and extended equipment life. These are referred to as customer non-energy benefits, and where they can be quantified, are included in the Total Resource Cost Test.

3.4 Cost Effectiveness

In assessing the Demand-Side Management Plan, BC Hydro included consideration of the cost-effectiveness of demand-side management initiatives using two tests:

- The Utility Cost Test: For the purposes of determining the cost-effectiveness of the fiscal 2020 to fiscal 2022 demand-side management expenditures, BC Hydro relied on the Utility Cost Test, using the market price of electricity to value the energy savings. This test is used to understand the impact of a demand-side management investment on BC Hydro's revenue requirement. Having a positive Utility Cost test result using BC Hydro's market price forecast would provide assurance that even surplus energy resulting from demand-side management would have a positive impact on BC Hydro's revenue requirements; and
- The Total Resource Cost Test: In accordance with the *Demand-Side Measures Regulation*, BC Hydro uses the Total Resource Cost Test as a determinant of whether an individual demand-side management initiative and the demand-side management portfolio as a whole are cost-effective, using the long-run marginal cost of electricity. The Total Resource Cost Test helps BC Hydro to assess how the cost of demand-side management compares to the cost of other supply-side resource options.

The cost-effectiveness of demand-side management initiatives is expressed in terms of three metrics (benefit-cost ratio, levelized cost and net present value). For benefit-cost ratios, higher is better and a ratio of greater than 1.0 means that benefits exceed costs. For levelized costs, lower is better. A negative net levelized cost indicates that non-energy benefits, such as capacity benefits or customer non-energy benefits, exceed the demand-side management costs. A larger negative value is better than a smaller negative value or any positive value. Levelized costs of demand-side management can be compared to the forecast prices of electricity such as the market price or long run marginal cost (LRMC).

The fiscal 2020 to fiscal 2022 demand-side management activities are expected to produce electricity savings at a lower cost than the market price or new supply. As discussed in Chapter 10, the LRMC is out of date, but the net levelized TRC of $14 per MWh indicates that the total portfolio would still be cost-effective against a range of values considerably less than $105 per MWh. The next table presents benefit-cost ratios and net levelized cost for the Demand-Side Management Plan from fiscal 2020 to fiscal 2022 for the two standard demand-side management cost tests: the Utility Cost Test and the Total Resource Cost Test.

Table 8 Benefit Cost Ratios and Net Levelized Costs ($/MWh)

	Benefit-Cost Ratios		Net Levelized Costs ($/MWh)	
	Utility Cost Test (Market Price at $30 per MWh)	Modified Total Resource Cost Test (LRMC at $105 per MWh)	Utility Cost Test ($)	Total Resource Cost Test ($)
Codes and Standards	n/a	n/a	n/a	n/a
Rate Structures	11.1	1.4	(4)	73
Programs (including TMP)[12]	1.7	3.6	12	(11)
Total Portfolio (including TMP)	1.1	2.5	27	14

Appendix A contains more detailed cost test results and the levelized resource costs of individual initiatives.

[12] In previous business plans, a prorated amount of costs from supporting initiatives was added to the cost of each program to assess cost effectiveness of the program per a 2004 BCUC directive. In this table, the allocation of support initiative costs onto programs has not been added, consistent with directions from the Demand-Side Measures Regulation. BC Hydro believes that the Demand-Side Measures Regulation has priority over the 2004 BCUC directive, and during the next Revenue Requirements Application we will be requesting that the directive be rescinded.

4 Demand-Side Management Plan Implementation

This section describes how the Demand-Side Management Plan is implemented by Conservation and Energy Management.

4.1 Governance and Change Process

4.1.1 Governance:

The Demand-Side Management Plan will be managed through the structure and controls built in the Conservation and Energy Management governance process, which is managed by the Conservation and Energy Management Steering Committee.

The Conservation and Energy Management Steering Committee monitors the performance of programs and initiatives on an ongoing basis and approves adjustments as required to ensure their appropriate performance. The primary performance metrics for the Demand-Side Management Plan are energy savings and costs.

4.1.2 Change Process

The Demand-Side Management Plan are reviewed and approved by the appropriate authority before implementation. Any subsequent deviations from the approved Plan will be managed through consultation, review, and approval from the appropriate parties.

4.1.3 Monitoring & Reporting:

The Management Steering Committee will monitor performance of the Demand-Side Management Plan on an ongoing basis, and report the performance to its stakeholders as required. The stakeholders include, but are not limited to the People, Customer & Corporate Affairs Management Team, BC Hydro Executive team and the BC Hydro Board.

4.2 Risk Management

Conservation and Energy Management's approach to demand-side management performance management is informed by the identification and assessment of related risks and the development of mitigation measures at various stages in the demand-side management process, from initiative design through implementation to evaluation. Risks are assessed and managed at the portfolio, initiative, and project level. This section describes the material risks that have been identified and key risk mitigation tactics undertaken for the three demand-side management tools and the Demand-Side Management Plan as a whole.

4.2.1 Codes and Standards Risks and Mitigation

The principal risks as they relate to codes and standards are:

- **Approval Risk:** Planned codes and standards are not approved by Government, or not approved at the planned time;
- **Coverage Risk:** Codes and standards do not cover as many technologies or building types as expected or prescribe less efficient standards than expected; and
- **Compliance Risk:** The level of compliance with a code or standard is less than expected.

A key aspect of codes and standards risk mitigation is that Conservation and Energy Management does not have direct control over the implementation of codes and standards and relies on the action of governments to deliver these savings. Thus there is uncertainty regarding the timing, coverage and efficiency level of codes and standards outlined in the Demand-Side Management Plan. These risks are mitigated in part by Conservation and Energy Management using its influence to support the implementation of codes and standards through its demand-side management programs and codes and standards supporting initiative.

In addition, Conservation and Energy Management monitors government approval of codes and standards and uses the best available information, including results from completed evaluations, to estimate codes and standards savings. As new information becomes available, Conservation and Energy Management incorporates this information into its estimates of codes and standards savings. If it becomes apparent that codes and standards savings might be less than planned, Conservation and Energy Management can respond in a number of ways, for example: Consider expanded demand-side management programs to capture some of the savings expected from a code or standard.

4.2.2 Rate Structure Risks and Mitigation

The principal risk as it relates to rate structures is:

- Customer Response Risk: The customer response to the rate structure is lower than expected.

As discussed in BC Hydro's 2015 Rate Design Application, this risk materialized with the Large General Service and Medium General Service rate structures, where evaluations found that energy savings from these rates were considerably less than planned.

BC Hydro mitigates this risk in several ways during design and implementation. First, BC Hydro has a rate design process that includes customer consultations, and culminates in a transparent public review of BC Hydro's rate design application by the British Columbia Utilities Commission. Second, the customer response to rate structures is forecasted using the best available information. As new information becomes available, BC Hydro incorporates this information into its estimates of rate structure savings. Third, in implementing rate structures, BC Hydro provides information to customers to educate them on the rate structure and how they can respond to it and achieve bill savings. Finally, BC Hydro's demand-side management programs are designed to complement and support the rate structure and customer response to price signals.

If rate structure savings are lower than planned, BC Hydro can take the following actions:

- Redesign rate structures;
- Increase customer communication and support effort related to rate structures; and
- Expand other demand-side management initiatives to achieve additional savings if needed and cost-effective.

4.2.3 Program Risks and Mitigation

The principal risks as they relate to programs are:

- Participation Risk: demand-side management programs do not achieve the expected level of participation;

- Savings Risk: The savings per participant in demand-side management programs is lower than expected; and
- Cost Risk: Program costs are higher than expected.

To minimize the risk of lower participation than planned, demand-side management programs are designed to address barriers to energy efficiency and elicit customer participation using information from BC Hydro customers, trade allies and other jurisdictions. Conservation and Energy Management also recognizes that changing customer expectations over time will mean that programs may need to adapt to achieve desired participation levels. Conservation and Energy Management also undertakes market and technical research into current and future demand-side management opportunities to develop the most effective initiative designs. In addition, conservation rate structures complement programs.

Programs also face a risk of delivering lower savings per participant than planned. This risk is mitigated by using a variety of sources on unit savings to forecast overall program savings, including market research, technical reviews of projects, measurement and verification results and program evaluations. In addition, if measurement and verification results indicate that less energy savings were received than the amount stated in the demand-side management incentive agreement, the incentive amount can be adjusted per the incentive agreement so that BC Hydro is not overpaying for reduced energy savings. In these agreements, BC Hydro has a mechanism to ensure that it is paying for verified savings. This linkage between measurement and verification results and incentive payments is not common among demand-side management programs in other jurisdictions.

If demand-side management program electricity savings or budget are not tracking to plan, BC Hydro can respond by:

- Modifying program advertising;
- Modifying the program application process or eligibility criteria;
- Modifying program incentives;
- Modifying the program approach; and

- Revising the list of qualifying products.

The flexibility of programs also provides a greater ability to adjust programs in response to savings shortfalls in other demand-side management tools. These mitigation measures, however, have limitations in the event a large, complex project (such as thermal-mechanical pulp) is delayed or cancelled.

4.2.4 Portfolio Risks and Mitigation

The portfolio risks are managed through the flexibility of adjusting the demand-side management plan as required based on the ongoing monitoring of plan performance. For instance, if performance falls below plan in one sector or initiative, Conservation and Energy Management can reallocate costs or resources between initiatives or sectors to improve the performance.

4.3 Electricity Savings Confirmation

Reliably estimating demand-side management electricity savings, upon which financial decisions are made and progress towards targets are reported, is a key aspect of managing demand-side management performance. Depending on the demand-side management initiative, there can be up to four distinct areas of activity that ultimately contribute to the confirmation of demand-side management savings estimates: technical review, site inspection, measurement and verification, and evaluation. Results from each area are used in project and contract management to ensure that BC Hydro receives the expected project benefits for its incentive payments. Conservation and Energy Management is selective in the use of these processes, and focuses its efforts where warranted to improve the accuracy of savings estimates and reduce exposure to the risks described above.

- **Technical Review:** The purpose of the technical review is to ensure that energy savings are adequately described and supported by appropriate engineering calculations. For residential initiatives and prescriptive measures in the commercial and industrial customer sectors, the technical review is typically used to assess energy savings as part of the program design. For the commercial and industrial sectors, the technical review is done before and shortly after a measure is implemented, and ensures that the following elements are in place for a specific measure: a description of the measure; a defined and quantified baseline condition; a system boundary; explicit engineering calculations of the electricity savings achieved; and documented and referenced assumptions that align with common industry standards and practices;

- **Site Inspection:** The inspection is conducted to confirm that the project is complete, was implemented as agreed with BC Hydro and to confirm or adjust the variables and assumptions used to estimate the energy savings during the technical review. Site inspection is performed on a sample of projects;
- **Measurement and Verification:** This is the quantification of individual project energy savings through analysis of actual project operating and performance data. On-site measurement and data collection, utility billing data and computer modelling may be used to analyze and confirm the energy and demand savings from individual projects. Conservation and Energy Management conducts measurement and verification on a sample of customer projects. At the initiative level, measurement and verification analysis is used to measure and confirm program assumptions such as hours of equipment usage or product specifications. In carrying out its measurement and verification work, Conservation and Energy Management is guided by an internationally accepted protocol for measurement and verification of energy saving projects; and
- **Evaluation:** Conservation and Energy Management evaluates demand-side management initiatives through studies and activities aimed at determining its effects. Evaluations use measurement and verification results and may also trigger additional measurement and verification activities to confirm technical assumptions on projects. In carrying out its evaluation activities, Conservation and Energy Management is guided by the California Evaluation Framework and Protocols and the U.S. Department of Energy Uniform Methods Project Protocols, which are generally regarded as the leading protocols for demand-side management evaluation in North America. Evaluation reports are reviewed by external demand-side management evaluation advisors and reviewed and approved by a cross-BC Hydro committee. This ensures the evaluation reports align with industry best practice. BC Hydro also files an annual report to the British Columbia Utilities Commission with Executive Summaries of the previous year's evaluation reports. Conservation and Energy Management periodically

updates reported demand-side management savings to reflect new information stemming from the steps outlined above, which provides a comprehensive process for estimating demand-side management savings.

5 Residential Sector Programs

5.1 Residential Sector Overview

BC Hydro's residential sector has over 1.7 million customer accounts and sales to this sector total approximately 17,350 GWh annually[13], representing 35 per cent of BC Hydro's annual load. The average residential account consumes about 10,000 kWh annually, although this varies widely with the type of home and the type of heating fuel used.

5.1.1 Residential Sector Strategic Approach

Programs are offered focusing on specific customer segments as well as specific products. These programs are designed to take into consideration: the opportunities identified in research, through program benchmarking, and feedback from the marketplace; reducing the barriers that exist for customers to adopt those technologies or behavioural changes; and finally partnerships that can be leveraged to successfully bring these programs to market.

Initiatives implemented to date have typically been through partnerships with both the private and public sectors, to ensure market impact. Rather than competing with existing channels, BC Hydro has leveraged the BC Hydro Power Smart brand and customer relationships in order to move customers towards existing channels that offer opportunities for electricity savings, while improving the ability of those channels to better meet our customers' needs. This approach has ensured a more sustainable impact on the channels that we are working through than could be achieved if BC Hydro sought to control a channel more directly. BC Hydro has leveraged additional funds from channel partners and other government sources, thereby improving the impact and cost effectiveness of different program offers.

BC Hydro has focused over the past several years on customers' evolving needs and how programs can be tailored or positioned to best resonate with people. The use of customer

[13] Sales by Revenue, April 2018.

analytics to better target customers who are more likely to participate in certain offers helps to ensure that the right message, reaches the right customer, via the right channel. Messaging will typically drive customers to the BC Hydro website where customers can find more detailed information and/or apply for programs.

Finally, these approaches and key partnerships can be used in the development of offers beyond conservation, such as capacity focused, low-carbon electrification[14], and the connected home. Many of the existing programs can be platforms for delivering these new offers to our customers and they also support codes and standards implementation by providing market intelligence about existing products and working to ensure that products are available and accepted by British Columbians prior to introducing a code or standard, thereby minimizing pushback from industry and the public.

5.2 Low Income Program

5.2.1 Overview

The Low Income program helps BC Hydro's lower income customers to reduce their energy consumption and lower their BC Hydro bills with an encompassing and free energy efficiency program offer. The Low Income program addresses the capital, awareness, education and other barriers that often prevent our lower income customers from improving the efficiency of their home. Low income households in both owner-occupied and rental accommodations are eligible. There are two key components to this program, seeking to address both the breadth and depth of our lower income customers' needs: Energy Savings Kits and the Energy Conservation Assistance Program.

Over fiscal 2020 to fiscal 2022, the Low Income program has increased expenditures to help BC Hydro's lower income customers with electricity bill affordability (see section 5.2.2 for more details). The program has had participation from Indigenous customers over much of the life of the program, and based on that experience and a trial in fiscal 2017 to fiscal 2018, a new approach to working with these communities will be introduced to better meet their needs.

[14] Low-carbon electrification is not included in this plan, incremental internal expenditure approval will be sought separately.

Since 2010, BC Hydro has partnered with FortisBC Energy Inc. to reduce costs and improve the effectiveness of providing this program to low income customers across the province. FortisBC Inc. is running a similar program modelled after the BC Hydro Low Income program in their electric territory. BC Hydro is also coordinating with Pacific Northern Gas in their service territory on delivery of the Low Income program.

Annual Plan	**$ million**	**GWh/yr**
F2020	5.8	9
F2021	6.9	9
F2022	7.8	9
Target Market	Lower Income Residential Customers (Statistics Canada's Low Income Cut-off threshold +30 per cent). Both owner occupied and renters.	
Key Components	Energy Saving Kits	
	Energy Conservation Assistance Program	
	Indigenous Customers Offer - New	
Cost Effectiveness	**Utility Cost (Market Price at $30 per MWh)**	**Modified Total Resource Cost (LRMC at $105 per MWh)**
Net Levelized Cost ($/MWh)	36	(29)
Net Present Value ($M)	(1)	35
Benefit Cost Ratios	0.9	3.5

Customer Benefits	**Industry Benefits**	**BC Hydro & Shareholder Benefits**
• Utility bill savings • Provides free access to energy efficient technologies and home improvements • Improved home comfort and safety • Increased knowledge of ways to lower energy bills • Supports owners and renters	• Supports B.C.'s home performance retrofit industry	• Generates positive earned media and customer satisfaction • Meet the Demand-Side Measures Regulation • Supports relationships with Indigenous communities • Supports the FortisBC Partnership

5.2.2 Description

	Detailed Description
Energy Saving Kits	The Energy Savings Kit is a package of basic energy saving measures provided at no charge that can be installed by most homeowners or tenants with limited or basic tools. Energy Savings Kits contain lighting-related products, water saving products (e.g., faucet aerators and a high performance showerhead), heat-loss products (e.g., draft proofing material, and window film) and general energy savings tips and brochures. In 2019, the program is expanding to provide participants window film on an annual basis at no cost. Window film is only used for one heating season and then removed. In addition, Energy Saving Kits will be provided at pre-qualified events (e.g., foodbanks, and Indigenous community events) and will not require a BC Hydro account number to receive a kit. Over the past two years, approximately 35 per cent of participants have been renters or tenants.
Energy Conservation Assistance Program	The Energy Conservation Assistance Program provides eligible BC Hydro low income Residential customers with a home evaluation, installation of energy saving products and education on what customers can do around their homes to save energy. There is no charge for the products or services provide through the program. Some of the energy saving products that may be installed include energy saving light bulbs, low-flow showerheads and faucet aerators, pipe wrap, draft proofing (e.g., door sweeps), an Energy Star refrigerator, a high-efficiency gas furnace (in conjunction with FortisBC Energy Inc.), and insulation for attics, walls and crawlspaces. Program criteria are being revised to enable more homes to receive weatherization upgrades and expanding the refrigerator replacement offer to apartments run by non-profits and co-op housing providers. Over the past two years, approximately 75 per cent of participants have been renters or tenants.
Indigenous Customers Offer	For customers on the integrated electricity system the Indigenous Customers offer, planned for late fiscal 2019, will partner with communities to support and encourage them to include energy efficiency measures when undertaking home renovations within their communities through their own channels. The program will provide funding for weatherization measures through a rebate model which will enable communities to combine multiple funding sources. The offer will also include a training component for community members on best practices for installing insulation for interested communities. For communities in the non-integrated system areas of the province, BC Hydro will be launching the new Non-integrated Areas program. A final component of Indigenous communities policy support is provided through BC Hydro’s Codes and Standards activities, these will work in conjunction with both customer offers described here.

5.3 Retail Program

5.3.1 Overview

BC Hydro seeks to influence our residential customers to purchase more energy efficient products, and leverages the retail channel to activate these transactions. The Retail

Program aims to advance the adoption of more energy efficient products by working with market partners to have the energy efficient products available on store shelves throughout B.C. at affordable price points, supported by knowledgeable sales staff.

The Retail program reaches large numbers of customers in a channel that they can utilize many times in a year, while offering a variety of low cost options or upgrades for residential customers (owners and renters) to become more energy efficient. Due to the partnerships with retailers (e.g., Home Depot, BestBuy) and manufacturers (e.g., Philips, Samsung), this program is able to leverage additional exposure in the form of flyer advertising, e-newsletters, websites and instore promotion, additional customer sales support from retail sales staff, and further discounting on products funded through manufacturers.

Key manufacturer and retailer channel partners are targeted to influence products stocked, promoted and how they are positioned. These partners represent the largest market share and widest exposure across the province. The program leverages the potential for low-cost and far-reaching public exposure through partner's flyers, promotions and space in-store. Joint utility and municipality collaboration allows for increased rebate offers to customers, operational efficiencies and enhanced customer experience. These partnerships, channels to market, and opportunities to leverage consumer engagement enable a platform for new offers such as connected home technology or demand response capable devices. The program is also designed to increase the market penetration of energy efficient products to set the stage for collaborating with governments and standards agencies to help push changes to energy efficient regulation.

Annual Plan	$ million	GWh/yr
F2020	2.1	6
F2021	2.1	5
F2022	2.2	5
Target Market	Residential customers who purchase product through the retail channel. Can include both owner occupied and renters (for lower cost product investments). Key partnerships are with retailers like Best Buy, Home Depot, Costco and a variety of appliance, lighting, electronics, and home improvement product manufacturers	
Key Components	Channel partnerships	
	Product Incentives	
	Advertising and promotions (often provided by the retailer/manufacturer partners)	
Cost Effectiveness	**Utility Cost (Market Price at $30 per MWh)**	**Modified Total Resource Cost (LRMC at $105 per MWh)**
Net Levelized Cost ($/MWh)	2	(6)
Net Present Value ($M)	6	19
Benefit Cost Ratios	2.0	6.0

Customer Benefits	Channel Partner Benefits	BC Hydro & Shareholder Benefits
• Better accessibility and availability to products • Reduced cost to purchase • Utility bill savings • Other non-energy benefits depending on the appliance/product (e.g., extra features, water savings etc.) • Easy to participate with low cost options for renters and home owners • Education and awareness • Customer satisfaction	• Increase sales with incentives and in-store execution • Campaign promotions and fulfilment educates their customers and drives traffic to their stores • Leverage other program initiatives • Partner satisfaction	• Positive public exposure in partner owned channels by leveraging long-standing relationships • Customer and channel partner satisfaction • Established channels to market can ease the expansion of any future customer offers • Supports Codes and Standards

5.3.2 Description

	Detailed Description
Channel partnerships	The program works with select retailers, manufacturers and supporting partners in order to collaborate on addressing market barriers to purchasing energy efficient products. Aligning with retailers who represent the largest market share, BC Hydro maximizes its resources and its partners' resources to increase participation, awareness and ultimately drive adoption of energy efficient products. Complementary manufacturing partnerships are chosen to further influence the campaign offers, driving participation, awareness and adoption. BC Hydro partners with FortisBC to reduce program costs, increase customer incentives and make it easy for customers to participate. FortisBC leverages the negotiations BC Hydro has developed with its channel partners. BC Hydro runs campaigns through the year that target various end-use categories. This approach to campaign management provides operational efficiencies while maximizing the time that offers are in market and available to assist customers. Partnering with local governments, BC Hydro is able to leverage municipal funding available to reduce water use and GHGs to increase customer incentives, drive participation, and make it easy for customers to do business with us.
Incentives	The program provides different incentives as needed, through various means designed to elicit the best market response. Downstream incentives are offered to residential customers to reduce the cost to purchase energy efficient products, driving awareness and partner engagement. The program provides mid-stream incentives where appropriate to retailers, to position, promote and drive sales of energy efficient products.
Advertising and Promotion	Typically twice a year, BC Hydro manages campaigns and offers at strategic retailers with specific manufacturers. By supporting channel partners through advertising, promotions and program collateral, the program leverages partner flyer exposure and other promotional channels as well as additional incentives from retailers and manufacturers to customers. The exposure that retail partners provide BC Hydro helps to stimulate interest and excitement amongst our customers in ways that we would not be able to achieve on our own. In store events also provide BC Hydro an opportunity to educate customers on energy efficient products and behaviors.

5.4 Home Renovation Rebate

5.4.1 Overview

The Home Renovation Rebate Program focuses on customers with electric heat, who typically have the highest electric bills as heating is normally 50 per cent of a home's energy consumption. The program seeks to motivate these customers to undertake energy efficiency upgrades to their existing homes, primarily focused on lowering their space heating load and hence making their electric bills more affordable. The program promotes upgrades to building envelopes (insulation, windows, draft proofing), space and hot water heating systems, and ventilation, with a combination of rebates for single and multi-upgrade improvements. The Program is jointly administered with FortisBC Energy Inc. and FortisBC Inc., allowing customers to access a single offer regardless of whether their homes are electric or gas heated. The Home Renovation Rebate budget was augmented to increase incentives for some measures (e.g., insulation) as well as expand the number of measures (e.g., heat pumps) for electrically heated customers to improve the affordability of their BC Hydro bills.

In addition to direct incentives, the program communications are aimed at program awareness and participation, and educating consumers on energy efficient home renovations. The program works with contractors, providing program details, training, sales support and recommendations on installation best practices in home energy retrofits to improve the availability and quality of home energy retrofit services in B.C. The program can be a platform for new offers that require expert installation such as demand response capable water heaters, whole home automation/connected home.

Annual Plan	**$ million**	**GWh/yr**
F2020	4.2	8
F2021	4.4	8
F2022	4.6	9
Target Market	Residential customers primarily with electric heating (owner and renter occupied buildings)	
Key Components	Rebates for building envelope improvements, heating systems, ventilation upgrades, and a multi-measure bonus.	
	Coordinated application and partner rebates – FortisBC, Province of BC, Municipalities (in development phase)	
Cost Effectiveness	**Utility Cost (Market Price at $30 per MWh)**	**Modified Total Resource Cost (LRMC at $105 per MWh)**
Net Levelized Cost ($/MWh)	(8)	47
Net Present Value ($M)	15	35
Benefit Cost Ratios	2.3	1.9

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Utility bill savings • Improved home comfort • Health, safety, comfort, and building durability as well as other non-energy benefits • Reduced maintenance • Easy access to coordinated utility program offers (one-stop-rebate shop)	• Increased sales of efficient products	• Support electrically heated customers to lower their bills • Align with Provincial interests • Flexible program platform can be leveraged for additional partners and more complex future initiatives including demand response and low-carbon electrification

5.4.2 Description

	Detailed Description
Program Rebates	The incentives are designed to reduce the customer's upfront cost of installing more efficient measures and technologies. Incentives also support consumer awareness of energy efficient technologies.
Partnerships and Coordination	The Program partners with FortisBC to offer a coordinated administrative and application platform for multiple home energy rebates. In addition, in fiscal 2019 the program is expanding to include rebate partnerships with the Province of B.C. and several municipal governments to provide additional rebates for participants by leveraging the existing program platform. This approach has provided internal efficiencies and improved the customer experience in finding and accessing related program rebates.

5.5 Non-Integrated Areas

5.5.1 Overview

This plan includes a deeper focus on energy efficiency activities and offers for customers living in non-integrated areas of BC Hydro's service territory. Reduction of consumption in these areas reduces high-cost electricity production as well as BC Hydro's GHG emissions from diesel generation. The majority of the activities are for residential customers, but there is also a small commercial component. This offer was informed by pilot work conducted in fiscal 2017 to fiscal 2019.

BC Hydro provides electricity to customers in Non-Integrated Areas (**NIA**) through a combination of diesel generating stations owned and managed by BC Hydro and small hydro plants (owned by BC Hydro or Independent Power Producers). NIA customers – including Indigenous customers – struggle to understand and pay their bills, and are often subject to higher bills as a result of poor housing construction and maintenance practices and severe weather conditions in some remote areas.

In our recent regulatory filings (Fiscal 2017 to Fiscal 2019 Revenue Requirements Application), interveners expressed a clear interest in and need for additional BC Hydro efforts to assist NIA communities in implementing DSM activities. Conservation and Energy Management has reflected this feedback in its plan by moving from pilot initiatives to a dedicated program for NIA communities.

This work stream includes new residential and commercial program offers to assist NIA customers in saving electricity, reducing utility bills and improving home comfort, while helping NIA communities to reduce their reliance on diesel generation, thereby reducing GHG emissions.

Annual Plan	**$ million**	**GWh/yr**
F2020	1.2	0
F2021	1.4	1
F2022	1.5	1
Target Market	Indigenous and Non-Indigenous customers living in one of BC Hydro's Non-Integrated communities	
Key Components	Residential rebates	
	Commercial Direct Install	
	Community Support	
Cost Effectiveness	**Utility Cost**	**Modified Total Resource Cost**
Net Levelized Cost ($/MWh)	175	117
Net Present Value ($M)	3	4
Benefit Cost Ratios	1.8	2.2

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Increased energy literacy • Improved home comfort and other non-energy benefits • Utility bill savings • Health, safety, and building durability • Reduced maintenance • Local economic development opportunities • Reduced reliance on diesel • Air quality and climate benefits (GHG reductions)	• Small local service providers and/or community members will be utilized where feasible • Local economic development opportunities	• Strengthened relationships and partnerships with Indigenous communities • Reputational benefits • Reduced costs of service • Energy savings and GHG reductions

5.5.2 Description

	Detailed Description
Residential Rebates	Residential opportunity assessments and energy conservation measures (**ECMs**) delivered by Indigenous governments (Bands, Tribal Councils), using local community members and contractors to perform the work. Training will be provided at different points through the project lifecycle to assist Indigenous governments in advancing home energy upgrades and accessing rebates (e.g., how to assess energy saving opportunities in the home, how to install basic energy savings measures, how to prioritize and plan for additional retrofit opportunities, best practices in air sealing and insulation for contractors/trades). ECMs include basic measures such as LED lighting, faucet aerators, basic draft proofing materials (weather-stripping, caulking, outlet gaskets. window film), pipe wrap, dryer rack, CO monitors and smart strips, as well as deeper measures such as windows and doors, insulation, advanced air sealing, ventilation systems, heat pumps and programmable thermostats.
Commercial Direct Install	Basic commercial ECMs (e.g., lighting and some refrigeration measures) are installed in commercial and community/Band-owned buildings by Alliance-approved vendors.
Community Support	Financial and technical support to Indigenous governments

5.6 Residential Energy Management Activities

5.6.1 Overview

The objective of the Residential Energy Management Activities is to provide information and tools that assist customers to optimize their energy use. This is accomplished through support of BC Hydro's residential Demand-Side Management programs, rates, and codes and standards efforts in achieving their respective energy management and market transformation objectives. The three key elements of the energy management activities include a behavior program, industry support, and access to energy data.

The centre-piece of the Residential Energy Management Activities is the Behavioural program designed to encourage residential customers to adopt more energy conscious behaviours and practices that lead to electricity savings and lower bills. The program relies on well-established behavioural change methods such as Feedback and Challenges. Customers don't need to invest in products, they only need to change how they use the products they already own.

Industry support is an important feature to provide customers with access to trained and qualified trade allies/supply-chain partners who can assist them in understanding their energy management options, providing an assessment, and completing their projects/making their purchases. While ensuring quality performance, these partnerships also lead to market push, ultimately resulting in the increased penetration of energy-efficient technologies and energy management solutions.

Providing feedback and energy data is a powerful tactic that results in increased awareness and insights, which in turn lead to adjustments in the operation of a household to optimize energy use. Detailed in-home consumption feedback from smart meter data is offered to all customers through the Energy Visualization Portal (**EVP**) on the BC Hydro website and for more engaged customers in near real-time via home energy monitors. The EVP presents customers with different and customizable views of their electricity consumption patterns (hourly, daily, weekly, monthly, and yearly), as well as comparisons to previous periods, similar homes nearby and average temperatures. Users can also view consumption forecasts, download their data and subscribe to various alerts. Through these different analytics tools in the EVP, the Behavioural program increases awareness and understanding of consumption patterns among BC Hydro's customers.

Annual Plan	$ million	GWh/yr
F2020	5.0	13
F2021	4.9	13
F2022	5.0	12
Target Market	All Residential customers who require assistance to make the best decisions around energy management for their household. Can be utilized by owners and renters	
Key Components	Detailed consumption feedback	
	Energy reduction challenges with membership	
	Energy Management Coaching and Home Assessments	
	BC Hydro Alliance of Energy Professionals (across all sectors)	
	External Workforce Capability Building (across all sectors)	
	Customer Information Support	

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Personal, relevant and actionable recommendations and tips • Proactive engagement and guidance from BC Hydro on energy management issues • Opportunity to earn rewards through successful Team Power Smart Challenges • Utility bill savings • Assistance in accessing qualified products and industry expertise • Increased availability of products and expertise, as well as quality within industry • Energy management information, advice, and program access support • Often low cost/ no cost advice for both home owners and renters	• Contests, promotions, and offers driving customers to products and channels that help customers manage their energy use • Promotion of third- party tools that support energy data such as in-home monitors and future mobile applications • Training and support on available BC Hydro programs, technologies, and changes codes and standards • Partners can expand their suite of products and service offerings to customer	• Utilizes smart meter data by presenting customers with rich and timely information • Provides a highly engaged and accessible group of customers for testing new products, services and programs and to act as advocates for energy management and as ambassadors for BC Hydro • Foundational platform from which to launch future new offers • The trade ally network effectively sells and promotes BC Hydro programs to customers • Market and technical insights including technology adoption, new customer opportunities and feedback on Demand-Side Management program effectiveness • Ensuring there are well training trades helps to reduce BC Hydro's risk of poor workmanship and/or unhappy customers • Communication channel with industry, and insight into various firms expertise • The extensive relationships with industry allows for the introduction of new services and solutions in the future.

5.6.2 Description

	Detailed Description
Detailed Energy consumption feedback	Customers receive access to tools that allow them to better understand their household electricity consumption. When they create a MyHydro profile and link their account they can log into BC Hydro's customer portal with their email address and password to access graphs with detailed consumption feedback from their smart meters. These graphs allow them to analyze their hourly, daily, weekly, monthly and yearly consumption patterns. Comparing their consumption to the previous year and to similar homes allows customers to assess whether there are any opportunities to reduce their consumption. They can also see the impact of the outside temperature on their electricity consumption and subscribe to a free email reminder service to help them log-in on a frequent basis. These analytics tools increase customers' awareness of their electricity consumption and it empowers them to look for opportunities to take action to reduce their bill. Home Energy Monitors connect wirelessly to a customer's smart meter and provide real-time energy information from SMI data. These devices are constantly evolving and BC Hydro and Powertech work closely with industry leaders to ensure system compatibility and a seamless and positive customer experience. BC Hydro will start a trial of Home Energy Reports: select customers will receive a print report with consumption graphs and other insights about their electricity consumption, as well as tailored recommendations and actionable tips. The use of Home Energy Reports is a tried and tested behavioural strategy to engage hard-to-reach target segments. It is already successfully deployed by around 100 North American utilities.
Energy Challenges and membership through Team Power Smart	Customers can become a member of Team Power Smart. This provides them several benefits, including the opportunity to enter into a Challenge to reduce their household electricity consumption by 10 per cent or more below the previous year's consumption. If they are successful they will receive a $50-bill credit. A Maintenance Challenge is also available; if they stay at or below the lower consumption level that was accomplished during their successful Reduction Challenge they will receive a $25 bonus. Challenge participants receive proactive reminders from BC Hydro to keep them engaged, status updates on how they are progressing with their Challenge and tips and advice on strategies and actions that can assist them in reaching their goal. Team Power Smart members can participate in members-only contests and benefit from offers; they also receive tailored communications by mail and email including progress updates, practical tips, and motivational stories, etc. This offer benefits both home owners and renters.

	Detailed Description
Energy Management Coaching and Home Assessments	Energy coaches provide personalized support and resources to assist customers in undertaking home energy management upgrades. Coaching can range from advice delivered by phone to personal support for implementing upgrades (such as helping review contractor bids). The program is building on energy coaching related services that were trialed in fiscal 2018 in partnership with six municipalities and the Government of B.C, which includes a coaching hotline and in-person coaching services. Home Energy Assessments (or home energy audits) provide a personalized overview of home energy use and energy saving opportunities. A comprehensive in-home assessment and modelling of home energy use completed by a licensed Energy Advisor is required to access the performance path program bonus for the Home Renovation Rebate program and serves as an important energy management support tool.
BC Hydro Alliance of Energy Professionals	The BC Hydro Alliance of Energy Professionals is a network of contractors, consulting engineers, manufacturers, distributors, retailers, and registered experts that will promote the use of energy management and efficiency solutions to our customers. BC Hydro leverages the Alliance members' ability to sell and promote energy efficient products, services and programs to our customers within the context of demand-side management programs which is a cost-effective approach to minimize program marketing expenditures. BC Hydro delivers training to Alliance members to ensure they are educated on energy management and trained on the details of the available BC Hydro programs. This goal is achieved in part through partnerships with associations for development and delivery of courses and workshops. The BC Hydro Alliance of Energy Professionals also enables Conservation and Energy Management to monitor and assess the quality of work that customers receive from Alliance members, and take remedial action if deficiencies are identified. With constant turnover in the distributor and retail channel, BC Hydro recognizes the need for substantial effort in regular training and education activities with sales associates. A coordinated approach with channel partners allows BC Hydro to take advantage of existing training infrastructure including product road shows, monthly meetings and online training to reach as many sales associates as possible around the province. This approach allows for sales associates to act as ambassadors for the program, as they educate and assist customers and drive sales of energy efficient products.
External Workforce Capability Training	A critical success factor for the Demand-Side Management Plan is that there is an available and accessible qualified installation contractors in place in B.C. BC Hydro plays an important role in identifying and filling skill gaps in the workforce by supporting the development of the professional home energy performance industry in B.C. by working with partners to support third party industry trades groups (e.g., the Home Performance Stakeholder Council), professional contractor training, and development and implementation of contractor accreditation and certification programs.
Customer Energy Information Support	BC Hydro assists our customers to resolve their energy related inquiries and become more educated on how to access our programs and energy saving opportunities. The Customer Support Centre – call centre provides a first call/email option for our customers to find out more about their specific energy inquiries. Additionally they provide, through the Business Help Desk (a group of specialized agents), a channel of support for specific energy management program inquiries.

6 Commercial Sector Programs

6.1 Commercial Sector Overview

BC Hydro's commercial sector, including small and medium businesses to key account managed large commercial customers, has over 95,000[15] customer accounts and sales to this sector total 15,700 GWh annually. The average commercial account consumes 99,000 kWh[16] annually, although there is a wide distribution of consumption among the various customer segments.

6.1.1 Sector Strategic Approach

The Commercial sector provides support and initiatives for customers to address their diverse needs and barriers. Programs are designed to take into consideration the technical and customer segment opportunities, reducing the barriers that exist for customers to adopt those technologies or operational changes, and finally developing partnerships that can be leveraged to successfully bring these programs to market. The suite of offers helps customers identify opportunities, adjust their business operations, and implement capital projects. This approach will achieve cost savings, keep rates low, and support a trusted energy advisor relationship with customers and BC Hydro. All the commercial programs have been designed as flexible platforms that can add new offers and services as customer needs evolve.

For the F2020-F2022 Demand-Side Management Plan, Commercial programs will continue to focus on delivering a variety of solutions that will help customers achieve energy savings, increase their energy literacy, and make it easier to do business with us. This includes:

- Providing customers with energy data information such as having access to tools, graphs, charts and reports that for instance identify unusual building consumption and changes in a building's energy performance;
- Supporting a strategic energy management approach to integrating energy efficiency considerations into ongoing customer business practices and company culture;

[15] Sales by Revenue, April 2018.
[16] 2014 Commercial End-Use Study, page 298.

- Focusing support to customers that require our help the most, such as small and medium businesses and Healthcare, Education, and Government sectors, while still ensuring all customers have an opportunity to participate;
- Raising awareness of the opportunities that exist for customers to save on their electricity bill and integrate best practices in their operations and buildings;
- Working with the BC Hydro Alliance of Energy Professionals who assist business customers find opportunities to save energy, install energy-efficient products, and ensure product availability;
- Providing customers with significant support through training, technical expertise, financing options, and funding to optimize the energy consumption in their buildings; and
- Support growth in market capability by continuing to support industry-driven efforts by creating the appropriate tools and resources and educational opportunities to deliver sustained, high quality services to the marketplace. These efforts help to drive market transformation and assist in the adoption and compliance of building codes.

6.2 Leaders in Energy Management – Commercial (LEM-C)

6.2.1 Overview

The Leaders in Energy Management – Commercial (**LEM-C**) program provides energy efficiency solutions to assist customers with their energy efficiency projects. The program is intricately linked to the Commercial Energy Management Activities to help customers overcome the management and business barriers to energy efficiency. This approach will achieve cost savings, helps with affordability and supports a trusted relationship with customers. This program targets BC Hydro’s commercial segment, including small and medium business to key account managed large commercial customers.

Given the design of the program and the relationship with the customers, it provides an important base to allow the addition of new initiatives as opportunities evolve in areas such as capacity focused DSM offers.

Annual Plan	**$M**	**GWh/yr**
F2020	9.0	51
F2021	9.1	47
F2022	9.2	39
Target Market	Public Sector (Healthcare, Education, Government) and Commercial customers. Small and Medium Business are also a key target.	
Key Components	Project Energy Study	
	Project Implementation Funding	
	Social Housing Retrofit Support Offer	
	BC Hydro Technical Expertise	
Cost Effectiveness	**Utility Cost (Market Price at $30 per MWh)**	**Modified Total Resource Cost (LRMC at $105 per MWh)**
Net Levelized Cost ($/MWh)	4	(39)
Net Present Value ($M)	35	195
Benefit Cost Ratios	2.5	4.0

Customer Benefits	**Industry Benefits**	**BC Hydro & Shareholder Benefits**
• Make smart choices with their power: Providing tools and new technologies, allowing customers to reap the benefits of cost savings. • Bill savings: Reduce customers' electrical operating costs. • Improve corporate culture • Remove financial barrier: Incentives to help overcome customers financial hurdle rates and lower project payback period to an acceptable level. • Other non-energy benefits depending on the end-use/project (e.g., maintenance, enhanced building value etc.) • Supports customers that need assistance in the public sector and small and medium sized businesses	• Support advancement in technology: Increase market demand that supports research and development towards more efficient end uses.	• Demonstrate commitment and support for helping customers to more easily do business with us: Seen as a trusted and credible partner to support customers and industry achieve their goals. • Foundational platform for capacity focused DSM • Retain flexibility: The offer can be adjusted quickly to changing internal and external demands by scaling up or down, adding funding partners or new program measures. • Support towards market transformation: Emphasis on market transformation and education of key stakeholders by providing the right tools and resources. • Support customer service: Ability to integrate customer strategy initiatives as necessary to ensure optimized delivery of offers.

6.2.2 Description

	Detailed Description
Project Energy Study	The Project Energy Study provides customers with detailed technical information, quantified energy information and expected implementation costs for specific projects. The study can be used to determine the most effective energy conservation measure for implementation that best fits the customer's needs. Energy Study eligibility criteria is only available to organizations with BC Hydro sponsored Energy Managers and Energy Manager Associates.
Project Implementation Funding	Project Implementation funding is available to help customers reduce the capital cost of implementing the identified measures. Upon review of the study and subject to adherence to program rules and passing economic cost tests, customers are offered a capital incentive agreement for signature. In addition, Business Energy Saving Incentives is an online process for simple one-to-one retrofits covering a wide range of technologies that is supporting all sizes of customers, particularly small and medium sized businesses. Project Implementation Funding eligibility criteria is only available to organizations with BC Hydro sponsored Energy Managers and Energy Manager Associates.
Social Housing Retrofit Support Offer	Newly introduced for fiscal 2019 is the Social Housing Retrofit Support Offer for Multi-Unit Residential that provides an opportunity for qualifying social housing providers (e.g., BC Housing, and the B.C. Non-Profit Housing Authority) to minimize their operating costs and improve whole building performance of their facilities through the more efficient use of natural gas and electricity. This offer is a partnership between FortisBC Energy Inc., FortisBC Inc., BC Hydro and the Government of B.C. (through Efficiency B.C.) and is offered throughout the British Columbia service territories of the utilities. Customers are allowed to utilize any of the four offers below: Energy study funding to review the potential energy conservation measures. Implementation support that provides engineering design, tendering and project management Rebates for upgrading eligible technologies for lighting, HVAC and commercial kitchen Rebates for low-carbon electrification opportunities
BC Hydro Technical Expertise	BC Hydro will provide project specific internal technical assistance and support to the customer throughout a project to allow for an integrated customer experience. Tools, such as project calculators, are also created to further support the customer that allows for a cost effective support model.

6.3 New Construction Program

6.3.1 Overview

The Commercial New Construction program provides industry training, customer coaching and financial support for the design and implementation of new high performing buildings. The program sets the stage for changes to energy efficiency requirements in Part 3 of the B.C. Building Code. This part of the B.C. Building Code covers large and complex buildings, such as hospitals, schools, and high-rise condo buildings. The activities of the program assist in the transition to more efficient building codes, but to be conservative the program does not take any benefit from the attribution of those codes saving.

The Province has committed to taking incremental steps to increase energy-efficiency requirements in the BC Building Code to make buildings net-zero energy ready by 2032. The BC Energy Step Code-part of the BC Building Code-supports that effort and was enacted in April 2017. It is anticipated that by 2022, there will be widespread voluntary adoption of the BC Energy Step Code by municipalities, and that this will signal the wind down of this phase of the program.

This program will then transition to a codes and standards strategy to most effectively sustain the drive towards more efficient buildings, freeing up resources to potentially focus on providing broader offers to the new construction sector such as low-carbon electrification,[17] demand response capable technologies and advanced connected building systems.

The Commercial New Construction program continues to provide a foundation of energy efficiency support and initiatives for customers, while building capability to transform the new construction market, leveraging new technology capabilities in the marketplace, and adapting to changing customer needs.

The program's key objective is to provide technical expertise and funding in the form of design and modelling support, energy studies, personalized coaching, and advanced training for the design and implementation of cost-effective energy efficiency measures and building systems that exceed building code requirements.

The Commercial New Construction program is also well established to assist in improving compliance levels with the BC Building Code and the Vancouver Building Bylaw given BC Hydro's expertise and interaction with different industry players. The program is playing a role to increase the compliance level of these codes by focusing on industry education and training, building information data sharing and including program requirements for all Whole

[17] Low-carbon electrification is not included in this plan; incremental internal expenditure approval will be sought separately.

Building Design projects to be physically inspected. By continuing to advance aggressive energy efficient building requirements and seizing the "one-time" opportunity to incorporate those measures into design and construction of new commercial buildings, the program also provides both support for the introduction of ongoing more aggressive building codes and the compliance of current codes and standards.

Annual Plan	**$ million**	**GWh/yr**
F2020	3.7	8
F2021	2.4	5
F2022	2.0	5
Target Market	New Construction projects focusing on Healthcare, Education, and Government, as well as support for other Commercial/Multi-unit Residential developers/owners.	
Key Components	Pre-engagement: Design team kick off meeting	
	Energy Study Proposal	
	Energy Study	
	Project Implementation Funding	
	BC Hydro Technical Expertise	
Cost Effectiveness	**Utility Cost (Market Price at $30 per MWh)**	**Modified Total Resource Cost (LRMC at $105 per MWh)**
Net Levelized Cost ($/MWh)	16	17
Net Present Value ($M)	4	34
Benefit Cost Ratios	1.5	3.0

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Bill savings: Reduce customers' electrical operating costs via energy efficient construction and operation of buildings. • Make smart choices with their power: Access to energy information and providing tools and new technologies, allowing customers to optimize energy efficiency and construct buildings that are more desirable for occupants. • Other non-energy benefits depending on the project (e.g., enhanced building value and lease rates etc.) • Remove financial barrier: Incentives to help overcome customers' financial hurdle rates and lower project payback period to an acceptable level.	• Platform to support market transformation through energy efficient design: Identify energy savings by promoting and funding the design of energy efficient buildings that exceeds the minimum building code legislation required, providing industry training and education to help condition the market for the introduction of the next building code. Furthermore, this transformation strategy serves to increase the industries' level of compliance with the current building code. • Support advancement in building design, systems and technology: Increase market demand that supports research, demonstration and development towards more efficient buildings and technologies.	• Demonstrate commitment and support for helping customers to more easily do business with us: Seen as a trusted and credible partner to support customers and industry achieve their goals. • Support customer service: Ability to integrate customer strategy initiatives as necessary to ensure optimized delivery of offers. • Retain flexibility: The program focus can be adjusted as the adoption of the BC Energy Step Code progresses, and new opportunities such as low-carbon electrification arise.

6.3.2 Description

	Detailed Description
Pre-engagement: Design team kick off meeting	Conservation and Energy Management will conduct a Design team kick-off meeting in the early stages of building design. It's essential for the success of the potential Energy Study to have a design team kick-off meeting with the customer, design team, and BC Hydro program representatives to ensure a good understanding of program's requirements and deliverables. This step occurs prior to submitting the Energy Modelling Study Proposal. This initial step helps customers and BC Hydro determine if there is a viable opportunity to explore. The Project Workbook contains preliminary building and/or equipment information and estimates for the project as well as relevant contact and project team information.
Energy Study Proposal	After a design kick off meeting is conducted and the project meets program core eligibility requirements, the applicant must complete and submit a complete Energy Study Proposal Workbook to BC Hydro. The purpose of this submission is to document the project details, including design team to be involved in the study with qualification, building baseline, scope of work, and the study cost breakdown for funding approval consideration.
Energy Study	The Energy Study provides customers with detailed technical information, quantified energy information and expected implementation costs. The study can be used to determine the most effective energy conservation measure for implementation. The study along with BC Hydro support includes among other detailed analysis: • Reviewing modelled baseline and proposed energy consumption; • Electrical and Mechanical Systems requirements; • Building Envelope thermal bridging analysis; • Costing; and • Design options, bundled measures along with interactive effects.
Project Implementation Funding	Project Implementation funding is available to help customers reduce the capital cost of implementing the identified measures. Upon review of the study and subject to adherence to program rules and passing economic cost tests, customers are offered a capital incentive agreement for signature.
BC Hydro Technical Expertise	BC Hydro will provide project specific internal technical assistance and support to the customer throughout a project to allow for an integrated customer experience.

6.4 Commercial Energy Management Activities

6.4.1 Overview

The objective of the Commercial Energy Management Activities is to provide information and tools that assist customers to optimize their energy use. These activities also support BC Hydro's commercial Demand-Side Management programs, rates, and codes and standards efforts in achieving their objectives. By encouraging and assisting customers in integrating energy efficiency into their ongoing business practices and company culture through a Strategic Energy Management approach, BC Hydro can both increase the confidence in, and quantity of demand-side management savings.

The Commercial Energy Management Activities provide Strategic Energy Management training and resources (including Commercial Energy Managers), audits, and support required to enable the customer to implement, operate, and maintain facility changes. As part of these, building energy monitoring and optimization are implemented to better understand and use customer energy data to improve their energy performance and increase building efficiency. The flexible design of the activities and the established relationships with the different customer segments establishes a platform to offer new services such as capacity focused demand-side management.

In addition, customers have access to trained and qualified trade allies/supply-chain partners to help them assess facility opportunities, complete their projects, and access energy information support. Customer interest from utilizing energy information generates market pull, while our partnerships (supply-chain and other) can lead to market push, ultimately resulting in the increased penetration of energy-efficient technologies and energy management solutions. These relationships with industry will also allow for a relatively seamless add new efficiency offers in the future.

Annual Plan	$ million	GWh/yr
F2020	6.2	n/a
F2021	6.1	n/a
F2022	6.1	n/a
Target Market	All Commercial customers who require assistance to make the best decisions around energy management for their business. Can be utilized by public sector, small and medium business, and private sector	
Key Components	• Energy Management Assessment and Plan • Energy Managers • Investigative Energy Study & Building Optimization Study • Energy Wise Network / Campaign in a Box • BC Hydro Alliance of Energy Professionals • External Workforce Capability Building • Customer Information Support	

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Energy management information, advice, and program access support • Assistance in accessing qualified energy management products and industry expertise • Increased availability of energy management expertise and quality within industry • Reduce customers' electrical operating costs • Improve corporate culture around strategic energy management • Low-cost/ no-cost support is particularly beneficial for the public sector and small and medium businesses	• Energy Management as a career has grown including all the associated support services • Training and support on BC Hydro programs, various technologies, and changes in codes and standards • Business development – Partners are able to expand their suite of products and services to customer • Support advancement in research and development of energy efficient end uses	• Improved communication channel with industry and customers • The trade ally network effectively sells and promotes BC Hydro programs to customers • Market and technical insights including technology adoption and new customer opportunities are more easily surfaced • Market feedback on Demand-Side Management program effectiveness • Risk mitigation by ensuring engineering consultants and contractors are trained and qualified • Foundational platform for future offers to this customer segment such as demand response, low-carbon electrification, or other technology or service

6.4.2 Description

	Detailed Description
Energy Management Assessment and Plan	Energy Management Assessment: A diagnostic workshop with an organization's senior management to review practices and procedures regarding the organizations energy management practices to move them towards best practices and feed into the Strategic Energy Management Plan. Strategic Energy Management Plan: A one to three-year plan that captures strategic (i.e., corporate policies, metrics, targets), enabling (i.e., recognition, behavioural change, organizational structure) and functional (i.e., operating procedure, procurement, reporting) energy management components. The plan captures energy savings opportunities and aligns with corporate budgets and targets.

	Detailed Description
Energy Managers	The Energy Manager represents the critical first step – secure a dedicated energy champion within an organization that can work with the company's senior management team to help create and implement a corporate level strategic energy management program with targets. The Energy Manager also utilizes various tools and resources (i.e., energy data, capital incentives, energy study funding, and behavioural/operational initiatives) to ensure the company's energy policies and long-term goals are met through energy savings initiatives. Energy Manager Associates are available to key account customers without an Energy Manager and help customers take a strategic approach to energy management and create organizational change to reduce energy waste and improve energy intensity. They provide customers with: access to educational and training events, resources and tools to develop Strategic Energy Management Plans, tracking and reporting templates, diagnostic workshops, and mentoring from BC Hydro funded Energy Managers. The Shared Energy Manager and the Business Energy Advisor is an adaptation of the Energy Manager model that is customized for small and medium business. These individuals will target select commercial customers utilizing various marketing techniques (i.e., propensity modelling) and introducing a strategic energy management concept and approach within their organization. Conservation and Energy Management will support and deliver technical training and education events for Energy Managers to further advance the skills and knowledge of best practices related to building systems, technology, and strategic energy management.
Investigative Energy Study and Building Optimization Study	The Investigative Energy Study is used to determine the most effective energy conservation measures for implementation across an entire building or campus. The study also includes financial analysis that includes payback and ROI, based on the recommended energy conservation measure solutions that best fits the customer's needs. The act of increasing building performance through improved operations (as opposed to equipment retrofits) is referred to as recommissioning. Recommissioning studies review the cost, energy savings, and payback of various operational measures (e.g., reducing equipment run time during unoccupied hours). Industry standards and technology advances, particularly in the area of software (e.g., artificial intelligence), are facilitating the development of new types of software tools to improve and optimize building operations. The Strategic Energy Management Hub is an online tool to support customers in the strategic management of their portfolio of buildings aligned with historical and active energy efficient projects with the ability to run energy analytics. Customers can improve building operations by leveraging new tools that access more granular building energy information such as Anomaly Detection and Diagnostics, Cumulative Sum of Saving Tool (shows the cumulative savings from energy management measures implemented in a building relative to a defined baseline), Consumption trends and Energy Use Intensity.

	Detailed Description
Energy Wise Network / Campaign in a Box	Change management includes social marketing and behavioural economic techniques to target end users to ensure a culture of energy management is embedded within the organization which helps to change the behaviours of employees. The Energy Wise Network provides customers with education, campaign toolkits, diagnostic tools, mentoring support, and funding to implement campaigns to engage employees in their organization to use energy wisely. Campaign in a Box provides a scalable version for small and medium businesses to seamlessly adopt within their organization.
BC Hydro Alliance of Energy Professionals	The BC Hydro Alliance of Energy Professionals is a network of contractors, consulting engineers, distributors and registered experts that will promote the use of energy management and efficiency solutions to our customers. BC Hydro leverages the Alliance members' ability to sell and promote energy efficient products, services and programs to assist our customers within the context of demand-side management programs which is a cost-effective approach to minimize program marketing expenditures. BC Hydro delivers training to Alliance members to ensure they are educated on energy management and trained on the details of the available BC Hydro programs. This goal is achieved in part through partnerships with associations for development and delivery of courses and workshops. BC Hydro has developed an online catalogue of energy efficient products that provides contractors, distributors, and manufacturers with easily accessible specifications of products that are supported within BC Hydro programs. The BC Hydro Alliance of Energy Professionals also enables Conservation and Energy Management to monitor and assess the quality of work that customers receive from Alliance members, and take remedial action if deficiencies are identified.
External Workforce Capability Training	A critical success factor for the Demand-Side Management Plan is that there is an available and accessible "energy efficiency skilled" workforce in place in B.C. BC Hydro plays an important role in identifying and filling skill gaps in the workforce by partnering with post-secondary institutions and industry associations who develop and deliver new training and educational programs. The objective of education and training is to develop and build market capacity of individuals that will be qualified to become energy managers and energy champions within customer and industry organizations as well as to grow the pool of qualified individuals who can join trade ally firms. This will support program participation, increase awareness and action and ultimately integrate efficiency into ongoing business processes. This initiative includes integrating energy management modules within targeted disciplines of academic and training institutions as well as the development of materials to educate customers and trade allies. This provides support for students enrolled in post-secondary institutions, addressing the adequacy requirements of the Demand-Side Measures Regulation.
Customer Energy Information Support	BC Hydro assists our customers to resolve their energy related inquiries and become more educated on how to access our programs and energy saving opportunities. The Customer Support Centre (call centre) provides a first call/email option for our customers to find out more about their specific energy inquiries. Additionally they provide, through the Business Help Desk (a group of specialized agents), a channel of support for specific energy management program inquiries.

7 Industrial Sector Programs

7.1 Industrial Sector Overview

BC Hydro's industrial sector is comprised of over 43,000 customer sites, from family-run farms to large mining operations. Sectors that are the most likely to engage in BC Hydro's industrial demand-side management programs include agriculture, manufacturing, transportation, forest products, pulp and paper, and mining.

7.1.1 Sector Strategic Approach

The Industrial programs are designed to capture demand side management energy savings at industrial facilities by helping customers overcome the financial, technical, and business barriers to energy efficiency. By encouraging and assisting customers in integrating energy efficiency into their ongoing business practices and company culture through a Strategic Energy Management (**SEM**) approach, BC Hydro can increase the quantity of demand-side management savings. For new facilities or system retrofits, BC Hydro also helps customers identify efficiency opportunities with education, resources and funding. Where needed, BC Hydro provides incentives to support the implementation of capital projects that would otherwise not happen.

The Industrial sector program is built on the foundation of SEM. Offers are available to all customer segments, with more focus on sectors that offer the largest and most cost-effective opportunities. The suite of offers includes financial resources as well as tools and education to help customers adopt an SEM model, identify and implement capital projects that will result in energy savings, and affect organizational culture to reduce energy waste and improve energy intensity. This approach will achieve cost savings, keep rates low, and support a trusted relationship with customers.

The design and implementation of BC Hydro's industrial demand-side management programs incorporate the following:

- Programs are designed to encourage the adoption of SEM principles, promoting efficiency and contributing to market transformation;

- Programs will be designed to be as flexible as possible, to allow for timely adjustments to meet BC Hydro's needs;
- Program delivery will be as broad as budgets allow, and enhance customer satisfaction with BC Hydro; and
- Programs will foster economic development in B.C., through the support of the energy efficiency industry, and the benefits to customers of lower energy costs.

As customer needs and expectations change and evolve, so will the Industrial sector programs. Placing more emphasis on SEM by leveraging new information and technology will provide customers with better insights on their electricity consumption. SEM also enables them to develop organizational energy efficiency policies and targets. Building relationships with customers centered on energy will allow BC Hydro to further adapt to changing customer needs, and to make informed decisions on potential future programs such as capacity focused demand-side management.

7.2 Leaders in Energy Management – Industrial (LEM-I)

7.2.1 Overview

The Leaders in Energy Management Industrial (**LEM-I**) program is designed to capture demand-side management energy savings at industrial facilities by helping customers overcome the financial barriers to energy efficiency. Customers have access to Energy Efficiency Feasibility Study funding to build the business case for electrical efficiency projects. Customers then have access to project incentives to reduce the payback required to make these projects financially feasible if needed.

The LEM-I program combines previous programs focused on industrial Transmission (Transmission Service Rate) customers and industrial Distribution (General Service Rate) customers separately. The newly combined LEM-I program will allow BC Hydro to find efficiencies in program delivery, maintain flexibility, and communicate with industrial customers in a way that is independent of rate class. Sectors covered are large customer segments with common interests and energy opportunities, including Pulp and Paper, Wood Products, Mining, Oil and Gas, Chemical, Cement, Manufacturing, Food and Beverage and Transportation.

The LEM-I program provides business case support to enable the customer to implement facility changes, and benefit from the Transmission Service Rate or General Service Rates. Customers can also access capital incentives for upgrades to existing plants or to support efficient plant expansions. When combined with the Industrial Energy Management Activities, a company can develop a comprehensive plan to continue saving energy at their facility.

Annual Plan	**$M**	**GWh/yr**
F2020	18.3	132
F2021	18.5	136
F2022	17.9	92
Target Market	Large Industrial (Transmission Service Rate) Customers. Approximately 170 sites. Largest 2,000 Industrial Distribution (General Service Rate) Customers. Approximately 43,000 small industrial customers also have access.	
Key Components	Energy Studies	
	Project Incentives	
	New Plant Design	
Cost Effectiveness	**Utility Cost (Market Price at $30 per MWh)**	**Modified Total Resource Cost (LRMC at $105 per MWh)**
Net Levelized Cost ($/MWh)	12	(22)
Net Present Value ($M)	37	267
Benefit Cost Ratios	1.8	4.4

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Bill savings: Reduce customers' electrical operating costs. • Remove financial barriers: Incentives to help overcome customers' financial hurdle rates and lower project payback period to an acceptable level. • Other non-energy benefits depending on the end-use/project (e.g., maintenance savings, enhanced output/product quality etc.)	• Competiveness: Builds more efficient and competitive industrial facilities in B.C. • Support advancement in technology: Increase market demand that supports research and development towards more efficient end uses. • Economic: Creates a need for services to support efficiency studies and equipment installations.	• Demonstrate commitment and support for helping customers to more easily do business with us: Seen as a trusted and credible partner to support customers and industry to achieve their goals. • Retain flexibility: The offer can be adjusted quickly to changing internal and external demands by scaling up or down, adding funding partners or new program measures. .

7.2.2 Description

	Detailed Description
Energy Studies	Conservation and Energy Management has assembled an external team of North America's top energy efficiency engineers/technologists to investigate and quantify energy efficiency opportunities within our customers' facilities. The LEM-I program offers Energy Efficiency Feasibility Studies to quantify opportunities and build the business case for project implementation.
Project Incentives	Incentives provide additional financial assistance to overcome the affordability barriers that have been impeding projects with longer payback periods.
New Plant Design	The New Plant Design initiative offers industry expertise to provide energy base lining and energy-efficiency design support for new or expanding facilities. These findings are combined with project incentives to encourage efficient designs that surpass industry standards.

7.3 Thermo-Mechanical Pulp Program

7.3.1 Overview

The Thermo-Mechanical Pulp Program provides assistance to BC Hydro's thermo-mechanical pulp customers to manage their electricity consumption and complete projects at their facilities. The program targets the six thermo-mechanical pulp sites and provides incentives for projects that help modernize their processes. Order in Council 404, dated July 14, 2015, directs the BCUC to allow BC Hydro to recover expenditures related to the TMP Program through rates to a maximum expenditure of $100 million.

Annual Plan	$ million	GWh/yr
F2020	0	0
F2021	27.2	100
F2022	0	0
Target Market	Thermo-Mechanical Pulp sites: Catalyst Paper, Powell River, Catalyst Paper, Crofton, Catalyst Paper, Port Alberni, West Fraser, Quesnel River Pulp, Canfor Pulp, Taylor	
Key Components	Energy Studies	
	Project Incentives	
Cost Effectiveness	**Utility Cost (Market Price at $30 per MWh)**	**Modified Total Resource Cost (LRMC at $105 per MWh)**
Net Levelized Cost ($/MWh)	23	34
Net Present Value ($M)	5	53
Benefit Cost Ratios	1.2	2.7

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Financial incentives for facility improvements. • Access to energy industry professionals. • Improved site viability	• Builds more efficient and competitive thermo-mechanical pulp facilities in B.C. • Creates a need for services to support efficiency studies and equipment installations	• Contributes to the demand-side management plan and reduces future generation costs. • Helps keep mills viable to retain revenue.

7.3.2 Description

	Detailed Description
Energy Studies	The Thermo-Mechanical Pulp program offers Energy Efficiency Feasibility Studies to quantify opportunities and build the business case for project implementation. Goal: Provide access to industry experts who can help industrial customers study facilities and build business cases for energy improvement projects.
Project Incentives	The incentive provides additional financial assistance to overcome the affordability barriers that have been impeding these large projects. Goal: Reduce payback periods and provide access to capital for hard-wired energy improvement projects that would otherwise not be implemented at thermo-mechanical facilities.

7.4 Industrial Energy Management Activities

7.4.1 Overview

The Industrial Energy Management Activities are designed to support industrial facilities by assisting customers overcome the management and business barriers to energy efficiency. By encouraging and assisting customers in integrating energy efficiency into their ongoing business practices and company culture through a Strategic Energy Management (**SEM**) approach, BC Hydro can increase the quantity of demand-side management savings.

Sectors are large customer segments with common interests and energy opportunities, including Pulp and Paper, Wood Products, Mining, Oil and Gas, Chemical, Cement, Manufacturing, Food and Beverage and Transportation.

The Industrial Energy Management Activities provide SEM training and resources including Industrial Energy Managers. Audits and support are provided to enable the customer to implement and maintain facility changes. Through SEM, customers will also benefit from the Transmission Service Rate or General Service Rates. As part of the program, Energy Monitoring and Targeting systems are implemented at customer sites to understand and use customer energy data to improve energy performance and increase operational efficiency. The flexible design and the relationships with the customers create a platform to offer new services such as capacity focused demand-side management.

Annual Plan	$M	GWh/yr
F2020	8.2	n/a
F2021	8.4	n/a
F2022	8.5	n/a
Target Market	Active partnerships with 83 Industrial sites. (Transmission Service Rate) Customers. Approximately 170 sites. Largest 2,000 Industrial Distribution (General Service Rate) Customers.	
Key Components	Strategic Energy Management – Industrial Energy Manager	
	Strategic Energy Management – Cohort Energy Manager	
	Strategic Energy Management – Regional Energy Manager	
	Energy Monitoring and Targeting	
	Energy Audits	
	BC Hydro Alliance of Energy Professionals (across all sectors)	
	External Workforce Capability Building (across all sectors)	

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Energy management information, advice, and program access support • Improve corporate culture around SEM: A strategic approach by supporting organizations to develop a sustained corporate level strategic energy management program. • Assistance in accessing qualified energy management products and industry expertise • Energy Monitoring and Targeting: Access to energy data to improve operational efficiency.	• Competiveness: Builds more efficient and competitive industrial facilities in BC. • Industry capacity: Support and grow the energy management industry through the BC Hydro Alliance of Energy Professionals. • Support advancement in technology: Increase market demand that supports research and development towards more efficient end uses. • Economic: Creates a need for services to support efficiency studies and equipment installations.	• Demonstrate commitment and support for helping customers to more easily do business with us: Seen as a trusted and credible partner to support customers and industry achieve their energy management goals. • Foundational platform for future offers to this customer segment: Demand response, low-carbon electrification, or any other technology or service. • Support Customer Service: Ability to integrate customer strategy initiatives as necessary to ensure optimized delivery of offers. • Retain flexibility: The offer can be adjusted quickly to changing internal and external demands by scaling up or down, adding funding partners or new program measures. • Support towards market transformation: Emphasis on market transformation and education of key stakeholders by providing the right tools and resources.

7.4.2 Description

	Detailed Description
Strategic Energy Management: Industrial Energy Manager	The SEM Industrial Energy Manager offer provides funding to industrial customers to embed strategic energy management practices into their organizations. BC Hydro will provide funding for an Industrial Energy Manager who will receive specialized training and knowledge on developing and implementing an SEM plan. The initiative includes energy assessments to assist customers to gain energy insights, build executive support for energy efficiency and define the energy opportunity and value proposition for their company. Industrial Energy Managers have access to additional funding and resources for Employee Awareness initiatives and enhanced Energy Monitoring and Targeting at their organization. The objective is to drive energy improvements through increased SEM practices at large industrial facilities with increased use of energy intelligence, monitoring and reporting, business processes, and awareness.

	Detailed Description
Strategic Energy Management: Cohort	The SEM Cohort Energy Manager offer is intended to build SEM at customer sites that are not large enough to support a dedicated Industrial Energy Manager. We bring together a group of industrial customers to work together and share knowledge related to building energy management in their business. The goal is to translate these insights into changes in daily business operations by using a customer's own energy data to build a facility-wide energy model that will help them to continuously improve their energy performance. Through the systematic use of energy data, operational models are created for small and medium industrial facilities that enable the identification and monitoring of energy improvements.
Strategic Energy Management: Regional Energy Manager	The SEM Regional Energy Manager offer is intended to build SEM at small to medium sized industrial customer sites. Two Regional Energy Managers will help small to medium sized industrial customers to understand SEM and enroll in the Operational Energy Analytics offer. Through Operational Energy Analytics leveraging SMI and MyHydro, the customers will go through an onsite audit and several months of data monitoring to enable operational savings at their facilities.
Energy Monitoring and Targeting	Energy Monitoring and Targeting is designed for SEM participants to identify process anomalies or new projects (operational or capital) that result in operational or hard-wired savings. Customers will also be able to quantify/validate savings through the development of an accurate energy monitoring and targeting model and deployment of reporting capability at the facility or subsystem level
Energy Audits	Conservation and Energy Management has assembled an external team of North America's top energy efficiency engineers/technologists to investigate and quantify energy efficiency opportunities within our customers' facilities. The Industrial Energy Management activities offer Plant-Wide Audits and End Use Assessments to identify energy-saving opportunities at industrial facilities. The objective is to provide access to industry experts who can help industrial customers audit facilities and identify energy improvement projects as part of a corporate strategic energy management plan.
BC Hydro Alliance of Energy Professionals	The BC Hydro Alliance of Energy Professionals is a network of contractors, consulting engineers, distributors and registered experts that will promote the use of energy management and efficiency solutions to our customers. BC Hydro leverages the Alliance members' ability to sell and promote energy efficient products, services and programs to assist our customers within the context of demand-side management programs which is a cost-effective approach to minimize program marketing expenditures. BC Hydro delivers training to Alliance members to ensure they are educated on energy management and trained on the details of the available BC Hydro programs. This goal is achieved in part through partnerships with associations for development and delivery of courses and workshops. The BC Hydro Alliance of Energy Professionals also enables Conservation and Energy Management to monitor and assess the quality of work that customers receive from Alliance members, and take remedial action if deficiencies are identified.

	Detailed Description
External Workforce Capability Training	A critical success factor for the Demand-Side Management Plan is that there is an available and accessible "energy efficiency skilled" workforce in place in B.C. BC Hydro plays an important role in identifying and filling skill gaps in the workforce by partnering with post-secondary institutions and industry associations who develop and deliver new training and educational programs. The objective of education and training is to develop and build market capacity of individuals that will be qualified to become energy managers and energy champions within customer and industry organizations as well as to grow the pool of qualified individuals who can join trade ally firms. This will support program participation, increase awareness and action and ultimately integrate efficiency into ongoing business processes. This initiative includes integrating energy management modules within targeted disciplines of academic and training institutions as well as the development of materials to educate customers and trade allies. This provides support for students enrolled in post-secondary institutions, addressing the adequacy requirements of the Demand-Side Measures Regulation.

8 Capacity Focused Demand-Side Management

8.1 Overview

Capacity-focused demand-side management initiatives were identified as a new area of potential in the 2013 Integrated Resource Plan and are currently being tested in the market to understand the magnitude and dependability of the capacity savings for inclusion in BC Hydro’s planning as potential alternatives to new generation capacity or grid (transmission or distribution) infrastructure. System capacity needs are during the high-demand winter season as well as shoulder months when the load resource balance is tight due to maintenance outages, whereas grid capacity needs depend more on the particular location.

Over the fiscal 2020 to fiscal 2022 period, this initiative will build on the work to date to further explore and identify the opportunity to use customer-based, demand-side measures as a resource to manage capacity constraints on the grid. These trials and pilots include:

- **Residential demand response trials** include the testing for customer acceptance and performance, including smart charging of electric vehicles, specialized charging stations for multi-unit residential buildings, behavioural demand response (Peak Saver), smart water heater controls, home-based storage (batteries), electric thermal storage and other emerging technologies;
- **Commercial and industrial demand response trials** include the use of customer-sited batteries, connected building technologies, building management system integration for demand management purposes, smart charging of electric vehicles (including fleets and employees) and vehicle to grid;
- **Localized demand-side management pilots** will leverage the combination of various demand response technologies tested in demand response trials in conjunction with targeted energy efficiency offers to meet the unique needs of a constrained distribution asset (such as a substation or feeder.) BC Hydro will pursue opportunities in constrained substations utilizing solutions tested in the residential, commercial and industrial demand response trials. BC Hydro plans to test out different solutions in a

number of constrained areas. This will allow BC Hydro to determine whether demand response activities can shift the timing of the peak demand of a local area;

- **Connected Home product trials** are designed to address this emerging market space that could have impacts on the utility in the context of both load management and energy efficiency. This area of investigation includes customer's acceptance and adoption of centralized home hubs and supporting equipment that facilitates new ways for customers to utilize energy in their home. This can include control equipment and portals that can provide more detailed and timely energy intelligence to occupants / homeowners. The goal is to understand how these new technologies could be used to help manage energy use and contribute to reducing the impact on local and system-wide capacity; and
- **Infrastructure Development** – research, analysis and development of core policies, procedures, support infrastructure, benefits and valuation of capacity initiatives, planner needs, and business models for various capacity-focused demand-side management programs including items such as settlement procedures and localized load forecast tool development. A key infrastructure component will be a Distributed Energy Resource Management system to address one of the important lessons learned to date from the various capacity-focused demand-side management activities: the need to have a system in place that can manage the devices, programs, customers and program operation, including direct communication to the end-use. To meet this need, BC Hydro has identified implementing a demand response management/distributed energy resource management system over fiscal 2019 to fiscal 2021.

This portfolio budget has been extended over a longer period of time than originally planned due to the complex nature of the impacts to BC Hydro's system and value streams, the desire to incorporate past learnings into the new activities, the rapidly changing technology landscape, and the long lead times required for some customer projects. The total amount of the required budget over fiscal 2017 to fiscal 2021 has also been reduced by 12 per cent.

Annual Plan	$ million	
F2020	6.9	
F2021	4.3	
F2022	0	
Target Market	All sectors	
Key Components	Residential Demand Response - appliances, electric vehicle chargers, storage, behavioural	
	C&I Demand Response – storage, EV charging, connected building, behavioural and operational	
	Localized demand-side management

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Financial incentives for shifting/curtailing load • Access to new controls or information to better manage energy and demand • Defers or eliminates construction in local communities • Improves local reliability • Supports electrification by helping to mitigate costs (e.g., panel management) • Better understanding of capacity opportunities (which is an area of investigation that customers have desired)	• Allows industry players to have more comprehensive solutions to provide customers (energy efficiency plus capacity initiatives) • Creates demand for products and services to support project implementation, such as equipment installations	• Defers generation capacity costs • Defers distribution capacity infrastructure costs • Integrates approach to jointly manage all aspects of electricity usage • Improves system reliability • Creates demand side flexibility • May facilitate electrification and customer connections to the system by addressing capacity constraints

8.2 Description

	Detailed Description
Demand Response	Demand response solutions for residential, commercial and industrial customers can help facilitate a more flexible load on the demand side, potentially creating efficiencies and cost savings for BC Hydro and the customer. This area continues to focus on exploring and developing experience with loads that can respond to conditions on the grid. These areas include: • Managed charging for residential and commercial passenger fleets, forklifts and other vehicles; • Energy storage (batteries, thermal storage); • Interactions and opportunities between energy storage, charging, and the grid; and • Other emerging opportunities for flexible load.
Localized Demand-Side Management	Localized Demand-Side Management projects target capacity constrained substations and distribution assets, through a combination of demand-side measures can be offered to reduce overall peak load and reduce the need for capital investment due to load growth. • Each geographically targeted area would receive a package of energy efficiency and demand response programs targeted towards the specific loads in the area. In the future, this package could also include distributed energy resources and storage. • Includes solutions for all sectors, based on opportunities in the targeted areas. For example, for a substation with a large residential load, water saving devices may help not only reduce overall energy use (energy efficiency through reducing the amount of hot water used) but can also help reshape load because most hot water usage is concurrent with system peaks.
Connected Buildings/ Facilities	For BC Hydro, the goal is to increase load flexibility by increasing the ability of buildings to interact with the grid and adjust loads to balance supply and demand. Connected buildings are emerging, as the internet of things allows for more granular control and monitoring. • For residential customers, there will be a variety of initial offers involving central hubs and connected devices such as thermostats. Participants receive equipment, are provided with energy conservation and connected technology use tips and are monitored to understand how they interact with this new information and control capabilities as well as the impact on their energy usage. • For a small number of customers, opportunities for connected, intelligent buildings will be examined through a series of trials. Participants will receive incentive funding towards the implementation and study of connected building technologies and their impacts. Industrial facilities will be able to integrate energy use dashboards and displays into their processes to manage real-time events on the system.

<table>
<tr><th></th><th>Detailed Description</th></tr>
<tr><td>Infrastructure Development</td><td>All program delivery requires infrastructure to support it, including core policies, procedures, skills and technology. This area focuses on understanding the different requirements of capacity-focused demand-side management vs existing conservation and energy efficiency offers and what gaps may need filling to roll out at scale.
Understand best practices for capacity-focused demand-side management program delivery
Test any IT or supporting systems (such as a Distributed Energy Resource Management system) to facilitate the efficient and effective operation of various programs.
Continue to work with internal stakeholders to understand benefit streams, valuation, operational requirements, and other stakeholder needs.</td></tr>

9 Codes and Standards

9.1 Overview

To achieve its energy conservation targets and as required by the Demand-Side Measures Regulation, BC Hydro supports government implementation of new and updated codes and standards, which set efficiency requirements in building codes, product and equipment standards, bylaws and community energy plans. BC Hydro drives and supports energy efficiency code and standard development by working with the Federal government, Government of B.C., key municipal governments and indigenous communities in B.C. through committees, programs and peer networks. In addition, the Codes and Standards initiative enables and facilitates implementation of new code requirements by driving and supporting capacity building initiatives in partnership with government, industry and educational facilities to transform the marketplace to energy efficient practices and products. These initiatives include project implementation funding offers, pilot projects, research, industry training and education programs, community planning support, and partial funding of positions within key organizations that support codes and standards development and implementation.

Codes and Standards activities target local governments, indigenous communities, the residential and commercial building sectors, as well as industry, supplier and manufacturing sector to achieve its market transformation objective. The positive, long-lasting relationships with stakeholders and successful deployment of initiatives can be utilized in the future to advance new offers.

Fiscal 2021	246	153	12	411
Fiscal 2022	150	125	7	282

Refer to Appendix C for detailed breakdown of energy savings by technologies.

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Energy conservation • Market transformation measures strongly integrate affordability factors • Tools, financial and technical support for communities (local governments and Indigenous Communities), as well as commercial Energy Management Activities • More high performance homes and commercial buildings in B.C. market	• Policy and Codes roadmaps provide market certainty • Local government support and implementation projects channeled to support market transformation • Collective forum for informing and advising on smooth market transformation • Partnerships, training and support for the building industry to move to more energy efficient building practices	• Driving market transformation through convening partnership efforts rather than program based approaches • Cost-effective demand-side management • Strengthens relationships with local governments and Indigenous Communities. • Relationships with Federal and Provincial governments to advance energy efficiency Codes and Standards

9.2 Description

	Detailed Description
Codes and Standards Investigation, Development & Implementation	The initiative seeks to address the availability, awareness, acceptance barriers that are holding back the development of new energy efficiency codes and standards, and the adoption of more energy efficient building practices and products. Those barriers are reduced by: • Providing technical and financial support to governments and standard developing organizations for the development and identification of comprehensive and effective energy efficiency standards, regulations, codes and other government policy instruments. • Building stakeholder support with other Canadian and U.S. utilities (e.g., in the Pacific Northwest) for changes to codes and standards. • Supporting trade allies and building officials in their compliance with codes and standards via training and education for industry. • Supporting governments in their compliance checking / enforcement of codes and regulations by providing market intelligence on energy-efficient equipment stocking and building construction practices as well as co-funding support for code compliance enhancement efforts with all three levels of government. This initiative is a specified demand-side measure per the Demand-Side Measures Regulation, and per section 3(1)(e), expenditures of 1 per cent of the Plan or $2 million are required to meet the adequacy requirements of the Demand-Side Measures Regulation. In this Plan, we expect to spend approximately $5.2 million annually on codes and standards support, and therefore meet the adequacy requirement.
Peer Networks	A critical element of market transformation is creating networks, maintaining partnerships and driving collective work plans so that partners coordinate the use of their different levers towards the common objectives. • Energy Step Code Council (21 government, utility and industry organizations): – Training and Communications Subcommittee; – Technical Subcommittee; – Compliance and Energy Advisor Subcommittee; – Local Governments Peer Network (large communities); and – Local Government Peer Network (small communities); • Building Officials' Association of BC (**BOABC**) Energy Foundations Program Peer Network; • Anticipated in the future: – Builder Peer Network through Local Energy Efficiency Partnerships (**LEEP**) and Canadian Home Builders Association (**CHBA**) National; – Realtor, Labeling and Consumer Awareness; and – Retrofit Network.
Community Planning	Funding for target market local governments (population over 75,000) to embed energy considerations in community planning processes. This offer supports community energy and emissions plans, local area plans (neighborhood plans), green building strategies and electric vehicle strategies.

	Detailed Description
Community Energy Manager, Building Department & Intern Offers	These offers support the addition of resources within target market local governments in order to implement work plans that make use of local governments levers to drive energy efficiency and broader offers at the community scale Work plan development includes strategic planning assessments and benchmarking with senior management from local governments.
Project Implementation Offer	Funding for target market local governments to support implementation of efficiency policies and actions at the community scale.
Indigenous Communities Policy Support	There are unique geographic and market barriers facing Indigenous and remote communities. In an effort to better understand and address these unique barriers, pilot activities were undertaken between fiscal 2017-fiscal 2019. New offers will be launched to provide capacity building support to Indigenous and remote communities as follows: • Funding for the development and implementation of community energy plans that articulate both short and long-term opportunities and actions for community energy management; • Funding for staff positions at the Band or Tribal Council level to embed knowledge and capacity in the community to support the advancement of programs and projects; • Delivery of education and skills training initiatives to build energy literacy in the community, empower community members to manage energy use and reduce energy costs, and foster local economic development opportunities related to energy (e.g., new high performance housing, energy efficient building upgrades, etc.); and • Funding and technical resources to support the development and implementation of energy efficient building policy to ensure that new buildings on reserve are built to higher energy performance standards (Energy Step Code) and that existing buildings are upgraded to improve energy performance over time. This policy and planning support will work in conjunction with the customer focused Indigenous offers within the Low Income Program (for BC Hydro grid connected customers) and the new Non-Integrated Areas program (for customers in communities that are not connected to the BC Hydro integrated electric system).

	Detailed Description
New Construction Capacity Building and Industry Support	BC Hydro works with residential builders, developers, energy advisors, realtors, other industry partners and government to create demand for and construct homes that are more energy-efficient than the B.C. Building Code minimum requirements. This helps to build awareness and acceptance of the role that step codes can play in transforming the market. Recognizing the need to move beyond influencing individual projects through an incentive strategy, this initiative focuses on activities that leverage deep market changes to transform the construction industry in four key ways: • Create opportunities for diverse access to builder and industry training and education on energy efficiency standards; • Build consumer awareness on the value of higher performance housing for their family and empower them to prioritize these features when buying or building a new home; • Collaborate with industry professional associations and market players to research and identify suitable high performance solutions for the B.C. residential construction market, support market accessibility and mass market adoption of these solutions; and • Work with local governments to streamline approaches to increase code compliance, policy development, and adoption of the BC Energy Step Code. Funding support is provided to local governments for step code implementation initiatives.

10 Rates

10.1 Residential Inclining Block Rate

BC Hydro introduced its Residential Inclining Block rate structure in October 2008. Customers are charged for electricity consumption at two rates, an initial Step 1 threshold of 1350 kWh per two-month billing period charges at a lower rate (as of April 1, 2018, 8.84 cents per kWh); and a higher rate for Step 2 consumption above that threshold (as of April 1, 2018, 13.26 cents per kWh). This provides customers with a price signal that encourages conservation.

The most recent Residential Inclining Block Evaluation Report[18] finds that no new incremental savings are anticipated in future years. However, the current pricing signal continues to encourage customers to maintain previous savings. As shown, no new incremental costs are planned.

Target Market	Residential Sector	
Cost Effectiveness	**Utility Cost (Market Price at $30 per MWh)**	**Modified Total Resource Cost (LRMC at $105 per MWh)**
Net Levelized Cost ($/MWh)	n/a	n/a
Net Present Value ($M)	n/a	n/a
Benefit Cost Ratios	n/a	n/a

10.2 Rate Schedule (RS) 1823, Stepped Rate

The Stepped Rate, also referred to as the Transmission Service Rate, applies to most large customers that are supplied with electricity at transmission voltages (60,000 volts or more). The rate has been in place since April 2006. There are approximately 145 transmission customer sites taking electricity service under the Transmission Service Rate.

[18] Evaluation of the Residential Inclining Block Rate F2013-F2017, April 2018.

The Transmission Service Rate is a two-tier (Tier 1 and Tier 2) inclining block conservation rate where annual energy consumption above a threshold is charged at a higher Tier 2 rate and annual energy consumption up to the threshold is charged at a lower Tier 1 rate. The energy consumption threshold is set at 90 per cent of the plant's historical annual energy consumption (called the Customer Baseline). The result is a 90:10 split in energy pricing. The Tier 2 price was established to provide a conservation price signal and is set based to reflect BC Hydro's Long Run Marginal Cost (**LRMC**). The Tier 1 price is derived from the Tier 2 price and the 90:10 Tier 1/Tier 2 pricing split to achieve revenue neutrality with the former flat rate structure, at 100 per cent of the plant's historical Customer Baseline consumption.

As of April 1, 2018, the Tier 1 price was 4.244 cents per kWh, and Tier 2 was priced at 9.509 cents per kWh. Customers are also charged for electricity demand at a flat rate $8.139 per kVA based on 30min peak kVA demand during High Load Hours (**HLH**).

Benefit Cost Ratios	11.1	1.4

11 Supporting Initiatives

11.1 Public Awareness

11.1.1 Overview

The Public Awareness Supporting Initiative is a set of foundational activities that increase the awareness of the general public and K-12 students/teachers about ways to increase energy conservation and energy efficiency, as well as help increase participation in various energy efficiency measures / programs as laid out in the Demand-Side Measures Regulation. Customers' energy literacy and receptiveness to the concept of energy efficiency is elevated as a result of these supporting activities that are designed to address two specific barriers to participation: awareness of activities and programs, and the acceptance of those programs.

This increased awareness and acceptance ultimately sets the stage for improved participation in a variety of behaviours and programs and the support of codes and standards. These activities cover a variety of channels designed to effectively reach a wide cross-section of customers and also includes a schools program.

11.1.2 Area of Focus

Annual Plan	$ million	GWh/yr
F2020	7.4	n/a
F2021	7.5	n/a
F2022	7.6	n/a
	Public Education and Awareness: communications strategies and campaigns delivered via all channels	
	Public Engagement: face-to-face coaching with customers in communities and at sponsorship events	
	Schools Program	

Customer Benefits	Industry Benefits	BC Hydro & Shareholder Benefits
• Builds awareness and understanding of Demand-Side Management programs • Provides customers one source of information and the knowledge to participate in programs	• Supports retailer and manufacturing partners through promotion of products and programs • Support teachers and the Ministry of Education to reach their goals	• Builds one cohesive story in the marketplace across residential, commercial and industrial programs. • Foundational supports for Demand-Side Management program targets • Program can expand to include new concepts around energy analytics and capacity focused offers. • Builds BC Hydro’s reputation and brand of being innovative and supporting a conservation culture.

11.1.3 Description

	Detailed Description
Public Education and Awareness	Continue with core focus on Fall and Spring conservation campaigns and build out more year round content through owned/digital channels. By using a combination of paid, owned and earned communications strategies, BC Hydro is able to reach customers with messages intended to elevate awareness of energy efficiency and encourage residential and business customers to undertake actions. Strategies and messages target a range of demographics including multilingual communications. Efforts place emphasis on digital channels, the development of rich content (video, animation etc.) and the role of social media in elevating awareness and engagement while maintaining a foothold in traditional channels where media consumption habits are still high (TV, radio). Driving customers to bchydro.com and powersmart.ca for in-depth information about tips and programs is a central part of the strategy, with a growing focus on mobile viewing habits. BC Hydro continues to cultivate a rich network of social media and eNewsletter subscribers who receive content daily and monthly outside of campaign windows. In addition, BC Hydro’s media strategy supports conservation year round through storytelling and sharing data and reports that are newsworthy and create buzz in traditional media channels and beyond to online channels.
Public Engagement	Engaging with customers face-to-face helps build awareness and gain support for energy efficiency activities. A focus on engagement allows for rich conversations and dialogue that spark an interest in conservation leading to action at home and in businesses. This initiative includes business and community outreach targeted primarily at home shows, retail stores, community events and business locations, providing information on energy tips, products, and programs. The team acts as personal energy coaches, delivering custom ideas and support to encourage the adoption of energy efficient products, services and behaviours. Focus will be on supporting high need/high opportunity communities such as indigenous communities, low income, and communities with capacity constrained electrical infrastructure.

	Detailed Description
Schools Program	The schools program targets K-12 teachers, students and administrators in an effort to foster awareness and build energy literacy in our next generation of customers through comprehensive, curriculum-based teaching materials, initiatives and face-to-face interactions. The program is primarily delivered through an online platform. The program also includes a strategy to capitalize on nation-wide events such as Environmental Week, Earth Day, and Water Week by creating premium materials and resources for teachers at key points throughout the school year. This support for students addresses the adequacy requirements of the Demand-Side Measures Regulation. The support for the post-secondary education component of the Demand-Side Measures Regulation is described within Commercial and Industrial Energy Management Activities.

11.2 Indirect and Portfolio Enabling

11.2.1 Overview

Running a broad portfolio of programs and initiatives requires additional support activities that are necessary to successfully design, develop, and implement a successful portfolio. These are referred to as Deferred Indirect and Portfolio Enabling activities.

These activities support BC Hydro's Demand-Side Management initiatives with general management and infrastructure, including Demand-Side Management planning and regulatory activities and the development and administration of policy and processes related to the effectiveness and integrity of Demand-Side Management initiatives.

Annual Plan	$ million	GWh/yr
F2020	7.1	n/a
F2021	7.4	n/a
F2022	7.5	n/a
Key Components	• General management • Information Systems • Support and Administration • Training and Education • Support Services	

11.2.2 Description

	Detailed Description
General Management	A portion of the Conservation and Energy Management's business unit's general management of people and resources.
Information Systems	Support, operation and management of Demand-Side Management information systems as well as the planning and management of system enhancements and improved functionality. Demand-Side Management information systems include: • A system to support business customer contact management, account views, project tracking, opportunity and sales management, and energy savings reporting; and • Energy Reporting: systems that support the ability to report on energy savings and program participation
Support and Administration	A portion of the Conservation and Energy Management business unit's general administrative functions including costs associated with administrative activities, photocopy and fax equipment, office supplies, as well as a portion of labour for individual timesheets, expense reporting and benefits administration.
Training and Education	Individual employee training related to demand-side management, including technical seminars and attendance at conferences.
Support Services	Regulatory activities that support regulatory filings and reporting. The development and updating of demand-side management strategy and policies, as well as modelling and cost-effectiveness analysis. Support activities related to the development, administration, and review of general processes, policies, and procedures related to the effectiveness and continuous improvement. Examples include measurement and verification protocols, business or financial audits, and quality assurance.

12 Key Program Assumptions

The following table provides the Key Program Assumptions of the adjustments that apply to the energy savings based on the activities from fiscal 2020 to fiscal 2022. Ranges indicate that there are sub-components within the initiative that have different adjustment factors. Further details can be found in Appendix B Portfolio-Wide Assumptions document.

Sector	Program	Compliance Rate (%)	Cross Effects (%)	Direct Rebound Effect (%)	Free Riders (%)	Market Effects (%)	Persistence (years)	Spill-over (%)
Cross Sector	Building Codes	63-100	0	0	n/a	n/a	30	n/a
	Product and Equipment Standards	70-100	0-6	0	n/a	n/a	30	n/a

	Non-Integrated Areas	Non-Install (%) 0-80	0-5.7	0-6	5-69	0	1-30	0-17
	Retail Program	Non-Install (%) 0-20	0-5.7	0	10-40	0	6-20	0-10
Commercial	Leaders in Energy Management – Commercial		0-4	0	0-25	0	2-30	0-22
	New Construction Program		1	0	22	0	18	7.6
Industrial	Leaders in Energy Management – Industrial		0	0	14-31.7	0	1-16	11-23
	Thermo-Mechanical Pulp		0	0	0	0	10	0

Definitions	
Compliance Rate	The rate at which customers, retail channels, or builder/develops actually meet the established code or standard (knowingly or unknowingly)
Cross Effects	The effect of an energy efficient action on one energy use causing a change in another energy use. For example, more efficient lighting products typically release less waste heat and thereby reduce air-conditioning load
Direct Rebound	The increased usage of a device or system because it is more energy efficient
Free-riders	Customers who participate in a demand-side management program but who would have undertaken the same change at the same time in the absence of the program
Market Effects	Refers to a change in the structure or functioning of a market or the behaviour of participants in a market that result from one or more program efforts. Typically these efforts are designed to increase the adoption of energy efficient products, services, or practices and are causally related to market interventions. Market effects may include participant and non-participant spillover and market transformation
Persistence	The timeframe during which demand-side management measures produce electricity savings that are attributable to the utility's actions
Spillover	Refers to program participants and non-participants whose energy savings measures occur through actions that are not part of a program, but which were influenced by the program (also called free drivers or tag-ons). Participant spillover is the additional energy savings that occur when a program participant independently installs additional energy efficiency measures or applies additional energy savings practices after having participated in the efficiency program, as a result of the program's influence. Non-participant spillover refers to energy savings that occur when a program non-participant installs energy efficiency measures or applies energy savings practices as a result of a program's influence

1. The purposes for showing the two fiscal 2019 columns above are: to have on record what the expected new incremental energy savings for fiscal 2019 are as per the Fiscal 2017 to Fiscal 2019 RRA DSM Plan. This will facilitate variance explanations of new incremental energy savings (actuals vs plan) in BC Hydro's year-end Report on Demand-Side Management Activities for fiscal 2019. The Updated Forecast of new incremental savings for fiscal 2019 is BC Hydro's view of expected savings, which was developed at the same time as the balance of the DSM Plan forecast.

2 Energy Management Activities enable and support the energy savings captured under other programs in the commercial and industrial sectors.

Revenue Requirements Application

Appendix X

Appendix B

Portfolio-Wide Assumptions

Timeframe for DSM Plan Analysis	Fiscal 2020-fiscal 2022: Aligns with the Annual Plan.
Inflation	2.0 per cent.
Discount Rates	6 per cent nominal and 4 per cent real, representing BC Hydro's corporate discount rates.
Avoided Costs	**Electric energy:** • Long Run Marginal Cost: $105 per MWh (Fiscal 2018 $) • Market Price: $30/MWh (Fiscal 2018 $) over a 15-year period from fiscal 2020 to fiscal 2034 **Generation capacity:** • Fiscal 2020 to fiscal 2022: $38 per kW-year (Fiscal 2018 $) • Fiscal 2023 to fiscal 2031: $60 per kW-year (Fiscal 2018 $) • Fiscal 2031 onwards: $123 per kW-year (Fiscal 2018 $) **Bulk transmission capacity:** • $0 per kW-year (Fiscal 2018 $) **Regional transmission and substation capacity:** • $13 per kW-year (Fiscal 2018 $) **Distribution capacity:** • $1 per kW-year (Fiscal 2018 $) **Natural gas:** • BC Hydro's forecast of wholesale natural gas prices at Sumas, or for the purposes of the modified TRC test, 100 per cent of the long-run marginal cost of electricity, converted to GJ.
Rates	The following BC Hydro rates were used to calculate customer bill savings and lost revenues: • Residential Inclining Block; • Small General Service; • Medium General Service; • Large General Service; and • Transmission Service.
Line Losses	Avoided electric energy and generation capacity costs are valued at the Lower Mainland, while avoided transmission and distribution capacity costs are valued in the regions. This requires an adjustment for line losses between customers and these points in the grid using the following values: • Distribution: 4 per cent; • Intra-regional transmission: 3 per cent; and • Inter-regional transmission: region-specific values.

Low Carbon Electrification Program

PUBLIC

LOW CARBON ELECTRIFICATION PROGRAM

Conservation and Energy Management

February 2019

Contents

BC Hydro
Power smart

1.0 Overview

In this appendix, we describe the Low Carbon Electrification (**LCE**) Demand-Side Management (**DSM**) Projects/Programs that we have undertaken and plan to undertake over fiscal 2019, fiscal 2020 and fiscal 2021. All of our LCE DSM Projects/Programs are within one or more class of undertakings prescribed under the Greenhouse Gas Reduction (Clean Energy) Regulation, issued under section 18 of the *Clean Energy Act*.

1.1 Greenhouse Gas Reduction Regulation

Section 18 of the *Clean Energy Act* requires the British Columbia Utilities Commission (the BCUC) to allow BC Hydro to collect sufficient revenue to recover costs incurred for prescribed undertakings. Section 4 of the Greenhouse Gas Reduction (Clean Energy) Regulation (B.C. Reg. 102/2012) (**GGRR**) defines eight classes of electrification prescribed undertakings corresponding to sections 4(2), 4(3)(a)(i), 4(3)(a)(ii), 4(3)(b)(i), 4(3)b)(ii), 4(3)(c), 4(3)(d) and 4(3)(e). Undertakings are in a class of undertakings defined in subsections 4(3)(a) to 4(3)(b) of the GGRR if they satisfy a cost-effectiveness test defined in subsection 4(1) of the GGRR.

The eight new classes of electrification undertakings prescribed by section 4 of the GGRR can be divided into two broad categories: those that are program based, similar to BC Hydro's demand-side management programs,[1] and those that are infrastructure based.[2] BC Hydro refers to its undertakings that fall within one of the classes in the former category as Low Carbon Electrification (**LCE**) Demand-Side Management (**DSM**) Projects/Programs, and to its undertakings that fall within one of the classes in the latter category as LCE Infrastructure Projects.

1.2 Scope of Appendix Y

Appendix Y focuses only on LCE DSM Projects/Programs BC Hydro has undertaken, or will undertake, that are in one or more classes of undertakings defined in sections 4(3)(a), 4(3)(b), 4(3)(c), and 4(3)(d) of the GGRR.

Since the Previous Application, there have been a number of developments on LCE DSM Projects/Programs. In July 2018, BC Hydro submitted its Fiscal 2018 Greenhouse Gas

1 Being the classes of undertaking prescribed by subsections 4(3)(a)(i); 4(3)(a)(ii); 4(3)(b)(i); 4(3)(b)(ii); 4(3)(c) and 4(3)(d) of the GGRR.
2 Being the classes of undertaking prescribed by subsections 4(2) and 4(3)(e) of the GGRR.

Reduction Regulation Annual Report (**Fiscal 2018 Annual Report**), a copy of which is provided as Appendix BB. In section 2.0 below, BC Hydro provides further details on LCE DSM Projects/Programs which were previously introduced in the Fiscal 2018 Annual Report and are in one or more class of undertakings defined in sections 4(3)(a) and 4(3)(c) of the GGRR. For the purpose of this document, these programs are referred to as “LCE Initial Projects”. Section 2.0 also provides past and forecast expenditures for these projects.

In section 3.0 BC Hydro provides details on a new LCE DSM Projects/Program, which has been developed following the Fiscal 2018 Annual Report. For the purpose of this document, this new program is referred to as the “BC Hydro LCE Program”. Section 3.0 also provides expenditures for components of the program, including forecast expenditures for the test period.

In section 4.0 BC Hydro will demonstrate the cost-effectiveness of its LCE DSM Projects/Programs that are in the classes of undertakings defined under section 4(3)(a) and 4(3)(b) of the GGRR.

1.3 Overview of LCE DSM Projects/Programs

Beginning in fiscal 2018, BC Hydro moved forward with the Initial LCE Projects to assess and support immediate low carbon electrification opportunities among our customers. These projects are within one (or more) class of undertakings defined in subsections 4(3)(a) and 4(3)(c). These Initial LCE Projects also

- helped us gain a greater understanding of the technology, market, and barriers that customers and BC Hydro would face when developing low carbon electrification options; and
- provided BC Hydro the ability to act early and capture time-sensitive opportunities that could help inform the development of a broader low carbon electrification plan.

The Initial LCE Projects were introduced in the Fiscal 2018 Annual Report. Those included projects where BC Hydro incurred and recorded actual costs in fiscal 2018. Also included in the Fiscal 2018 Annual Report was a forecast of expenditures related to other projects where BC Hydro made preliminary funding commitments but there were no actual costs for those projects in fiscal 2018. In section 2.0 and Table 2-1 and Table 4-1, BC Hydro provides further information on the Initial LCE Projects where BC Hydro will expect to incur expenditures in fiscal 2019 and beyond.

In fiscal 2019, Government launched the EfficiencyBC program to reduce greenhouse gas emissions in the province. This $24 million, Government funded program provides financial incentives to help households and businesses save energy and reduce greenhouse gas emissions by switching to high-efficiency heating equipment and making building-envelope improvements. BC Hydro is delivering the fuel switching component of the EfficiencyBC program on Government's behalf, within our service territory. This component helps customers switch from fossil fuels to our clean electricity. The expenditures associated with implementing the EfficiencyBC program are borne by Government and not BC Hydro ratepayers.

Coinciding with delivering the fuel switching component of the EfficiencyBC program and further to the Initial LCE Projects, BC Hydro has developed the BC Hydro LCE Program, a new BC Hydro funded low carbon electrification program. The program has been coordinated to align with, and not overlap with, government funded greenhouse gas emissions reduction programs. Specifically, the BC Hydro LCE Program has been developed to reach customers not addressed by EfficiencyBC or by Government funded transportation programs. The BC Hydro LCE Program is described in section 3.0 and Table 3-1. The BC Hydro LCE Program has components that are within one or more class of undertakings defined by subsections 4(3)(a), 4(3)(b), 4(3)(c), and 4(3)(d) of the GGRR. As shown in Table 4-1 below, the undertakings in the classes defined in section 4(3)(a) and 4(3)(b) of the GGRR are cost-effective.

Should Government bring forward additional programs in the future that would overlap with activities planned or underway with funding from BC Hydro, we can make adjustments to our plans to ensure that any overlap is needed and by design.

BC Hydro expects to develop a future plan for low carbon electrification that is informed by the learning gained through the Initial LCE Projects and the BC Hydro LCE Program as well as Government's CleanBC Plan.

2.0 BC Hydro Funded Initial Low Carbon Electrification Projects

The Initial LCE Projects are in one or more class of undertakings defined in subsections 4(3)(a) and 4(3)(c). The details of these Initial LCE Projects are provided below.

Programs Under Subsection 4(3)(a)

- Customer Project 1 [redacted] and Project 2 [redacted] – [redacted]: BC Hydro provided funds to [redacted] to assist in the acquisition, installation, and use of equipment that uses electricity to power natural gas production, instead of the customer burning their own gas to power gathering, transport and processing operations.
- Customer Project 3 – Thompson Rivers University: BC Hydro provided funding to Thompson Rivers University to assist in the acquisition, installation, and use of equipment that uses electricity (electric boilers) instead of natural gas boilers in a new building.

Projects/Programs/Expenditures under subsection 4(3)(c)

In general, the projects/programs/expenditures within a class of undertakings defined in this subsection are for researching new applications of technologies that have not been proven in or adopted in BC, or are projects with specific customers researching technology applications where the learnings from the projects will inform future BC Hydro programs and customer opportunities.

- Project 4 - [redacted]: The focus of this project was to examine a portion of the customer's industrial process heating requirements and technology alternatives with the intent of determining if a viable fuel switching technology solution may exist specific for the customer. Process heating is typically supplied by natural gas, or propane. This work investigated if an opportunity existed to use electricity in place of fossil fuels for [redacted] and also potentially for other BC Hydro customers.
- Project 5 - [redacted]: The focus of this project was to enable the customer to have research completed by comparing two material handling options. The status quo option of using diesel fueled trucking was compared to options that would utilize electric conveying technology. The objective of the research was to determine whether the conveyor option is worth pursuing beyond the conceptual stage.

- Project 6 - [redacted]: The focus of this project was to examine technology alternatives for the customer to use electricity for [redacted] materials handling. The current materials handling method [redacted] involves use of diesel fueled equipment to remove the [redacted] from the [redacted], and [redacted] trucks (diesel fueled) to transport the [redacted] back into the [redacted]. The project examined a potential electrified system [redacted].
- Project 7 - Translink: Translink, along with the Centre for Urban Transit Research Innovation Consortium and BC Hydro, is conducting a pilot project which replaces four diesel buses with four electric-battery buses and two charging stations. The two year pilot project will evaluate the feasibility of technology using electric battery buses and charging stations on a broader basis.
- Project 8 - Vancouver Fraser Port Authority: This project focused on low carbon drayage and was the first phase of research into ways low carbon technologies could be introduced into the local heavy duty transportation network to reduce carbon emissions. Drayage referrers to transporting goods a short distance via ground freight.
- Project 9 - Integral Group Consulting: This research project consists of 6 individual buildings selected to represent a sampling of various building types, building code requirements, technologies, and studies the low carbon electrification opportunities that we may see come forward as implementation projects in these building types.
- Project 10 - Thompson Rivers University: The focus of this project is to research the potential of a five-Year “building by building” retrofit approach, considering a number of technologies that could lead to a new strategy to electrify building systems instead of using other sources of energy that produce more greenhouse gas emissions.
- Project 11 - Wildsight, with support from Columbia Basin Trust – This project is examining the feasibility of conducting a truck stop electrification pilot project in the Golden area. Truck stop electrification (**TSE**) technology allows those in the long haul trucking industry the opportunity to connect to the electrical grid rather than idling their truck engines while stopped or overnighting. Idle reduction saves significant diesel fuel combustion avoiding CO2 emissions.

Table 2-1 below outlines BC Hydro's expenditures for the Initial LCE Projects in each fiscal year, including the test period.

Table 2-1 – Expenditures for Initial LCE Projects

Initial LCE Projects		Expenditures ($ million) [3]

[3] Expenditure shown in Table 2-1 includes costs recorded in fiscal 2018, as well as expenditures forecast for projects which BC Hydro has made preliminary funding commitments.

3.0 BC Hydro LCE Program

The BC Hydro LCE Program, commenced in fiscal 2019, focuses on opportunities in industrial process, transportation, and new construction, and include components in one (or more) class of undertakings defined in subsections 4(3)(a), 4(3)(b), 4(3)(c), and 4(3)(d). A component of the BC Hydro LCE Program may be developed to focus on, for instance,

- Providing funds to enable energy management and audit services to our customers or educating and training customers regarding their energy use;
- Carrying out public awareness campaigns respecting energy use;
- Providing financial support to customers to assist them with the acquisition, installation and use of equipment that uses or affects the use of electricity;
- Providing funding to conduct research and pilot projects respecting technology that may enable our customers to use electricity; and
- Supporting standards making bodies in their development of standards respecting technologies that use electricity instead of other sources of energy.

The following Table 3-1 provides a high level overview of the components of the BC Hydro LCE Program and the relevant subsections of the GGRRs.

BC Hydro
Power smart

Table 3-1 –Component Description of the BC Hydro LCE Program

Components	Detailed Description	GGRR Subsection
Energy Management Studies and Incentives	Studies and Assessments – BC Hydro provides funding toward studies and assessments to assist customers, or those who may become customers, to identify and develop project opportunities involving the acquisition, installation, or use of equipment that uses electricity instead of other sources of energy that produce more greenhouse gas emissions. Project Incentives - BC Hydro provides project incentive funding to reduce the cost of projects to assist customers, or those who may become customers, with the acquisition, installation, or use of equipment that uses electricity instead of other sources of energy that produce more greenhouse gas emissions. Funding is provided direct to customers or in some cases direct to persons who -design, manufacture, sell, install or in the course of operating a business, provide advice respecting equipment that uses or affects the use of electricity, -or design, construct, manage or, in the course of operating a business, provide advice respecting energy systems in building or facilities, -or design, construct or manage district energy systems.	4(3)(a), 4(3)(b)
Public Awareness Campaigns	BC Hydro carries out a set of activities that educate and increase public awareness respecting the use of electricity instead of other sources of energy that produce greenhouse gas emissions. These activities cover a variety of channels and leverage specific partners such as retailers and manufacturers who have existing channels available to them that, when combined with BC Hydro's support, can reach a wide cross-section of relevant customers	4(3)(a), 4(3)(b)
Research and Pilots	BC Hydro works with customers and provides funding toward the research and development of technology, or pilot projects, that may enable the customers to use electricity instead of other sources of energy that produce more greenhouse gas emissions.	4(3)(c)
Standards Enabler	BC Hydro works with standards making bodies such as various levels of government, who are responsible for land use, building codes, product and equipment standards, policies, bylaws, and community plans, to advance standards for technologies that use electricity instead of other sources of energy that produce more greenhouse gas emissions, or technologies that affect the use of electricity by other technologies that use electricity instead of other sources of energy that produce more greenhouse gas emissions.	4(3)(d)

Components	Detailed Description	GGRR Subsection
Education & Training	BC Hydro delivers education and training to the BC Hydro Alliance of Energy Professionals (Alliance) members to ensure they are educated with respect to energy use and greenhouse gas emissions as well as trained on the details of the BC Hydro LCE Program. The Alliance is a network of contractors, consulting engineers, distributors and registered experts that provide energy management solutions to our customers. This group designs, manufactures, sells, and installs equipment that uses or affects the use of electricity. BC Hydro leverages the Alliance members' ability to sell and promote products, services, and our programs to our customers to encourage them to use electricity instead of other source of energy that produce more greenhouse gas emissions.	4(3)(b)

Table 3-2 below outlines expenditures for the BC Hydro LCE Program components in each fiscal year, including the test period.

Table 3-2 – BC Hydro Funded Low Carbon Electrification Program Expenditures

BC Hydro LCE Program		Expenditures ($ million)					
GGRR Regulation Subsection	**Program Component**	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
4(3)(a), 4(3)(b)	Energy Management Studies and Incentives	-	1.51	3.10	7.00	2.49	14.11

4(3)(b)	Education & Training	-	0.01	0.04	-	-	0.05
4(3)(c)	Research and Pilots	-	0.01	0.10	-	-	0.11
4(3)(d)	Standards Enabler	-	0.23	0.65	-	-	0.88
Program Total		**-**	**2.35**	**4.80**	**7.00**	**2.49**	**16.65**

4.0 Cost Effectiveness

As shown in Table 2-1 and Table 3-2 included in section 2.0 and section 3.0, respectively, BC Hydro has chosen to engage in undertakings that are within one (or more) class of undertakings defined in sections 4(3)(a), 4(3)(b), 4(3)(c) or 4(3)(d) of the GGRR. Undertakings are in a class of undertakings defined in section 4(3)(a) and 4(3)(b) of the GGRR if they meet the cost-effective test. The cost-effectiveness test requires that each undertaking that is an undertaking within the class of undertakings defined by subsections 4(3)(a) or 4(3)(b) of the GGRR have a positive net present value (**NPV**), with the measure of a program's NPV being that of all of the programs that fall within the class of undertakings described in subsections 4(3)(a) and 4(3)(b) of the GGRR. Specifically, benefits mean all revenues BC Hydro expects to earn as a result of implementing LCE projects/programs falling under subsections 4(3)(a) or 4(3)(b), less revenues that BC Hydro expects to earn from the sale of that electricity to export markets. Costs mean all the costs BC Hydro expects to incur to implement LCE projects/programs falling under subsections 4(3)(a) or 4(3)(b), including development and administration costs. Furthermore, the GGRR cost-effectiveness test is measured only at the time BC Hydro decides to carry out a projects/programs. There is no other cost-effectiveness test applicable to prescribed undertakings.

The Table 4-1 below shows the NPV of all BC Hydro's projects/programs prescribed under section 4(3)(a) and 4(3)(b) of the GGRR including BC Hydro's proposed low carbon electrification expenditures for fiscal 2020 and fiscal 2021. The NPV $134.7m indicates that these undertakings are cost-effective.

Table 4-1 – Cost Effectiveness

A	B	C	D	E		F		G	
GGRR	**Project/ Program/ Contract/ Expenditure**	**Expenditure ($ million)**	**Cost Effectiveness (F18 $million)**	**Additional Energy Consumption (MWh/year)**		**Additional Demand (MW)**		**Estimated GHG Emission Reductions (tonnes CO2e/year)**	
		Total	**GGRR NPV to 2030 (F2031)**	**Incremental**	**Cuml.**	**Incremental**	**Cuml.**	**Incremental**	**Cuml.**
4(3)(a)	Project 1	16.20	64.32	268,056	268,056	36.0	36.0	158,090	158,090
4(3)(a)	Project 2	13.50	110.20	223,380	491,436	30.0	66.0	131,742	289,832
4(3)(a)	Project 3	0.28	110.50	2,737	494,173	0.0	66.0	562	290,394
4(3)(a)(b)	BC Hydro LCE Program[4]	15.66	134.71	108,337	602,509	17.3	83.3	56,896	347,290
	Total	**45.64**	**134.71**	**602,509**	**602,509**	**83.3**	**83.3**	**347,290**	**347,290**

One of the legal consequences of BC Hydro's program or project being in a class of prescribed undertakings under section 18 of the *Clean Energy Act* is that BC Hydro is entitled to recover the costs of our electrification programs or projects in rates. The expenditures BC Hydro incurs in regard to its LCE DSM Projects/Programs are sought to be deferred to the DSM Regulatory Account in this application.

4 The BC Hydro LCE Program includes costs and benefits related to the class of undertakings defined in sections 4(3)(a) and 4(3)(b) of the GGRR.

Report on Demand-Side Management Activities for Fiscal 2017

July 12, 2017

Table of Contents

List of Tables

1 Introduction

This BC Hydro annual report to the British Columbia Utilities Commission (**BCUC or Commission**) on Demand-Side Management (**DSM**) activities provides information on DSM expenditures, electricity savings, plan performance and mitigation measures for the 2017 fiscal year (**F2017**), which is the twelve months ending March 31, 2017. This annual report is filed in compliance with the following Commission Directives:

- Directive 69 from the Commission Decision on BC Hydro's F2005/F2006 Revenue Requirements Application (**F05/F06 RRA**);
- Directive 16 from the Commission Decision on BC Hydro's 2006 Integrated Electricity Plan and Long Term Acquisition Plan (**2006 IEP/LTAP**); and
- Directives 36 and 38 from the Commission decision on BC Hydro's 2008 LTAP.

Directive 69 of the F05/F06 RRA Decision directed BC Hydro "to provide information to the Commission for on-going review of Power Smart performance through:

- Executive Summaries of milestone evaluation reports and full final evaluation reports for each program;
- Semi-annual reports on DSM activities which, amongst others, will include:
  - ▶ detailed breakdown of OMA expenses related to support activities carried out within the Power Smart group and in other departments that support the Power Smart organization;
  - ▶ detailed description of the functions of portfolio level costs and how these costs are allocated to programs;
  - ▶ summaries of the overall performance of Power Smart with reference to program objectives; and
  - ▶ variances of fiscal year budgeted and actual deferred capital expenditures and explanation of variances."

Directive 16 of the 2006 IEP/LTAP Decision directed BC Hydro "to continue to file reports on DSM performance as described in Directive 69 of the F05/F06 RRA Decision included in Order No. G-96-04 and to file its Semi Annual Demand-Side Management Reports in the same format as the June 2005 Report with the following enhancements:

Provide annual and cumulative totals since program inception;

(i) Express these values on a per unit basis; and

(ii) Provide the benefit to cost ratios for the three DSM tests."

Directive 36 of the 2006 IEP/LTAP Decision directed BC Hydro to switch from semi-annual to annual DSM performance reports. Directive 38 from the same Decision directed BC Hydro to include in these reports:

> "metrics for each initiative, achievements in relation to milestones, and description of past or planned mitigation measures where warranted. These mitigation measures should include shifting program resources and alternative supply options for each program. Ongoing DSM performance reporting should demonstrate how BC Hydro is continuously pursuing DSM and that specific programs are cost-effective."

BC Hydro files its evaluation reports pursuant to Directive 69 of the F05/F06 RRA Decision separately. This annual report addresses the balance of Directives 69 and 16, as well as Directives 36 and 38 of the 2006 IEP/LTAP Decision.

2 Expenditures and Electricity Savings for Fiscal 2017

BC Hydro's DSM expenditures[1] in F2017 totalled $97.4 million while net incremental DSM electricity savings totalled 602 GWh/year. Expenditures were $16 million or 14 per cent below the F2017 DSM Plan presented in BC Hydro's Fiscal 2017 - Fiscal 2019 Revenue Requirements Application (**F2017-F2019 RRA**).

1 Comprising all DSM-related deferred operating expenditures. DSM operating expenditures are presented in Table 6 of this report.

Overall, net incremental electricity savings as shown in Table 1 were 3 GWh/year or 1 per cent above the DSM Plan.

Table 1 presents planned and actual DSM expenditures and net incremental electricity savings in F2017.

Table 1 Expenditures and Net Incremental Electricity Savings for F2017

	Expenditures[1]				Net Incremental Electricity Savings			
	Plan[2]	Actual	Variance		Plan[2]	Actual[3]	Variance	
	$ 000	$ 000	$ 000	%	GWh/yr	GWh/yr	GWh/yr	%

Notes:

1 Including all DSM-related deferred operating expenditures that are relevant for DSM cost-effectiveness.

2 Plan figures are from BC Hydro's F2017-F2019 RRA, Appendix W.

3 Reported savings from codes and standards and residential inclining block and general service rate structures are based on planned estimates as well as evaluated results.

The following corresponds to the information provided in Table 1 and are explanations for the above variances:

Codes and Standards	
Residential	Expenditures were approximately on plan. Electricity savings were above plan due to an adjustment of the allocation of savings between codes and standards and other lighting-related DSM programs as a result of the general service incandescent lamps regulation by the federal government.
Commercial	
Industrial	
Rate Structures	
Residential Inclining Block Rate	Expenditures were approximately on plan. Electricity savings were on plan.
General Service Rate	No further conservation is forecast from the general service rate as BC Hydro has revised its conservation forecast to zero due to the outcomes of the F2014 LGS/MGS evaluation report.
Transmission Service Rate	Expenditures were below plan due to the timing of the Transmission Service Rate evaluation, deferral of consultation activities for phase two of the Rate Design Application and the ability to move forward with a lower cost solution for invoice and billing data centralization. Electricity savings were below plan primarily due to a reduction in incremental customer self-generation due to F2016 customer self-generation actuals being higher than planned.
DSM Programs	
Residential Sector	
Behaviour	Expenditures were below plan due primarily to delays in a planned project to enhance energy insights provided to customers. Electricity savings were approximately on plan.
Refrigerator Buy-Back	The program has ended per the new DSM Plan in the F2017-F2019 RRA.
Low Income	Expenditures and electricity savings were above plan due to higher than planned participation in the Energy Saving Kit and Energy Conservation Assistance portions of the program offer. This was largely due to strong promotional campaigns as well as leads generated through the BC Hydro call centre resulting in higher volumes of lower cost Energy Savings Kits.
New Home	The program has ended per the new DSM Plan in the F2017-F2019 RRA.
Retail	Expenditures and electricity savings were above plan due to the success of the lighting campaign.
Home Energy Retrofit Offer	Expenditures and electricity savings were approximately on plan.
Sector Enabling Activities	Expenditures were below plan due to planned activities being deferred or cancelled.
Commercial Sector	
Leaders in Energy Management - Commercial	Expenditures and electricity savings were below plan due to customer decisions to delay or cancel projects.
New Construction	Expenditures and electricity savings were below plan due to customer decisions to delay or cancel projects.
Sector Enabling Activities	Expenditures were below plan due to planned activities being deferred or cancelled.

Industrial Sector	
Leaders in Energy Management – Transmission	Expenditures were below plan due to a number of incented projects being deferred by customers to F2018. Electricity savings were above plan due to cost effective energy savings related to strategic energy management activities.
Thermo-Mechanical Pulping	Expenditures were for studies to support the Thermo-Mechanical Pulping projects that will be implemented in future years.
Leaders in Energy Management – Distribution	Expenditures were below plan due to projects being cancelled or deferred by customers and a slower launch on strategic energy management initiatives targeting small and medium businesses. Electricity savings were approximately on plan.
Load Displacement	The program has ended per the new DSM Plan in the F2017-F2019 RRA.
Sector Enabling Activities	Expenditures were below plan due to planned activities being deferred or cancelled.
Capacity Focused DSM	Expenditures are below plan due to project delays and project cost efficiencies related to selected initiatives as well as lower volume than planned within the industrial load curtailment pilot.
Total Programs	Expenditures were below plan primarily due to projects not completing as planned in the commercial sector. Electricity savings were above plan primarily due to the success of strategic energy management activities in the Industrial Leaders in Energy Management - Transmission program and Residential Retail program.
Supporting Initiatives	
Public Awareness	Expenditures were approximately on plan.
Indirect and Portfolio Enabling	Expenditures were below plan primarily due to lower volume of IT support and enhancements required.
Portfolio Total	Expenditures were below plan primarily due to customer decisions to delay or cancel projects in the commercial sector. Electricity savings were approximately on plan due to the success of strategic energy management activities in the Industrial Leaders in Energy Management - Transmission program and Residential Retail program.

3 Expenditures to Date

BC Hydro's DSM expenditures from F2016 through F2017 totalled $242.6 million. Table 2 presents DSM expenditures from April 1, 2015 to March 31, 2017.[2]

Table 2 Expenditures since F2016

	F2016 ($ 000)	F2017 ($ 000)	Total ($ 000)
